CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal exgineering, construction work, inspection, estimating. Opening sought with architects as reinforced concrete designer and engineer; other opening considered. Toronto-Hamilton area preferred. Apply to Box No. 107-W.

CIVIL ENGINEER, graduate '26, with fair knowledge of French. Experience as instrumentman on surveys, maintenance engineer on railway construction, and resident engineer on railway construction. Available at once. Apply to Box No. 149-W.

CIVIL ENGINEER, B.Sc., Jr.E.I.C., with general engineering experience in construction, estimating, draughting, preliminary designing and building maintenance, desires position with opportunities. At present employed as buildings supervisor in public utility company. Available on short notice. Apply to Box No. 173-W.

ENGINEER, with over twenty years experience with leading industrial and construction companies in Canada with wide and varied experience in the construction, engineering and mechanical field, desires position as supervisor, estimator, or general superintendent of construction company. Age 51, married, bilinguist, A.M.E.I.C. Apply to Box No. 196-W.

ELECTRICAL ENGINEER, B.Sc., E.E., A.M.E.I.C., Canadian, age 29, single, graduate Canadian university 1924. Have been with large power company in U.S.A. since graduation, ten months on sub-stations, remainder of time on design, construction and operation of overhead and underground distribution and transmission system. At present employed by same company. Would like return to Canada. Available on reasonable notice. Apply to Box 236-W.

Situations Wanted

CIVIL ENGINEER. A.M.E.I.C., graduate, R.P.E.P.Q. Twenty years experience surveying and construction hydro-electric, railways, and paper mills, desires position. Will go anywhere if terms satisfactory. Apply to Box No. 294-W.

CIVIL ENGINEER, B.A., B.Sc., with six years experience on surveys; layout and construction of hydro-electric works; design of highway bridges and construction of highways; desires position as assistant engineer on design and construction of reinforced concrete and steel structures. Available on short notice. Location immaterial. Apply to Box No. 301-W.

INDUSTRIAL ENGINEER, thirty-five years of age, graduate of a well-known university, twelve years experience in design, construction, maintenance and changes in production methods in industrial plants, including several years in pulp and paper industry in complete charge in large mills of all engineering, maintenances, and development work; still engaged; desires to establish new connection. Apply to Box No. 320-W.

CIVIL ENGINEER, B.A.Sc., A.M.E.I.C., M.P.E.O., age 37, desires a permanent position as chief draughtsman or plant engineer, preferably in Toronto or district. Seventeen years experience with consulting engineers on industrial, structural and railway work, hydro-electric plants and pulp and paper mills. Some mechanical and electrical experience. Apply to Box No. 332-W.

CIVIL ENGINEER, A.M.E.I.C., Reg. Pro. Eng. Ont. and N.B., age 47, married, twenty years experience in this country; twelve years in Scotland as construction and municipal engineer, specializing in roadway, water and sewer works, desires similar position, available forthwith. Just completed sewer and waterworks schemes for town in Maritime Province. Have also been engaged as engineer and superintendent with contractors on steam shovel excavation, concrete and caisson works for large buildings in Toronto, etc. Apply to Box No. 336-W.

CIVIL ENGINEER, B.Sc., fifteen years experience, including surveying, construction, mining and tunnelling. Available at once. Will go anywhere, but prefer Eastern Canada. Apply to Box No. 346-W.

CIVIL ENGINEER, grad. '29, eleven months on construction, three months on road location, five months in draughting office, desires position on construction or would like to enter draughting office with possibilities in steel and reinforced concrete design. At present employed. Apply to Box No. 352-W.

SUPERINTENDENT, competent electrical superintendent, wishes position with large industrial or power supply company. New construction programme preferred. Experienced in engineering, designing and electrical construction of power houses, sub-stations and industrial control work. Available on short notice. Apply to Box No. 353-W.

ELECTRICAL ENGINEER, graduate McGill Univ. Experience, draughting, checking, short wave radio research, radio operating (ship and shore), demonstrating, electrical measurements and radio laboratories, department electrical engineering; at present demonstrating physics department. Desires position with opportunities, preferably radio work. Location immaterial. Apply to Box No. 356-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., is open for engagement. Twenty-four years general experience both as engineer and as contractor. Has specialized in the construction of wharves, dams, foundations, etc. Apply to Box No. 358-W.

ELECTRICAL ENGINEER, graduate N.S.T.C., Halifax, 29 years of age, two years experience in power transmission and distribution with a large power company in province of Quebec, two years electric test and inspection, W.E. and Mfg. Co., East Pittsburgh, Pa., one year electrical maintenance in large mill. Experience with telephone transmission, substation layout, electrical installation and layout for factories. At present employed. Apply Box No. 361-W.

MINING ENGINEER, graduate, age 32, A.M.E.I.C., ten years experience in design, construction, erection and maintenance of paper mill and mine buildings and machinery. Several years on hydro-electric work in charge of surveys and investigation; desires permanent connection with mining or paper company. Apply to Box No. 362-W.

MECHANICAL ENGINEER, B.A.Sc., Univ. of Toronto 21, A.M.E.I.C., married. Pulp and paper mill maintenance experience: draughting, layout of buildings, machinery and piping, mechanical design. Also experienced in reinforced concrete and steel building design and construction work. Desires position of permanency in plant engineering or maintenance work with reliable organization offering opportunities for advancement. Apply to Box No. 370-W.

CONSTRUCTION SUPERINTENDENT, with twenty-five years experience on hydro-power developments, paper mills and general building construction. Apply to Box No. 372-W.

ELECTRICAL ENGINEER, B.Sc. '23, A.M.E.I.C., experience, estimating pole line, cable and wire layouts, supervising estimates, in charge of cost inventory and appraisal work, in charge of draughting, records and budget control work, instructing engineering principles. Seven years with one company. Four years instructing in electrical engineering at evening classes, desires position along the above lines with opportunities. Best of references. Apply to Box No. 376-W.

STRUCTURAL DRAUGHTSMAN, age 31, well educated, with experience in designing and supervision, desires a change of position and location. Preferably north western Canada. Apply to Box No. 378-W.

CONSTRUCTION ENGINEER, Canadian, speaking and writing French and English, A.M.E.I.C., P.E.Q. Twenty years experience in water power development, roadway, water and sewer works, as engineer in charge or superintendent, desires position. Available on short notice. Apply to Box No. 380-W.

GRADUATE ENGINEER, N.S. Tech. Coll., age 25, desires permanent position with industrial concern. Since graduation has spent two years apprenticeship with Can. Westinghouse Co. Apply to Box No. 382-W.

COST ACCOUNTANT, graduate civil engineer who has specialized in construction costs, desires new connection. Especially familiar with hydro-electric and paper mill construction accounting, including preparation of cost statements, installation of stores and time-keeping systems, etc. Apply to Box No. 389-W.

Situations Vacant

ENGINEER, wide awake and progressive, preferably technically trained man with several years sales experience, familiar with sanitary requirements of municipal and industrial water systems. Submit with application complete details of education and positions held to date. Apply to Box No. 505-V.

DRAUGHTSMEN. Experienced in A.C. and D.C. machines, switchboard wiring diagrams and station arrangements, industrial control apparatus. State age, experience in detail, and salary expected. Location, central Ontario. Apply to Box 506-V.

RECENT GRADUATE, in electrical or mechanical engineering, for general industrial work. Work part in office and part in the plant. Must be competent to do transit work and levelling in connection with laying out new building sites. Location, Northern Quebec. Apply to Box No. 508-V.

MECHANICAL DRAUGHTSMAN wanted, with good technical training and acquainted with heavy duty cranes, regulating gates, movable bridges, etc. Not over 30 years of age. Apply, giving full personal particulars and salary expected, to Box No. 509-V.

MECHANICAL ENGINEER, graduate with three or four years experience in industrial plant maintenance, for metallurgical plant in province of Quebec. Permanent connection for right applicant. Please give complete information. Apply to Box 516-V.

DRAUGHTSMAN, with experience in laying out and designing strutural work, preferably with some mechanical experience. Location near Montreal. Apply at once to Box No. 517-V.

RECENT GRADUATE, to assist in office of inspection company. Location Montreal. Apply to Box No. 522-V.

CHIEF DRAUGHTSMAN, Canadian college graduate, with varied experience as to draughting room routines as applied to both civil and mechanical engineering with a good deal of experience in working with tradesmen and salesmen relative to general engineering problems. Apply to Box No. 523-V.

MECHANICAL ENGINEER,—A well known automobile manufacturing company has an opening for a mechanical engineer with several years experience. Automobile experience not necessary. The work is in the engineering department on production, and offers an excellent opportunity for advancement. Apply to Box No. 524-V.

ELECTRICAL ENGINEER, graduate in electrical engineering, good draughtsman, for planning of mechanical equipment in industrial buildings, some experience preferred State age, experience, references, and enclose sample of drawings. Apply to Box No. 525-V.

DESIGNING DRAUGHTSMAN. — Excellent opening for right man with large newsprint company, centrally located. Apply, stating age, experience and salary expected, to Box No. 527-V.

CHIEF OF PARTY—Competent, experienced chief of party wanted for reservoir flow line survey in northern Quebec. Should be able to speak both French and English. Please give full particulars as to age, experience and references in first letter. Apply to Box No. 529-V.

RESEARCH ENGINEER, graduate of recognized university; age not over 35; at least two years experience in research in connection with synthetic resins; able to read and write English, French and German; preferably one with a thorough knowledge of timber, lumber and veneers. Apply to Box No. 531-V.

MECHANICAL ENGINEER, graduate, with from two to five years experience, for a large industrial company with headquarters in Montreal. Apply, giving full particulars as to experience, to Box No. 535-V.

ELECTRICAL ENGINEER, recent graduate. One who has taken General Electric or Westinghouse students' course. Apply to Box No. 536-V.

CIVIL ENGINEER, graduate, with from one to five years experience in construction and maintenance for a large industrial company with headquarters in Montreal. Apply, giving full particulars, to Box No. 537-V.

INSTRUMENTMAN, on railway surveys and construction work for an industrial company in northern Quebec. Apply to Box No. 539-V.

OFFICE ENGINEER, required for an industrial company in northern Quebec, for general engineering work. Apply to Box No. 540-V.

MECHANICAL ENGINEER, with four or five years experience for plant maintenance. Canadian, graduate engineer. Apply to Box No. 541-V.

WATERWORKS ENGINEER, with experience on the design of filtration plants. Please state experience and salary expected in first application. Interviews will be arranged with suitable applicants. Apply to Box No. 543-V.

DESIGNING ENGINEERS.—Two assistant designing engineers with structural designing experience on filtration plants preferred. Please state experience and salary expected in first application. Interviews · will be arranged with suitable applicants. Apply to Box No. 544-V.

CHEMICAL ENGINEER, experienced man preferably with college training as chemical engineer, desired to form and organize a control department in a large paper mill. This position will offer great opportunities for the right man. Previous training or experience in research work or control essential. Please state particulars of education, experience, together with salary required. Apply to Box 545-V.

STEAM POWER ENGINEER. Young man with college training and experience in handling of steam power desired to fill permanent position with a large and progressive paper company. Previous experience in analysis and investigation of production and distribution of steam essential. Must be agreeable to start at a reasonable salary. This position offers splendid opportunities with favourable chance for advancement. State particulars, history and salary desired. Apply to Box No. 546-V.

PAINT AND VARNISH FORMULATOR. Wanted at Montreal experienced industrial paint and varnish formulator. Should possess a science degree from a reputable university, and be thoroughly trained and experienced in the matching, formulation and manufacture of industrial railway paint and varnish products, preferably one of three or four years experience as general superintendent of a large railway paint and varnish manufacturing concern. Salary $5,000. Age limit 55 years. Married. Transportation advanced. Permanent position. Apply to Box No. 547-V.

TOWN ENGINEER, for town in Maritime Provinces. Please give full details of experience and salary required. Apply to Box No. 548-V.

Preliminary Notice

of Applications for Admission and for Transfer

April 22nd, 1930

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in June 1930.

R. J. Durley, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for a least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ASHFORD—ARTHUR GEORGE, of Montreal, Que., Born at Newport, Monmouthshire, England, Oct. 21st, 1879; Educ., 1897-1906, Newport Technical Institute; 1906-10, civil engrg. asst., Alexandra Docks and Railway, Newport, Eng.; 1910-15, senior transitman, C.P.R.; 1915-19, overseas., Can. Engrs., Capt.; 1921-24, contractors chief engr. on highway and bridge constrn., Bristol, England; 1924-26, contractors chief engr. i/c constrn. of New Racecourse, Chepstow, England; Mar. 1927, transitman, divn. engr's office, Toronto, and from Jan. 1928 to date, bridge dept., C.P.R., Montreal, reinforced concrete design and detailing, largely on Toronto Terminal.

TREASURER
F. P. SHEARWOOD, Montreal, Que.

SECRETARY
R. J. DURLEY, Montreal, Que.

OFFICERS OF BRANCHES

HALIFAX
Chairman, W. P. COPP
Vice-Chair., C. St.J. WILSON
Sec.-Treas., R. R. MURRAY, 87 Cambridge St., Halifax, N.S.
Executive, D. S. WICKWIRE, J. L. ALLAN, G. T. MEDFORTH, L. ALLISON, W. H. NOONAN, J. J. SEARS, L. M. MATHESON, G. S. STAIRS, J. D. FRASER
(Ex-Officio) H. F. BENNETT, F. R. FAULKNER

CAPE BRETON
Chairman, A. L. HAY
Vice-Chair., A. P. THEUERKAUF
Sec.-Treas., S. C. MIFFLEN, Dom. Coal Co. Ltd., Glace Bay, N.S.
Executive, C. M. SMYTHE, J. P. COTTER, J. A. FRASER, Y. C. BARRINGTON, M. DWYER.

SAINT JOHN
Chairman, W. J. JOHNSTON
Vice-Chair., J. N. FLOOD
Sec.-Treas., A. A. TURNBULL, 348 Douglas Ave., Saint John, N.B
Executive, G. A. VANDERVOORT, C. C. LANGSTROTH, H. F. MORRISSEY
(Ex-Officio) E. T. OWENS

MONCTON
Chairman, M. J. MURPHY
Vice-Chair., L. H. ROBINSON
Sec.-Treas., V. C. BLACKETT, Eng. Dept., C.N.R., Moncton, N.B.
Executive, J. R. FREEMAN, T. L. LANDERS, J. G. MACKINNON, G. E. SMITH, C. S. G. ROGERS, F. WILLIAMS
(Ex-Officio) F. O. CONDON, H. J. CRUDGE

SAGUENAY
Chairman, R. E. PARKS
Vice-Chair., S. J. FISHER
Sec.-Treas., R. LANCTOT, 7 Lafontaine Ave., Chicoutimi, Que.
Executive, H. R. WAKE, G. E. LAMOTHE, J. A. KNIGHT, G. O. VOGAN

QUEBEC
Hon. Chair., A. R. DECARY
Chairman, A. B. NORMANDIN
Vice-Chair., S. L. deCARTERET
Sec.-Treas., P. METHE, Ecole Technique, Blvd. Langelier, Quebec, Que.
Executive, H. CIMON, T. J. F. KING, L. C. DUPUIS, A. LARIVIERE
(Ex-Officio) W. G. MITCHELL

ST. MAURICE VALLEY
Chairman, ELLWOOD WILSON
Sec.-Treas., R. MORRISSETTE, City Engr., Cap de la Madeleine, Que.
Executive, H. DESSAULLES, B. GRANDMONT, A. A. WICKENDEN

MONTREAL
Chairman, D. C. TENNANT
Vice-Chair., A. DUPERRON
Sec.-Treas., C. K. McLEOD, 1440 St. Catherine St., W., Montreal, Que.
Executive, A. COUSINEAU, P. E. JARMAN, W. McG. GARDNER, J. A. LALONDE, N. L. MORGAN, F. NEWELL
Ex-Officio) F. A. COMBE, FRASER S. KEITH, G. R. MacLEOD, O. O. LEFEBVRE, F. P. SHEARWOOD, P. B. MOTLEY, J. A. McCRORY, JULIAN C. SMITH, J. L. BUSFIELD

OTTAWA
Chairman, F. H. PETERS
Sec.-Treas., F. C. C. LYNCH, Nat. Resources Intelligence Service, Dept. of the Interior, Ottawa, Ont.
Executive, G. A. BROWNE, V. M. MEEK, L. L. BOLTON, W. L. CASSELS, W. F. M. BRYCE
(Ex-Officio) N. CAUCHON, C. CAMSELL

PETERBOROUGH
Chairman, R. C. FLITTON
Secretary, S. O. SHIELDS, 2 Chester St., Claraday, Ont.
Treasurer, A. B. GATES
Executive, A. L. KILLALY, B. OTTEWELL, W. E. ROSS, E. R. SHIRLEY, H. R. SILLS
(Ex-Officio) R. L. DOBBIN, W. M. CRUTHERS

KINGSTON
Chairman, D. M. JEMMETT
Vice-Chair., A. JACKSON
Sec.-Treas., L. F. GRANT, Royal Military College, Kingston, Ont.
Executive, A. G. MacLACHLAN, F. R. HENSHAW, L. M. ARKLEY
(Ex-Officio) W. L. MALCOLM

TORONTO
Chairman, J. J. TRAILL
Vice-Chair., C. S. L. HERTZBERG
Sec.-Treas., J. J. SPENCE, Eng. Bldg., University of Toronto, Toronto, Ont.
Executive, F. B. GOEDIKE, J. W. FALKNER, A. B. CREALOCK, G. H. DAVIS, J. R. COCKBURN, C. B. HAMILTON
(Ex-Officio) J. G. R. WAINWRIGHT, R. B. YOUNG, L. W. WYNNE-ROBERTS

HAMILTON
Chairman, W. F. McLAREN,
Vice-Chair., F. P. ADAMS
Sec.-Treas., J. R. DUNBAR, Can. Westinghouse Co., Ltd., Hamilton, Ont.
Executive, J. B. CARSWELL, H. S. PHILLIPS, E. M. COLES, G. A. COLHOUN
(Ex-Officio) H. A. LUMSDEN, E. H. DARLING

LONDON
Chairman, W. G. URE
Vice-Chair., W. R. SMITH
Sec.-Treas., F. C. BALL, City Engr's Dept., London, Ont.
Executive, D. M. BRIGHT, J. FERGUSON, E. V. BUCHANAN, R. W. GARRETT, G. E. MARTIN
(Ex-Officio) W. P. NEAR, W. M. VEITCH

NIAGARA PENINSULA
Chairman, E. G. CAMERON
Vice-Chair., WALTER JACKSON
Sec.-Treas., R. W. DOWNIE, Welland Ship Canal, Thorold, Ont.
Executive, N. BATES, F. L. HAVILAND, H. M. KING, E. P. MURPHY, W. R. MANOCK, J. E. SEARS, C. W. WEST, J. K. WYMAN
(Ex-Officio) A. J. GRANT, C. H. SCHEMAN, M. B. ATKINSON

BORDER CITIES
Chairman, ORVILLE ROLFSON
Vice-Chair., R. J. DESMARAIS
Sec.-Treas., R. C. LESLIE, 1618 Giles Blvd., Windsor, Ont.
Executive, C. G. R. ARMSTRONG, F. STEVENS, H. J. COULTER
(Ex-Officio) A. E. WEST, L. M. ALLAN

SAULT STE. MARIE
Chairman, C. H. E. ROUNTHWAITE
Vice-Chair., A. H. RUSSELL
Sec.-Treas., A. A. ROSE, 34 The Drive, Sault Ste. Marie
Executive, J. W. LeB. ROSS, J. M. SILLIMAN, R. A. CAMPBELL, J. G. DICKENSON
(Ex-Officio) J. H. JENKINSON, A. E. PICKERING

LAKEHEAD
Chairman, C. B. SYMES
Vice-Chair., D. G. CALVERT
Sec.-Treas., GEO. P. BROPHY, P.O. Box 86, Port Arthur, Ont.
Executive, D. C. CHISHOLM, J. C. MEADER, W. H. SOUBA, G. R. DUNCAN
(Ex-Officio) H. S. HANCOCK, D. G. CALVERT

WINNIPEG
Chairman J. W. PORTER
Sec.-Treas., E. W. M. JAMES, 255 Balfour Ave., Winnipeg, Man.
Executive, A. L. CAVANAGH, F. G. GOODSPEED, R. W. MOFFATT, G. S. ROXBURGH, T. C. MAIN
(Ex-Officio) F. H. MARTIN, C. H. ATTWOOD

SASKATCHEWAN
Chairman, W. G. WORCESTER
Vice-Chair., D. A. R. McCANNEL
Sec.-Treas., R. W. E. LOUCKS, Surveys Br. Land Titles Office, Regina, Sask.
Executive, J. M. CAMPBELL, D. A. SMITH, R. A. SPENCER
(Ex-Officio) H. R. MacKENZIE

LETHBRIDGE
Chairman, C. S. CLENDENING
Sec.-Treas., Wm. MELDRUM, Galt Mines, C.P.R., Lethbridge, Alta.
Executive, R. LIVINGSTONE, N. MARSHALL, N. H. BRADLEY, R. F. P. BOWMAN
(Ex-Officio) J. B. deHART, G. N. HOUSTON

EDMONTON
Chairman, JULIAN GARRETT
Vice-Chair., C. A. ROBB
Sec.-Treas., W. E. CORNISH, University of Alberta, Edmonton, Alta.
Executive, T. W. BROWN, R. M. DINGWALL, R. J. GIBB, H. J. MacLEOD
(Ex-Officio) R. W. ROSS, E. STANSFIELD

CALGARY
Chairman, B. RUSSELL

Hydraulic Fill on the Ghost Power Development

W. H. Abbott, A.M.E.I.C.,

Hydraulic Superintendent, The Foundation Company of Canada.

Paper read before the Montreal Branch of The Engineering Institute of Canada, April 27th, 1930.

In the hydro-electric development on the Bow river, which was recently completed for the Calgary Power Company, over one-half of the length of the dam is made up of earth fill.

The concrete portions of the dam and the power house are of practically standard design and did not present any serious difficulties in construction.

The two earth fill portions of the dam, owing to some novelty in their design and the methods of construction, may be of some interest.

The development is known as the "Ghost Power Development" to distinguish it from other water power developments of the Calgary Power Company on the Bow river. It is located at the junction of the Ghost river with the Bow, about 35 miles west of Calgary, Alta.

As the total length of the dam is 4,840 feet it was not practicable to make a plan of the dam for reproduction, but an aerial photograph, shown as figure No. 1, will give a general idea of the dam and show the relation of the two earth fills to the concrete portions of the dam.

The storage basin extends about 8 miles up the Bow river and 3 miles up the Ghost. It is called "Lake Gaherty."

The dam consists of four main parts. On the right of the view can be seen the "north earth fill," about 740 feet in length, which forms the north end of the dam and the tie-in to the north bank of the Bow river. The concrete emergency sluiceway and the intake dam are in the old bed of the Bow and are about 928 feet long. In the centre can be seen the "south earth fill" forming that portion of the dam between the intake dam and the main sluiceway. This earth fill is about 2,020 feet long. The south end of the dam consists of the main sluiceway and the spillway.

The location of the power house can be seen. There are two main units of 18,000 h.p. with a penstock installed for the future addition of another unit of the same capacity. There is also a station service unit of 1,450 h.p.

The maximum head is 108 feet, with a possible draw-down of 35 feet in the storage basin.

The two earth fills were distinctly separate as to source of material, type of construction, and the pumping and hydraulic equipment.

The "north earth fill" was a semi-hydraulic, or puddle, earth fill, and the "south earth fill" an hydraulic fill dam.

The construction camp and the gravel pits are in the foreground and the main line of the Canadian Pacific Railway on the left side of the view.

North Earth Fill

The method or type of construction to be used to tie in the north end of the dam to the north bank of the Bow river was quite a problem. The location of the concrete portion of the dam was fixed by the location of the rock in the bed of the Bow river.

The extension of the main concrete dam, or a concrete wall into the bank, was not economically possible owing to the distance it would have been necessary to go, and the excessive depth of the excavation required.

Some consideration was given to the idea of merely trimming the east bank of the Ghost river and covering the prepared slope with precast concrete slabs, put in place by being strung on wires on the bank and designed to interlock.

The bedrock was of lenticular sandstone, sloping down to the west, or upstream, at an inclination of about 18°. The rock was covered with a layer of hard blue clay varying in thickness from three to ten feet. Over this the bank was of compact fine sand of very uniform size and covered with an overburden of gravel about ten feet in thickness. The elevation of the top of the clay band ran from 3,839 to 3,850, and the top of the bank was about 3,950.

The top of the clay could be very clearly followed along the bank owing to the numerous small springs and the moisture showing at this level.

No trace of sand or gravel was found in the clay and it was very hard and impervious.

After tests of the sand from the bank for stability etc. had been made it was decided to excavate the bank down to the impervious clay band by hydraulic methods. A semi-hydraulic fill would then be raised from the end of the concrete dam for a distance of 740 feet up the Ghost river. The plan of the dam as designed is shown as figure No. 2.

The dam is of full section at the south end until the downstream face merges into the north bank of the Bow. From there on the dam forms a blanket over the bank of the Ghost river.

A trench had been dug to bedrock from the end of the concrete dam, partly as an exploratory trench and also to

Figure No. 1.—Aerial Photograph of Dam showing Relation of Two Earth Fills to Concrete Portions of Dam.

be used in case it were found necessary to extend the concrete wall into the bank. This trench was filled with concrete and can be seen in figure No. 2. This core wall was surrounded by the deposited clay core and improved the sealing at the junction between the earth fill and the concrete dam. A 4-inch tile pipe drain with open joints was laid along the downstream face of the wall.

A channel was dug for the diversion of the flow of the Ghost river to the west side. Two cofferdams were built, one at the top of the original channel to divert the flow into the diversion channel and the other at the lower end of the channel to retain as much as possible of the material sluiced out of the bank.

The pumping equipment was installed on the upstream crib for the preliminary excavation work and was later moved to the Bow river for the hydraulic fill.

It consisted of two 10-inch by 10-inch centrifugal pumps, direct connected to 300 h.p., 1,800 r.p.m., 2,200 v., 3-phase motors.

These two pumps supplied water to the monitors through a 14-inch pipe line. The pipe line was of flanged iron pipe of number 10 gauge where the pipe line was in a more or less permanent location. The lines which had to be moved frequently were of number 12 gauge slipjoint pipe. Burlap was used in the joints and the leakage was almost negligible.

The hydraulic excavation was started at the south end of the dam in order that the depositing of the clay core might start as soon as possible, using the old Calgary-Banff highway. The excavation was done with one monitor and was carried down to bedrock on each side of the concrete core wall, and then to the clay band for a distance of 75 feet from the end of the concrete dam.

The monitor was then moved to the north end of the cut and the excavation to the full section was carried from there to the first cut. A view of the hydraulic excavation at the north end is shown in figure No. 3. The pump house can be seen on the left and the diversion channel in the foreground. The original channel of the Ghost river is under the sluiced sand near the far bank. About 65 per cent of the material sluiced out of the bank was retained within the limits of the dam.

It was difficult to maintain the required slope of $1\frac{1}{2}$ to 1 on the side of the cut. The sand stood nearly vertical and was very compact. Some trimming had to be done by machine and hand after the hydraulic work was finished. The sand ran very freely and filled the old channel and part of the diversion channel, the top of the sluiced material being very nearly level across the Ghost basin. The overburden from the top of the bank remained in the cut.

While the hydraulic excavation was being done the clay core was deposited around the concrete core wall at the south end and a gravel levee was dumped by trucks along the upstream toe of the dam. This gravel levee was over the old channel of the Ghost and helped to retain a considerable quantity of the sluiced material.

When the hydraulic excavation had been completed a trench of an average width of 30 feet was dug through the gravel and sand remaining in the cut. This trench was for the clay core base and was dug down to the clay band. At the north end of the fill it was necessary to sheet the sides of this trench as there was a depression in the clay base and the water percolating through the bank collected

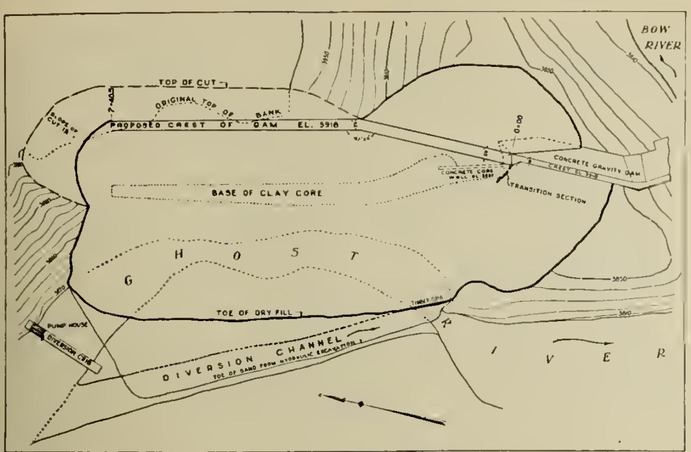

Figure No. 2.—Plan of North Earth Fill.

there. A good contact between the clay core and the clay band was made over the length of the dam, and great importance was given to ensuring that the base was clean and was the surface of the main clay bed before the clay core was deposited.

The height of each lift of the clay core was between 6 to 8 feet up to elevation 3865. Above this elevation the clay was still deposited in low lifts on the portion of the dam between the concrete dam and the north bank of the Bow river. Along the bank of the Ghost the clay was dumped from the top of the bank.

As the clay core was being deposited by trucks gravel levees were being raised along the upstream face. One monitor was installed at each end of the fill and material washed down into the dam between the gravel levees and the clay core. A flume was used to convey this material over the clay core at the south end.

The raising of the gravel levees could not keep pace with the hydraulic fill. Small levees to retain the sluiced material were thrown up by dragline. The material was sluiced down from the top of the bank and baffle boards were used along the face of the clay core to prevent any of the clay being washed out.

Figure No. 4 shows the "north earth fill" about three-quarters completed. The storage pond is rising and the dragline on the bank is excavating clay and loading trucks at one of the clay pits. Most of the clay from this pit was dumped in front of the monitor at the south end of the fill and sluiced down with the material from the bank.

In the cross-sections of the completed dam, shown in figure No. 5, it will be noted that the dam was raised considerably higher than the original design, particularly as shown on sections 5+00 and 7+00. This was done by throwing down a portion of the top of the bank by dragline to allow for any settlement of the fill. The clay core is also higher than the original design, mainly on account of the clay being dumped from the top of the bank.

The areas of the hydraulic fill as shown are smaller than the actual areas covered. The water and the finer sluiced material percolated through the gravel along the face of the clay core and the resultant puddled material formed areas larger than as shown.

At the commencement of the work the amount of clay suitable for the core which could be obtained within any economical distance of the work appeared very small. Another deposit of clay was discovered, however, and the amount finally obtained was quite sufficient. The pits were ploughed and the trucks loaded by scrapers from overhead platforms and by draglines. The best of the material was picked as far as possible.

A general analysis of the east bank of the Ghost and two of the clay pits is given below:

Classification	Diameter MM	Percentage by weight		
		Bank	Pit No. 2	Pit No. 4
Fine gravel......	5.0 – 1.0	0.3	0.3	0.0
Coarse sand.....	1.0 – 0.5	1.0	0.6	0.3
Med. sand.......	0.5 – 0.25	12.9	2.2	0.4
Fine sand.......	0.25 – 0.10	61.0	11.4	2.6
Very fine sand...	0.10 – 0.05	14.8	26.9	8.2
Silt............	0.05 – 0.005	3.5	36.5	39.4
Clay............	0.005 –	6.5	22.1	49.1

There was some delay to the hydraulic work on account of a sudden rising of the Bow river in June. This had no serious effect, although the pumps and motors on the crib were covered with about ten feet of water for about two days. The "megger" showed no resistance between the windings and the stator of the induction motors. They were dried out in two days by means of a compressed air dryer made on the job. This drier had been designed and made to dry out one of the 4,000 kv.a. transformers in the temporary substation which had been soaked with water from a broken cooling coil.

South Earth Fill

It is difficult to classify the "south earth fill" as a semi-hydraulic or a full hydraulic fill dam. It is really a true hydraulic fill with a gravel blanket on each face.

A plan and profile of the dam is given in figure No. 6. It will be seen that the centre line of the fill is not a straight line. This location of the dam, as well as that of the concrete dams at both ends, was determined by the location of the bedrock found by test pits.

The ends of the concrete dams at the junction with the fill were of special design to form transition sections. At the north end of the fill an entrance was provided to the tunnel in the main concrete dam. A ladderway ran down from the top of the dam and was covered with precast semi-circular concrete blocks. These blocks were 8 inches in height and were put in place as the earth fill was raised.

The level of the pool in the hydraulic fill was regulated by the flow of water over the blocks into the tunnel. This waste water was carried down the tunnel in a trough at the side of the walkway, and discharged into the river through a temporary opening in the upstream face of the dam.

This method of regulating the pool was used for the north half of the fill until the dam was about half completed when the remainder of the blocks were put in place and the waste pipes installed in the fill were used.

At the north end of the fill a timber crib, loaded with rock from the excavation of the power house site, was built

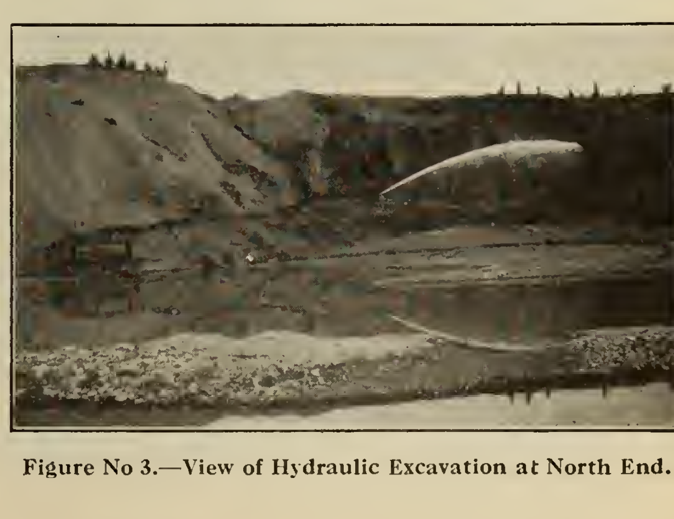

Figure No 3.—View of Hydraulic Excavation at North End.

Figure No. 4.—View of North Earth Fill about Three-quarters Completed.

to prevent the possibility of the upstream toe of the fill sliding into the river at this point.

The hydraulic plant was built on each side of a ridge which ran through the centre of the dam. The plant was in two separate units to take advantage of the high ground for the flow of the material to the pumps. These were known as the north and south units.

The pumps for the supply of water for the sluicing and pumping of the material were installed on a crib in the Bow river. This crib formed part of the cofferdam necessary for the construction of the intake dam and the power house.

The equipment consisted of:

Four 10 inch by 10 inch centrifugal pumps direct connected to 125 h.p., 1,200 r.p.m., 2,200 v., 3-phase motors.

The water was pumped through a 24-inch wood stave pipe line to the plant. This pipe line was 1,400 feet in length and was brought to the top of the bank from the pump house on a grade of 50 per cent and from there to the plant on a trestle with a grade of 3 per cent. The static head on the pipe was 60 feet.

The saddles supporting the pipe on the trestle were lubricated with soft soap for expansion of the line and the south end was free. No trouble was experienced with this line after the wooden joints had swollen.

Two pressure pumps were connected to the clear water line to provide water for the monitors. These pumps were 12 inch by 10 inch centrifugal pumps driven by 300 h.p., 1,800 r.p.m., 2,200 v., 3-phase motors, starting direct from the line.

The pressure pipes to the monitors were 6-inch diameter flanged cast steel pipe. The pressure used varied from 75 lbs. per sq. inch to 125 lbs. per sq. inch.

The tracks from the clay pits to the plant can be seen on the downstream berm of the south half of the dam. The gravel fill had been brought up to this elevation before the installation of the pumping equipment was completed and served to carry the tracks across the low ground. A double track was laid as far as the plant and then single tracks branched to each unit.

A plan of the south unit of the plant is shown in figure No. 7. The unloading track for the clay trains was carried on a trestle along the side of the hogboxes at a height of 12 feet above the floor. This track was extended past the end of the hogboxes to allow the empties to be pushed past the hogbox in the case of being unloaded on one hogbox only. A platform for the men unloading the trains ran the length of the unit.

The material for the hydraulic fill was obtained from two clay pits situated about 5,000 feet southwest of the plant. These pits were located by an extensive series of test pits dug over the valley of the Bow and the hills on the south side of the valley. The clay was chosen for its high standard of imperviousness as determined by tests made in Washington. The formation consisted of about eight feet of granulated clay over beds of solid blue and yellow clay. The amount of gravel found in the clay pits was thought to be too low for the formation of the beaches in the fill, and a gravel pit was located close to the clay pits to make up this deficiency. This pit was never used as it was found that the clay was not broken up in passing through the screens and pumps and formed a large percentage of the beaches.

The clay pits were one above another on a side hill and were excavated by two 2¼-yard steam shovels. Owing to the hardness of the clay it was necessary to shoot the banks ahead of the shovels. This difficulty did not extend for the full length of the pits and, after the best of the material had been taken, the original pits were abandoned for two other pits at the foot of the hill where a more easily handled good quality clay was found.

An analysis of the clay is given below:

Size MM	Percentage by weight
5.000 – 1.000	2.4
1.000 – .500	3.4
.500 – .250	3.6
.250 – .100	8.3
.100 – .050	22.1
.050 – .005	32.9
.005 – .000	27.3

Six trains of 12 cars each of two cubic yards capacity were used and they were routed to the two units to keep the supply of material on the hogboxes as uniform as possible.

As will be seen in figure No. 7, the hogboxes were divided in two parts by a partition down the centre. The floors were sloped from the sides to the centre, and the centre formed a trough sloping down to the outlet to the screens.

The monitors shown were size 2 hydraulic Giants about six feet in length. The nozzles used were 2¼, 2 and 1½ inch diameter, depending upon the nature of the material being received. These did not have to be changed very often. In the event of a block in the entrance to the screens the monitors could be directed into the waste pipes shown. This did away with the necessity of closing the valves on the pipe lines when the openings had to be cleared of large clay lumps.

The material was kept moving as uniformly as possible in order to maintain uniform operation of the dredge pumps. This required a certain amount of skill on the part of the operators, and the monitor men became quite proficient.

A plan of the pump house is shown in this figure. The description of the pumping equipment is also given. The

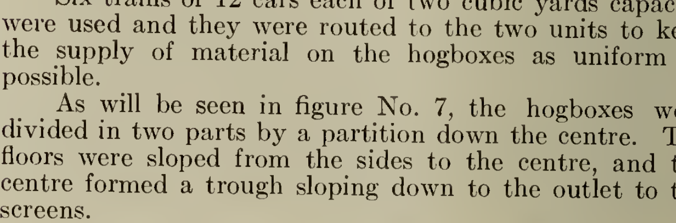

Figure No. 5.—Sections of North Earth Fill.

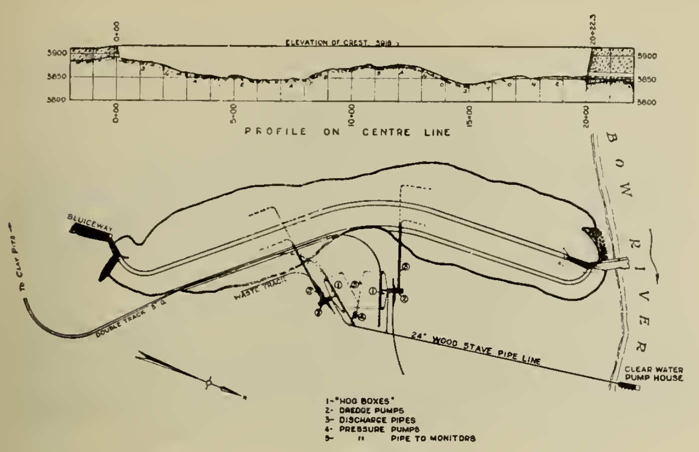

Figure No. 6.—South Earth Fill and Hydraulic Plant.

dredge pumps were for 140 feet head and a capacity of 3,000 gals. per minute.

The two pipes carrying the material into the dam were 10-inch diameter cast steel flanged dredge pipe. The flanged portion of the pipe line was carried about halfway up the fill and the remainder was laid with the same size slip-joint pipe. The flanged pipes were turned through 90° every 12,000 cubic yards of pumped material. This lengthened the life of the pipe and only a few lengths had to be replaced during a life of about 100,000 cubic yards each.

The waste tracks are shown passing over the discharge pipes. This view is of the south unit, on the other unit the tracks were clear of the pipe lines.

Some special tools for speeding up the joining and uncoupling of the slip joint pipes were designed and made on the job.

A section through one of the hogboxes is shown in figure No. 8. This shows the general arrangement of the equipment. The material was dumped from the trestle on the floor of the hogbox and the capacity of the hogbox was sufficient for about three hours run, in case of trouble at the clay pits or with the trains.

The floor of the south unit was made of concrete. Large boulders were available on the site from the excavation for the sumps and were laid close together with a flat face up. These were laid in a lean mixture of concrete and mortar poured over them. The mortar wore away very quickly but there was no further apparent signs of wear.

The floor of the north unit was of 2-inch plank protected with ¼-inch steel plates.

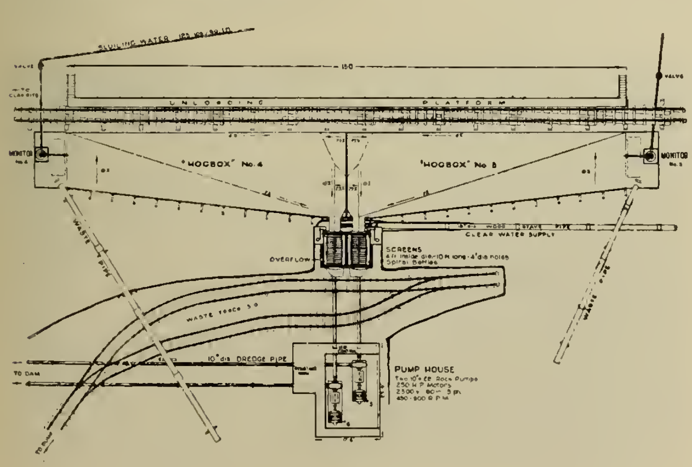

Figure No. 7.—Hydraulic Fill Plant—South Unit.

The operation was not of sufficient duration to determine which floor was the more economical. No repairs to the floors or walls were necessary during the work.

On both units the walls were of 2-inch plank protected at the ends near the outlet to the screens with ¼-inch steel plates.

A screen of wire netting was erected along the top of the walls to prevent small pebbles being thrown over by the water. It would have necessitated heavy bracing to raise the walls and these screens were quite efficient.

The outlets to the screens were of ¼-inch plate and made in semi-circular form with a flat bottom. The inside edges were turned up inside the hogbox and spiked to the walls. There was very little trouble with these.

The screens were of the revolving type and were inclined ¼ inch to the foot. This slope was adopted after some trial as the best slope depended upon the nature of the material. The screens were driven at a speed of 7 r.p.m. by 7½ h.p., 1,200 r.p.m. motors through reduction gears. The overall length of the screens was 10 feet, with 6 feet effective for the screening, and an inside diameter of 4 feet. The perforations were originally 6½ inches in diameter. This was reduced to 4 inches as the material was very solid and there were more large lumps coming into the dam than were required for the beaches. It was also thought that some of the trouble experienced with the pumps, of which more later, was caused by the large proportion of boulders and clay lumps.

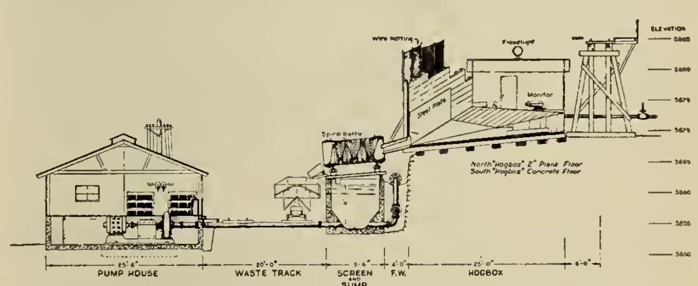

Figure No. 8.—Section of Hydraulic Fill Plant.

There was another development in the screens which proved very efficient. This was the spiral baffles shown inside the screen. These were made by cutting circular segments, 8 inches wide, out of ½-inch steel plate and welding the ends of the pieces together. The outside diameter of the baffle was calculated to give an interval between the plates when installed in the screen, of about 24 inches.

The made up baffle was simply drawn out like a spring and pulled into the screen. The tendency to close up held the plates firmly against the inside of the screen and further strengthening was given by angles rivetted to the screen at each end and in the centre of the baffle. These baffles lasted out the job.

The material rejected from the screens was dumped into cars through small chutes. This material was used to build levees along the banks of a new channel for the spillway water.

The screened material fell into the sumps below the screens. These sumps were of concrete with the bottom and sides protected by ¼-inch steel plates. The inside dimension of each sump was 8 feet x 6 feet with a depth of 7 feet to the centre of the pipes. The clear water pipe line came in at the back of the sump at the bottom, and the amount of water was regulated by a valve on this line.

The suction pipes to the pumps were 10-inch diameter flanged cast steel pipe and were immediately opposite the clear water pipes.

Figure No. 9.—View of North Unit.

An opening was cut in the side of the sump at the top, the bottom of the opening being 6 feet above the centre line of the pipes. This opening could be seen from the operating platform in the pump house and the water was regulated so that it was kept nearly level with this opening.

Only one pump is shown in the figure to avoid confusion. The racks at the back of the pump house are the resistance grids to control the speed of the motors, and the controller is shown on the platform at the right of the pump house. These controllers were drum switch speed regulators.

Two separate 2,200-volt lines were run from the substation to each pump house. This was to avoid both pumps being shut down on account of trouble on one of the lines.

A length of 18-inch wood stave pipe about 16 feet long was attached to the clear water line and stood nearly vertical over the pipe. This relieved the pipe line of any danger due to high pressure or the vacuum which might be caused by the shut down of the clear water pumps. It took the place of a relief valve on the pipe line, and, as it could be seen from the pressure pump house, it enabled the operator to regulate his valves on the pressure line when the water was low due to any trouble at the clear water pumps.

In figure No. 9 is shown a view of the north unit. This shows the pump house and a train dumping on one of the hogboxes. It will be noted that this train is dumping on one half of the unit only and the empties are out on the extension of the trestle.

A picture of the sluicing operations in the hogbox is shown in figure No. 10. This shows the operator, or monitor man, sluicing down the material with a monitor. It was taken at the commencement of the operations and there are several features which were later installed not shown. Such as the wire netting screen along the top of the walls and the steel plates on the walls and floor of the hogbox.

The screens are shown in figure No. 11. Only one unit was operating when this picture was taken and the spiral baffles can be seen in the screens. The screens and the operating mechanism were all housed in and the gears and rollers protected by metal covers.

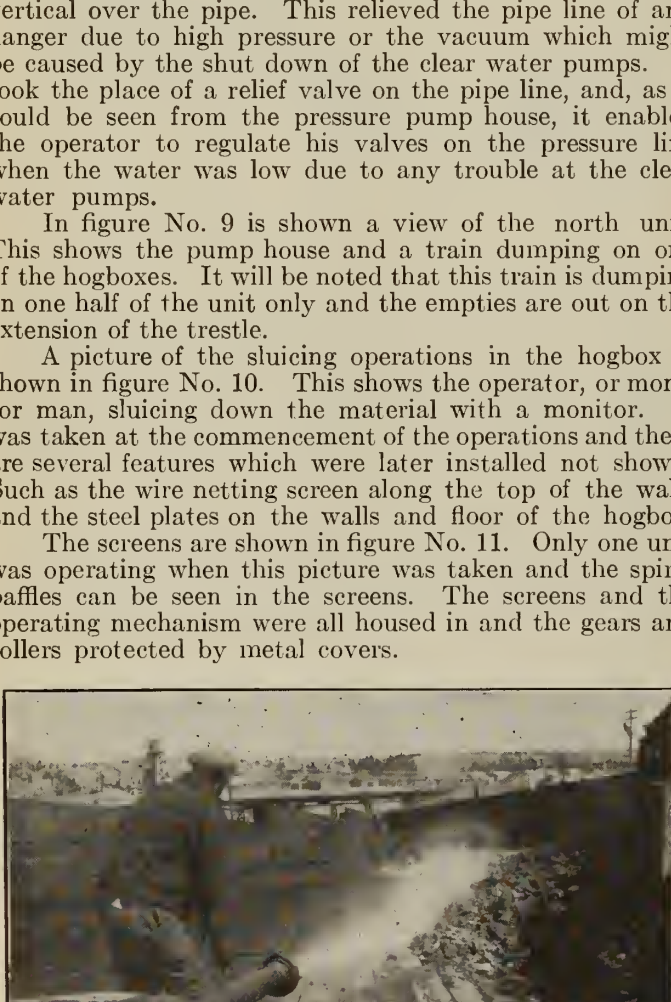

Figure No. 10.—Sluicing Operations in Hog box—Earth Fill Dam.

The operator in the pump house can see the operation of the screens and the level of the water in the sumps from the window and he kept a report sheet on which was entered every half hour, the vacuum on the intake pipes, the pressure on the discharge pipes, the amperes on the motors, and the height of water in the sumps. Other items were also entered on these sheets such as, the cause of delays, the number of cars received during each shift and the elevation of the core pool. This information was all entered up and forms a very complete record of the work.

All the equipment operated satisfactorily with the exception of the dredge pumps with which some trouble was experienced. This equipment was all new and had been made expressly for this work. In figure No. 12 is shown one of the original pump casings. These casings were circular with circular volute and had no liners.

This casing had pumped only 7,660 cubic yards of material when a large crack developed at right angles to the shaft and at the bottom of the casing above the discharge. This crack was welded and when the pump had run another 1,430 cubic yards another crack developed along the same line at the top of the casing. Rods were then bent around the outside of the casing and welded as shown.

Figure No. 11.—View of Screens.

All the casings received with the pumps and the spares cracked in the same manner. New casings were cast in Calgary to our own design from scrap car wheels.

One of these casings ran to the end of the work and was still in good condition after a duty of 59,140 cubic yards pumped. Two of the casings wore through at the bottom after pumping about 45,000 cubic yards each, and these were built up. None of the casings cast in Calgary showed any signs of cracks.

At the same time the impellers, or runners, on the pumps were showing some weakness. The impellers received with the pumps showed an average life of about 4,000 cubic yards. The rule then was to run the impellers for about 3,000 cubic yards, or until the vanes showed about 3 inches worn off, and then replace them. The worn impellers were then built up in Calgary and used again.

The breakage of an impeller causes a great deal of delay, as the pump line is full of material and has to be taken apart to be cleaned out.

All these impellers were three port impellers and a two port impeller was tried out. This only ran 4,100 cubic yards when the operation of the pump became very bad, vibration was set up, probably due to uneven wear on the vanes.

The makers had a man on the work testing the operation of the pumps to determine if possible the cause of the

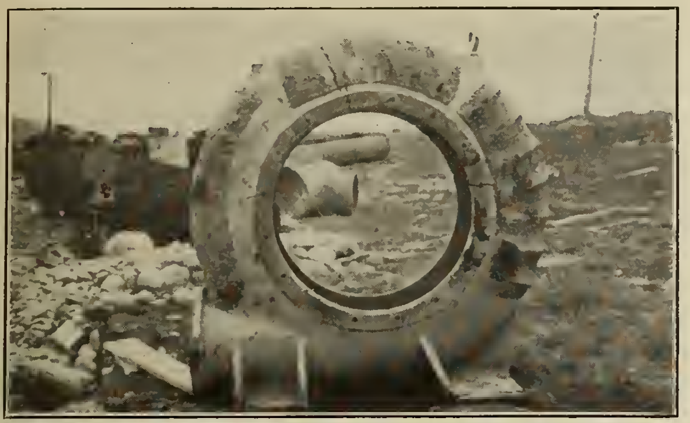

Figure. No. 12.—View of Original Pump Casing.

breakages. They could not find anything wrong and the pressures were very conservative. The maximum pressure on the discharge pipe at the highest lift was only 55 lbs. per square inch and the load on the motors about 150 h.p.

It is understood that a pump casing and impeller will wear faster when pumping small percentages of solid matter than when pumping a high percentage.

The maximum rate obtained with this material was 74.5 cubic yards and the average rate was 49.8 cubic yards per pump hour. This is equivalent to an average percentage of solid matter of 5 per cent. On a four hour test, with good material in the hogboxes and the pumps operating against a head of 45 feet, the average was 112 cubic yards per pump hour, or about 11 per cent solid.

Of course, these figures are of little value on account of the impossibility of determining the average speed at which the pumps were run. The average consistency was probably about 9 per cent.

The inclination of the outside face of the vanes was very flat. This face followed the radius of the circular ends of the impellers for about one-half the length of the vane and then turned down toward the centre at an angle of about 80°.

It was thought that the trouble, both in the casings and the impellers, might be caused by material being jammed between the impeller and the casing by these flat vanes.

Impellers were cast in Calgary to the design of the Foundation Company. The inside wearing edge was strengthened by the insertion of a piece of steel plate. This was held in place by welding as shown in the figure.

The new impellers proved very good, the average life was 41,300 cubic yards.

Figure No. 13.—Impeller.

There was another improvement, probably due to the change in the design of the impellers. The original impellers were frequently blocked by long stones. There were no stone blockages after the new impellers were installed.

The re-design of the impellers is also thought to have had a considerable effect on the life of the new casings as they were installed at about the same time.

The method of raising the dam is shown in the upper drawing on figure No. 14. The dredge pumps are shown on the right with the pipe lines to the dam. One pipe from each unit was carried across the fill in a light temporary trestle. These trestles were built about 8 feet in height and as the fill was raised new trestles were erected on top of them.

A plank bridge was kept over the pipe lines for the trucks depositing gravel in the downstream levee.

The dam was originally intended to be entirely hydraulic fill. Owing to the shortness of the season in which hydraulic work could be done, gravel levees were deposited by trucks during the winter preceding the commencement of the hydraulic work.

The hydraulic fill was brought to the top of the upstream levee and above this small levees were raised to retain the pumped material. These small levees were made with 3 feet by 15 feet planks on edge and backed with clay from the beaches.

It was later decided to continue the raising of the gravel beaches by trucks, and these were brought to the top of the fill on each face.

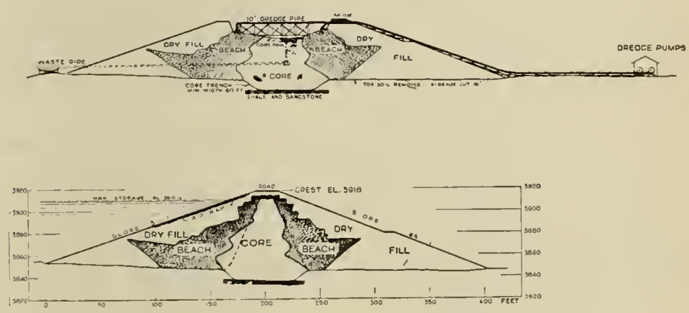

Figure No. 14.—Sections of South Earth Fill.

The discharge pipes were run along the inside edge of the gravel fill, and were 10-inch diameter slip joint pipe. There was no indication of any leakage of the core pool water through the beaches and the gravel levees.

The water in the clay core and the beaches appeared to be given up through the surface. Small springs could be seen on the beaches and also on the clay core when the core pool was low.

The overflow pipes were 14 feet in diameter and in two foot lengths. The pipe was held in a concrete block with a discharge pipe line running out through the upstream face of the dam, in order that the fines in suspension in the water might settle in the comparatively still water above the dam.

To raise the pool additional lengths of pipe were added to the vertical pipe line. Every alternate length was of a diameter to fit closely inside the other, so that each added length raised the water level one foot.

Three overflow pipes were installed and there was no trouble with any of them.

The lower drawing in figure No. 14 shows the dam as completed. The ground under the base was stripped to an average depth of 18 inches and a trench was dug along the centre line for the core base. The trench was excavated to bedrock and was equal in width to the height of the dam at any point, with a maximum width of 60 feet.

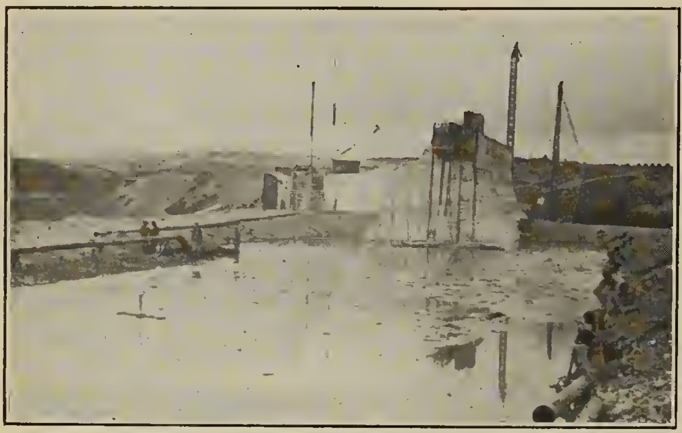

Figure No. 15.—View of Discharge Pipe in Dam and Core Pool.

The width of the core at any height was maintained to equal the remaining height of the dam as closely as possible.

The control of the width of the core depended a great deal on the percentage of fines in the pumped material. This, of course, had to be about 25 per cent more than that necessary for the theoretical width of the core as a certain proportion would remain in the beaches.

A record of the outline of the clay core was kept by examination of the fill on each lift. The edge was considered to be where there was no trace of gravel or any lumps of clay. This was not a definite line as the fine material extended into the beaches, and it was considered that the beaches, being made up to a large extent of clay lumps with this fine material forming a binder, were as impervious as the clay core.

A view of the discharge pipes in the dam and the core pool is shown in figure No. 15.

Some of the pressure cells, which were installed to measure the pressure in the clay core, can be seen on the concrete transition section in the background. Also the semi-circular segments over the ladderway into the tunnel in the dam can be seen.

A view of the fill from the north end is given in figure No. 16. The small float near the centre of the clay core is attached to a 6-inch diameter iron ball which was used to give some indication of the consolidation of the clay core by the amount of penetration over a period of several days. This test was of little value as a wet core would support the ball almost indefinitely after the initial penetration. The float indicated, to some extent any shifting of the core.

The last of the fill was done in the dry with trucks.

Clay was dumped on top of the wet hydraulic clay fill and sides brought up with gravel.

Rip-rap was placed along the upstream face of the fill to protect the face from ice.

The average lift of the dam was 3.4 feet per week, and the maximum for one week was 5.5 feet. The maximum yardage pumped in 24 hours was 4,035 cubic yards.

The wastage amounted to 16.5 per cent, and this was partly due to the clay from the first pits being nearly unbreakable.

In figure No. 17 are given the results of tests made to determine the consolidation of the clay core. The installation of seven "Goldbeck" pressure cells on the concrete transition section at the north end of the fill are shown on the right.

The cell is a flat circular box of 5½ inches in diameter. The top of the box makes contact with a button inside the cell. This cover is a thin diaphragm. A short pipe of ⅛ inch diameter provides an opening at the side of the cell, and an insulated wire passes through this pipe and is connected to the button which is insulated from the casing of the cell.

The cells were mounted with two pipes leading to the top of the concrete dam and an extension to the wire passed through one of the pipes to the top. Short lengths of pipe were left at the end of the pipes below the cells to catch any scale from the pipe lines.

Five of the cells were mounted with the faces nearly vertical and the other two with the faces horizontal.

Another two cells were placed at the middle of the dam, and the results from these were similar to the ones shown.

The air line was connected to one of the pipes and the other was left open. Air was blown through the pipes and the cell to remove any condensation in the pipes which might affect the contact of the diaphragm cover with the button. One pipe was then closed at the top and the air pressure put on the cell until the contact was broken. The pressure was read at this instant, and some of the results are shown on the diagrams.

It will be seen that at the commencement of the fill the pressures are very nearly equal to the equivalent hydrostatic pressure and then gradually become greater. The relation of the vertical pressures to the lateral gives an indication of the consolidation of the core. The vertical pressures increased more rapidly than the lateral and this difference was quite marked for some time. Then the vertical pressures remained nearly the same at all heights of the dam and the lateral pressures continued to increase until, as shown on the last diagram, they were almost equal to the vertical pressures.

It was considered that this was due to the clay having become so consolidated that the readings did not show the pressures due to the static head. The clay was so solid that the pressures shown were those needed to raise the diaphragm forming the cover of the cells by compressing the clay the five-ten thousandth of an inch required to break the contact with the button.

It can be seen that the equivalent hydrostatic pressure on the last diagram is nearly the same as the pressures read in the core. This is due to the clay pressures remaining nearly constant although the head was increasing. The equivalent hydrostatic head does not seem to be of any value as an indication of the consolidation of the core in this case.

Some tests were made by sounding with a length of one-inch pipe in the clay core. No definite idea of the consolidation of the core could be obtained by this means.

Figure No. 16.—View of Fill from North End.

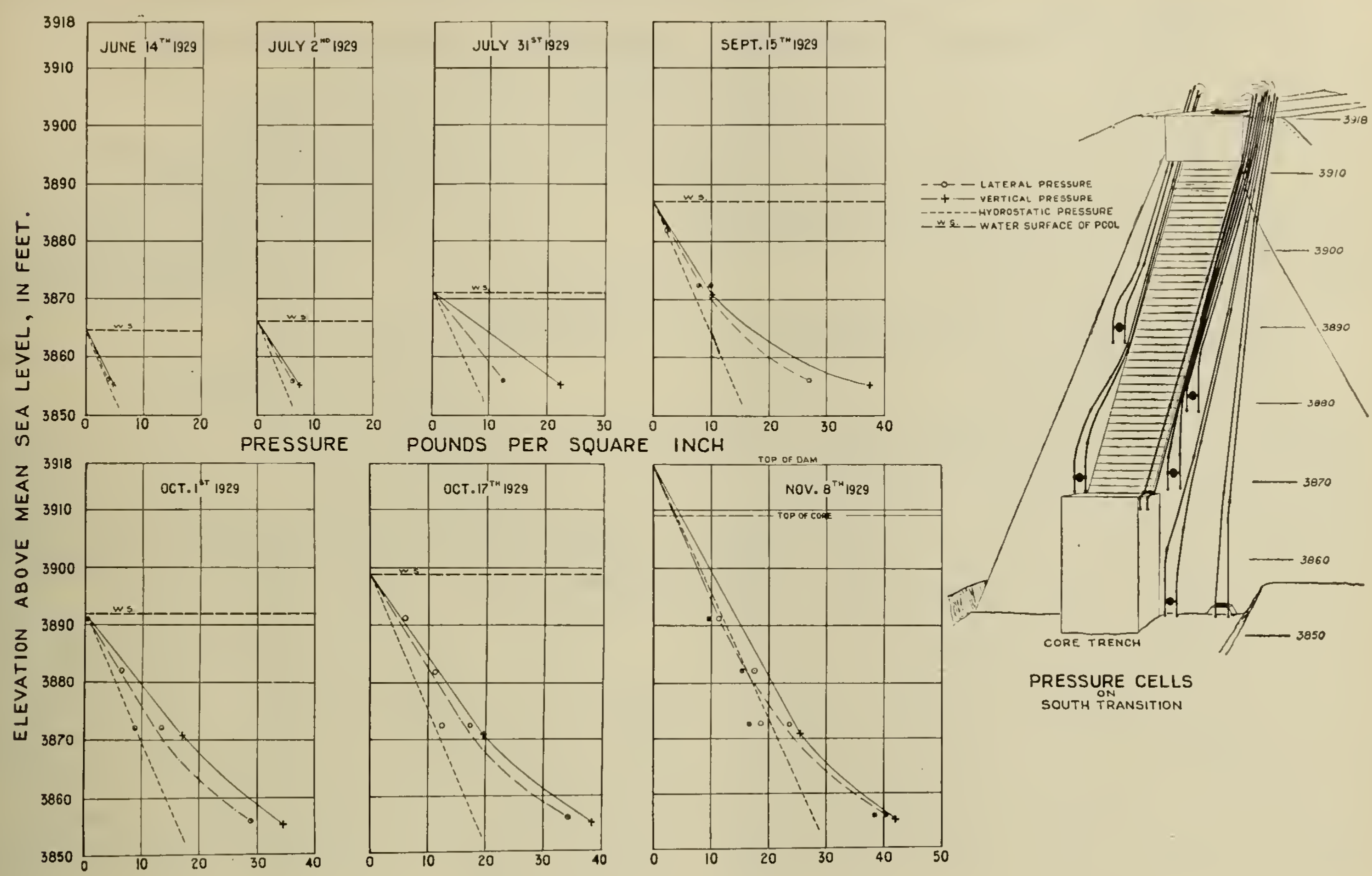

Figure No. 17.—Pressure Diagrams.

The testing apparatus used consisted of a small lamp connected in series with the button and the cover of the cell through the pipe line, and a pressure gauge. The current for the lamp was supplied by two dry batteries. The equipment was made up on the job.

The quantities in the north and south earth fills may be of interest:

North Earth Fill.

Excavation, hydraulic.......	79,000	
machine........	18,000	
Total.....................		97,000 c.y.
Fill, gravel by truck.........	144,000	
clay " "	53,000	
hydraulic..............	13,000	
Total..................		210,000 c.y.

South Earth Fill.

Stripping..................	18,000	
Core trench excavation......	25,000	
Total..................		43,000 c.y.
Fill, gravel by truck.........	624,000	
hydraulic..............	398,000	
Total..................		1,022,000 c.y.

The design of the concrete dam and the earth fill sections was made by the Montreal Engineering Company, with Dr. T. H. Hogg, M.E.I.C., of the Ontario Hydro-Electric Power Commission, as consulting engineer.

The design of the power house superstructure and all the construction work was done by the Foundation Company of Canada. The bridge piers and the excavation of the clay pits was done by sub-contract, Campbell Brothers doing the latter work.

The Water Problem in Oil and Gas Fields

W. P. Campbell,

Office of the Supervisory Mining Engineer, Department of the Interior. Calgary.

Paper read before Lethbridge Branch of The Engineering Institute of Canada, January 25th, 1930.

So important is the water problem in oil and gas fields that it must be reckoned with at every stage in the development of the field. It creates difficulties:—

(1) In the drilling of wells.
(2) In the maintenance of producing wells.
(3) In the proper abandoning of wells which have become unproductive.

When it is considered that only about 20 per cent of the oil underground is ever recovered, and that one of the chief factors which militates against more efficient recovery is water, which has been permitted to enter the oil sand from points above or below the same, in the drilling process, or is found in contact with the oil or gas in the producing zone. In view of this, any measures which can be employed to prevent the flooding of oil sands by water, and thereby prolong and maintain the productivity of oil and gas horizons, are certainly to be welcomed and encouraged. J. B. Case[1] puts it very ably when he says, "Efficiency in oil field development is the production of oil, free from water for the longest possible time in a manner to recover the greatest ultimate quantity from the underlying pool. Any conditions that prevent the accomplishment of this and which can be remedied are out of harmony with recognized principles of proper oil field practice and are detrimental to the best financial interests of the operators and landowners."

Oil "Sands"

Before discussing the problem further, it might be of interest to consider very briefly the nature of the formations in which *oil*, *gas* and *water* are found in oil fields. Sandstone beds, or "sands" as they are called in the industry, and limestone formations act as reservoirs for all three, singly and in combination. Of course, all sands do not necessarily contain any one of the three. The reason for their accumulation in the sand and lime zones is more or less evident, as the sandstone and porous and fractured limestone offer less resistance to their movement than do shales and clay, hence the tendency is to migrate to the areas of lower resistance to movement. Due to geophysical changes and forces, the entrapped material may become subject to great pressures, which condition manifests itself when the overlying impervious shales are penetrated by the drill. Water might rise, when a sand is reached, to a considerable height in the well, or may even overflow. In like manner, oil and gas may be under very great pressure and come from the well with great force, as in the case of the Turner valley wells which have reached the lime. The sands may not be uniform in texture but may contain lenses which are open grained and others which are tight. This lack of uniformity has an important bearing on the recovery of oil from horizons in which water has penetrated, as the tendency is for segregation of oil to take place in the tight lenses of the sands, and be held there while water replaces the oil in the looser areas. The result is, that wells will finally produce largely water, in spite of the fact that a large quantity of oil is still in the oil sand. Some interesting laboratory experiments have been carried out by the United States Bureau of Mines to prove this point.[2]

[1] Chief Deputy Supervisory, Dept. of Petroleum and Gas, State of California.

[2] Ambrose, A. W.—"Underground Conditions in Oil Fields," U. S. Bureau of Mines, page 70.

Classification of Oil Field Waters

In the industry, oil-field waters are divided into classes and are classified according to their relation to the oil producing zone, or zones.

The following classes are used:

(1) Top water.
(2) Middle or intermediate water.
(3) Lenticular water.
(4) Edge water.
(5) Bottom water.

The first class, "top" water, is water or waters which are met with above the oil producing zone; they may appear at relatively shallow or at considerable depth but so long as they are above the producing zone they are called "top" waters.

"Middle or intermediate" waters are those which occur between oil and gas sands. At early stages in the development of a field these might be regarded as bottom waters, until such time as a lower oil sand is discovered.

"Lenticular" water, is water carried by a water sand which pinches out in a field, and consequently may be met in one part of a field and not in another.

"Edge" water, is the water found in an oil sand in contact with the oil. It may not be apparent at first, but makes its appearance gradually as the oil is withdrawn from the sand.

Lastly, there is "bottom" water, which is the water that comes from beneath the lowest oil bearing zone in an area. It is not, in the initial stages at least, in contact with the oil, but may readily invade the oil sand if not taken care of.

The accompanying figure No. 3 will make clear the distinctions in the various classes of water enumerated above.

Water Troubles

All the classes of water just mentioned are capable of making trouble for the oil operator if proper precautions are not taken. With the exception of edge water, all can be satisfactorily dealt with, when correct measures have been taken in drilling the initial wells in an area. Edge water, however, is a very different matter from the others. In many fields, it may not appear for years, but when it does it marks the beginning of the end of that field. Methods have been employed, with more or less success, to hold back edge water encroachment but at best these merely delay the approach of the evil day when the field goes to water. In other fields edge water may make itself evident in the early stages of development, but not in such large quantity that it is considered detrimental; however, as the oil sand becomes depleted, the percentage of water increases until the oil practically disappears, or the quantity of oil recovered does not pay for the pumping of the oil and water mixture.

An example,[3] of what this means in actual practice, is shown in figure No. 4.

Sometimes bottom water is mistaken for edge water and cases are on record where wells, thought to be useless on account of edge water trouble, have been brought into good production by successful plugging off of bottom water. The productivity of oil sands containing water may be greatly improved by proper pumping methods. Wells

[3] Ambrose, A. W., *loc. cit.*, page 76.

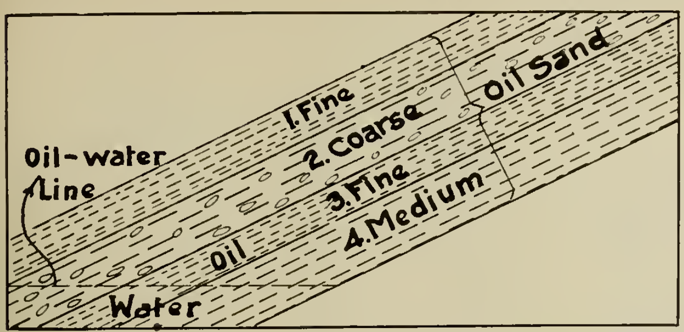

Figure No. 1.—Sketch showing Sand Texture and Original Relation of Oil and Water.

have been ruined by too great a rush to get the flush production; these might have produced a very much greater ultimate quantity of oil if the operators had been content with a lower daily production from the start. In view, therefore, of the inevitable end that awaits oil fields, it is surely to the interest of all operators that every reasonable precaution be taken to guard against the menace of all waters, particularly those waters the proper handling of which is largely a matter of care and suitable measures while the well is being drilled.

Water Sand Records

The drilling of an oil well means the outlay of a considerable amount of money. Of this sum, the actual amount required, in time and material for shutting off water, would represent a very small percentage of the total cost, and yet the whole success of the venture might hinge on the manner in which this was done. Even in the drilling of what is termed a "wild cat" well, where the primary object is information as to oil sands, it is just as important that every water sand be carefully recorded and proper measures taken to keep out the water as it is to record oil shows. The information obtained, by keeping such records, may be of the greatest value in event of the well proving to be a productive one. Since the first well drilled in any new field is more or less in the nature of a "wild cat" well, the recording of every item of information regarding water sands is highly important. It is evident then that the time to take the water problem in hand is when the field is first entered, and in order that the most accurate records of water sands be obtained it is essential that the initial wells be drilled with percussive tools, of which the familiar cable tools are a type. Only by their use can the lesser water sands and also oil and gas sands be detected and the exact depth at which they occur determined.

Having established the depths at which water, oil and gas sands were met with, information is now on hand as to the procedure to be followed if later wells are drilled by rotary. If these records are not first obtained small but useful oil and gas sands may be passed up, and water sands entirely overlooked which may later seriously endanger the productivity of the whole field. One unfortunate feature of the water problem is that not infrequently properly drilled wells are ruined through the carelessness of others in not shutting out water.

Sampling of Water in Sand

In dealing with the water problem, the petroleum engineer has called the chemist to his aid. Hence, in addition to logging carefully the exact depth at which water sands occur, he takes a representative sample of the water that comes from the particular sand. The sample should be truly representative, for upon this fact much might later depend. In taking a proper sample, certain precautions are necessary; the drilling water, in the case of cable tools and the mud fluid when the rotary is used, should be bailed from the well and the incoming water allowed to flush out the sand. Bailing should then be continued until all possible contamination by drilling water has been eliminated. The importance of this procedure cannot be over emphasized, for after all the analysis of a water merely tells what is in the sample received, consequently the greatest care should be exercised in obtaining a true sample of the water. If this procedure in sampling were followed with all waters encountered, and these waters carefully shut off before drilling be resumed, exceedingly reliable information would be obtained which could be of great use to the petroleum engineer. While government regulations in the province of Alberta make the sampling of all oil well waters obligatory, the operators, for their own interests, should see to it that their employees comply with not only the letter but the spirit of the regulation by taking true samples. For it is only along these lines that worthy and serviceable data can be collected which will materially assist in the development of commercial oil and gas fields.

Water Analysis[4]

For purposes of identification of oil-field water, use is made of the fact that every water carries certain mineral salts in solution. The amount may vary in different waters from a low to a high concentration. Well waters from Alberta oil fields, which have been examined by the department to date, lie between 0.02 and 23.0 per cent solutions of salts. As a general rule the dissolved salts appear to be more or less characteristic of the formations in which the waters are found. There are exceptions, however, the waters from the Milk river sand being a case in point; the waters from this sand vary quite considerably in different areas. On most fields the waters in different horizons vary to such a degree that identification is comparatively easy; in others they may be very similar, in which case dependence cannot be put entirely on the analysis of the water but must be considered along with whatever may be known of the drilling operations and the geology of the area.

Analysis of Water

The analysis of water, for oil-field purposes, consists in finding out what salts are in solution, or rather in determining what ions are present in the water. The constituents which predominate in oil-field waters, and the quantitative determination of which is sought, are: sodium, potassium, calcium, magnesium; and the acid radicles chloride, sulphate, bicarbonate, and carbonate. There are other constituents sometimes determined, but their amount is so small, generally, as to be negligible for ordinary purposes of description and identification.

Methods of Analysis

Time need not be taken here to describe the actual methods employed in analyzing the water. The methods outlined in any standard work on analytical chemistry are satisfactory for the purpose.

Methods of Reporting

In the past the results of oil-field water analyses have been reported to the petroleum engineer in a variety of ways; hypothetical combinations of several types, the Palmer system,[5] and the ionic system, were common. The Palmer system of interpreting water analyses has been in use for some time among oil men in the United States, and it has many excellent features. Though primarily used in classifying and comparing surface waters, it has also value in comparing oil-field waters. The Palmer method considers the reactive capacity of the various ions, rather than the relative concentration of the ions. The reactive capacity, or 'reactive value,' of each ion is calculated by dividing the concentration in milligrams per litre of each ion by the appropriate equivalent combining weight, oxygen 8, expressed in milligrams. Stabler[6] arrives at the same result by multiplying by the reciprocal of the corresponding equivalent combining weights. These reciprocals are called "reaction coefficients." From the sum of the reaction values of all the ions, the reaction value of each ion is calculated in percentage. The waters are compared on this basis. This is as far as the Palmer method is usually followed in reporting oil-field water analysis, although the complete system carries the analysis a step further; but that need not be discussed here.

The ionic form of reporting water is the simplest. It gives the chemical constituents of a water in the exact proportion in which they are present, and the plain statement of fact without any assumption being made. Reistle,[7] who has had a wide experience in dealing with the oil-field water problem in the United States, has this to say regarding the ionic statement: "For describing and identifying or differentiating any two waters, this system of reporting analyses is undoubtedly the most convenient and reliable; it cannot be misleading."

Table No. 1, illustrates the calculation of Palmer's reacting value from the ionic statement.

Graphic Classification of Water

Where a large number of waters are to be compared it is often found more convenient to represent them graphically than to compare them as groups of figures. Several graphic methods have been in use. No one of them is

Table No. 1

Radical	Parts per million (milligrams per litre)	Reaction co-efficient	Reacting value	Reacting value (Palmer) per cent	Per cent by Weight
Calcium *Ca*	1,500	.0499	74.87	4.6	3.2
Magnesium *Mg*	512	.0822	42.11	2.6	1.1
Sodium *Na*	15,878	.0435	690.39	42.8	33.3
Chloride $-Cl$	25,322	.0282	714.33	44.2	53.0

Bicarbonate $-HCO^3$	262	.0164	4.29	0.3	0.5

perfect but the most recent one to the writer's knowledge, the Parker method,[8] appears to have fewer faults than any of the others. It was first used in comparing the oil-field waters of Trinidad. In the analyses which are given below, the Parker method is used, with a few changes to suit the special requirements of Alberta waters.

Characteristics of Waters

Just to what degree the character of a water is influenced by the structure in which it is entrapped, or moves, and how much of the original character is still retained, is a question about which there can be justifiable differences of opinion. That changes do take place, the example of the different waters from the Milk river sand is evidence. There are without doubt, in Alberta, oil-field waters which are "connate" waters. These waters have retained many of the marks of their original character and appear to have been influenced but little by their surroundings. Iodine is present in most brines met with, which is suggestive as to their origin.

Deep waters encountered in Alberta fields are almost wholly chlorides of sodium, calcium and magnesium. Sodium chloride is most prevalent, and magnesium chloride least. So far, only one exception to this rule has been noted, in which case the calcium chloride content exceeded the sodium chloride. A certain amount of bicarbonate is carried in the very heavy brines but it never exceeds 1,000 p.p.m. An interesting fact, worthy of more than passing notice, is the entire absence of sulphates in many of these brines. Sea water contains sulphates; consequently one would expect to find them in the oil-field brines. Rarely in Alberta are sulphates found in a brine at all near an oil-sand. This may perhaps be simply a coincidence, but it is certainly an interesting fact nevertheless. There is one well being drilled at present where the sulphate content of the deep waters is just the reverse of what is usually found in brines. Up to the present this well has shown little or no evidence

of oil. It is not being suggested that there is any relation between the sulphate content of waters and the presence of oil, although the query might be raised.

The absence of sulphates in oil-field brines has been known a long time, and two theories have been brought forward to explain this phenomenon. The older theory suggests that sulphate removal is brought about by reduction to hydrogen sulphide, the reducing agent being 'dead' organic matter present in, or contiguous to, the water-sand. This reaction can be brought about in the laboratory, but it only takes place at very high temperatures. Time as well as temperature is a factor in chemical reactions; consequently, given time enough, the reaction might be possible at relatively low temperatures. A recent theory, brought forward by Bastin,[9] explains the reduction of sulphates by the action of bacteria. Oxygen is removed by the bacteria and the sulphates are reduced to hydrogen sulphide. Bastin has gathered some very fine experimental evidence in favour of his theory. He does not, however, exclude the possibility of the older theory.

Shallow waters differ from deep, in that there is more likelihood of their dissolved solids reflecting the nature of the overlying strata. It has been pointed out above that the amount of dissolved solids in surface waters is very much lower than in the deeper waters. This is due largely to the nature of the dissolved salts, for with but few exceptions sulphates and bicarbonates predominate in surface and shallow waters. Since the calcium salts of these acids are not very soluble, there is a limit to the quantity of these salts which can be held in solution. Sodium is the chief alkali, metal or earth, present in surface waters; occasionally, the calcium and magnesium content exceeds it, but this only occurs in waters of low concentration. The chloride content of surface waters is almost negligible, unless the waters are found in the neighbourhood of salt deposits, e.g., the waters from the McMurray area. Here the character of the water is reflected by the formation.

In most oil fields, methods of correlation have depended on the facts that:

(1) Concentration increases with depth.
(2) The sulphate content decreases with depth.
(3) The carbonate-plus-bicarbonate content decreases with depth.

For some areas in Alberta, all three conditions hold good, but only the first has anything like a general application to all fields. The bicarbonate and sulphate content of Alberta oil-well waters appears to vary quite a bit in different fields. In most cases the deep waters have less than the shallow waters, but in some wells the deep waters may contain more than the waters higher up.

Use Made of Water Analysis by Petroleum Engineers

With reliable records on hand, as to the depths at which water sands were struck and the analyses of these waters, the petroleum engineer has information which is of great value to him in laying plans for the drilling of other wells in the area. For example: he knows the depths at which water shut-off jobs would have to be done, he can estimate closely the amount and dimensions of casing required for the new wells and can decide beforehand the most economical use he can make of it, commensurate with safety. In addition to this, unsuccessful water shut-offs can be checked and the source of water, which might later make its appearance in a completed well, can be identified; for having on record the analysis of all waters encountered in drilling the well, and the depths at which they occurred, the trouble can be overcome with less difficulty than if no

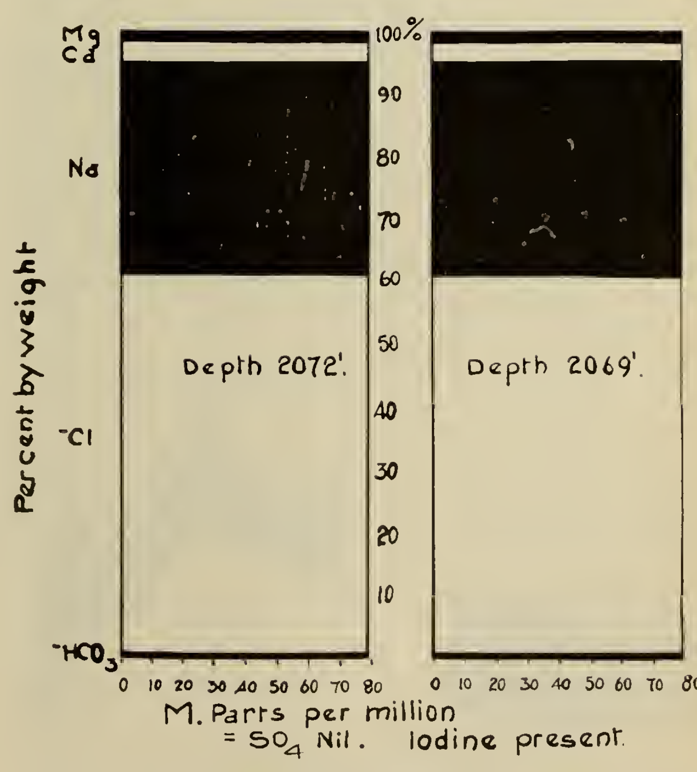

Figure No. 5.—Wainwright Area — Water from Same Horizon in Different Wells.

Figure No. 6.—Milk River Sand — Water from Same Sand — Different Fields.

such record had been kept. With the use of just such information as has been enumerated, progressive engineers have saved their companies hundreds of thousands of dollars in the oil fields of the United States. Figure No. 9 shows improved production after water has been shut-off.[10]

Cementation

The next step in a properly drilled well is to shut off the water, but this should not be proceeded with before careful tests have been made to ascertain the exact depth of the water sand. This is important, as setting the casing too high is just as bad as a poor job although everything may have been perfectly done. The water shut-off should be done so effectively that the water will give no further trouble during the life of the particular field. It is generally useless to attempt to pump a water sand dry. Formation shut-off jobs may sometimes prove effective where cavings become packed around the casing but there is an element of uncertainty in this. The most reliable if not the only means employed in shutting out water effectively is cementation. The work of cementation stated simply consists of surrounding the casing or water string set at a convenient point below the water sand with cement, from the bottom of the casing, to a point well above the water sand. The actual carrying out of this operation and the realization of the desired result is, however, a somewhat hazardous affair that calls for careful consideration before being attempted, and thorough work in the undertaking. There is a feeling in certain quarters that anyone can cement a well, but judging by the member of failures to do this it does not appear to be quite so simple as is popularly thought. Even those who make it their sole business cannot report 100 per cent results. So much depends on the effectiveness of a water shut-off, that no reasonable expense and effort should be spared in securing it. Failure means a great deal of added expense. Recementing may have to be attempted, provided circulation can be established; failing this, drilling may be proceeded with, but on account of the water in the hole progress will be very much slower. An additional string of casing will now be necessary to shut the water out; this is an added expense besides decreasing the size of the hole. Quite often small but useful gas horizons, with volume sufficient to run the boilers and supply the camp, have been drowned out by water standing in the hole from unsuccessful water shut-off jobs. For these reasons, therefore, the actual operation of cementation should be entrusted to competent men only, and even in their hands it may prove difficult and not always successful. It should be borne in mind that no two wells are exactly alike; different methods will be necessary in different wells. Conditions, too, vary in the different fields, making the cementation difficult or comparatively easy. There are fields in Alberta which present peculiar difficulties in making successful water shut-offs on account of the nature of the formation. This is especially true of those areas where the structure is more or less unconsolidated or where local fractures and fissures occur. At the present time there is a company operating in Alberta which makes a business of cementing wells. They guarantee to place the cement where it is supposed to go, which at least suggests that they have some confidence in their work. Even if it does cost more to have cementation jobs done by such a company, it may prove to be more economical in the long run. When cementation has been done, ample time should be allowed for thorough setting of the cement before drilling is proceeded with. It is poor economy to recommence drilling before the cement has had time to set properly and incur all the inconveniences of an unsuccessful shut-off. It is also essential that agitation of the cement from gas or movement from other causes be entirely avoided during the setting period, otherwise what would be a successful job may prove to be a failure.

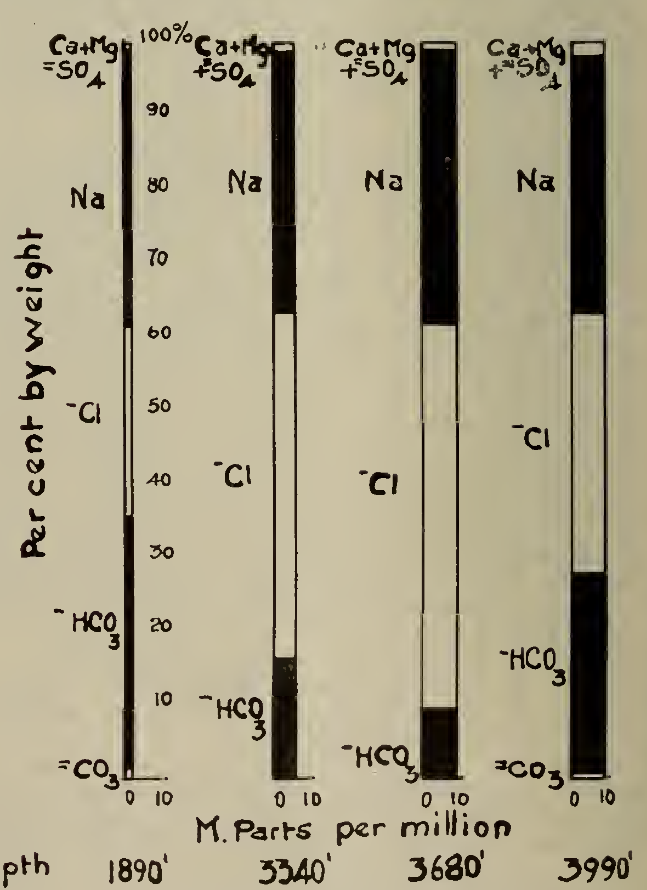

Figure No. 7.—Medicine Hat—Different Waters from Same Well.

(10) Ambrose, A. W., *loc. cit.* p. 99.

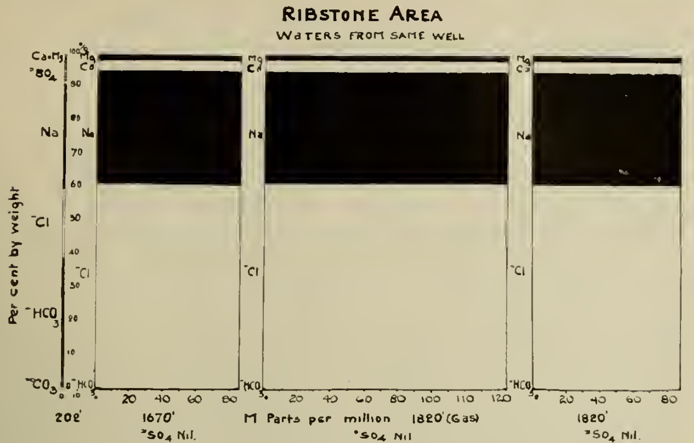

Figure No. 8.—Note Similarity of Waters Encountered at 1670′ and 1820′. A Clear Case of Incomplete Shut-off at 1670′. The Water Marked 1820′ (Gas) was blown from the Well when Gas was struck.

Taking the simplest case of cementation as an example, the procedure is as follows:—

(1) Circulation is established, i.e. it is made certain that there is a free passage from the inside of the casing up between the outside of the casing and the formation.

(2) Neat cement of suitable quantity and consistency is introduced into the bottom of the hole or inside the casing—there are a variety of ways in which this can be done.

(3) Pressure is applied on the column of cement so that it is forced from the bottom or out of the casing into the space between the outside of the casing and the formation. The pressure should be maintained undiminished until the cement has thoroughly hardened.

Many modifications in procedure will be necessary to fit the particular circumstances. In the case of very deep wells, cementation is more intricate and much ingenuity and very elaborate equipment is necessary for its successful accomplishment but the final result is just as has been described.

There are many cementation methods in use at present, some of which are protected by patents. The Perkins and Haliburton processes are well known; the latter is being used quite extensively in this province. The tubing and dump bailer methods are in common use, the latter being of great service in cable tool drilling where pumps for circulating are not available.

The methods of cementation which have just been mentioned have to do more particularly with water encountered in the drilling of new wells, i.e. with "top" and perhaps "intermediate" waters. If the water problem were confined to these alone, its solution would be comparatively easy but the real problem has to do with water troubles which arise in producing wells. These water troubles require somewhat different treatment and are much more difficult to deal with. Water may get into a producing well from various sources. Casing joints may be defective, or the casing itself may have been damaged, permitting surface water to seep in. Water may break through from water shut-off jobs which were improperly done. The producing zone itself may contain water in the form of edge water, and bottom water may have been permitted to invade the producing zone when the drill has penetrated the underlying water sand, lastly water may find its way into a properly drilled well from other wells, in the same area, in which the necessary precautions have not been taken to protect the oil zone by shutting off water sands. When water appears in a producing well, the first step is to determine if possible the source of the water. If the operator has been careful in taking samples of water encountered in drilling the well, and has had analysis made of these, he has a ready means whereby he can check up whether these waters are responsible for the trouble. If care has not been exercised and mixing has been permitted in taking these original samples, the identification of the water is made very difficult. Should the analysis of the intruding water prove to be one of those which was sampled, the depth at which the trouble is seated is known.

The next step is to find out just how the water is getting into the well. If the water is of surface origin, sometimes the water string joints may be responsible and these may be tightened up. Cases are on record where water strings in producing wells have been screwed up as much as 26 inches, with successful exclusion of water. It may prove to be that water is leaking past the casing shoe, which has been set a little above the bottom of the water sand; in this event driving the casing may be effective in keeping out the water. It may be found that the casing has collapsed in which case it would have to be swaged out and a bridge set at some point below the damaged length, then cement forced through the opening into the space between the two strings of casing. The use of tubing with packers set at some point below the place of entry of the water has proved useful, where other means have failed. Only a few of the possibilities have been suggested but perhaps sufficient has been said on this point to indicate the real difficulties that the petroleum engineer is faced with, first in locating the seat of the trouble, and second in successfully correcting it after the cause has been discovered.

If the water proves to be different from any of those of which records are on file, the new water may be edge or bottom water. Examination of other wells further down the dip may decide whether it is edge water or not. There appears to be a general feeling among those whose business it is to see that the maximum amount of oil is produced from an oil sand, that operators are too easily discouraged when water appears which is suspected of being edge water. An honest attempt to shut off such water has often been rewarded with success. Even after several failures success has come, for what was thought to be edge water proved to be simply bottom water. When the bottom water is under considerable head the shutting off presents many difficulties. Lead and lead wool plugs have been employed with fair success, but as a general rule cementation, where at all possible, is much more satisfactory. For edge water little can be done. Compressed air methods have been tried but these have proved merely palliatives.

Examples of methods of dealing with water troubles might be multiplied but it must be evident that all the aspects of so wide a subject cannot be fully dealt with in the course of so short a paper.

Figures Nos. 10 and 11 demonstrate the reality of the water problem in some of the oil and gas areas in Alberta.

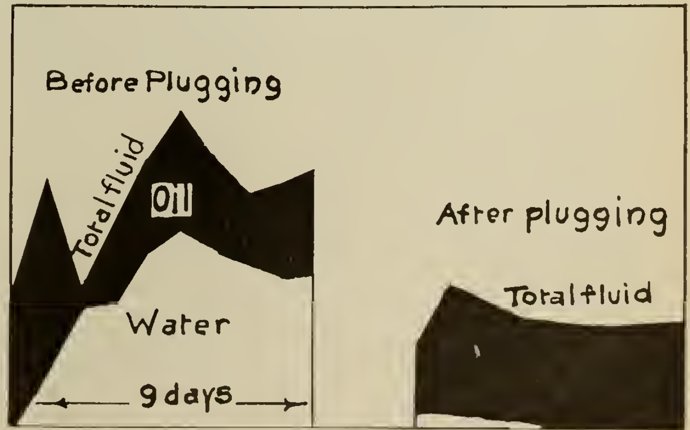

Figure No. 9.—Sketch showing Production of Oil Well before and after Plugging off Bottom Water. The Source of the Water was determined by Chemical Analysis.

A Short Monograph on Nomography (Part I)*

F. M. Wood, A.M.E.I.C.,
Lecturer, McGill University, Montreal.

Nomography may be defined as the science of representing the relations between variables in a graphical form, and by its aid solutions of formulae may be obtained in a graphical manner. It has as its foundation analytic or co-ordinate geometry, and may be considered as one of the youngest of the mathematical sciences, since it was not developed to any extent until the last decade of the nineteenth century, when D'Ocagne and his successors demonstrated its utility and, incidentally, gave it a name.

It is unfortunate for those of us who claim English as our mother tongue that most of the work on the subject has been done by the French. It seems to the writer to be an added misfortune that nearly all of these writers have employed cumbersome analytical methods, which tend to discourage the engineer at the outset. D'Ocagne for instance devotes little time to the use of the determinant notation, which the author thinks is of the greatest help not only in the study of the theory but also in the practical solution of particular problems. One of the best books on the subject written in recent years in the English language is that by Hewes and Seward. This, however, is in the nature of a text book, and several types of chart are discussed which are interesting for academic reasons but are not suitable for practical application.

This paper has been written with three main objectives:

(1) To simplify the study of the theory for the practising engineer.
(2) To codify if possible, the various types of formulae and their corresponding charts.
(3) To point out the desiderata of a good chart and show how these may be obtained.

With regard to the methods employed in obtaining the chart, they should be simple, clear, and flexible, in order to permit ready adjustment to the peculiar properties of the particular problem in hand. The chart itself, when complete, should be not only clear and simple to read, but also accurate and adequate over the range of values of the variables to be encountered.

Types of Nomograms

We may divide nomograms into two main classes:

(1) Those whose solution is given by the intersection of lines.
(2) Those whose solution is obtained by the collinearity of points.

The first class has been called "charts of intersection" (d'entrecroisement) by D'Ocagne. Another name that suggests itself is "charts of concurrence."

The second class are now generally known as "alignment" charts. They may also be called "charts of collinearity." There is a close mathematical connection between these two types which will be pointed out later in an appendix. Their relationship is analogous to that between poles and polars in geometry.

Both types of chart are popular and both have their good and bad points. Let us take an example of each to illustrate this. In the chart of intersection for Scobey's formula $Q=1.272\,D^{2.65}H^{0.555}$ (figure No. 5), there is a set of horizontal lines for values of H, a set of vertical lines for values of Q, and a third set of inclined lines for value of D. Any point on the chart denotes a particular value of each of the variables H, Q, and D, since it has a definite position with respect to each of the three sets of lines, and we may consider that each point on the chart is a point of intersection of an H line, a V line, and a D line. The chart is constructed in such a way that three such values for H, V, and D will satisfy the given equation.

*Part II, with appendices, will follow in a later issue of The Journal.

Turning now to the alignment chart for the same equation, (figures Nos. 10 or 11), we notice that any straight line drawn across the chart will cut the three scales H, Q, and D at particular values of the variables H, Q, and D. These scales are so constructed that any three such values of H, Q, and D will satisfy the given equation.

In comparing the two types of chart, it may be said that the charts of intersection are more easily made, mainly because the theory on which they are based is not very difficult to master. However, they are confined to problems and equations involving at most three independent variables. In some respects these charts furnish a better picture of the relationship between the variables than the alignment charts do. They have also the advantage that solutions may be obtained without the use of a straight edge. Against these, we may say that their chief disadvantages are (1) their heavy appearance which renders them somewhat confusing to the reader, and (2) the fact that the method used in solution does not permit of the accuracy obtainable with the alignment chart. It is generally found much easier to interpolate between two points on a line than between two parallel lines, especially when two such interpolations must be made simultaneously, as in the case of the chart of intersection.

Intersection Charts for Two Variables

These charts are based on the elementary theory of co-ordinate geometry. They may be constructed in either of the two systems of co-ordinates (a) rectangular or (b) polar. The polar system is useful in cases where one of the variables is an angle. In either system, one of the variables is allotted to one of the co-ordinates, and the second variable to the other. Points are located whose co-ordinates satisfy the relationship between the variables, and the locus of these points furnishes the general solution. Examples are given of the solution of $V^2=2gH$ (figures Nos. 1 to 4). In these charts it is seen that the variable H has been allotted to the X axis, and the variable V to the Y axis.

Scales

At this point it seems advisable to discuss the proper selection of scales for the co-ordinates. There is a choice as regards (1) type, and (2) size. The types of scale may be classified as follows:

(a) Ordinary linear scale, in which points representing uniformly increasing values are equidistant. (Figure No. 1.)

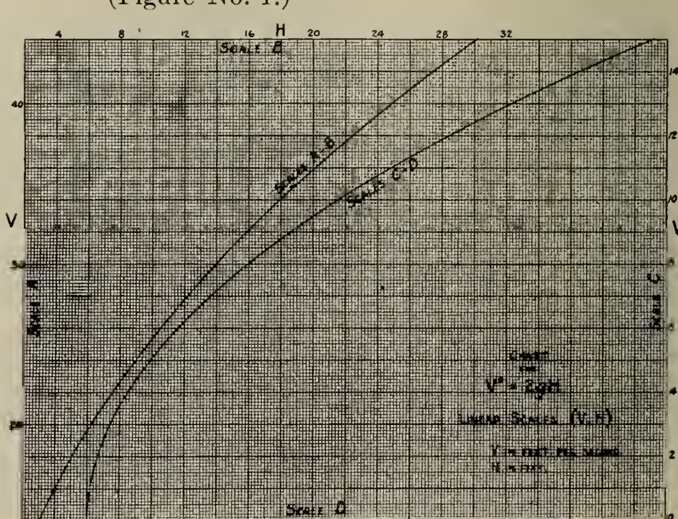

Figure No. 1.

(b) Logarithmic scale, in which the distances between the points are proportional to the differences between the logarithms of the values they represent. (Figure No. 2.)

(c) Power, or functional scale, in which the graduations are spaced in accordance with the values of some power or function of the variable. (Figures Nos. 3 and 4.)

The logarithmic scale is virtually a functional scale, but deserves particular mention because of its extensive use.

By "size of scale" is meant the actual distance on the chart corresponding to a definite change in value of the variable.

The selection of the size of the scale is governed by the range in value of the variable. Consideration should also be given to the angles of intersection between the various sets of lines. The most suitable angles for accurate reading are between 30° and 90°. In some cases it may be necessary to make two charts, each covering part of the range of values, in order that the required accuracy may be obtained. As an illustration, in figure No. 4, it was decided to break up the range of values of V and H into two scales each. The total range for V is 2 to 50, one scale covering the values 2 to 15, and the other the values 15 to 50. Taking the lower scale, $\frac{1}{V^2}$ varies between $\frac{1}{4}$ and $\frac{1}{225}$, and the range covered is $.25 - .00445 = .24555$ units, say .25 units. Since there are 15 main divisions, we make 15 divisions $= .25$ units or one unit $= 60$ divisions. The lower end of the scale is marked $V = 2.0$ and represents $\frac{1}{4} \times 60$ or 15 divisions, so that the divisions decrease as we go up the scale. The value $V = 3$ corresponds to $\frac{1}{9} \times 60 = 6.667$ divisions, and the value $V = 3$ is marked at the point $15 - 6.667$ or 8.333 divisions from the bottom. It is readily seen how a suitable adjustment of the size of scale may be made in each particular case.

The selection of the type of scale depends on the type of equation involved. If the equation is made up of the sum or difference of functions of the variables, the linear scale or the functional scale may be most suitable. If the equation involves the product of powers of the variables, especially when the powers are fractional, the logarithmic scale may prove most effective. A study of the four charts of the relation $V^2 = 2gH$ will illustrate these points. The linear chart gives a curve for the locus, whereas the V^2 chart gives a straight line. It is a debatable point which chart is the easier to construct, and which the more accurate in solution. In the case of the V^2 chart we can avoid the trouble of making a V^2 set of lines by plotting a V^2 scale on ordinary graph paper, as in our figure. This, however, is liable to cause confusion. The straight line locus is preferable to the curved in that all intersections are at a suitable angle. This advantage is more apparent than real because the answer must in the end be read on an irregular scale. In order to straighten out the curved locus of the linear scale we have been forced to warp this linear scale

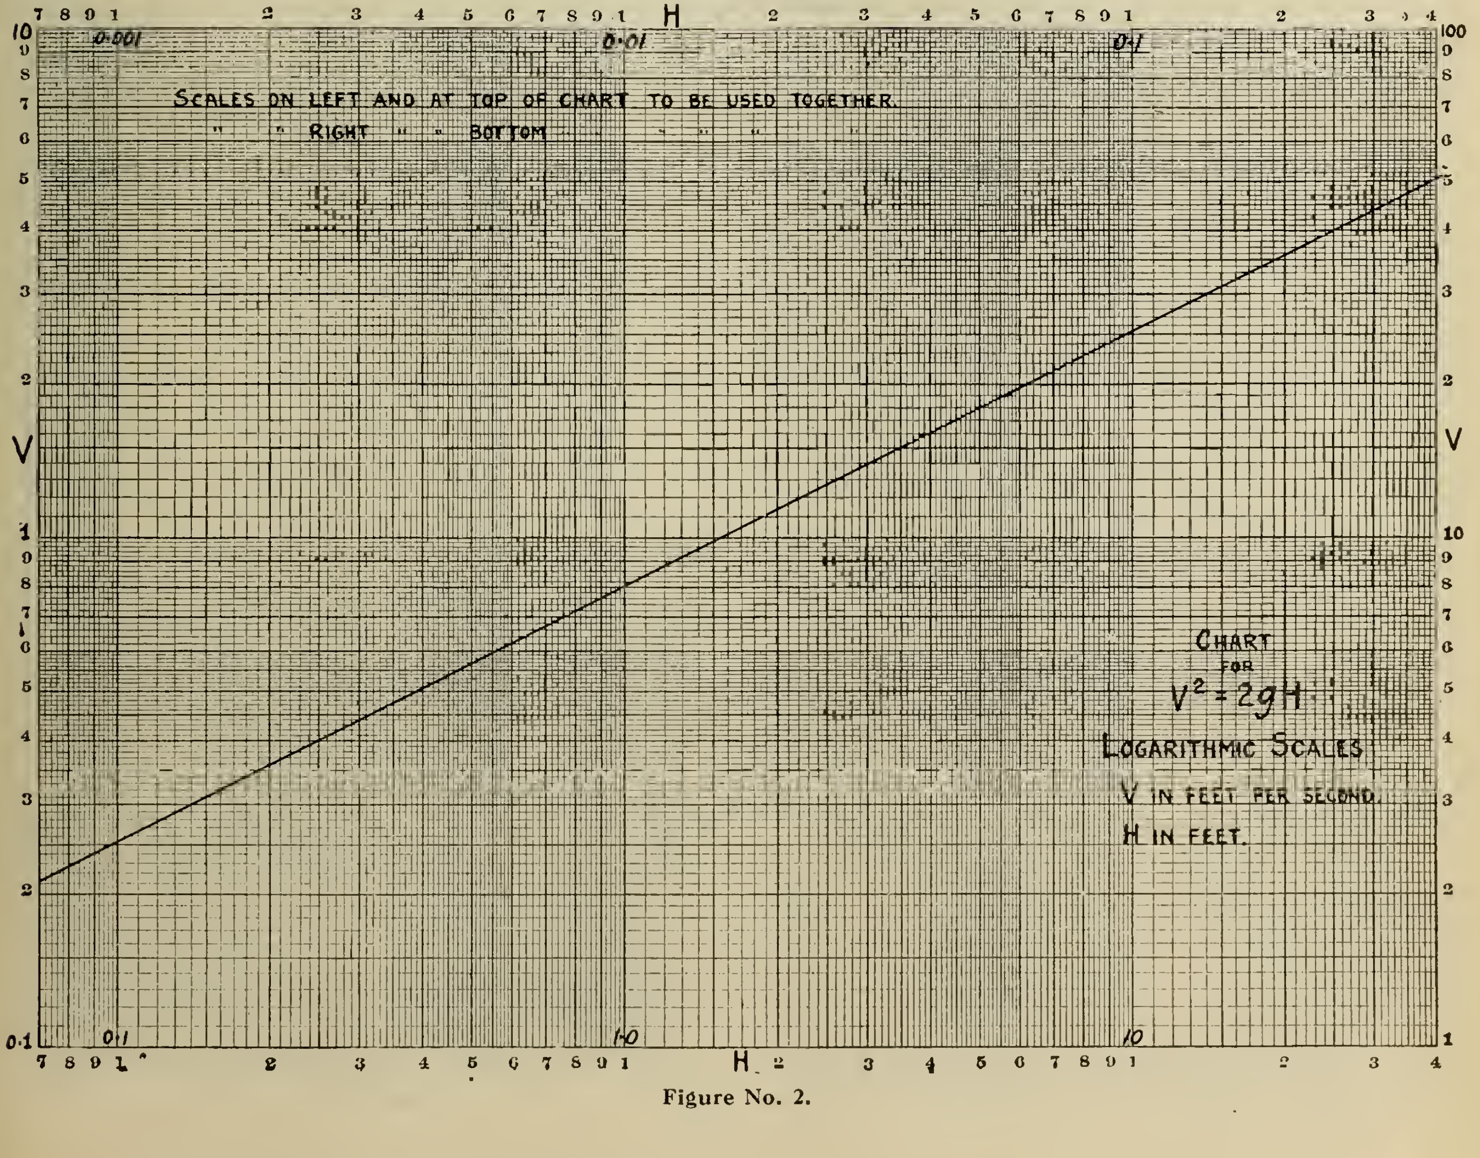

Figure No. 2.

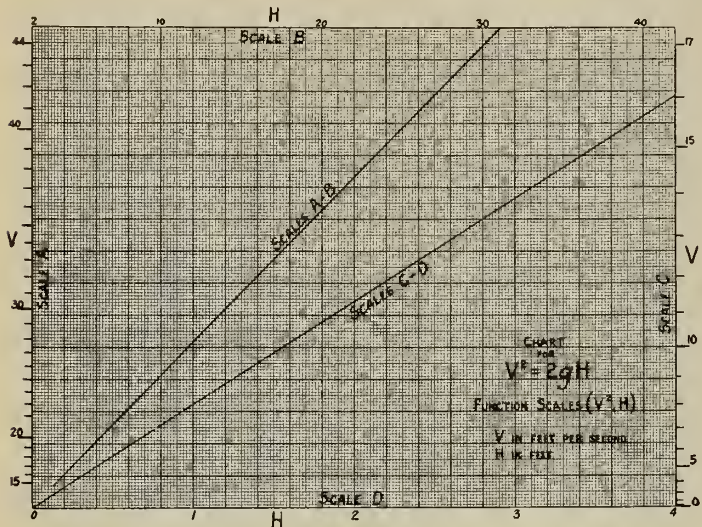

Figure No. 3.

into a V^2 scale. It is seen that in contrast with the uniform accuracy in reading the H scale the accuracy in solving for V is greater for higher values of V for both types of chart. This is why a second chart is necessary, covering the lower values of the variables.

Turning now to the inverse function scales (figure No. 4) the accuracy here is greater for the lower values of the variables. This is generally true for inverse scales and they should be chosen whenever greater accuracy is required over the lower range of values. The three charts of figures Nos. 1, 3, and 4 have been plotted for similar ranges in value of the variables to facilitate comparison.

Figure No. 2, based on logarithmic scales, has been plotted on commercially available paper. This has a great disadvantage in that it limits the range of values of the variable, and also fixes the size of the scale. Two sets of scales have been allotted to the one locus in order to minimize this defect and our H scales range from 0.07 to 40 and from 0.0007 to 0.4. Nevertheless, the logarithmic scales have the advantage of providing a much more extensive range of values than the other types, and in this case the ratio of highest to lowest value of H is 40/.07 or approximately 600. Another advantage is that the accuracy of solution is independent of the numerical value of the variable, being determined by the number of significant figures, and not by the position of the decimal point. Of course the accuracy is greater between the values 1 and 2 than higher up along the scale.

Some problems may require the use of more than one type of scale. In this case the logarithmic scale was convenient for higher values of S, but the linear scale was more suitable for lower values, which extended down to zero. Other examples may require different types of scale for the different variables, as may be noted in the example of figure No. 6, where the formula has two linear variables and one of the other variables is an exponent. Semi-logarithmic paper is very convenient for use with formulae of the type $10^V = H$, which should be transformed to the form $V = \log H$.

Intersection Charts for Three Variables

An example of this type of chart is given in figure No. 5, for solution of Scobey's formula. These charts are an extension of the charts for two variables, and since polar co-ordinates are seldom used in cases of three variables, and as the principle is the same for both types of co-ordinates, we will confine our discussion to the rectangular type of co-ordinates.

It is customary to allot one variable to one axis and a second variable to the other axis. In this way each point in the plane represents by its co-ordinates a particular value of each of the two variables. Two sets of lines, one vertical and the other horizontal, may be marked off with values of their respective variables. With linear scales, these lines will be equally spaced but with functional scales along the axes, they will not be spaced uniformly. A third set of lines must now be constructed, each line denoting a particular value of the third variable. This set of lines must be placed so that any point in the plane will determine a particular value for each of the three variables, and these values will satisfy the given equation. This result may be realized by taking each value of the third variable in turn, and finding a set of simultaneous values of the other two variables which go with it. These points are all joined up to give the locus for this particular value of the third variable.

Let us make this clear by means of the example in figure No. 5. We will assume that the logarithmic form of the equation has been chosen,

$$\log Q = \log 1.272 + 2.65 \log D + 0.555 \log H.$$

The logarithmic scales $\log Q$ and $\log H$ have been selected, the Q scale being placed horizontally because a greater range of values is required for Q than for H. In order to obtain the D set of lines, we transform the equation to read:

$$\log Q - 0.555 \log H = \log 1.272 + 2.65 \log D.$$

If now we represent $\log Q$ by x and $\log H$ by y this becomes

$$x - 0.555\, y = \log 1.272 + 2.65 \log D,$$

a set of straight lines for different values of D. It is therefore sufficient to find only two simultaneous sets of values for Q and H corresponding to each value of D. If this D set of lines were curved it would be necessary to find a series of simultaneous values of x and y (i.e. of Q and H) for each particular value of D, and join these points (x, y) in a locus.

In this case we may fix the value of $H = 0.1$ for one set of points, and it will be necessary to solve the equation

$$\log Q - 0.555 \log 0.1 = \log 1.272 + 2.65 \log D.$$

Each particular value of D will determine the correct value of Q which will determine the corresponding point on the line $H = 0.1$. Thus for $D = 10$, we find

$$\log Q = \log 1.272 + 2.65 \log 10 + 0.555 \log 0.1,$$

or $Q = 158$. Hence one point on the $D = 10$ line is given by $H = 0.1$ and $Q = 158$. In a similar manner a set of points may be marked off along the upper line $H = 10$, and also along the centre line $H = 1.0$, covering a range in values of the variable D. The centre set of points are used mainly as a check, but they are necessary for the upper and lower values of the variable, where the D lines do not extend

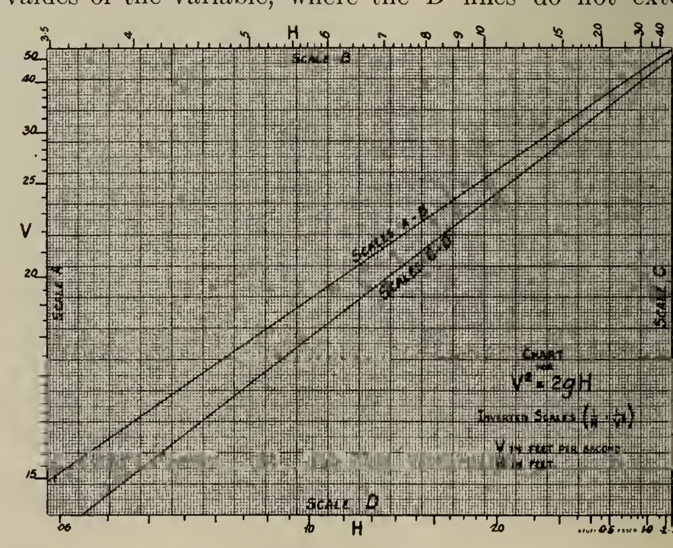

Figure No. 4.

across the paper. We can check up on the draughting work by verifying that the D lines are parallel, and inclined at an angle of $\cot^{-1} 0.555$ to the horizontal.

In making these intersection charts for three variables on prepared graph paper, it is evident that at least one set of lines must be drawn diagonally, while the other two variables may be allotted to the two perpendicular sets of lines (linear or logarithmic) already printed on the paper. It is necessary therefore in each formula to decide which of the variables will have the simplest values in practice, and pick this variable for the diagonal set of lines. Thus in Scobey's formula, the variable D or the diameter of the pipe is most suitable for this set of lines, since almost all diameters are chosen in integral, half or quarter feet. Regarding the range of values to be covered by the chart, this is known in most practical cases for two of the variables at least, and the third variable must be made to conform to these.

It is seen that a set of V lines has also been drawn on Scobey's chart. These were obtained in a similar way to the D lines, from the relation $V^{2.65} = KQ^{.65}H^{.916}$ which can be obtained readily from the given equation between Q, H, and D. We have thus two charts drawn on one piece of paper and any two simultaneous values of two of the variables Q, H, D, and V will give directly a solution for the other two variables.

It is evident that any intersection chart for three variables may be constructed by the method illustrated above, but it is advisable to choose the scales along the principal axes in such a way as to give a set of straight lines for the third variable. If the third set of lines is curved there is a great amount of labour involved in constructing them. Suppose for instance we had kept Scobey's formula in its original form $Q = 1.272\ D^{2.65} H^{0.555}$. With simple linear scales for Q and H along the axes, the D set of lines would have been given by the relation

$$QH^{-0.555} = 1.272\,D^{2.65}$$

which results in a set of curves $xy^{-0.555} = \text{Constant}$.

Summarizing analytically our discussion of intersection charts for three variables:

The general equation for this type of chart may be expressed $f(\alpha\beta\gamma) = 0$ where α, β, and γ are the three variables. By assigning particular values K to the variable γ, our equation becomes $f(\alpha, \beta, K) = 0$.

If we represent values of α by some functional scale along the x axis, and values of β by some other functional scale along the y axis, the equation will take the form $F(x, y, K) = 0$. The functional scales for α and β should be chosen in such a manner as to make this last equation in x and y as simple as possible. Each value $\gamma = K$ gives us a curve $F_1(x, y) = 0$ and this curve when plotted may be marked $\gamma = K$.

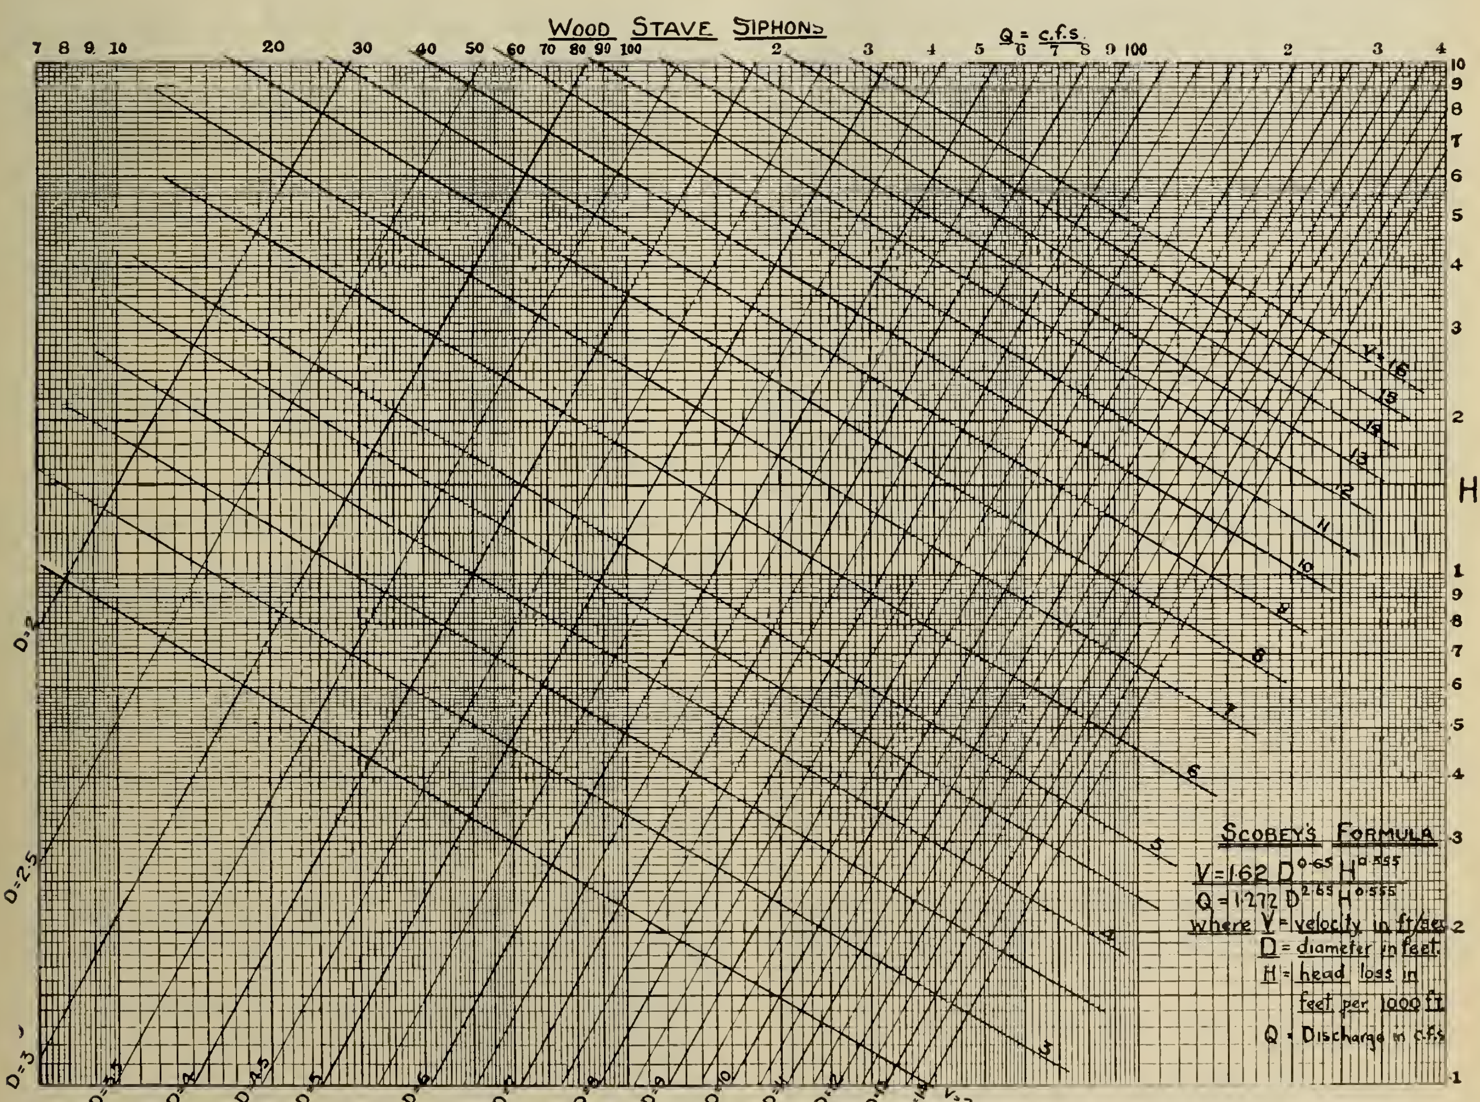

Figure No. 5.

The scales for α and β need not necessarily be functional. When for instance the chart is the outcome of certain test data, it may be found advisable to pick the α and β scales arbitrarily, although the usual practice in such cases is to choose a simple scale.

Example for our summary:

$$F(a, T, G) = (a^2-1) - T^3 - 6G = 0.$$

Assuming that variable "a" is placed along the x axis, and the T variable along the y axis, it would be convenient to have functional scales $x = a^2-1$, and $y = T^3$.

Then the G lines will be given by the equation

$$x - y = 6G.$$

Alignment Charts

In this type of chart graphical solutions may be obtained for equations involving three or more variables. The simplest case is that with three variables. The solution of this chart is given by the collinearity of three points, each of which is situated on a scale representing one of the variables. The more complicated formulae which involve more than three variables are solved either by a repeated use of the collinearity idea, or else by a combination of the collinearity principle with charts of intersection.

As has been indicated in the introductory paragraphs, the determinant notation is a great help in the study of the theory of the alignment chart, and it is also useful as an instrument in the construction of particular nomograms. A considerable amount of work must be done in transforming the appearance of every nomogram after its general outline has been decided on. Each problem calls for its own special treatment, the final form of the chart depending on the ranges of value of the variables and the degree of accuracy required in solution, as well as on the limitations caused by the appearance of the given equation. Whatever the method of attack, this work of transformation cannot be carried out efficiently unless the underlying principles are understood.

The problems in both theory and practice are solved in such a neat and logical way, with the aid of determinants, that it seems well worth while to spend a little time in reviewing the rules of this mathematical symbolism.

As we deal with determinants of the third order, which are always equated to zero, the rules themselves are simple and the novice will not find their application difficult. It will be found advisable to devote some time to practice in the use of the rules, and in checking up their validity, before proceeding with their application.

Determinants—Summary of Rules for Transformation, Etc.

Definition:—

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} \equiv a_1(b_2c_3 - b_3c_2) - a_2(b_1c_3 - b_3c_1) + a_3(b_1c_2 - b_2c_1)$$

A particular case of this determinant of the third order is

$$\begin{vmatrix} a_1 & b_1 & 1 \\ a_2 & b_2 & 1 \\ a_3 & b_3 & 1 \end{vmatrix} \equiv a_1(b_2 - b_3) - a_2(b_1 - b_3) + a_3(b_1 - b_2)$$

Rule 1. Multiplying all the members of a column or of a row in a determinant by some multiple m, is equivalent to multiplying the whole expression (or determinant) by m.

$$\begin{vmatrix} ma_1 & b_1 & c_1 \\ ma_2 & b_2 & c_2 \\ ma_3 & b_3 & c_3 \end{vmatrix} = \begin{vmatrix} a_1 & b_1 & c_1 \\ ma_2 & mb_2 & mc_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = m\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix}$$

Rule 2. The value of the determinant remains unchanged when the members of any column (or row) are

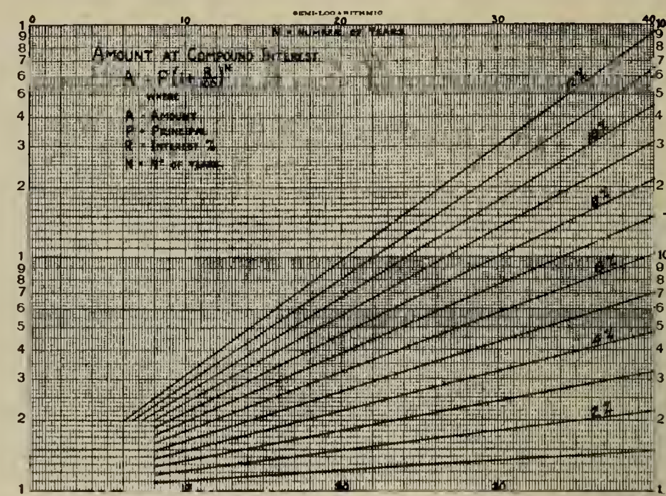

Figure No. 6.

increased or reduced by some fixed multiple of the corresponding members of another column (or row).

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = \begin{vmatrix} a_1 - nc_1 & b_1 & c_1 \\ a_2 - nc_2 & b_2 & c_2 \\ a_3 - nc_3 & b_3 & c_3 \end{vmatrix} = \begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 + na_1 & b_2 + nb_1 & c_2 + nc_1 \\ a_3 & b_3 & c_3 \end{vmatrix}$$

Rule 3. The interchanging of two adjacent rows (or columns) changes the sign of the determinant.

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = -\begin{vmatrix} a_1 & c_1 & b_1 \\ a_2 & c_2 & b_2 \\ a_3 & c_3 & b_3 \end{vmatrix} = -\begin{vmatrix} a_2 & b_2 & c_2 \\ a_1 & b_1 & c_1 \\ a_3 & b_3 & c_3 \end{vmatrix}$$

Rule 4. Changing rows to columns does not change the determinant.

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = \begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix}$$

Rule 5. Three equations

$$\left.\begin{matrix} a_1x + b_1y + c_1 = 0 \\ a_2x + b_2y + c_2 = 0 \\ a_3x + b_3y + c_3 = 0 \end{matrix}\right\} \text{ will be true}$$

simultaneously if

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = 0.$$

The converse of this also holds true.

Rule 6. Three points in the co-ordinate plane $(a_1\ b_1)$, $(a_2\ b_2)$, and $(a_3\ b_3)$ will be collinear if

$$\begin{vmatrix} a_1 & b_1 & 1 \\ a_2 & b_2 & 1 \\ a_3 & b_3 & 1 \end{vmatrix} = 0.$$

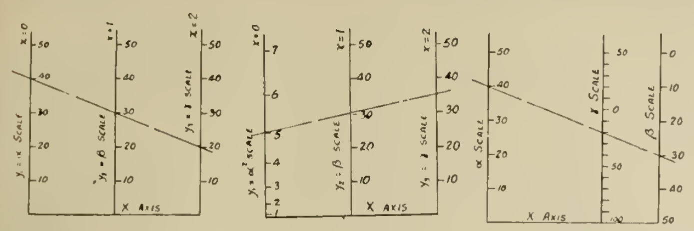
The converse of this also holds true.

It should be noted that whenever the determinant is equal to zero, our rules one and three have an added significance. For instance, multiplying the determinant by m will not alter the truth of the equation; neither will the interchange of two adjacent rows or columns. In other words, we may apply any of the four transformations described by these rules without affecting the value of the determinant when it is equated to zero.

Rule 5 is the basis of the charts of intersection.

Rule 6 is the basis of alignment charts.

Rule 5 is to be dealt with in the appendix, but has not been used in the discussion of intersection charts just concluded.



$\alpha + \gamma - 2\beta = 0$ $\alpha^2 + \gamma - 2\beta = 0$ $\alpha + \gamma - 2\beta = 0$

Figures Nos. 7, 8 and 9.

Alignment Charts

According to rule 6, three points $(x_1 y_1)$, $(x_2 y_2)$ and $(x_3 y_3)$ are collinear if

$$\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix} = 0.$$

Expanded, this gives us the equation

$$x_1 (y_2 - y_3) - x_2 (y_1 - y_3) + x_3 (y_1 - y_2) = 0.$$

Alignment Charts of Three Parallel Straight Lines

This is the simplest case, in which the scales for the three variables lie along parallel straight lines. Let these lines be $x = 0$, $x = 1$, and $x = 2$. The co-ordinates of any three points on these lines are $(0, y_1)$, $(1, y_2)$, and $(2, y_3)$. If we mark off a simple linear scale on each of these lines starting with zero at the X axis in each case, then the ordinates y_1, y_2, y_3 will be identical with the scale readings. If we place the α scale along $x = 0$, the β scale along $x = 1$, and the γ scale along $x = 2$, where α, β and γ signify three variables then there are three relations $y_1 = \alpha$; $y_2 = \beta$; $y_3 = \gamma$.

The three points $(0, y_1)$, $(1, y_2)$ and $(2, y_3)$ are collinear if

$$\begin{vmatrix} 0 & y_1 & 1 \\ 1 & y_2 & 1 \\ 2 & y_3 & 1 \end{vmatrix} = 0.$$

Replacing y_1, y_2 and y_3 by the variables, this gives

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & \beta & 1 \\ 2 & \gamma & 1 \end{vmatrix} = 0.$$

Conversely we may say that if

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & \beta & 1 \\ 2 & \gamma & 1 \end{vmatrix} = 0$$

then the three points $(0, \alpha)$, $(1, \beta)$, and $(2, \gamma)$ will be collinear.

Our determinant form expands to $-1(\alpha-\gamma) + 2(\alpha-\beta) = 0$ or $\alpha - 2\beta + \gamma = 0$ so that the three scales α, β, and γ, parallel and equally spaced, furnish a nomogram for this equation.

Suppose now we alter one of the scales, and in place of the α scale mark down an α^2 scale. That is to say, points at distances of 1, 4, 9, 16 etc. from the X axis will be marked $\alpha = 1, 2, 3, 4$, etc. Then the relation holds $y_1 = \alpha^2$.

Our condition of collinearity becomes

$$\begin{vmatrix} 0 & \alpha^2 & 1 \\ 1 & \beta & 1 \\ 2 & \gamma & 1 \end{vmatrix} = 0$$

or expanded $\alpha^2 - 2\beta + \gamma = 0$, a new equation in α, β, and γ. This equation will be satisfied for values of α, β and γ corresponding to points on the three scales which are collinear. Given a value of α and β, the satisfying value of γ may be obtained by drawing a straight line through the points marked with these values on the α^2 and β scales and finding where this line cuts the γ scale. A similar operation may be performed given any two of the variables, to find the third, (figures Nos. 7 and 8).

In general the scales may be marked off as functions of the three variables, so that the nomogram for the general equation $f(\alpha) - 2\phi(\beta) + \psi(\gamma) = 0$ is

$$\begin{vmatrix} 0 & f(\alpha) & 1 \\ 1 & \phi(\beta) & 1 \\ 2 & \psi(\gamma) & 1 \end{vmatrix} = 0$$

three parallel equidistant scales

$$x = 0;\quad y = f(\alpha);$$
$$x = 1;\quad y = \phi(\beta);$$
$$x = 2;\quad y = \psi(\gamma);$$

In future it will be assumed that the symbol α does not denote the simple variable, but designates a function of some variable. When we speak of an α scale or a β or a γ scale, we will mean functional scales of three variables. This is done to simplify the notation.

We have seen that the chart with three parallel scales solves an equation made up of the sum of three functions of independent variables. It is almost always necessary to transform this elementary form of the determinant because in every example it will be found that the size of the scales is unsuitable on account of the range of values taken by the variables. It will also be found that the scales are not opposite each other, and should be modified in some way so that a compact chart is obtained.

A good illustration of this is given in the chart of figure No. 10, which is drawn according to the elementary form of the determinant for the equation $Q = 1.272\, D^{2.65} H^{0.555}$ This equation was transformed into the sum of three variables by taking logarithms, giving

$$\log Q = \log 1.272 + 2.65 \log D + 0.555 \operatorname{Log} H,$$

or $(2.65 \log D + \log 1.272) + (0.555 \log H) - \log Q = 0.$

Comparing this with the equation $\alpha + \gamma - 2\beta = 0$ we see that the determinant form is

$$\begin{vmatrix} 0 & (2.65 \log D + \log 1.272) & 1 \\ 1 & \frac{1}{2} \log Q & 1 \\ 2 & 0.555 \log H & 1 \end{vmatrix} = 0.$$

It should be noted that we have arranged the variables in such a way as to obtain positive terms in the determinant form.

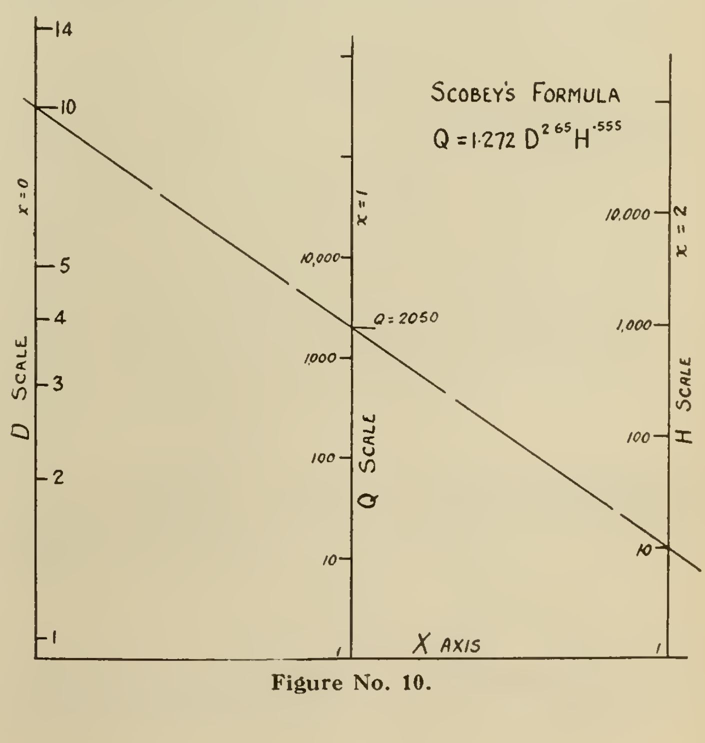


Figure No. 10.

Figure No. 10* has been drawn accordingly, with three scales

$x = 0;\ y = 2.65 \log D + \log 1.272;$
$x = 1;\ y = \frac{1}{2} \log Q;$
$x = 2;\ y = 0.555 \log H;$

This chart is not suitable for practical solutions because the scales do not suit the ranges of values of the variable met with in practice. Although D varies from 1 to 14, it is seen that Q varies from 1 to 1,000,000, and H from 1 to 100,000.

In studying the length and range for the D scale, suppose that 2.65 log 14 equals 6 inches approximately. Thus 3.04 scale units = 6 inches, or one scale unit (i.e. the distance between $D = 10$ and $D = 1$), is approximately 2 inches. If the Q scale were plotted to this size, since it is a scale of $\frac{1}{2} \log Q$, the distance between $Q = 1$ and $Q = 10$ would be about one inch. Similarly for the H scale.

Suppose we wish the chart to show a range of values of Q from 10 to 4,000 c.f.s. On the above scale the distance between these values of Q is $2 \times \frac{1}{2} \log \frac{4000}{10}$ or 2.6 inches. Therefore we must enlarge the Q scale 6 : 2.6 or 2.3 times.

The values of D met with in practice vary between 2 and 14 so we must alter the D scale and enlarge it in the ratio

$$\frac{\log 14}{\log 14 - \log 2} = 1.356.$$

The relative enlargement of the Q scale with respect to the D scale is therefore $\frac{2.3}{1.356}$.

The log H scale will then look after itself, i.e. it must conform to the sizes of the other two scales, but it is still necessary to arrange that the D and Q scales commence and end on the same level.

In other words the values $D = 2$ and $Q = 10$ must lie approximately on a horizontal line.

We will now show how the scales may be enlarged by any multiple number of times, and then translated vertically with respect to each other. After obtaining general formulae for these transformations, we will return to the particular solution of Scobey's formula.

The determinant in the elementary form is

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & \beta & 1 \\ 2 & \gamma & 1 \end{vmatrix} = 0.$$

This must first be altered to the form

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & m\beta & 1 \\ ? & ?\gamma & 1 \end{vmatrix} = 0.$$

First Method (analytical)

Assume the new form to be

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & m\beta & 1 \\ k & n\gamma & 1 \end{vmatrix} = 0.$$

Then

$$\left.\begin{array}{l} \alpha - 2\beta + \gamma = 0 \\ (1-k)\ \alpha + mk\beta - n\gamma = 0 \end{array}\right\} \text{ are identical.}$$

Therefore $\frac{1-k}{1} = \frac{mk}{-2} = \frac{-n}{1}$, whence $(1-k)\ 2 = -mk$

$$\text{or } k = \frac{2}{2-m}$$

On substitution it follows that $n = k - 1 = \frac{m}{2-m}$.

Therefore the new form is

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & m\beta & 1 \\ \frac{2}{2-m} & \frac{m\gamma}{2-m} & 1 \end{vmatrix} = 0.$$

*As printed, figure No. 10 is approximately one half the size named.

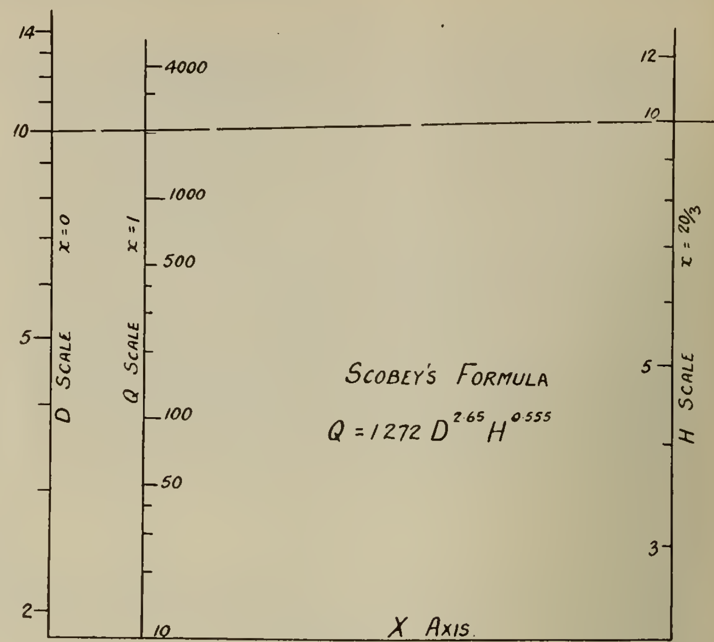

Figure No. 11.

Second Method:

This employs successive transformations of the original determinant form, and a little practice with the rules renders these operations comparatively easy. The analytical method has one disadvantage in that it is necessary to assume the final determinant form. The second method is more straightforward. Thus, we proceed:—

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & \beta & 1 \\ 2 & \gamma & 1 \end{vmatrix} \rightarrow \begin{vmatrix} 0 & \alpha & 1 \\ m & m\beta & m \\ 2 & \gamma & 1 \end{vmatrix} \rightarrow \begin{vmatrix} 0 & \alpha & 1-0 \\ m & m\beta & m-m \\ 2 & \gamma & 1-2 \end{vmatrix} \rightarrow \begin{vmatrix} 0 & \alpha & 1 \\ m & m\beta & 0 \\ 2 & \gamma & -1 \end{vmatrix}$$

$$\rightarrow \begin{vmatrix} 0+m\,.\,1 & \alpha & 1 \\ m+m\,.\,0 & m\beta & 0 \\ 2+m\,.-1 & \gamma & -1 \end{vmatrix} \rightarrow \begin{vmatrix} m & \alpha & 1 \\ m & m\beta & 0 \\ 2-m & \gamma & -1 \end{vmatrix} \rightarrow \begin{vmatrix} 1 & \alpha & 1 \\ 1 & m\beta & 0 \\ \frac{2-m}{m} & \gamma & -1 \end{vmatrix}$$

$$\rightarrow \begin{vmatrix} 1 & \alpha & 1 \\ 1 & m\beta & 0 \\ 1 & \frac{m\gamma}{2-m} & \frac{-m}{2-m} \end{vmatrix} \rightarrow \begin{vmatrix} 1 & \alpha & 1-1 \\ 1 & m\beta & 1-0 \\ 1 & \frac{m\gamma}{2-m} & 1+\frac{m}{2-m} \end{vmatrix}$$

$$\rightarrow \begin{vmatrix} 0 & \alpha & 1 \\ 1 & m\beta & 1 \\ \frac{2}{2-m} & \frac{m\gamma}{2-m} & 1 \end{vmatrix} = 0$$

To a beginner, the above sequence may seem difficult to plan, and execute. Experience is essential for proficiency in this work. However, the above has been given mainly to show what a neat tool this notation affords us. The checking up of the steps will be left as an exercise for the reader.

The second transformation necessary is to translate one scale vertically with respect to the other. This may be done as follows:

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & m\beta & 1 \\ \frac{2}{2-m} & \frac{m\gamma}{2-m} & 1 \end{vmatrix} \rightarrow \begin{vmatrix} 0 & \alpha+n\,.\,0 & 1 \\ 1 & m\beta+n\,.\,1 & 1 \\ \frac{2}{2-m} & \frac{m\gamma}{2-m}+n\,.\,\frac{2}{2-m} & 1 \end{vmatrix}$$

or

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & m\beta+n & 1 \\ \frac{2}{2-m} & \frac{m\gamma+2n}{2-m} & 1 \end{vmatrix} = 0$$

where the $m\beta$ scale has been moved vertically upwards n units with respect to the α scale.

Returning to the particular case of Scobey's formula, we must first transform the determinant using

$$m = \frac{2.3}{1.356}, \text{ say } 1.7$$

This gives

$$\begin{vmatrix} 0 & (2.65 \log D + \log 1.272) & 1 \\ 1 & 0.85 \log Q & 1 \\ \frac{20}{3} & \frac{1.7 \times 0.555}{0.3} \log H & 1 \end{vmatrix} = 0.$$

The lowest point on the D scale is now

$$2.65 \log 2 + \log 1.272 = 0.80$$

The lowest point on the Q scale is

$$0.85 \log 10 = 0.85$$

These units are almost equal, so that it is not necessary to translate any of the scales vertically with respect to any other. However, if we had wished to lower the Q scale 0.05 with respect to the D scale, this could have been effected by the transformation:

$$\rightarrow \begin{vmatrix} 0 & 2.65 \log D + \log 1.272 & 1 \\ 1 & 0.85 \log Q - (.05 \times 1) & 1 \\ \frac{20}{3} & \frac{1.7 \times 0.555}{0.3} \log H - \left(.05 \times \frac{20}{3}\right) & 1 \end{vmatrix} = 0$$

All that remains to be done now is to choose the size of the scales.

The D scale starts at 0.80 unit for $D = 2$ feet and finishes at

$$2.65 \log 14 + \log 1.272 = 3.14 \text{ units for } D = 14 \text{ feet,}$$

a range of 2.34 units.

We must for convenience choose the log scales making 2.34 units = about 6 inches or 1 unit = 2.564 inches. We will make log 10 scale $2\frac{1}{2}$ inches; i.e. $2\frac{1}{2}$ inches represents unity.

In order to make all the scales start from the X axis we will make the last transformation

$$\begin{vmatrix} 0 & 2.65 \log D + 1.272 - 0.80 & 1 \\ 1 & 0.85 \log Q - .05 - 0.80 & 1 \\ \frac{20}{3} & \frac{1.7 \times 0.555}{0.3} \log H - \frac{1}{3} - 0.80 & 1 \end{vmatrix} = 0$$

Figure No. 11 has been drawn accordingly.*

In our discussion so far we have taken a certain determinant form of the equation $\alpha - 2\beta + \gamma = 0$ and shown how this form may be altered to give a suitable location and size of scales in the resulting nomogram. Let us now tackle the problem from another angle and see how we can obtain the determinant equation from the given algebraic form.

By comparing with our previous work, we see that the equation $\alpha + \beta + \gamma = 0$ may be expressed

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & -\frac{1}{2}\beta & 1 \\ 2 & \gamma & 1 \end{vmatrix} = 0$$

There is another way of doing this, by building up the determinant as follows:

We will start off with the skeleton form

$$\begin{vmatrix} ? & 0 & 1 \\ ? & 1 & 1 \\ ? & 2 & 1 \end{vmatrix} = 0$$

Here we have left the first column to be filled in by the variables, instead of the second column. This will simplify the building-up process, and after that has been done we can interchange the first and second columns, giving the final form.

We first try α in the top blank space. Then its coefficient is $(1-2)$ or -1. The coefficient of the second blank space is $-(0-2)$ or 2. Therefore if we try the β variable there, our given equation $\alpha + \beta + \gamma = 0$ will require an insertion of $-\frac{1}{2}\beta$ giving

$$\begin{vmatrix} \alpha & 0 & 1 \\ -\frac{1}{2}\beta & 1 & 1 \\ ? & 2 & 1 \end{vmatrix} = 0$$

The last blank space has a coefficient $(0 - 1) = -1$ so that we may place γ there, giving

$$\begin{vmatrix} \alpha & 0 & 1 \\ -\frac{1}{2}\beta & 1 & 1 \\ \gamma & 2 & 1 \end{vmatrix} = 0,$$

or expanded $\quad -\alpha - \beta - \gamma = 0.$

The correct form of this for plotting is

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & -\frac{1}{2}\beta & 1 \\ 2 & \gamma & 1 \end{vmatrix} = 0$$

If in our building-up process, we had put α at the top and tried the γ variable next, we would have obtained the final form

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & -\frac{1}{2}\gamma & 1 \\ 2 & \beta & 1 \end{vmatrix} = 0$$

It is evident by comparing the last two determinants that an interchange of the β and γ scales causes a change in sense for each; also that the scale in the centre is reduced in size (in this case of equidistant scales by a half). We can formulate rules in accordance with this knowledge. Thus, in equations of the form $\alpha + \beta + \gamma = 0$ when two of the variables increase or decrease together, these variables should be placed on the outside scales. In this way the lines of intersection will always be near the horizontal, giving good intersections on the scales.

To illustrate the above, figure No. 9 has been constructed, which differs from figure No. 7 in that the β and γ scales have been interchanged. The elementary form for this nomogram is

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & -\frac{1}{2}\gamma & 1 \\ 2 & -2\beta & 1 \end{vmatrix} = 0,$$

obtained from the preceding determinant by substituting -2β for β. First we must reduce the β scale by half if we wish it to be the same size as in figure No. 7.

This operation gives

$$\begin{vmatrix} 0 & \alpha & 1 \\ 2 & -\frac{1}{3}\gamma & 1 \\ 3 & -\beta & 1 \end{vmatrix} = 0$$

The steps here are

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & -\frac{1}{2}\gamma & 1 \\ 2 & -2\beta & 1 \end{vmatrix} \rightarrow \begin{vmatrix} 0 & \alpha & 1 \\ 1 & -\frac{1}{2}\gamma & 1 \\ 1 & -\beta & \frac{1}{2} \end{vmatrix} \rightarrow \begin{vmatrix} 0 + 2 \times 1 & \alpha & 1 \\ 1 + 2 \times 1 & -\frac{1}{2}\gamma & 1 \\ 1 + 2 \times \frac{1}{2} & -\beta & \frac{1}{2} \end{vmatrix}$$

$$\text{or} \begin{vmatrix} 2 & \alpha & 1 \\ 3 & -\frac{1}{2}\gamma & 1 \\ 2 & -\beta & \frac{1}{2} \end{vmatrix} \rightarrow \begin{vmatrix} 1 & \alpha & 1 \\ \frac{3}{2} & -\frac{1}{2}\gamma & 1 \\ 1 & -\beta & \frac{1}{2} \end{vmatrix} \rightarrow \begin{vmatrix} 1 & \alpha & 1 \\ 1 & -\frac{1}{3}\gamma & \frac{2}{3} \\ 1 & -\beta & \frac{1}{2} \end{vmatrix}$$

$$\rightarrow \begin{vmatrix} 1 & \alpha & 1 \\ \frac{2}{3} & -\frac{1}{3}\gamma & 1 \\ \frac{1}{2} & -\beta & 1 \end{vmatrix} \rightarrow \begin{vmatrix} 6 & \alpha & 1 \\ 4 & -\frac{1}{3}\gamma & 1 \\ 3 & -\beta & 1 \end{vmatrix} \rightarrow \begin{vmatrix} -6+6 & \alpha & 1 \\ -4+6 & -\frac{1}{3}\gamma & 1 \\ -3+6 & -\beta & 1 \end{vmatrix}$$

$$\text{or} \quad \begin{vmatrix} 0 & \alpha & 1 \\ 2 & -\frac{1}{3}\gamma & 1 \\ 3 & -\beta & 1 \end{vmatrix} = 0$$

In its present form the α scale runs from 0 to 50, and the β scale from 0 to $-$ 50. Therefore we must raise the β scale 50 units, giving the final form.

$$\rightarrow \begin{vmatrix} 0 & \alpha + 0 . \frac{50}{3} & 1 \\ 2 & -\frac{1}{3}\gamma + 2 . \frac{50}{3} & 1 \\ 3 & -\beta + 3 . \frac{50}{3} & 1 \end{vmatrix} \rightarrow \begin{vmatrix} 0 & \alpha & 1 \\ 2 & -\frac{1}{3}\gamma + \frac{100}{3} & 1 \\ 3 & -\beta + 50 & 1 \end{vmatrix} = 0$$

If possible it is advisable to place the variables which are the most independent of each other, or which are given in any particular problem, on the outside scales.

*As printed, figure No. 11 is approximately one half the size named.

Then if these scales cover the full range of values of these variables, we need not worry about the third variable in the middle of the chart since all possible lines of intersection will cut the middle scale within the bounds of the chart. In this connection if we turn to figure No. 11 we notice that the range of values for H is from 3 to 12. We would be sure to get a suitable range for H if we placed its scale in the centre. Another procedure would be to reduce the Q scale slightly. A summary of determinant forms for the "three parallel line" type of nomogram follows:

Equation $\alpha + \beta + \gamma = 0$

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & -\frac{1}{2}\beta & 1 \\ 2 & \gamma & 1 \end{vmatrix} = 0 \qquad \begin{vmatrix} 0 & \alpha & 1 \\ 1 & m(-\frac{1}{2}\beta) & 1 \\ \dfrac{2}{2-m} & \dfrac{m\gamma}{2-m} & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & m(-\frac{1}{2}\beta) + n & 1 \\ \dfrac{2}{2-m} & \dfrac{m\gamma + 2n}{2-m} & 1 \end{vmatrix} = 0$$

(Cannot be used for $m = 2$)

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & -\frac{1}{2}\beta & 1 \\ 2 & \gamma & 1 \end{vmatrix} = 0 \qquad \begin{vmatrix} 0 & \alpha & 1 \\ \dfrac{2}{m+1} & \dfrac{-m\beta}{m+1} & 1 \\ 2 & m\gamma & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} 0 & \alpha & 1 \\ \dfrac{2}{m+1} & \dfrac{-m\beta + n}{m+1} & 1 \\ 2 & m\gamma + n & 1 \end{vmatrix} = 0$$

(Cannot be used for $m = -1$)

To reverse the β and γ scales with respect to the α scale we interchange the variables β and γ, obtaining

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & -\frac{1}{2}\gamma & 1 \\ 2 & \beta & 1 \end{vmatrix} = 0 \qquad \begin{vmatrix} 0 & \alpha & 1 \\ 1 & m(-\frac{1}{2}\gamma) & 1 \\ \dfrac{2}{2-m} & \dfrac{m\beta}{2-m} & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & m(-\frac{1}{2}\gamma) + n & 1 \\ \dfrac{2}{2-m} & \dfrac{m\beta + 2n}{2-m} & 1 \end{vmatrix} = 0$$

and

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & -\frac{1}{2}\gamma & 1 \\ 2 & \beta & 1 \end{vmatrix} = 0 \qquad \begin{vmatrix} 0 & \alpha & 1 \\ \dfrac{2}{m+1} & \dfrac{-m\gamma}{m+1} & 1 \\ 2 & m\beta & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} 0 & \alpha & 1 \\ \dfrac{2}{m+1} & \dfrac{-m\gamma + n}{m+1} & 1 \\ 2 & m\beta + n & 1 \end{vmatrix} = 0$$

Any other reversal of scales may be obtained by rearranging the given equation. This could have been done for the second set of forms given above by writing the equation $\alpha + \gamma + \beta = 0$.

Illustration. Solution of the quadratic equation (figure No. 12). The form $x^2 - 2bx + c = 0$ is used. The solution for this is $x = b \pm \sqrt{b^2 - c} = b \pm p$ and the chart is constructed to solve the equation $p^2 = b^2 - c$. If this is written $p^2 + c - b^2 = 0$ and compared with $\alpha + \beta + \gamma = 0$ the determinant form is found to be

$$\begin{vmatrix} 0 & p^2 & 1 \\ 1 & -\dfrac{c}{2} & 1 \\ 2 & -b^2 & 1 \end{vmatrix} = 0$$

Since solutions are obtained by intersections on the p scale it is advisable to have the c scale as close as possible to the p scale, maintaining suitable sizes of the scales.

A multiple $m = \frac{4}{3}$ is chosen for the c scale and the scale lines are at

$$x = 0, \quad x = 1, \quad \text{and} \quad x = \frac{2}{2-m} = 3.$$

Of course we could get around this difficulty by placing the p scale in the centre, but the result of this operation would be a reversal of the c scale with respect to the b scale, which is not desirable.

The revised determinant is

$$\begin{vmatrix} 0 & p^2 & 1 \\ 1 & -\frac{2}{3}c & 1 \\ 3 & -2b^2 & 1 \end{vmatrix} = 0$$

Four different nomograms have been constructed on the chart. In nomogram (1) the transformation has been made

$$\rightarrow \begin{vmatrix} 0 & p^2 & 1 \\ 1 & -\frac{2}{3}c + 30 & 1 \\ 3 & -2b^2 + 30 \times 3 & 1 \end{vmatrix} \text{ or } \begin{vmatrix} 0 & p^2 & 1 \\ 1 & -\frac{2}{3}c + 30 & 1 \\ 3 & -2b^2 + 90 & 1 \end{vmatrix} = 0.$$

The X axis cuts the scales at

$p = 0$; $\frac{2}{3}c = 30$; $2b^2 = 90$; or $p = 0$; $c = 45$; $b = 3\sqrt{5} = 6.71$. The X axis has been placed in the centre of the chart.

Nomogram (2) is based on the transformation.

$$\rightarrow \begin{vmatrix} 0 & p^2 & 1 \\ 1 & -\frac{2}{3}c + \frac{260}{3} & 1 \\ 3 & -2b^2 + 260 & 1 \end{vmatrix} = 0,$$

and the X axis cuts the scales at values

$$p = 0; \quad c = 130; \quad b = \sqrt{130} = 11.4.$$

Nomogram (3) has the X axis shifted down to the value $p = 10$, near the bottom of the chart. The c scale has been translated to give a corresponding value of $c = -15$. In nomogram (4) the X axis remains at $p = 10$ but the corresponding value of c has been changed to 85.

It is seen that the alignment chart lends itself to the superimposing of different ranges of value of the variables. Such a treatment would lead to confusion in an intersection chart.

The scales in the X direction are not affected in the least by the size of the scales in the Y direction. Our first column in the determinant for the quadratic tells us that the distance between the p and c scales is half that between the c and b scales. We do not alter the validity of the equation by multiplying all the terms of the first column by some constant K.

Two Parallel and One Diagonal Scale

All charts of this type may be developed from the simple case where the scales are placed on the lines $x = 0$, $x = 1$, and $y = 0$. The determinant form is

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & \beta & 1 \\ \gamma & 0 & 1 \end{vmatrix} = 0,$$

which expands to

$$\alpha(1 - \gamma) + \beta\gamma = 0$$

or

$$\alpha + \beta\left(\frac{\gamma}{1-\gamma}\right) = 0,$$

a product of two functions equal to a third function, e.g.

$$P = QR.$$

Such an equation could of course be put in the logarithmic form $\log P = \log Q + \log R$ which gives a chart with three parallel scales.

Suppose we start afresh with the equation $\alpha + \beta\gamma = 0$. Comparing this with the equation $\alpha + \beta\left(\dfrac{\gamma}{1-\gamma}\right) = 0$ above, we see that α and β are unchanged but $\dfrac{\gamma}{1-\gamma}$ has become a new γ. Writing this $\gamma_2 = \dfrac{\gamma_1}{1-\gamma_1}$ we find $\gamma_1 = \dfrac{\gamma_2}{1+\gamma_2}$,

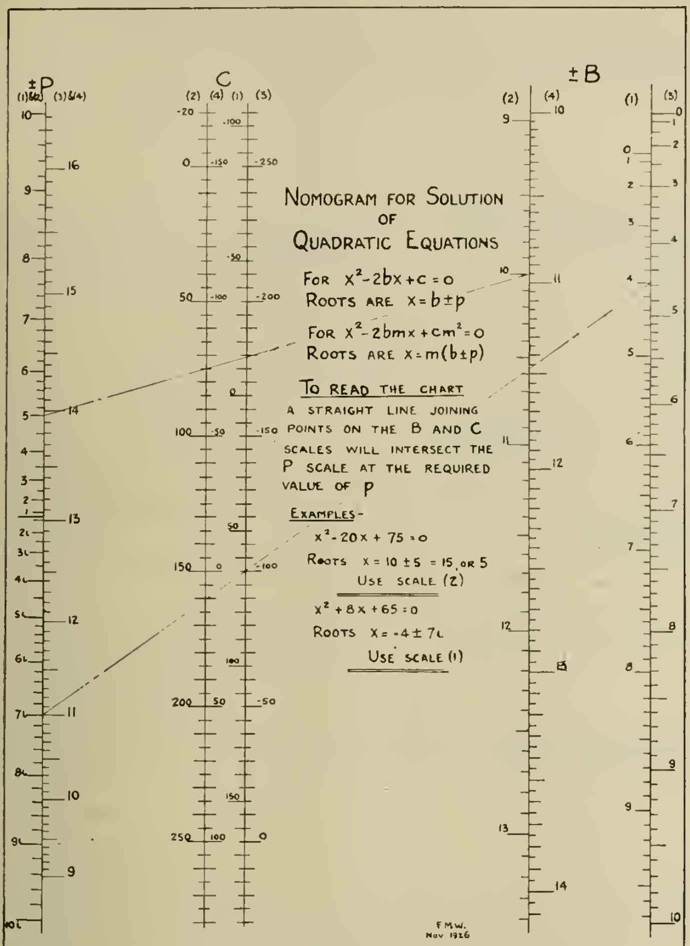

Figure No. 12

so that the determinant form for $\alpha + \beta\gamma = 0$ is

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & \beta & 1 \\ \frac{\gamma}{1+\gamma} & 0 & 1 \end{vmatrix} = 0.$$

This could have been done as follows:

A first trial determinant is found

$$\begin{vmatrix} \beta & -1 & 1 \\ \alpha & \gamma & 1 \\ 0 & 0 & 1 \end{vmatrix} = 0$$

Here we must try and separate the α and γ terms. Hence

$$\rightarrow \begin{vmatrix} \beta & -1-\gamma.1 & 1 \\ \alpha & \gamma-\gamma.1 & 1 \\ 0 & 0-\gamma.1 & 1 \end{vmatrix} \text{ or } \begin{vmatrix} \beta & -1-\gamma & 1 \\ \alpha & 0 & 1 \\ 0 & -\gamma & 1 \end{vmatrix}$$

$$\rightarrow \begin{vmatrix} \beta & 1 & 1 \\ \alpha & 0 & 1 \\ 0 & \frac{-\gamma}{-1-\gamma} & 1 \end{vmatrix}$$

or

$$\begin{vmatrix} 1 & \beta & 1 \\ 0 & \alpha & 1 \\ \frac{\gamma}{1+\gamma} & 0 & 1 \end{vmatrix} = 0,$$

as before.

If plotted according to this form, the chart will be U-shaped (see figure No. 13). If α and β are both positive or both negative the intersection lines will cut the γ scale on the outside of the U. The α and β scales should therefore be arranged to lie on opposite sides of the X axis, and the chart will then appear as in figure No. 13a.

The chart is still unsuitable for plotting and it must be transformed so that the α and β scales are on the same level. The γ scale will then run diagonally across the chart (see figure No. 13b).

When the variables α and β are of the same sign the first trial determinant is

$$\begin{vmatrix} \beta & 1 & 1 \\ -\alpha & \gamma & 1 \\ 0 & 0 & 1 \end{vmatrix} = 0,$$

and this transforms to

$$\begin{vmatrix} 1 & \beta & 1 \\ 0 & -\alpha & 1 \\ \frac{\gamma}{\gamma-1} & 0 & 1 \end{vmatrix} = 0,$$

corresponding to figure No. 13a.

To secure the form of figure No. 13b the following simple transformation is made:

$$\begin{vmatrix} 1 & \beta & 1 \\ 0 & \alpha & 1 \\ \frac{\gamma}{\gamma+1} & 0 & 1 \end{vmatrix} \rightarrow \begin{vmatrix} 1 & \beta + n.1 & 1 \\ 0 & \alpha + n.0 & 1 \\ \frac{\gamma}{\gamma+1} & 0 + n.\frac{\gamma}{\gamma+1} & 1 \end{vmatrix}$$

or

$$\begin{vmatrix} 1 & \beta + n & 1 \\ 0 & \alpha & 1 \\ \frac{\gamma}{\gamma+1} & \frac{n\gamma}{\gamma+1} & 1 \end{vmatrix} = 0$$

for the case when α and β happen to have opposite signs, and

$$\begin{vmatrix} 1 & \beta & 1 \\ 0 & -\alpha & 1 \\ \frac{\gamma}{\gamma-1} & 0 & 1 \end{vmatrix} \rightarrow \begin{vmatrix} 1 & \beta + n & 1 \\ 0 & -\alpha & 1 \\ \frac{\gamma}{\gamma-1} & \frac{n\gamma}{\gamma-1} & 1 \end{vmatrix} = 0$$

for the case when α and β are of the same sign. In both cases the β scale has been translated upwards n units. n may be any constant, positive or negative, (in figure No. 13b, $n = -50$).

There is another transformation which must be studied in connection with this type of chart, the transformation by means of which one scale is enlarged with respect to another scale. Since the γ scale is the only one running in the horizontal direction, we need not consider its enlargement. This may be obtained by simply multiplying all terms of the first column by a constant K.

It is best to enlarge the scales first before translating them. The steps for this enlargement are:

$$\begin{vmatrix} 1 & \beta & 1 \\ 0 & \alpha & 1 \\ \frac{\gamma}{\gamma+1} & 0 & 1 \end{vmatrix} \rightarrow \begin{vmatrix} m & m\beta & m \\ 0 & \alpha & 1 \\ \frac{\gamma}{\gamma+1} & 0 & 1 \end{vmatrix}$$

$$\rightarrow \begin{vmatrix} m & m\beta & m - m \\ 0 & \alpha & 1 - 0 \\ \frac{\gamma}{\gamma+1} & 0 & 1 - \frac{\gamma}{\gamma+1} \end{vmatrix}$$

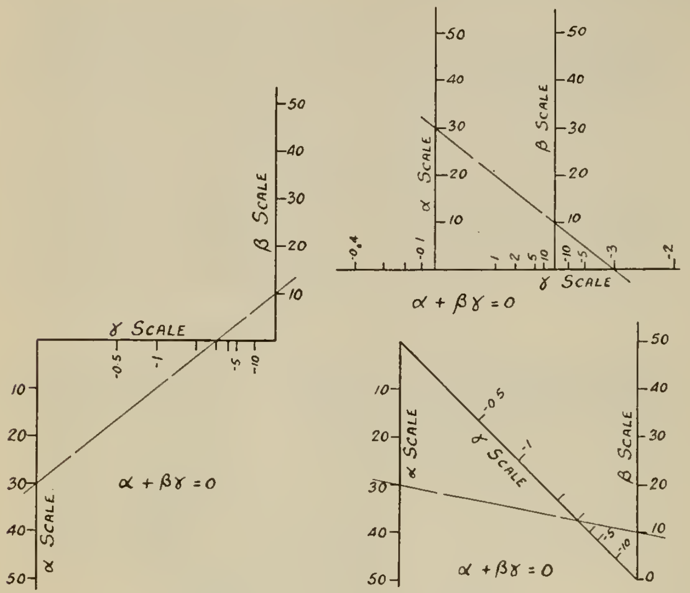
or

$$\begin{vmatrix} m & m\beta & 0 \\ 0 & \alpha & 1 \\ \frac{\gamma}{\gamma+1} & 0 & \frac{1}{\gamma+1} \end{vmatrix} \rightarrow \begin{vmatrix} m + m.0 & m\beta & 0 \\ 0 + m.1 & \alpha & 1 \\ \frac{\gamma}{\gamma+1} + m.\frac{1}{\gamma+1} & 0 & \frac{1}{\gamma+1} \end{vmatrix}$$

or

$$\begin{vmatrix} m & m\beta & 0 \\ m & \alpha & 1 \\ \frac{m+\gamma}{\gamma+1} & 0 & \frac{1}{\gamma+1} \end{vmatrix} \rightarrow \begin{vmatrix} 1 & m\beta & 0 \\ 1 & \alpha & 1 \\ \frac{m+\gamma}{m(\gamma+1)} & 0 & \frac{1}{\gamma+1} \end{vmatrix}$$

$$\rightarrow \begin{vmatrix} 1 & m\beta & 0 \\ 1 & \alpha & 1 \\ 1 & 0 & \frac{m}{m+\gamma} \end{vmatrix} \rightarrow \begin{vmatrix} 0 & m\beta & 1 \\ 1 & \alpha & 1 \\ \frac{m}{m+\gamma} & 0 & 1 \end{vmatrix} = 0.$$



Figures Nos. 13, 13a and 13b.

The β scale has been multiplied by m, but it is on the wrong side of the chart, so we transform again

$$\rightarrow \begin{vmatrix} 0 & m\beta & 1 \\ -1 & \alpha & 1 \\ \dfrac{-m}{m+\gamma} & 0 & 1 \end{vmatrix} \rightarrow \begin{vmatrix} 0+1 & m\beta & 1 \\ -1+1 & \alpha & 1 \\ -\dfrac{m}{m+\gamma}+1 & 0 & 1 \end{vmatrix}$$

or

$$\begin{vmatrix} 1 & m\beta & 1 \\ 0 & \alpha & 1 \\ \dfrac{\gamma}{m+\gamma} & 0 & 1 \end{vmatrix} = 0$$

Translating the β scale with respect to the α scale gives

$$\begin{vmatrix} 1 & m\beta + n & 1 \\ 0 & \alpha & 1 \\ \dfrac{\gamma}{m+\gamma} & \dfrac{n\gamma}{m+\gamma} & 1 \end{vmatrix} = 0.$$

A summary of transformations for this case follows.

Equation $\alpha + \beta\gamma = 0$, or $\dfrac{1}{\alpha} + \dfrac{1}{\beta} \cdot \dfrac{1}{\gamma} = 0.$

(a) For α and β like in sign

$$\begin{vmatrix} 1 & \beta & 1 \\ 0 & -\alpha & 1 \\ \dfrac{\gamma}{\gamma-1} & 0 & 1 \end{vmatrix} = 0 \qquad \begin{vmatrix} 1 & m\beta & 1 \\ 0 & -\alpha & 1 \\ \dfrac{\gamma}{\gamma-m} & 0 & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} 1 & m\beta + n & 1 \\ 0 & -\alpha & 1 \\ \dfrac{\gamma}{\gamma-m} & \dfrac{n\gamma}{\gamma-m} & 1 \end{vmatrix} = 0$$

(b) For α and β opposite in sign

$$\begin{vmatrix} 1 & \beta & 1 \\ 0 & \alpha & 1 \\ \dfrac{\gamma}{1+\gamma} & 0 & 1 \end{vmatrix} = 0 \qquad \begin{vmatrix} 1 & m\beta & 1 \\ 0 & \alpha & 1 \\ \dfrac{\gamma}{m+\gamma} & 0 & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} 1 & m\beta + n & 1 \\ 0 & \alpha & 1 \\ \dfrac{\gamma}{m+\gamma} & \dfrac{n\gamma}{m+\gamma} & 1 \end{vmatrix} = 0$$

Of course these transformations in case (b) might be dispensed with if we expressed the given equation

$$\alpha + (-\beta) \quad (-\gamma) = 0$$

Illustration. Stadia equation

$$V - (100\,I + 1)\,\tfrac{1}{2}\sin 2\,\alpha = 0.$$

The functions V, I, and α may be assumed positive, so we take the initial determinant form

$$\begin{vmatrix} 1 & (100\,I + 1) & 1 \\ 0 & -V & 1 \\ \dfrac{\frac{1}{2}\sin 2\alpha}{1+\frac{1}{2}\sin 2\alpha} & 0 & 1 \end{vmatrix} = 0.$$

Suppose we wish to show a range of values of I from 0 to 5.0, of V from 0 to 40. Then the I scale is 500 units long and the V scale 40 units. Therefore we must choose

$$m = \tfrac{40}{500} = 0.08.$$

The first transformation gives

$$\begin{vmatrix} 1 & 0.08\,(100\,I + 1) & 1 \\ 0 & -V & 1 \\ \dfrac{\frac{1}{2}\sin 2\alpha}{0.08+\frac{1}{2}\sin 2\alpha} & 0 & 1 \end{vmatrix} = 0.$$

To make the scales on the same level we make $n = -40$ and obtain

$$\begin{vmatrix} 1 & 40 - 0.08\,(100\,I + 1) & 1 \\ 0 & V & 1 \\ \dfrac{\frac{1}{2}\sin 2\alpha}{0.08+\frac{1}{2}\sin 2\alpha} & \dfrac{20\sin 2\alpha}{0.08+\frac{1}{2}\sin 2\alpha} & 1 \end{vmatrix} = 0.$$

(see figure No. 14).

There is a third type of alignment chart sometimes used for equations of the type $\alpha + \beta\,\gamma = 0$. It is given by the determinant form

$$\begin{vmatrix} \beta & -1 & 1 \\ \alpha & \gamma & 1 \\ 0 & 0 & 1 \end{vmatrix} = 0,$$

which we have already used in connection with the Z-type of chart just discussed. It may be said, however, that these charts are more difficult to construct and are also more confusing during the solution of problems. They will not be dealt with further for this reason, but a summary of forms of these determinants is given in Appendix B.

(*To be continued*)

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XIII JUNE 1930 No. 6

A Question Frequently Asked

Our members, when confronted with one of the Secretary's periodical communications regarding annual fees, or when discussing the affairs of The Institute, often ask themselves or their fellow members, "What do I get out of The Institute?" A question which would naturally follow, "What do I do for The Institute?", does not occur so frequently. The stereotyped answer to the first query is, that one gets out of any organization like The Institute the equivalent of what one puts into it — and with interest. This is undoubtedly stereotyped, but absolutely true.

Every member has now the opportunity of rendering a service to The Institute which will only take a few minutes of his time, but which will enable him to give real help in the preparation of a review of the present situation as regards the remuneration of himself and his fellow engineers in Canada. While it cannot be definitely undertaken that immediate benefit will result to each individual member, the benefit to the profession at large must react in favour of the membership generally. The service desired is the filling in of a questionnaire, supplying information regarding the member's career and remuneration for the benefit of the recently appointed Committee on Classification, Remuneration and Tariff of Engineers, in order that basic data may be at hand on which that committee can work.

It will be recalled that in 1920 a committee was appointed by Council to study the same subject, its report having been published in the Engineering Journal for October 1923. That report, which is now out of print, has been widely circulated, and has been of considerable utility to public bodies and other organizations responsible for the employment of engineers, as well as to our own members. This being the case, Council has thought it advisable to appoint a committee to review the question and make new recommendations, if necessary, to meet present-day requirements.

As a first step in the committee's investigations, a questionnaire is being sent to all members of The Institute, asking for specific information regarding their careers and remuneration, the object being to collate the particulars received from individuals and obtain a broad picture of the conditions now existing. As in all statistical questions, the utility of the information received will be in proportion to the number of individuals replying. The returns will be handled in the same way and with the same secrecy as a letter ballot, and there will be no attempt in any way to identify the member with the form he returns, which of course will not bear his signature.

For its work the committee needs collective results, trends and averages, and there will be no prying into individual cases. Every member is therefore earnestly requested to give his personal assistance by filling in and returning the questionnaire, which will be in his hands at about the same time as this number of The Engineering Journal.

The Work of the Canadian Engineering Standards Association

This Association has now completed the eleventh year of its activities, and the record of its progress, as shown in its Year Book for 1929, which has just been received, is very satisfactory.

The Year Book contains the latest information regarding the activities of the Association, its finances, organization and method of work, and it is interesting to note that during the past year six new specifications, revised editions of two existing specifications, and the second edition of the Canadian Electrical Code, have been completed. An encouraging number of projects for further work are in progress, and the practical interest in the movement which has been shown by industry has been evidenced by substantial contributions to the working funds of the Association.

The Association very properly emphasizes the policy and method of work which has been adopted from the beginning. The idea that a standardizing body of this kind can assume the role of a dictator and enforce its findings is quite foreign to the principles of the Canadian or any of the other national standardizing bodies. In all cases the association organizes working committees on which manufacturers and users nominate the majority of the members who take part in the actual discussion of the problem and handle the technical work. The results, on which all interests concerned are thus in agreement, carry with them no idea of compulsion, and are adopted and used by reason of their inherent suitability.

Further, it is the practice of the Association to take action only on subjects for which no industrial standards or schemes of simplified practice have yet been adopted in Canada, or where the limitations imposed by Canadian requirements have not been adequately recognized by the standards of their allied bodies.

The expenditure of the Canadian Engineering Standards Association, amounting last year to some $15,000, is covered by contributions from industry, and by a grant from the National Research Council, of which body the Association acts as one of the advisory committees. This figure may be compared with the larger sums expended in Britain, where a government grant of $25,000 per annum is received, or in the United States, where the American Standards Association contemplates an expenditure of $450,000 during the next three years. From the record of the Association's work, however, it is evident that Canada and its industries are receiving real value for the money expended.

The Year Book touches briefly on the topic of international standardization, a subject on which some progress has been made, although there is naturally great difficulty in co-ordinating the work of more than twenty national standardizing organizations, representing industrial communities whose commercial competition is sometimes very keen.

It may be noted that the Association now has five hundred and fifty individual members, has published twenty-nine standards, has twenty-six standardization projects under way, and is supported by the National Research Council and by sixty-eight organizations as sustaining members.

Meeting of Council

A meeting of Council was held on Tuesday, May 6th, 1930, at eight o'clock p.m., with President A. J. Grant, M.E.I.C., in the chair, and seven other members of Council present.

The minutes of the meeting held on April 11th, 1930, were taken as read and confirmed.

It was decided that the 1930 Plenary Meeting of Council should be held on Monday, Tuesday and Wednesday, September 22nd, 23rd and 24th, 1930.

It was noted with much appreciation that an engraving of the late Sir John Fowler, President of The Institution of Civil Engineers, 1868, had been presented to The Institute by Mrs. Wilfrid Bovey, in memory of her father, Mr. J. G. Macklin, who became a member of the Canadian Society of Civil Engineers in 1887, and who died in 1917. The Secretary was directed to convey to Mrs. Bovey the sincere thanks of Council for this gift.

A copy of the revised Engineering Profession Act of the Province of Alberta, which received assent on April 3rd, 1930, was noted, and the Secretary was directed to congratulate the members in Alberta on securing such effective legislation.

A letter was presented from J. G. Desbarats, C.M.G., M.E.I.C., Deputy Minister, Department of National Defence, advising that special arrangements would be made for representatives from The Engineering Institute of Canada to visit the mooring tower at St. Hubert and H.M. Airship R. 100 during her stay in Montreal. The date of arrival and other items on the programme were not yet known, so that it was impossible to set an exact date or time for this visit. Probably from forty to fifty members could be admitted on board

Scrutineers were appointed to canvass the ballot for the amendments to the By-laws, returnable on May 12th, 1930.

Six resignations were accepted.

A number of applications for admission and transfer were considered, and the following elections and transfers were effected:

Elections		Transfers	
Assoc. Members	3	Assoc. Member to Member	4
Juniors	1	Junior to Assoc. Member	5
Affiliates	1	Student to Assoc. Member	3
Students admitted	8	Student to Junior	6

The Council rose at eleven fifty-eight p.m.

The Scientific Development of Aeronautics

Public attention is naturally attracted by the commercial rather than by the scientific progress of aviation. Statistics as to the number of miles flown, the increase in the use of the air-mail and the safety of travel by air, while impressive, give no information as to the intensive experimental and scientific study which has made these achievements possible. The Reports of the Aeronautical Research Committee of Great Britain,(1) dealing with hundreds of complex problems occurring in connection with aeronautics, give the reader some idea of the way in which such questions are being attacked there. Other countries, particularly the United States, France and Germany, are equally active in investigation, and all are carrying on research along lines undreamt of twenty years ago.

In connection with airships, the British investigations in progress include such topics as a general research on the structure of the wind, dealing with the variation of wind force and direction, particularly during the passing of squalls and storms; the question of the factors of safety required in airship construction; protection of airships from electrical discharges; fire prevention; model tests in connection with the strength of the envelope and structure, and many other points related to the air-worthiness of airships.

In aero-dynamics much work has been done on "scale effect," for which an allowance has to be made in the prediction of full-scale resistance from model data, and studies have been made with a view to the reduction of the head resistance of aeroplanes, as affected by the interference of projections from the body. From this point of view it is particularly desirable to improve the performance of aeroplanes having air-cooled engines, and a considerable reduction in total resistance has been obtained by placing stream-line rings in front of a body having radial air-cooled cylinders. Such work is of importance in connection with the development of aeroplanes having extremely high speeds. It is hoped to bring the performance of an aeroplane with an air-cooled engine to within a few miles per hour of that of an aeroplane with a water-cooled engine.

In regard to propellers, it has been necessary to consider the mutual interference of the air-screw and the aeroplane body, the effect of air-screws running at high tip speeds, and the flow of fluids near models, both from the experimental and the theoretical standpoint.

Routine tests as to stability and control are, of course, made on all new types of aeroplane, and it has been a difficult problem to design and construct research instruments which will be suitable for test purposes and which will give automatic records of the motions of an aeroplane during test flying, so that a judgment may be formed as to fore and aft and lateral stability and control. It is hoped to develop a recording system which will give definite information as to the flying qualities of a new type of aeroplane, independently of the test pilot's opinion as to the merits of the machine.

There are, of course, many other problems in connection with stability and control which await solution. Among these may be mentioned that presented by the aeroplane which will not come out of a long spin; the effect of auto-slots and pilot planes, and the flutter of aeroplane wings.

In connection with engines, the more important matters dealt with have been the torsional vibration of crankshafts, the development of a compression-ignition engine, economy in fuel consumption, and investigations on air-cooled cylinders. It would obviously be a great advantage if a compression-ignition engine could be employed for aeroplanes, as in this case it would be possible to dispense

(1)Technical Report of the Aeronautical Research Committee, 1928-29. H. M. Stationery Office, 1929. Price, 30/- net.

with the elaborate electrical ignition system which gives rise to so many difficulties in connection with radio reception on aeroplanes in flight.

Much experimental work has been done in connection with materials, particularly in connection with elasticity and fatigue. Corrosion of alloys used in aeroplane construction is greatly affected by the fatigue of the material due to repeated alternating stress, and there are many aspects of this question which still require investigation.

Researches are contemplated which will be directed towards the avoidance of noise, both as affecting the passengers in the cabin of an aircraft and persons living in the neighbourhood of aerodromes. Such noises are due to a variety of causes, including the propeller, the engine exhaust, and engine clatter. Types of instruments are being developed for noise measurement.

It is interesting to note that the Aeronautical Research Committee carries on its work in close consultation with the aircraft industry in Great Britain, and that friendly relations also exist between that Committee and the United States National Committee for Aeronautics. This is particularly desirable, as it affords an opportunity for avoiding unnecessary overlapping of experimental work and, in important researches, makes it possible to exchange instruments, methods of work and information.

Recent Graduates in Engineering

Congratulations are in order to the following Students and Juniors of The Institute who have recently completed their course at the various universities.

Queen's University

Governor-General's Medal in Applied Science

Leavens, John Wright, B.Sc., (Me.), Bloomfield, Ont.

The E. T. Sterne Prize for a summer essay

Dore, Jackson Ira, B.Sc., (Chem.), Ottawa, Ont.

Degree of B.Sc. (with honours)

Hall, Donald Dixon, B.Sc., (Me.), Fenwick, Ont.

OBITUARY

Edward Francis Troughear Handy, M.E.I.C.

It is with deep regret that we record the death of Edward Francis Troughear Handy, M.E.I.C., which occurred at Halifax, N.S. on May 4th, 1930.

Mr. Handy was born in Dublin, Ireland, on June 1st, 1871, and, coming to Canada at an early age, received his education at Upper Canada College, Toronto, and matriculated at Trinity University in 1893. He attended the School of Practical Science, University of Toronto, during the years 1893 to 1895.

In 1896-1897, Mr. Handy was chainman and rodman on the construction of the Ottawa, Arnprior and Parry Sound Railway and from 1898 to 1899 he was doing the same work on the construction of the Crow's Nest Pass Railway. From June 1899 to June 1900 he was engaged on prospecting for minerals. Returning to railway work in 1900 Mr. Handy became leveller on surveys for the Algoma Central Railway, and was later leveller and resident engineer for the Canada Northern Railway. From March to June 1902 he was front picket on a survey of the Toronto-Parry Sound line for the Canadian Northern Railway, and from 1902 to 1904 he was connected with the Halifax and South Western Railway as leveller, transitman and resident engineer. From 1904 to 1906 Mr. Handy was resident engineer for the Canadian Northern Railway, and subsequently was engaged on locating on Holston river branch, Virginia and South Western Railway, in 1907 and 1908 he was an assistant engineer on the same line. From May to October 1908 Mr. Handy was engaged on fruit farming in British Columbia. From October 1908 to April 1909 he was with the B.C. Electric Railway Company, and from June to September 1909 he was building a logging railway for the Heaps Lumber Company at Ruskin, B.C. From that time until 1910 Mr. Handy was with the Western Canada Power Company on contour work, and located and built their railway from Ruskin to Stave Falls, B.C. Becoming connected with the Canadian Northern Pacific Railway he was in charge of a party locating on the mountain section, and in August 1911 Mr. Handy was appointed division engineer on the construction of the same road.

For the past ten years Mr. Handy has been connected with the highways department of Nova Scotia, and at the time of his death he was inspecting engineer for the department.

Mr. Handy joined The Engineering Institute as a Student on December 17th, 1896, transferred to the class of Associate Member on October 12th, 1905, and became a full Member on July 20th, 1915.

PERSONALS

A. R. Decary, D.A.Sc., M.E.I.C., has been elected president of the Montreal branch of the Aviation League of Canada.

Major E. C. G. Chambers, A.M.E.I.C., who since 1925 has been located at headquarters, Military District No. 1, London, Ont., has been transferred to West Point barracks, Victoria, B.C.

G. W. Babbitt, S.E.I.C., who graduated from the University of New Brunswick in 1928 with the degree of B.Sc., is now with the Canadian and General Finance Company Ltd., Toronto, Ont.

W. F. Dechman, S.E.I.C., who has been office engineer for the New Brunswick International Paper Company at Dalhousie, N.B. since 1929, has joined the staff of the Bolivian Power Company, Ltd. at La Paz, Bolivia.

E. W. Dill, S.E.I.C., who graduated from the University of Toronto in 1928 with the degree of B.A.Sc., and has since that time been on the engineering staff of the Gatineau Power Company at Ottawa, Ont., has now become connected with the Beauharnois Construction Company at Beauharnois, Que.

W. E. Adlington, Jr.E.I.C., has been appointed assistant chemist of the Forest Products Laboratories, Montreal. Mr. Adlington, who graduated from the Massachusetts Institute of Technology in 1927 with the degree of B.Sc., was formerly chemical engineer with J. T. Donald and Company Ltd., Montreal.

Engineer-Commander G. L. Stephens, M.E.I.C., has been appointed to a position in England which will detain him there for a year or more, and will be located at the Woolston works of Thornycrofts Ltd., at Southampton. Commander Stephens has been engineer officer of H.M.C.S. Patriot at H.M.C. Dockyard, Halifax, N.S., since 1926.

J. A. McCoubrey, A.M.E.I.C., formerly resident engineer for the Canadian Pacific Railway at Shaunavon, Sask., has been transferred to Coronation, Alta. as assistant engineer. Mr. McCoubrey has been conected with the Canadian Pacific Railway Company since 1904 with the exception of the period from April 1915 to July 1919, when he was engaged on municipal work.

J. J. Macdonald, M.E.I.C., is at present associated with Major J. R. Grant, M.E.I.C., consulting engineer for the Burrard street bridge, Vancouver, B.C. From April 1928 until recently Mr. Macdonald was in charge of the design and construction of the Nova Scotia Public Cold Storage Plant, at Halifax, N.S., for F. W. Cowie, M.E.I.C., the consulting engineer for that project.

F. L. Grindley, Jr.E.I.C., is resident engineer with the Northern Alberta Railways. Mr. Grindley graduated from the University of Alberta with the degrees of B.A. and B.Sc. in 1925 and 1926 and has since that time been engaged on railway work, with the exception of the period October 1st, 1926 to May 1st, 1927, when he was with the Aluminum Company of Canada at Arvida, Que.

J. J. Freeland, A.M.E.I.C., is with the engineer department of the E. B. Eddy Company at Hull, Que. Mr. Freeland graduated from McGill University in 1915 with the degree of B.Sc. From 1927 to March 1930 Mr. Freeland was with the Lake St. John Power and Paper Company Ltd., and just prior to accepting his present position he was for several months with the Fraser-Brace Engineering Company at Montreal.

P. J. MacDonald, A.M.E.I.C., formerly a member of the firm of Reilly and MacDonald, engineers and surveyors, Swift Current, Sask., has been appointed district engineer for the Saskatchewan Department of Highways at Swift Current. Mr. MacDonald has been located at Swift Current since 1910 when he entered business as a contractor, installing sewer and water works, etc. In 1913 he became a member of the firm of Martyn and MacDonald, consulting engineers.

C. H. Speer, M.E.I.C., formerly works engineer with Algoma Steel Corporation at Sault Ste. Marie, Ont. has gone to England, where he will identify himself with steel interests there, taking up residence in London for a time. Mr. Speer has been connected with the Algoma Steel Corporation at Sault Ste. Marie since 1909, except for a short period in 1913 when he was with the Bethlehem Steel Corporation at Buffalo, and during the war period when he was in charge of a shop engaged in the manufacture of shells at Midland, Ont.

Norman B. McLean, M.E.I.C., has been appointed chief engineer of the St. Lawrence ship channel, Department of Marine and Fisheries. Mr. McLean, who was formerly assistant chief engineer, has been on the staff of the St. Lawrence ship channel since 1901, with the exception of the years 1915 to 1918, when he was overseas with the 124th Battalion. Mr. McLean graduated from the Royal Military College, Kingston, in 1892, and from 1892 to 1898 was assistant engineer on the Soulanges canal. From 1898 to 1901 he was assistant engineer with the Department of Public Works, engaged on surveys, wharf construction, and the survey of French river.

R. M. Legate, A.M.E.I.C., is now electrical engineer with G. D. Peters and Company of Canada, Montreal. Mr. Legate graduated from the University of New Brunswick in 1924 with the degree of B.Sc., and secured the degree of M.Sc. in 1928. From July 1928 to 1929 Mr. Legate was resident engineer in charge of construction of the outdoor station and station building of the Atwater avenue sub-station of the Montreal Light, Heat and Power Company, and from January 1929 he was working on transmission line and synchronous condenser and system short-circuit studies for various companies owned by the International Power Company. He spent four months in Porto Rico as resident engineer in charge of design and construction of a hydro plant, for the Montreal Engineering Company Ltd.

R. R. Duffy, A.M.E.I.C., has been appointed district sales manager for Price Brothers Sales Corporation, at Montreal, Que. Mr. Duffy graduated from Acadia University in 1910 with the degree of B.Sc. in arts, and from McGill University in 1913 with the degree of B.Sc. in applied science. He was overseas from 1915 to 1919 as a lieutenant in the Canadian Engineers, and on his return became outside manager and vice-president of W. H. Duffy, Sons, Ltd., at Hillsboro, N.B. In 1923-1924 he was with the logging division of the Bathurst Company at Bathurst, N.B., and from February to November 1924 he was with the Brompton Pulp and Paper Company at East Angus, Que. In November 1924 Mr. Duffy became connected with Price Brothers and Company Ltd., being in the engineering division at Kenogami, Que., assistant land surveyor and later assistant logging engineer at Chicoutimi, Que.

P. G. Gauthier, A.M.E.I.C., has joined the engineering staff of the Beauharnois Construction Company at Beauharnois, Que. Mr. Gauthier graduated from McGill

University in 1921 with the degree of B.Sc. and was demonstrator in engineering at the same university sessions 1921-1922 and 1922-1923. From 1923 to 1925 Mr. Gauthier was with the Quebec Development Company at Isle Maligne, Que. being in charge of a field party in connection with the development of the Duke Price Power Company at that point. In 1925-1926 he was in charge of a party taking topography for the location of the Aluminum plant and city of Arvida, and in charge of field engineering for the construction of roads, water lines, sewers and houses for the city of Arvida. From December 1926 to July 1927 Mr. Gauthier was in charge of field location in connection with a transmission line from Isle Maligne to Mistassini. In 1927 he joined the staff of the Alcoa Power Company and until 1928 was located at Chute-à-Caron. From 1928 to the present time he has been with the same company at Kenogami, Que.

ELECTIONS AND TRANSFERS

At the meeting of Council held on May 6th, 1930, the following elections and transfers were effected:

Associate Members

CARR-HARRIS, Gordon Grant Macdonnell, assistant professor, civil engineering, Royal Military College, Kingston, Ont.

GILLESPIE, James, B.A.Sc., (Univ. of Toronto), Director of Department of Engineering, Central Technical School, Toronto, Ont.

PRENDERGAST, Ralph Macauley, B.A.Sc., (Univ. of Toronto), sales engr., apparatus sales divn., Canadian General Electric Co. Ltd., Ottawa, Ont.

Junior

McDONALD, Donald John, B.A., B.Sc., (Queen's Univ.), engineering department, Bell Telephone Company of Canada, Montreal, Que.

Affiliate

LEGATE, John James de Conlay, with Arthur Surveyer & Company, Montreal, Que.

Transferred from the class of Associate Member to that of Member

BOWMAN, Henry Alexander, chief engineer, reclamation branch, Department of Public Works Manitoba, Winnipeg, Man.

DESSAULES, Henri, B.A., B.Sc., (Ecole Polytech.), local agent and resident engr., Shawinigan Water & Power Company, Shawinigan Falls, Que.

McCOLL, Charles Ross, B.Sc., (Queen's Univ.), engineer of Town of Sandwich and general practice as Ontario Land Surveyor and Civil Engineer, Windsor, Ont.

TAYLOR-BAILEY, Frank Whitham, B.Sc., (McGill Univ.), Vice-President in charge of sales Dominion Bridge Company, Limited, Montreal, Que.

Transferred from the class of Junior to that of Associate Member

JULIAN, Fennell T., B.A.Sc., (Univ. of Toronto), supt., with J. A. Vance. A.M.E.I.C., General Contractor, Woodstock, Ont.

MARCH, Joseph Wade, B.Sc., (N.S. Tech. Coll.), instr'man and dftsman., International Paper Company, Gaspe Basin, Que.

MITCHELL, John Clarence, M.C., B.A.Sc., (Univ. of Toronto), engr. in charge of constrn. and mtce., Domestic Storage & Forwarding Company, Ltd., Toronto, Ont.

WALKER, Melvyn Lothian, B.Sc., (McGill Univ.), mech'l. engr., Dominion Rubber Co., Montreal, Que.

WOOLWARD, Charles Desmond, B.Sc., (McGill Univ.), engr., Foundation Company of Canada, Ltd., Montreal, Que.

Transferred from the class of Student to that of Associate Member

GOOD, Earl Franklin, B.A.Sc., (Univ. of Toronto), struct'l. designer, Messrs. Harkness & Hertzberg, Toronto, Ont.

HAGUE, Edward Cousins, B.Sc., (McGill Univ.), research engineer, Victor Talking Machine Co. of Canada, Montreal, Que.

STEEVES, Samuel Merritt, B.Sc., (Univ. of Man.), topog'l. engr., Department of Mines, Ottawa, Ont.

Transferred from the class of Student to that of Junior

BOULTON, Beverley Knight, B.Sc., (McGill Univ.), elect'l. engr., Beauharnois Construction Co., Beauharnois, Que.

BOWMAN, Ronald Fraser Patrick, B.Sc., (Univ. of Alta.), transitman, mtce. of way, C.P.R., Lethbridge, Alta.

BRYANT, James Sanborn, B.Sc., (McGill Univ.), student apprentice, Southern Canada Power Company, Montreal, Que.

CRAIG, James William, B.Sc., B.E., (Univ. of Sask.), ceramic engr., National Research Council, Ottawa, Ont.

MITCHELL, James Murray, B.Sc., (McGill Univ.), central district traffic supt., Bell Telephone Company of Canada, Montreal, Que.

STYLES, Hugh John, B.Sc., (Queen's Univ.), elect'l. inspr., Welland Ship Canal, St. Catharines, Ont.

Students admitted

BRYDEN, Donald Charles, B.A., B.Sc., (Univ. of Alta.), engrg. apprentice, Canadian Westinghouse Company, Hamilton, Ont.

CAMPBELL, Hugh L., (Undergrad., Univ. of N.B.), Salisbury, N.B.

LINGLEY, Harold Percival, (Undergrad. Univ. of N.B.), 24 High Street, Saint John, N.B.

MacDERMOTT, Kenneth Weston, (Undergrad., Univ. of N.B.), Gagetown, N.B.

PIDOUX, John Leslie, (Undergrad., Univ. of Alta.), University of Alberta, Edmonton, Alta.

STRATTON, Leslie Robertson, (Undergrad., Univ. of N.B.), 28 Exmouth Street, Saint John, N.B.

SINCLAIR, Donald Bellamy, (Undergrad., Mass. Inst. Tech.), 205 Cambridge Street, Winnipeg, Man.

STEPHENSON, Stephen, (Oxford and Cambridge local exam.), asst. field engr., Bell Telephone Company of Canada, Kingston, Ont.

Recent Additions to the Library

Proceedings, Transactions, etc.

Presented by the Societies:
- Corporation of Quebec Land Surveyors: Roll of Members, 1930.
- The Asphalt Association: Eighth Annual Asphalt Paving Conference.
- American Society of Civil Engineers: Year Book, 1930.
- The Royal Society of Canada: Programme of Papers, May Meeting, 1930, at Montreal.

Reports, etc.

Dept. of Mines, Canada:
- Rapport du Ministère des Mines pour l'Année financière se terminant au 31 mars, 1929.
- The Canadian Mineral Industry in 1929.

Dominion Water Power and Reclamation Service, Canada:
- Irrigation series, Bulletin No. 7: Irrigation Practice and Water Requirements for Crops in Alberta.
- Annual Report, 1927-28.

Dept. of National Defence, Historical Section, Canada:
- Map: The Western Front, Situation on Sept. 15, 1918.

Provincial Town and Rural Planning Advisory Board, Alberta:
- Annual Report of the Director of Town Planning for the Year 1929.

City of Winnipeg Hydro-Electric System:
- 18th Annual Report, December 31, 1929.

The Saint John Harbour Commissioners:
- Annual Report, 1929.

Harbour Commissioners of Vancouver, B.C.:
- Annual Report, 1929.

Bureau of Standards, United States:
- Commercial Standard CS7-29: Standard Weight Malleable Iron or Steel Screwed Unions.
- CS9-29: Builders' Template Hardware.
- CS17-30: Diamond Core Drill Fittings.
- Misc. Publication No. 109: Chart for Determining the Helix Angles of Screw Threads.
- Circular No. 381: Socium Oxalate as a Standard in Volumetric Analysis.

Bureau of Mines, United States:
- Technical Paper No. 471: How Leakage of Current from an Electric Shot-Firing Circuit Causes Misfires.
- Bulletin No. 319: Coal Mine Fatalities in the United States, 1928.

Geological Survey, United States:
- Bulletin No. 788: Topographic Instructions of the United States Geological Survey.

Engineer Dept., United States:
Statistical Report of Lake Commerce Passing Through Canals at Sault Ste. Marie, Michigan and Ontario, during Season of 1929.

The Port of New York Authority:
Ninth Annual Report, Dec. 31, 1929.

Illinois State Water Survey:
Bulletin No. 38: Illinois River Studies, 1925-1928.

City of Boston, Mass.:
Annual Report of the Public Works Department for the Year 1928.

Ohio State University:
Engineering Experiment Station Bulletin No. 54: Cold Crushing Strength of Fire Brick. Circular No. 20: A Decade of Progress in Highway Research.

Technical Books, etc.

Purchased:
H. M. Stationery Office, London: National Physical Laboratory. Collected Researches, Vol. 21, 1929, Paper 15-19: (1) "Three Papers on the Investigation of Wireless Waves arriving from the Upper Atmosphere"; (2) "The Cause and Elimination of Night Errors in Radio Direction-Finding"; (3) "The Attenuation of Wireless Waves due to the Resistance of the Earth."

Presented by Canadian Engineering Standards Association:
Standard Specification No. G30: Billet-Steel Reinforcing Bars (2nd ed.).
No. G31: Rail Steel Reinforcing Bars (2nd ed.).
No. G32: Steel Wire for Concrete Reinforcement (2nd ed.).

American Railway Signaling Principles and Practices. Chapter 6: Direct Current Relays. Chapter 11: Alternating Current Track Circuits.

Presented by American Institute of Steel Construction, Inc.:
Facts and Figures about Structural Steel, March, 1930 (2nd ed.).

Summer Convention

The American Institute of Electrical Engineers will hold its annual summer convention at the Royal York Hotel, Toronto, Ont., June 23rd to 28th, 1930, and have extended to the members of The Engineering Institute a cordial invitation to attend any or all of the events of the convention in which they may be interested. Mr. W. L. Amos, Secretary of 1930 Summer Convention Committee, is located at 190 University Avenue, Toronto, Ont.

Third International Congress for Applied Mechanics

The Third International Congress for Applied Mechanics is taking place at Stockholm, Sweden, on August 24th to 29th, 1930.

In September 1922 there was a private meeting between several scientists interested in hydrodynamic and aerodynamic questions. As the conference had an unexpected measure of success, the idea was conceived of issuing the invitation to an international congress of applied mechanics at Delft in 1924. The second congress was held at Zurich in 1926.

Further information regarding this third international congress can be had by applying to Professor W. Weibull, Tekniska Hogskolan, Valhallavagen, Stockholm.

Ferranti Electric Limited, 26 Noble street, Toronto, Ont., have just issued a new 52-page bulletin on instrument transformers. It embodies all general information on current and potential transformers, testing standards, etc., used. Diagrams are given for all ordinary connections of meters and indicating instruments with current and potential transformers. There is also a complete listing of indoor and outdoor types of instrument transformers with ratings, photographs, weights, dimension drawings and tables. Two-colour accuracy curves of ratio and phase angle are given for each type and rating. Outdoor metering equipments are also described. Copies will be gladly furnished upon request to the company.

The establishment of Whiting Corporation (Canada) Limited, with head office at 129 Adelaide street, West, Toronto, Lieut.-Col. James Mess, president, has added a third unit to the present engineering and sales organizations, known as Dominion Flow Meter Company, Ltd., and Diesel Power, Limited. The new company, with its own engineering and sales organizations, will specialize in the sale of Whiting cranes, foundry and railway equipment, Swenson evaporators, and pulp mill and sugar machinery, and Grindle pulverized coal system.

BRANCH NEWS

Halifax Branch

R. R. Murray, A.M.E.I.C., Secretary-Treasurer.

The regular meeting of the Halifax Branch was held on March 20th in the St. Julien room of the Halifax hotel, at 6.15 p.m.

There were thirty-six present and the meeting was presided over by Prof. W. P. Copp, M.E.I.C.

The minutes of the February meeting were approved after which Chairman Copp introduced Mr. W. L. Davies, manager of the Starr Manufacturing Company in Dartmouth, N.S., who, he said, would deliver an address on the "Manufacture of Skates."

Mr. Davies began by describing the evolution of the skate from the first skates made from the bones of animals; next came the skate of wood with an iron runner or blade affixed, which came about the third century. There was no change in method until in 1867 the "Acme," the first all metal skates, was invented by Mr. John Forbes of Dartmouth, N.S. Next came the skeleton type of skate until the tubular type was introduced in England in 1887. This style of skate came on the Canadian market in 1889. And, finally, we have the "figure" skate for fancy skating.

During twenty-five years approximatively 2,000,000 pairs of "Acme" skates were made and were widely popular. In fact the Starr Company had control of the world's markets in skates. Their manufacture was stopped 7 or 8 years ago and today but few pairs are sold.

Shortly after the Acme was invented it was copied by German makers and was, ironically enough, called the Halifax. The competition was not very keen, however.

The skeleton skate weighs only 22 ounces and will carry a load of 250 lbs. They are blanked out in three operations. To effect this in one operation would require a pressure of 180 tons. Only one pair in 1,000 is rejected as below standard.

The principal cost in a skate is the finish. Hot rolled steel is used because cold rolled steel does not finish well. Twelve hundred pairs per day are polished. Crucible steel is used in the best grades of skates but sometimes cast steel is used in the cheaper grades. The crucible steel has a hardness factor of 80 to 85 per cent and it holds a keen edge.

Only five years ago 70 per cent of skates made were of the blade type but today only about 20 per cent are made, the balance, 80 per cent, are the tubular type.

These tubular skates weigh but 11 ounces each. A few years ago two men were required to manufacture 4 pairs per day; today 35 men produce 1,000 pairs daily. These skates are made from straight carbon steel. The runners of these skates were formerly soldered; later welded. Now no solder or weld is used.

The company are testing for improvements all the time and it is hoped, shortly, to be able to burnish tubular skates as well as flats, instead of polishing them.

Chromium plating is not favoured by the company. It is expected that they will be able to use a new plating material containing only 18 per cent chromium and 8 per cent nickel. Corrosion is found to be a great difficulty in this climate.

The Starr Manufacturing Company are the largest skate producers in the world. Their markets are everywhere besides in Canada and the United States, which latter country absorbs about 30 to 40 per cent of the output.

Skates are manufactured automatically, the only hand work being on the finish. The figure skate is a one-piece skate and is made solely by hand work. It is modeled after the European type. Their best customer is Australia.

Due to artificial ice rinks skates have a market in all countries, no matter what the climate.

Mr. Davies described the method of plating skates and remarked that, whilst the output was 40,000 pairs annually five years ago, this year the output is 200,000 pairs.

They have also gone into the production of roller skates and will turn out 25,000 pairs this year.

Mr. Davies concluded his well delivered and interesting address with the observation that there are 59 operations in the making of a skate and while they have some difficulty at times in getting the correct grade of steel they continue to experiment for the best results.

Lt.-Col. Simmonds, president of the Starr Company, in a few remarks gave Mr. Davies great credit for the progress of the company and considered him a most valuable man.

Lt.-Col. Simmonds gave us some reminiscences of earlier days in skate making and stated that Russia is the only country where Starr skates are not sold.

He finally invited the members to visit the plant at a future date and Chairman Copp said that the invitation would be accepted and a visit arranged for.

A very hearty vote of thanks was tendered Mr. Davies for his address.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, A.M.E.I.C., Branch News Editor.

Chamber of Commerce Meeting

The members of the Hamilton Branch of The Engineering Institute of Canada were invited by the Hamilton Chamber of Commerce to attend their annual meeting at the Royal Connaught hotel on April 22nd. The speaker of the evening was R. O. Sweezey, B.Sc., M.E.I.C., of the Beauharnois Power Development, who spoke on "Waterpower Developments Along the St. Lawrence River." He strongly advocated the development of the St. Lawrence waterways as an entirely Canadian project.

Waterpower of Canada has been rapidly developed within the past 25 years, Mr. Sweezey pointed out. Ontario is now using 2,000,000 h.p., whereas eight years ago consumption was but half that total. He predicted that within 10 years the amount will have increased to 4,000,000 h.p. The Beauharnois development now generates 500,000 h.p., and Mr. Sweezey estimated a maximum of 2,000,000 h.p. in 10 years.

Emphasizing the importance of the development of waterways and energy, the speaker referred to the advantage of easy access to the markets of the world. When navigation is open from tidewater to inland ports, shown to be a possibility as far as Niagara falls, ships from all parts of the world will carry raw materials and create a demand for diversified industry.

Joint Meeting with the A.I.E.E.

The annual joint meeting of the Hamilton Branch of The Engineering Institute of Canada and the Toronto section of the American Institute of Electrical Engineers was held in the Westinghouse auditorium on Friday, April 25th. H. A. Lumsden, M.E.I.C., chairman of the Hamilton Branch, called the meeting to order and then handed it over to F. F. Ambuhl, chairman of the Toronto Section, A.I.E.E., who introduced E. F. W. Beck of the Westinghouse Electric & M'fg. Co. of East Pittsburgh. Mr. Beck's address was on "Lightning Studies and Field Surge Investigations."

Mr. Beck dealt with the status of lightning studies in the United States and showed lantern slides of portable laboratories and other equipment that were used in the studies.

Mr. Beck had a portable laboratory set up on the platform of the auditorium and gave a demonstration of the effects of the artificial lightning. The total voltage of each lightning bolt was recorded on a photographic plate by a Klydonograph, invented by L. R. Peters of the Westinghouse Electric and Manufacturing Company in 1923.

An accurate history in millionth of a second intervals told the characteristics of each bolt. The oscillograph, which made this possible, was developed by the Westinghouse Electric and M'fg. Co. under the Harald Norinder patents.

Mr. Beck concluded his talk with a demonstration of the latest development in the devices to stop the ravaging effects of lightning, the porous block lightning arrester. It reduces the mighty stroke of millions of volts to a quiet unobstrusive filtering of numerous sparks the size of a pin-head.

At the conclusion of his talk, Mr. Beck was tendered a hearty vote of thanks by the joint meeting. Refreshments were served by the Westinghouse Company to all present.

Annual Meeting

The Annual Meeting of the Hamilton Branch was held at the Tamahaac Club, Ancaster, on Wednesday, April 30th. H. A. Lumsden, M.E.I.C., occupied the chair and after dinner called for the Executive Committee report and the report of the Scrutineers. W. F. McLaren, M.E.I.C., the Secretary-Treasurer, presented the Executive Committee report which is given below.

Report of Executive Committee for the Year ending May 31st, 1930

The Branch held 9 meetings during the year as follows:—

1929

Sept. 27.—"Institute Affairs" by E. G. Cameron, A.M.E.I.C. Attendance 35.

Nov. 6.—"Machine Tools" by Graham Bertram, M.E.I.C.
"Coke Ovens" by J. E. Grady, A.M.E.I.C.
"Power Factor" by J. R. Dunbar, A.M.E.I.C. Attendance 36.

Dec. 5.—"Engineering Developments in the Army" by Maj. Gen. McNaughton, M.E.I.C. Attendance 50.

1930

Jan. 14.—"Leaside Transformer Station" by C. F. Publow and H. E. Brandon, A.M.E.I.C. Attendance 60.

Feb. 21.—"Engineering in Europe" by Prof. R. W. Angus, M.E.I.C. Attendance 30.

Mar. 19.—"Recent Developments in Arc Welding" by R. E. Smythies, M.E.I.C. Attendance 40.

April 22.—Chamber of Commerce—"St. Lawrence Power" by R. O. Sweezey, M.E.I.C. Attendance 12.

April 25.—Joint A.I.E.E. "Lightning Studies" by E. F. W. Beck. Attendance 320.

April 30.—Annual. "Hudson River Bridge" by F. W. Skinner Attendance 76.

A total of nine meetings were held with an average attendance of 70 and an average cost of $35.00 per meeting.

Special attention might be called to the Branch meeting of September 27th when Institute affairs were discussed. The speaker called attention to the vote taken last year or increase of fees, only about 900 members voting out of some 3,600. Following this up on December 2nd, your executive proposed an alternative method of increasing the funds of The Institute by equalizing the fees, that is, requiring Branch non-residents to pay the same fees as Branch residents and also requiring Associate Members to pay the same fees as members after 10 years. They also proposed to revise method of financing the Branches, by giving each Branch $150.00 and a 10 per cent rebate on fees, instead of the present rebates of 20, 25 and 30 per cent.

This proposal was sent to all Branches for comments, but only five acknowledged same. None of the Branches approved the proposal. The Lethbridge Branch preferred their proposal of financing Branches to ours. Their proposal was $15.00 per meeting approved by Council and 10 per cent rebate of fees. The chief difficulty with the Lethbridge scheme was that Council had to approve programme of meetings in advance.

The Saskatchewan Branch preferred to await "report of committee appointed by headquarters."

The Niagara Peninsula Branch opposed the proposal and thought Associate Members would resign rather than pay an increased fee after 10 years.

Headquarters, however, stated that their proposal to increase fees would again be put up to the membership and requested us to withhold action; besides drawing our attention to Section 75 of the by-laws requiring the signatures of 20 corporate members to any proposed change in by-laws. We agreed to postpone action.

A long questionnaire from headquarters re publications, occupied the attention of your executive on January 27th.

Altogether 9 executive meetings were held with an average attendance of 5 out of 9.

Class	Membership Resident	Non Res.	Total	Last Year
Members	25	6	32	27
Associate Members	47	10	57	62
Juniors	8	6	14	14
Students	32	6	38	38
Affiliates	3	0	3	0
Branch Affiliates	21	0	21	24
Total	136	28	164	165

Financial Statement as of May 31st, 1930.

Receipts		
Brought forward	$1,022.85	
Rebates 30 per cent fees	246.00	
Branch News	27.40	
Branch Affiliates	60.00	
Bank Interest	35.94	
Re-sale April 1929 Journal	1.00	
		$1,393.19
Expenses		
Printing	$ 57.82	
Postage and Stationery	25.88	
Cafeteria and Dinners	96.95	
Speakers' Expenses	11.05	
Telegrams and Miscellaneous	3.67	
Stenographer	50.00	
Annual Dinner	93.75	
	$ 339.12	
Balance	1,054.07	
		$1,393.19

The scrutineers reported that the following officers had been elected for the ensuing year:

Chairman..........W. F. McLaren, M.E.I.C.
Vice-Chairman..........F. P. Adams, A.M.E.I.C.
Secretary-Treasurer..........J. R. Dunbar, A.M.E.I.C.
Committeemen..........E. M. Coles, A.M.E.I.C.; G. A. Colhoun, A.M.E.I.C.

With the continuing members of the Executive Committee, this leaves the branch with the following officers to carry on its affairs for the coming year:

Chairman..........W. F. McLaren, M.E.I.C.
Vice-Chairman..........F. P. Adams, A.M.E.I.C.
Secretary-Treasurer..........J. R. Dunbar, A.M.E.I.C.
Committeemen..........J. B. Carswell, M.E.I.C.; H. S. Phillips, M.E.I.C.; E. M. Coles, A.M.E.I.C.; G. A. Colhoun, A.M.E.I.C.
Past-Chairman..........H. A. Lumsden, M.E.I.C.
Councillor..........E. H. Darling, M.E.I.C.

After dinner the meeting adjourned to the lounge.

Frank W. Skinner, consulting engineer, New York city, the speaker of the evening, discussed the Hudson river suspension bridge, and illustrated special design, features and comparative data on other notable bridges with lantern slides.

The Hudson river bridge will have a span of 3,500 feet, double that of the great suspension bridge, which was built when construction commenced, and nearly double the longest span of any description in the world, namely, the 1,800 foot Quebec bridge, being the most magnificent of all cantilevers and a monument alike to its engineers and to the Dominion.

The Hudson river bridge, he continued, would cost a total of $75,000,000, and would carry at first eight traffic lines of the heaviest automobiles and trucks, a capacity of more than 30,000,000 vehicles annually, which might be practically doubled by the making of a second lower roadway. This bridge, he said, exemplified the inherent beauty of the suspension bridge, as well as the great strength, durability, rapidity and economy of construction, etc. that makes it a successful competitor with all other types for spans exceeding 1,000 feet, and the only type which with present materials and machinery, could be built to at least a length of 5,000 or 6,000 feet with regard to economical considerations, while its possibilities, regardless of financial reasons, would permit of still longer spans.

Each of the four great cables of the Hudson river bridge contains more than six thousand parallel steel wires, forming 62 endless skeins reaching continuously from anchorage to anchorage, nearly a mile apart.

R. K. Palmer, M.E.I.C., of the Hamilton Bridge Works, moved a vote of thanks to the speaker which was carried with hearty applause.

London Branch

F. C. Ball, A.M.E.I.C., Secretary-Treasurer.
Jno. R. Rostron, A.M.E.I.C., Branch News Editor.

A paper on "Harbour Engineering" was given by H. B. R. Craig, M.E.I.C., at the regular monthly meeting of the Branch on April 16th in the Public Utilities Commission's board room, twenty-six members and guests being present.

The chair was occupied by W. G. Ure, O.L.S., A.M.E.I.C., who in introducing the speaker called attention to the extensive experience Mr. Craig had had in the subject on which he was going to speak as he had for a large number of years held the post of divisional engineer in the Public Works Department of Canada and had been located at Windsor and latterly London, Ont.

Mr. Craig had now left the Department and had commenced private practice as a consulting engineer. Further introduction from him was unnecessary as he, Mr. Craig, was so well known.

Mr. Craig opened by saying that he was pleased to have been asked to speak before the Branch and although he had given a paper some five or six years ago he had collected different data for this occasion. A humourous collection of engineering maxims taken from the "Canadian Engineer" of 1908 was then read by him by way of an "entrée" to the substantial meal which was to follow.

Harbour engineering could be classed as one of the oldest forms of engineering and the speaker traced the building of harbour works from the time of the Egyptians, Greeks and Romans to the present day. Mention was made of the artificial harbours of Tyre and Sidon, Alexandria, Athens, Carthage, Vestria and various British and Scottish harbours.

With regard to harbour works authorities mention was made at some length of the Stevenson family, Dr. Cunningham and others. Particular reference was also made to David Stevenson's "Civil Engineering in North America."

Harbours for the most part were built at natural outlets of rivers and streams and, owing to the sand bars, training walls were necessary, likewise piers and jettys. Sometimes these latter constituted themselves into groynes and possibly reconstruction would be necessary.

Artificial harbours were formerly usually constructed of timber which has now given place to concrete.

The drift of Lake Erie is from the west and there are three harbours on the north shore, viz. Port Stanley, Port Bruce and Port Burwell, that are costly, requiring breakwaters and a good deal of dredging. Lake Huron is more rocky and the littoral drift less, therefore the cost is not so great as on Lake Erie.

There can be no definite layout or standard for any harbour, the engineer must use his skill and judgment in each particular case and make his scheme fit in with the existing physical conditions to get the best and most economical results. Surveys must be made, soundings and borings taken, investigations made as to the direction and magnitude of currents, character of bottom for anchorage purposes, etc. before definite plans of the work can be made.

Formulae were given for determining the height and strength of the waves under storm conditions and instances were cited showing the lifting force of the water under these conditions, blocks of stone or rock weighing from two to ten tons having been lifted and carried up slopes inland.

There are two kinds of waves known as "oscillatory" and "translatory," the former being those at right angles to and caused by the wind over deep water and the latter those waves which turn over at the crest and break owing to the feet of the waves being retarded by some obstruction notably on reaching shore. However, translatory waves may occur in deep water owing to unseen obstructions or undulations on the bed of the ocean or lake.

Mention was made of ocean currents, particularly the Gulf Stream, and the evaporation of water under head conditions. Also of the wind and methods of locating the storm centres.

Harbour engineering covered a large variety of work and it was up to the engineer to study cause and effect very closely before designing his structure.

A number of questions were asked of the speaker and discussion centred round the problem of harnessing the power of the tides. A short description of one of the proposals for doing this at the Bay of Fundy was given by G. E. Martin, A.M.E.I.C., of the Public Works Department.

During the latter part of the evening an exhibition of moving pictures was given by E. V. Buchanan, M.E.I.C., manager for the Public Utilities Commission.

These movies had been taken by Mr. Buchanan himself and so were doubly interesting. The first set consisted of views of the Windsor-Detroit tunnel works and the Ambassador bridge. These were taken on the occasion of the visit of the Branch last year and depicted a number of the members in various antics in their efforts to see the works, besides views of the works themselves. Needless to say some of these created a hearty laugh and were much enjoyed.

The second set were pictures taken on and during the visit of Mr. Buchanan and his family to the Old Country, also last year. Pictures were shown, taken at the ports of sailing and during the voyages, both on the outward and return journeys, and the many places visited in Scotland and England. The first of the pictures in this category were taken at Hamilton, Scotland, a modest mining town with picturesque surroundings and chiefly notable as the birthplace of E. V. Buchanan. Following this, views were shown of places and people in Scotland at Stirling, Braemor, Edinburgh (including the Forth bridge), Loch Lomond, the Clyde and Greenock. In England at London, Hampton Court, the Thames river and Eton College, Windsor and the exhibition at Newcastle. Notable amongst the views shown at Edinburgh were those of the Scottish National War Shrine. Mr. Buchanan laid particular stress on the beauty and impressiveness of this edifice.

The pictures were beautifully clear and distinct and were greatly enjoyed even to that of a close-up of a black specimen of an Aberdeen terrier viewing the operations with an unperturbed dignity all his own. The exposition was given by Mr. Buchanan in his own inimitable style and was full of running and piquant yet descriptive comment. To a facetious remark that his father was a better looking man than he was Mr. Buchanan got back by saying "that might be just possible."

The evening was thoroughly enjoyed by all present and a cordial vote of thanks was moved to the speakers by the chairman and unanimously carried.

Hudson River Suspension Bridge

A well-attended extra meeting of the London Branch was held on May 1st in the city hall assembly room, F. W. Skinner, consulting engineer of New York, N.Y., being the speaker and his subject, "The Hudson River Suspension Bridge."

W. G. Ure, A.M.E.I.C., city engineer of Woodstock, Ont., chairman of the Branch, presided and after disposing of the minutes and other business of the Branch, called upon D. M. Bright, A.M.E.I.C., consulting engineer, of London, Ont., to introduce the speaker.

Mr. Skinner said that the Hudson river bridge connecting the states of New York and New Jersey was unique, inasmuch as the centre span is the longest ever erected in the world. Long spans, Mr. Skinner said, had been perfected only within the last fifty years, one hundred years ago what were considered to be long spans were now hardly worth the name. In pioneering days, timber-framed structures were built up to two hundred feet span and later up to three hundred feet with the aid of supplementary iron rods. Later again, spans of five hundred feet were accomplished by the use of wrought iron trusses and by the advent of structural steel the spans of bridges increased by leaps and bounds.

There might be said to be three types of long span bridges—(1) trussed arches, (2) steel cantilever trusses and (3) suspension bridges. Two examples were mentioned of the first class, one at Hellgate of 1,016 feet span and another (in construction) at Staten Island of 1,050 feet. The Canadian structure at Quebec and the Forth bridge in Scotland come into the second class, both of them being around 1,800 feet span. The economic length of span of this type of bridge is 2,500 feet with a dead load five times the weight of the live load. In the third class the Brooklyn bridge with a span of 1,696½ feet was not exceeded until about four or five years ago by the design of the Ambassador bridge between Detroit, Mich., and Windsor, Ont.

Arch and cantilever bridges are rigid and suitable for smaller spans, suspension bridges develop greater flexibility and permit of much larger stresses and overloads. They are graceful and light in appearance and furthermore cheaper, for spans over 1,000 feet. They can be built in places where it would be impossible to erect other types of bridges, such as over raging torrents or yawning chasms. This was illustrated by a view of the Royal George suspension bridge with a span of 880 feet, 1,053 feet above the Colorado river. The Hudson river bridge with a span of 3,600 feet is now well advanced and it is expected, will be complete and ready for opening to traffic by 1932.

Contrary to usual practice, the contractor was made responsible not only for carrying this work out according to the specifications, but was also held responsible for the design of the structure. Messrs. John A. Roebling and Successors of Trenton, N.J., who obtained the contract for the cables therefore had to verify all the data and calculations necessary for the design, and conduct an exhaustive number of preliminary tests. This preliminary work cost the firm in the neighbourhood of $330,000 for laboratory and mechanical tests. Special machines and equipment were laid down at their Trenton plant for this work. Owing, however, to this preliminary work, which included minute planning of operations in advance, the work on the ground was proceeding with unparalleled rapidity.

The four cables, having a diameter of 36 inches, contain 107,000 miles of steel wire. Each cable is a mile long between anchorages and is made up of 62 strands, containing about 432 cold drawn steel wires of .196 inch diameter each. Each large cable carries a dead load of 39,000 pounds and a live load of 9,000 pounds per lineal foot.

The cables are supported at either bank by two steel towers, 650 feet high and containing 20,000 tons of steel each. There is a proposal for encasing these towers in concrete, much to the speaker's disgust, for Mr. Skinner considers that the tracery work of the steel is far more preferable on aesthetic grounds than a mass of opaque concrete.

The anchorages on the New Jersey side are embeded in solid rock and an elaborate system of tunnelling and shafting was carried out in forming the anchorage. On the New York side the concrete anchorage contains 140,000 cubic yards of concrete and is contained in a handsome structure 200 feet square and 155 feet high. The weight of this anchorage block is around 520,000,000 pounds and the tension exerted by the anchor cables is about half of that weight.

Mr. Skinner's remarks were illustrated by a large number of photographs and diagrams etc., shown upon the screen, and some of these views depicted very clearly the placing of the nine working cables and the frames and gear fixed upon them for spinning the cables. Exhaustive tests were made of these cables beforehand and precautions taken to ensure uniform elongation under stress. They were drawn across the river on barges and slung over the steel towers and afterwards elaborate platforms were slung from them to accommodate the workmen. The carbon, cold drawn, steel wires (.196 inch diameter) were then drawn (or spun) in units at an even tension across the span and adjusted with mathematical precision to the exact curve and sag required to give perfectly uniform tensions in the large cable of which they formed the units. An interesting feature was the splicing of these wires. They were placed end to end in a steel sleeve two and a half inches long and enormous pressure exerted all around the sleeve. In tests made afterwards the wire itself failed away from the joint. Every eight minutes six loops of these wires were drawn across the span, this constituting a speed of construction four times as rapid as any previous operation of the kind. Electric light and power installations were installed for this work together with an elaborate signalling system for synchronizing the operations. Four hundred and thirty-two wires constituted a strand and when one strand was completed the wires were bound together by adhesive tape. Each strand when complete was heptagonal in form and the sixty-two strands formed the whole cable of 36-inch diameter. Circular rings of steel were then placed in position, then rings carrying a number of powerful jacks which exerted an enormous pressure evenly over every part of the circumference of the 36-inch circle. So highly were the wires compressed together that a photographic section of the cable after this treatment gave all the appearance of a section of a solid 36-inch steel bar.

The temporary working cables were afterwards cut up as required and used for the vertical hangers from the main cables. The steel stiffening trusses carrying a roadway 130 feet wide and accommodating eight lanes of heavy highway traffic were slung from these hangers. Provision is also made for the instalment at a later date of a lower steel deck to carry steam and electric railroads.

The speaker referred in high terms to the efficiency of the Roebling plant and of their success in developing the manufacture of high tension steel wire to its present strength of from 220,000 to 280,000 pounds per square inch.

The Hudson river bridge will constitute the longest span up to date, but the speaker hinted at still greater achievements for this type of structure in the near future, one of 4,400 and another of over 5,000 feet span.

The total cost of the bridge will be in the neighbourhood of $75,000,000 of which the cables alone absorb $12,000,000.

In answering a question Mr. Skinner said that contraction and expansion in the cables was taken care of by their rise and fall which would amount to from two to three feet under different temperatures.

A hearty vote of thanks was proposed by J. Ferguson, A.M.E.I.C., seconded by J. R. Rostron, A.M.E.I.C., and unanimously carried.

Inspection Tour

The regular May meeting of the London Branch held on May 10th, 1930, took the form of an inspection tour of the rail relaying operations of the Canadian Pacific Railway on the company's main line between Windsor and London. This visit was made possible by the courtesy of S. W. Crabbe, division superintendent, and A. O. Wolff, M.E.I.C., and was well attended by members and guests, amongst the latter being several from the Canadian National Railways and the Michigan Central Railway.

The party was taken to the scene of the present rail-laying job on the main line between London and Windsor, near Caradoc, on the work train. The Canadian Pacific is replacing the 85-pound rail with 100-pound rails on the main line and are doing so by methods new to railroad construction engineering.

On other railroads and formerly on the Canadian Pacific, the rails are replaced one at a time, 18 men lifting one rail into place, coupling and spiking it. By the new method the rails are first rolled off flat cars along the track, then one small gang couples them in lengths of three and sets them on the edge of the ties.

When the actual replacement is to take place one group of men walk along the track loosening spikes on the inside of the old rail. They are followed by a group who pry the old rail to the inside of the track, the outside spikes being left in the ties as a guide for the new rail. The new rails, in lengths of three, are then pried over in an upright position and lifted into place by means of six tripods and levers. With this equipment they are easily swung into place. Another group follow and spike the new rails and another to bolt the joints.

A crew with an air compression bolt tightener apparatus follow, tightening the joints at the rate of 17 seconds a joint.

One crew described as above proceeds along the south rail of the track and are followed by a similar crew on the north track. Then following both crews is the work train. The old rails, which remained coupled for the distance of almost a mile, are pried over the new rail at one end and then shoved over to one side by the work train so that the old rail is left to the outside of the track ready for uncoupling, the new rail is in its place and another page of history written.

The crews walk right along the track and average nearly 12 miles daily. The insertion of rail anchors and new tie plates, as well as other minor adjustments, are done later by the regular section crews.

All the old rails are graded and marked and will be used in spurs, branch lines and sidings and for repair purposes where 85-pound rails are still in use. The manner in which the rails are "closed" to allow a train to pass is very interesting, a tapered rail being jointed from the new to old rail in a very few minutes and the train passing with little or no delay.

Canadian Pacific road engineers explained that while the saving of time on the entire job is worthy of consideration, the operating of regular trains, according to regular schedule while the work is in progress on a one-line track, is permitted only by use of this new, rapid and improved method.

The work train which follows the men along the track is made up of tool cars, sleeping cars for the men and their regular dining cars. S. W. Crabbe, division superintendent, and A. O. Wolf, division engineer, explained the details of each operation to the party of visitors.

A rock ballasting crew, working on the same line, was also seen by the party. The laying of new heavy rails and rock ballasting of the line is part of a programme costing $500,000, being done on the London division in preparation for heavier equipment and traffic. When the London division work is completed the railway will have heavy rail and rock ballasted track from Quebec to Chicago.

W. J. Shaw, A.M.E.I.C., St. Thomas division track engineer of the Michigan Central Railway, and J. Ferguson, A.M.E.I.C., with a similar position on the Canadian National, thanked Mr. Crabbe and Mr. Wolf for their hospitality on the inspection trip and said that the work being done by the Canadian Pacific on this job was something new in their experience.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

At a supper meeting of the Branch, held on April 14th, a very interesting address on the subject "Some Aspects of Clay and Burned Clay Products" was delivered by G. S. Stairs, B.Sc., A.M.E.I.C., Director of L. E. Shaw, Ltd., Avonport, N.S., and Chipman, N.B. L. H. Robinson, M.E.I.C., Vice-Chairman of the Branch, presided. Immediately following the supper several enjoyable clarinet selections were rendered by Dr. F. E. Burden, after which the Chairman introduced the speaker of the evening.

Some Aspects of Clay and Burned Clay Products

The outstanding properties of clay are its plasticity and imperviousness to water when moist and the ease with which it can be converted into a stone-like mass when heated to a high temperature. In the process of manufacture, the clay is moulded by any one of three methods. In the soft mud process, water is added until the clay is of the consistency of soft paste and is pressed into wooden moulds. In the stiff mud process less water is added — the clay is less plastic and must be forced into the moulds. In the dry press process the moisture content is reduced to twelve or fifteen per cent. The clay is then granulated and screened and conveyed to a pressing machine and pressed in steel moulds.

Having been moulded by whatever process used the product is then dried. For this purpose use is made in modern plants of waste heat from the kilns. The drying period varies from a minimum of eight hours to several days.

The final process of manufacture is the "burning" of the product. The speaker referred to the impurities occurring in clay and the heat treatment necessary for their elimination. Aided by charts and diagrams, Mr. Stairs described in detail the various types of kilns in use. Finally a motion picture film was shown illustrating the operation of a modern clay product plant.

Mr. Stairs' address was followed by an extended discussion.

A vote of thanks moved by H. J. Crudge, A.M.E.I.C., seconded by C. S. G. Rogers, A.M.E.I.C., was tendered the speaker by the presiding Chairman.

Visit of the General Secretary

A special meeting of the Branch was held on April 29th, on the occasion of the annual visit of R. J. Durley, M.E.I.C., General Secretary of The Institute. M. J. Murphy, A.M.E.I.C., presided. Mr. Durley outlined the progress being made towards co-ordination of provincial associations and The Institute. Considerable interest was aroused on learning of the proposal to send out to the membership a secret questionnaire dealing with the matter of remuneration.

Following a round-table discussion, the proceedings were brought to a close with the serving of "smokes" and light refreshments.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

On April 3rd, A. W. K. Billings, M.E.I.C., vice-president in charge of Operations for the Canadian and General Finance Corporation, addressed the Montreal Branch, taking as his subject "Water Power in Brazil."

Mr. Billings told how that country which is estimated as being the richest in the world in potential water power has been and is being developed largely by Canadian capital and enterprise. Thirty-two years ago, Fred S. Pearson, a noted American engineer, who later went down with the Lusitania, visited the south in search of health. He was attracted by the possibilities of the country and on his return interested a group of Canadian capitalists. These men, headed by Sir William Mackenzie, and ably assisted by Sir Alexander Mackenzie as resident executive in Brazil, and F. A. Huntress who directed the technical end for twenty-five years.

"To-day," Mr. Billings continued, "the light, power and transportation, gas and telephone service of Sao Paulo, Rio de Janeiro, Santos and the surrounding region, representing over two-thirds of the water power developed in Brazil are directly due to the courage and enterprise of this one Canadian company, known there as the 'Light' or the 'Canadian Company'."

After a brief sketch of Brazil, drawing attention to the fact that in area it was comparable to the United States or Canada, and that it had a population of 39,000,000, the lecturer went on to say that only a small part, namely the plateau of the southern portion, temperate in climate, well populated with five types of Brazilian and European settlers, was of interest in connection with the water power. This region, he explained, produces 70 per cent of the world's supply of coffee and has many important towns and cities, Rio de Janeiro with a population 1,300,000 and the modern Sao Paulo with 1,050,000 as well as the important seaport of Santos.

An outline of Brazil's physiography made clear the peculiar structure to which it owes its water power potentialities. The great inland plateau, the Serra do Mar, rose slowly ages ago, breaking along faults parallel to the present coast, but few of the rivers could keep pace with the rise by cutting down their courses to the ocean. The result is that with few exceptions the rivers of this region flow to the interior forming the great river basin of the Parana and Paraguay. These rivers in their courses cross many beds of harder rocks usually basalt, and the resulting cascades and rapids cut long canyons in these beds.

Added to this unusual physiographical structure of the region must be added another feature, the climate, which is abnormally rainy. At the crest of the plateau of the Serra do Cubatao development of the Brazilian Traction Company, the average rainfall is about sixteen feet. Last year it was twenty-two and a half feet, and in each of two months, February and December, was fifty-two inches.

Estimates of the available horse power in Brazil range from 20,000,000 to 600,000,000 h.p., the usually accepted figure being in the neighbourhood of 43,000,000. It was pointed out by the speaker however, that extreme caution was advisable in considering the available statistics in this country.

After discussing in some detail the different falls and water power sources in the region, Mr. Billings turned his attention to some of the typical power plants. At the time the earliest ones were built, the largest water wheel units were only 5,000 kilowatts while now 70,000 to 80,000 h.p. is the maximum in single units and steam turbines have been built in units up to 260,000 h.p. Details were given of the plants at Marmelos, Parahyba, Bananeiras, Alberto Torres, Itatinga, Usina Isabel, etc. The largest development in South America is the Serra do Cubatoa near Sao Paulo, with two units producing a maximum of 96,000 h.p. and an ultimate projected capacity of 750,000 h.p. The second largest plant is on the lower portion of the Parahyba river, while another important plant belonging to the Brazilian Company is at Riberroa das Lages, where 85,000 h.p. is developed.

The speaker next discussed the question of markets and went on to tell of other potential sources of wealth. This portion of Brazil is largely dependent on coffee production and textile manufacturing for its prosperity. Little is known of the mineral wealth but indications are that this is by no means small. In this connection Mr. Billings said that bauxite which to-day is so essential as the raw material for the production of aluminum and which seems principally in semi-tropical countries like Brazil, is known to exist over wide areas but has not yet been prospected or developed. Manganese, lead and silver, some gold, diamonds in quantity, phosphate rock, nickel and other minerals of importance are known to exist, even comparatively close to the thickly-settled portions, but so far have received too little attention.

In conclusion, Mr. Billings spoke in optimistic vein of the future possibilities of Brazilian development, and of the pride which Canadians should take in the fact that an important part of the past development has been and is still being led by Canadian interest.

P. S. Gregory, M.E.I.C., occupied the chair, and a large number were in attendance.

C.N.R. Shops, Point St. Charles

A very interesting description of the new locomotive shop and power house of the Canadian National Railways at Point St. Charles was given by Mr. J. Roberts, supervisor of shop methods, in a paper delivered before the Montreal Branch on April 10th.

By means of slides, Mr. Roberts traced the history and development of locomotives from the early days of the old Grand Trunk at Longueuil in 1853. He then went on to show how the development in motive power had been met in the construction of the modern shop with its huge cranes and many other facilities necessitated by present-day conditions.

It was pointed out by the speaker that the locomotive shop was only the first step in a five-year construction programme. During the present year a grey-iron foundry, material storage midway and light repair shop were contemplated. In 1931 the construction of a new passenger shop was to be undertaken, in 1932 a large machine shop and wood mill was scheduled, while in 1933 a freight car shop would complete the programme.

The power house was completed on December 1st, 1928, and is located on the south side of the locomotive shop. It consists of a four storey red brick building with reinforced concrete foundations and a water tank providing 150,000 gallons storage adjoins it at the west end. The boiler room contains 2 large pulverized fuel fired boilers, built for 400 pounds pressure, while the engine room equipment consists of one 1,000 k.w. d.c. turbo-generator, one 500 k.w. a.c. steam driven auxiliary generator and two 2,500 cubic foot steam-driven air generators and two 2,500 cubic foot steam driven air compressors together with switchboards and auxiliaries.

A very comprehensive description of the details of the locomotive shop was also given by Mr. Roberts and this was accompanied by a large number of well selected slides which gave the audience a clear conception of all the details.

J. T. Farmer, M.E.I.C., occupied the chair.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.

The Branch held a dinner meeting on April the twenty-ninth, at the Leonard hotel, St. Catharines, and thirty-six members attended. The speaker was Frank W. Skinner, consulting engineer, of New York City. The subject was "The 3,500-foot Span of the Hudson River Bridge, and Comparative Construction Features of Largest Typical Spans."

Mr. Skinner asserted that the suspension type becomes economic for heavy traffic when spans exceed 1,000 feet, and is imperative where the longest span bridges are necessary. He also appears to believe that John A. Roebling was the very finest of artisans, and his successors and associates were foremost in developing, manufacturing and constructing steel wire ropes and cables. Despite these prejudices, or perhaps on account of them, he gave one of the most instructive discourses on methods of construction that we have had the pleasure of listening to for some time. His slides were equally perfect, showing the different steps of spinning the immense cables in place, also other construction details such as the anchorages and cofferdams for the main piers, and winding up with notable examples of almost every other conceivable type of long span bridge, comparative advantages, disadvantages and limitations, and especially their erection methods and equipment, that are important elements of cost and difficulty.

The Hudson river suspension bridge has four main cables, each 36 inches in diameter, and nearly one mile long, containing 26,474 individual wires. These wires are 0.196 inches in diameter, and are cold drawn from acid open hearth carbon steel with an ultimate strength up to more than 288,000 pounds per square inch. To get this strength a very careful selection of the ore is made, but no alloy is used, as experience has shown that any subsequent form of heat treatment is unnecessary if not actually undesirable. The quality of the cable wire much exceeds specification requirements, that call for 150,000-pound yield point and 220,000 ultimate strength. The working stress is 82,000 pounds per square inch.

After the wires are drawn and hot galvanized in the shops, they are shipped to the bridge site on reels and, as the spinning progresses, the end of one wire is pressure-welded with a sleeve to the end of the wire on the next reel, thus insuring 100 per cent splices.

One end of the continuous wire is made fast to the strand shoe at the anchorage, and a bight is carried at a constant tension over the two towers and down to the anchorage at the other side where it engages another strand shoe, thus building up for each cable 61 434-wire endless wire strands 4½ inches in diameter. Each strand with its anchor eye-bar thus has 217 bights of straight parallel wires which, when completed, are placed in the saddles and adjusted with pulling jacks and shims to give exactly the same tension (and consequent sag of about 225 feet) to each strand. The final operation consists of compressing these 61 strands into the circular cable, and binding this with soft wire covered with a weather-resisting preparation.

A $600,000 working platform was built under the main cables, and this of itself, was no mean engineering feat. After much experiment, a method was evolved for sway bracing by means of heavy cross struts and wire ropes attached to the main piers, which was nearly perfect, and steadied the platform under the most violent wind conditions. The 36 2-15/16-inch supporting cables were all pre-stretched, thus ensuring an equal amount of sag thereafter. This pre-stretching is an entirely novel feature, and one which will probably have a great influence in future suspension bridge construction. It was the fact that no two twisted cables would stretch exactly the same amount after a period of service which instigated the spinning of cables *in situ*. With pre-stretched cables this defect is now overcome and main cables may be built up much more rapidly and at less cost by hauling across large diameter strands composed of twisted wire ropes.

The east anchorage consists of mass concrete 150 feet high based on rock, and weighs nearly 260,000 tons; other than this, it had few remarkable features, but the westerly one was constructed in two rock tunnels, driven while other work was going on overhead. A shaft and drift were sunk below the tunnels, and, from the drift, excavations proceeded in a diagonal upward direction, the muck gravitated to the feet of the tunnels, and was then removed through the horizontal drift, and hoisted through the shaft.

The contractor for the main piers adopted the unusual course of using open cofferdams, rather than caissons, for this work. Despite an 80-foot hydrostatic head, which necessitated sheet piles 89 feet in length, the operation was quite successful. Rectangular cells built up of steel sheet piling enclosed the 98 x 108-foot pier area across which heavy timber bracing was placed as the water level was lowered. The cells were filled with concrete at the bottom, and rock or sand fill towards the top. There was only one accident when some piles of a cell blew in at the base, but this breach was speedily mended with little trouble.

The cost of the cables alone amounts to nearly $13,000,000, and this contract was awarded to the firm of John A. Roeblings Sons Co., whose name has been associated with wire and cable manufacture for nearly a century. In the year 1843 John A. Roebling constructed the 196-foot Aqueduct bridge in Pittsburgh, one of the first suspension bridges in America, and later he built the Brooklyn suspension bridge, the first one to be built with steel wire cables; also the famous Niagara 800-foot railroad suspension bridge, and his successors have built many more notable ones, and have furnished cables for most of the suspension bridges in the United States.

The speaker gave a few statistics concerning the Hudson river bridge, which are noted below:

Total estimated cost $75,000,000.
Span between main towers 3,500 feet.
Sag of cables between towers 325 feet.
Height above water of towers 635 feet.
Height above water of lower deck 213 feet.
Dead load per lin. ft. 37,000 lbs.
Design live load per lin. ft. 9,000 lbs.
Width of deck 117 feet.
Yearly capacity of upper deck, more than 30,000,000 vehicles.
Estimated amortization period 22 years.
Estimated revenue in 23rd year $12,000,000.
Total weight of cables, 28,000 tons.
Maximum daily rate of cable laying, more than 123 tons.

Messrs. Grant, Little, Gisbourne, Jackson, and others plied the speaker with questions at the close of the meeting, in answer to which he stated that no definite life can be placed on this type of steel structure. The Brooklyn bridge has been in use for over 50 years, and is now safely carrying more than its designed load; the steel work in the roof of the Madison Square Garden had not been painted for 40 years, and yet a recent examination showed it to be in perfect condition. With proper design and careful maintenance, steelwork has an unlimited life.

In Mr. Skinner's opinion, no esthetic advantage will be gained by encasing the steel towers with concrete as proposed. Such a casing would be unlikely to crack, as the cables are not moored to the towers, and therefore any tower movement due to expansion or contraction will be but slight. The rise and fall of the deck due to temperature changes will be several feet. The bridge will be opened to traffic with one deck only in 1932; a lower deck and stiffening trusses will be added at some later date.

At the conclusion, president A. J. Grant, M.E.I.C., and Walter Jackson, M.E.I.C., moved and seconded a vote of thanks. This was tendered to the speaker by E. G. Cameron, A.M.E.I.C., who was in the chair.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

The Engineer in Japan

A popular illustrated lecture was given by the Ottawa Branch in the lecture hall of the National Museum on the evening of April 16th, 1930, at which John Murphy, M.E.I.C., of the Department of Railways and Canals, delivered an illustrated address entitled "A Trip to Japan." The meeting was presided over by J. E. Noulan Cauchon, A.M.E.I.C., in the absence of John McLeish, M.E.I.C., the regular chairman of the Branch.

Mr. Murphy during the autumn of 1929 was the official representative of the Railway Commission and of the Department of Railways and Canals at the World Engineering Congress and the World Power Conference meetings which were held at Tokyo at the same time that the meetings of the Relations Conference were being held in Kyoto. During the course of his address Mr. Murphy related incidents in connection with these various conferences. Three thousand delegates from all parts of the world attended the engineering meetings, the Japanese engineers themselves taking a very active part in all the proceedings. Nine hundred technical papers, prepared in thirty different countries and dealing with every branch of engineering and allied undertakings, were presented.

The visiting delegates were welcomed by members of the Imperial Japanese family, the Prime Minister and his cabinet, as well as by a small army of Japanese engineers and their families. Their stay was made pleasant by the residents, as well as profitable. Free railway transportation was presented to the delegates and their families over the 8,300 miles comprising the government railway system.

The organizing abilities of the Japanese were well illustrated by the manner in which all matters relating to these most extensive conferences were arranged. The extent of the conferences may be realized when it is stated that concurrently 14 sectional sessions took place during the ten days of meeting. An immense amount of work was accomplished, and the "proceedings" will constitute a great engineering library of the world's present up-to-date practice.

Nor was the social side of the conference neglected. In all, there were some 91 functions—receptions, garden parties, musicales, theatre parties, luncheons, dinners and various forms of Occidental entertainment. A unique feature, for instance, of the garden parties was the millions of chrysanthemums which were on display in the public park during the course of the sessions.

The reconstruction work in Tokyo and Yokohama, stated Mr. Murphy, has been carried out with great completeness and has made these two cities marvels of beauty. Of the disastrous earthquake and fire of seven years ago few traces are left.

Many of the beautiful hand-coloured lantern slides exhibited by Mr. Murphy of Japan and her people created as much interest as his references to the engineering meetings.

It is worthy of note that all the proceedings at the meetings were carried on in the English language. The study of English is compulsory in the schools. Even the "stop" and "go" traffic signals used on the streets and the names of all the railway stations are posted in English.

In conclusion Mr. Murphy stated that engineering and educational progress in Japan are equal to that of any other country anywhere. Many of their young men have visited other parts of the world and by energetic study and apprenticeship have acquired a marvellous store of knowledge relating to all walks of life. These men are now working with great success for the glory of their island empire.

Industrial Development of the Sudbury Area

At a noon luncheon at the Chateau Laurier on May 8th, the guest speaker was Mr. E. A. Lapierre, member of Parliament for the constituency of Nipissing in the House of Commons for the past ten years and for the past thirty-five years a resident of northern Ontario. John McLeish, M.E.I.C., chairman of the local Branch of The Institute, presided and among the guests at the head table was R. J. Durley, M.E.I.C., of Montreal, secretary of The Institute.

Mr. Lapierre stated at the commencement of his remarks that possibly no other mineral area had commanded greater attention, not only from mining men but also from financiers, industrialists and those engaged generally in commercial pursuits, than had the Sudbury basin. The first recognition of the possibilities of this region was given in a report of the Geological Survey, then under the directorship of William Logan, later Sir William Logan, in 1857. This report was by Alexander Murray who found copper at a point indicated by S. C. Salter, Ontario provincial land surveyor, who was engaged on meridian line surveys in the vicinity.

Mr. Lapierre then traced the development of the mining area. At the time of the construction of the Canadian Pacific Railway, in 1883, the vicinity of the present Murray mine was reached. Traces of mineralization had been found in the neighbourhood while the construction was going on, which gave rise to the aforesaid Murray mine. This mine was most spectacular in its development but was overshadowed later by the Creighton mine. These and other mining properties passed successively through different hands and some were abandoned.

In the early days of the Sudbury basin the country was looked upon almost entirely as a copper producing area. But as nickel began to be used more and more as an alloy in the manufacture of steel, the nickel-producing feature of the district assumed a greater importance and abandoned copper properties became active as nickel producers.

The speaker referred to the importance of nickel in the manufacture of armaments during the War and recalled the exploit of the German submarine "Deutschland" which in 1916 took over to Germany a cargo of nickel for use in armament manufacture, repeating the performance four or five months later.

At this time the British Government decided to take an interest in and to finance the construction of an extra refinery in Canada, under a company known as the British America Nickel Company. On account, however, of a cutting down of the prospective demands for nickel, looking forward to a World Disarmament Conference and also on account of the high cost of labour, the operations were carried on at a loss for one year and as a result the British America Nickel Company closed its doors. Shortly afterward the International Nickel Company curtailed their operations considerably.

Fortunately, however, the future of this great industry was not entirely lost sight of. Immense sums of money were spent in experimentation, the results of which have transformed an industry from one of war purposes to one of ordinary peace-time business.

In investigating properties that had been abandoned, no more spectacular discovery as the result of diamond drilling has been made than in the old abandoned Frood mine. Following upon this, other investigations have been made and discoveries have taken place on properties which a generation ago would not have been considered of any potential value. The International Nickel Company have been finding the demand for monel metal has been increasing, so that it has been decided to retain the Creighton mine and re-open the Frood mine as further supplies. At a depth of 2,800 feet at the latter mine it was realized from a study of the cores from the drills that this mine possessed the richest single copper ore body on the American continent.

This extraordinary occurrence gave rise to further diamond drilling on the adjoining property with a result that the reserves of copper ore under the combined holdings of the two properties are the largest on the American continent. These spectacular developments give a feeling of permanency to the Sudbury region and ensure its place as one of our largest mining centres.

Figures were quoted regarding expenditures already made due to the mining activities of the Sudbury region, Sudbury itself as a result having grown in recent years from a population of 9,000 to 18,000.

The speaker thereupon expressed the hope that the new discoveries taking place from time to time are merely sign-posts of what the future will bring. For instance, only within the last week or so, stated the speaker, important discoveries have taken place, the importance of which have not yet been fully realized. Samples of norite and schist have been brought in by prospectors from a certain region in the vicinity of Sudbury that have been found upon analysis to contain cinnabar and mercury itself in a metal form. The samples showed 2.54 per cent of mercury which gives a market value to the ore of $70.20 per ton.

From 1896 to 1907 there was considerable agitation for the refining of the copper nickel ores in Canada. Ores mined by the Canadian Copper Company were partially refined at Sudbury and then forwarded in a matte form to New Jersey where they were completely refined by the Orford Copper Company. The International Nickel Company decided to build at Port Colborne a refinery for the treatment of these ores and millions were spent for this purpose.

Coming now to the future of northern Ontario, Mr. Lapierre elaborated upon the great possibilities of the pre-Cambrian shield of northern Canada. He referred to the opinion expressed by Dr. Corliss who stated that Canada holds within this pre-Cambrian formation the greatest potential wealth of all our natural resources and that the time is not far distant when mining in Canada will have superceded agriculture as the greatest source of Canada's natural wealth.

On the eve of this development, Canada with over 90 per cent of the world's nickel—having long since out-distanced New Caledonia in nickel production—holds a pre-eminent position in regard to nickel production. The mines with depth reveal a tremendous increase in copper content as seen by the production of the Frood mine. The speaker stated that within the city of Sudbury undoubtedly the next three or four years would witness the greatest transformation ever seen in any northern Ontario city.

The future which he saw in Sudbury itself would be repeated in other sections of northern Canada, particularly in northern Manitoba, Quebec and British Columbia.

Peterborough Branch

S. O. Shields, Jr.E.I.C., Secretary.

B. Ottewell, A.M.E.I.C., Branch News Editor.

Aluminum

At the regular meeting of the Branch held April 10th, 1930, Mr. H. H. Richardson, chief of the technical staff of the Aluminum Company of Canada, Limited, gave an address on the "Development of Aluminum as an Engineering Material."

Spectacular applications like its use for aircraft construction have advertised the case of aluminum and its alloys so that it has long since outgrown the cooking untensil field.

Aluminum alloys are available with strengths comparable to soft steels. However in its application the burden of proof is on the aluminum manufacturer, since the average engineer is not prone to make use of materials of which he has very little knowledge and experience.

When investigating the use of aluminum there are two vital points of interest, viz., the methods used by the producer and the manufacturing facilities available. Producers of aluminum alloys are prepared to furnish all the data on aluminum alloys that are ordinarily available for steel alloys.

As regards manufacturing facilities, sheets are produced of such a size that 3 make a tank car and structural shapes are rolled identical to those of the steel mill, i.e. 90 ft. long and 12 sq. in. cross section. Aluminum is alloyed, heat treated and worked.

Soft aluminum sheet has a tensile strength of approximately 14,000 lbs. per sq. in. and an elongation of 40 per cent. Cast aluminum has less tensile strength and very much less elongation. By rolling commercially pure aluminum it is possible to increase the tensile strength from 14,000 to 25,000 lbs. per sq. in.

An increase in the strength of castings is obtained by alloying. By adding copper, etc. there is an increase in the casting strength up to 30,000 lbs.

Heat treatment has been practised in both the cast and wrought forms for 8 or 10 years. The heat treatment of aluminum and its alloys is somewhat similar to that of steel. The best heat treated aluminum alloy has a tensile strength of 50,000 lbs. per sq. in. However with the duraluminum type 60,000 lbs. is reached. By heat treating a variety of results are possible. For instance adding 8 per cent copper to aluminum casting gives 20,000 lbs. strength whereas adding only 4 per cent copper and heat treating gives 40,000 lbs.

In the use of structural shapes it is of interest to note that the stiffness depends upon the modulus of elasticity and the cross section used, as a consequence for a given loading it is possible to use lighter beams of aluminum than of steel. Roughly, the saving in weight in truck bodies and railway cars (with aluminum at cost of 20 cents per lb.) results in operating cost reductions so that the added cost is returned in a year.

A hearty vote of thanks was accorded Mr. Richardson for his interesting lecture.

Rural Power Service

The distribution of electricity to the country districts of Ontario was the subject of an address by J. W. Purcell, of Toronto, engineer of the Hydro Electric Power Commission of Ontario, before the Peterborough Branch, April 24, 1930.

Mr. Purcell was introduced by R. L. Dobbin, M.E.I.C., Chairman for this meeting.

Tracing the birth of hydro power back to the year 1902, when a small group of men in Berlin (now Kitchener), who were having trouble with their electric light plant, petitioned Brigadier-General Mitchell to address them on the subject of obtaining power from Niagara Falls, the speaker went on to pay tribute to the memory of Sir Adam Beck, whose foresight and ability has been responsible for the rapid and phenomenal development of hydro power.

From the idea of these men originated the system which supplies power on a co-operative basis. The power turned on in Kitchener in 1910 was 1,000 h.p., and to-day the Commission is generating 1,300,000 h.p. for the whole province. The growth in twenty years has exceeded that of any other industry with the possible exception of the radio and automobile industries.

During 1929, 1,150 miles of rural lines were constructed at a cost of $2,500,000 to serve the needs of 6,700 consumers, bringing the total to 5,280 miles serving 38,000 consumers. The province is doing a great deal for the farmer in order to give him the benefit of cheap electric power. It is hoped thus to prevent or at least reduce, the continual exodus of people from the rural districts to the cities.

The speaker dealt thoroughly with the question of rates and showed how the present low rates to the consumer had been derived. Many fine slides were used to illustrate the address, including statistical data, and photographs of rural lines and installations, showing the many applications of electric power on farms.

After a number of questions had been ably answered by the speaker, V. S. Foster, A.M.E.I.C., conveyed the appreciation of the meeting in a hearty vote of thanks for this interesting address.

Joint Meeting with A.S.M.E. and Toronto Branch, E.I.C.

A new departure was made by the executive of the Peterborough Branch, in the organization of a most successful joint meeting with the Ontario Section of the American Society of Mechanical Engineers and the Toronto Branch of The Institute on Thursday, May 8, 1930.

Under the chairmanship of R. C. Flitton, several sub-committees had charge of the arrangements and the following programme was prepared:

3.00 p.m.—Visitors will meet at the Empress hotel where they will be divided into groups by the excursion committee, according to the excursions they wish to take, as follows:
Plant of Canadian General Electric Co. Ltd.

Plant of Western Clock Company Ltd.
Plant of Quaker Oats Company Ltd.
Plant of De Laval Company Ltd.
Peterborough water filtration plant.
Peterborough lift lock.
5.00 p.m.—Bowling tournament at Duffus' alleys.
7.30 p.m.—Dinner at Empress hotel.
Address by Mr. R. O. Sweezey, M.E.I.C.—"Water Powers."

The visitors to the number of 25 arrived by car about 3 p.m. and were met at the Empress hotel by the reception committee. With the choice of several industrial plants and other points of interest to visit, all elected to see the works of the Canadian General Electric Company. They were received at this received at this plant by Mr. E. G. Patterson, works manager, and were divided into several parties with members of the engineering staff as guides.

In the short time at disposal, a comprehensive tour of the works was undertaken, and the visitors expressed great interest in many special machines and processes.

Following this a 5 pin bowling tournament at the Duffus alleys occupied the attention of the visitors and members, the prizes being graciously provided by the A.S.M.E. executive.

At 7.30 p.m. approximately 125 members and guests gathered at the Empress hotel for the banquet. Prominent guests included R. O. Sweezey, M.E.I.C., president of Beauharnois Power Corporation, Hon. E. C. Drury, former premier of Ontario, His Worship Mayor Denne and numerous ladies.

In view of the prominence of Mr. Sweezey as a water power authority, his address on the Beauharnois development was followed with close interest, and is quoted in part as follows:

Mr. Sweezey said that in 1912 he was sent to western Canada to investigate the possibilities of water power for the western cities. It was a disappointing trip. He found that the rivers in the west, which are fed from the glaciers in the Rockies, drop to a very low point in the winter and are inclined to flood in the summer time. It was not an attractive proposition at all. In 1913 he was attracted by the possibilities on the St. Lawrence river, and wondered why he had gone west, when at Canada's front door existed the greatest water power in the world. He was sent to investigate the stretch of the river between Lake St. Francis and Lake St. Louis, and was amazed at the simplicity with which that stretch could be developed. After some time he found that there were difficulties in the way of development—three difficulties, physical, political and legal.

In discussing the question with engineers he found that while they realized the physical possibilities they would not contemplate the legal and the political difficulties, and when speaking with the politicians or legal men they would stress the physical difficulties. It was difficult to get them to see the same point of view. Men of finance did not wish to undertake any development and the war came along and the matter was shelved. After the war Mr. Sweezey was able to make a deal with the rightful owners of this stretch of water way, and at an expenditure of $100,000 was able to overcome the legal and political difficulties.

The speaker stated that the St. Lawrence river has a drainage area of 300,000 square miles. The stretch between Prescott and Montreal is the neck of the bottle wherein is the greatest water power flow in the world.

It takes only one per cent of water of the St. Lawrence for navigation purposes, and obviously the other 99 per cent is for power. The speaker thought that the greater part of the waterway development has been saddled with too high a cost, and that dams should be paid for in proportion.

Mr. Sweezey continued to speak of the enviable position which Canada holds in the world, which is simply demanding more power, and explained the value of tide water power over inland water power.

In the development of the St. Lawrence, he continued, we are aware of our responsibility resting upon us. We have tried to approach this problem as Canadians in an effort to develop Canada's resources, and there are a great many Canadians who are alive to the importance of this undertaking and are glad to follow us through to a successful conclusion. When we approached the public to finance us just a few weeks after the greatest financial collapse the world has known we set out to sell $30 million securities and were over-subscribed inside of 24 hours.

Since that issue made in December last, half a million found its way into the States, two million to Great Britain, and one million to the continent. We are quite satisfied that in future financing we can place all in Canada. It is an entirely Canadian undertaking.

During the evening an orchestra composed of student members of the Branch provided musical entertainment and the film "There's always room at the top," produced by the Branch, was shown and received with its usual success.

Saint John Branch

A. A. Turnbull, A.M.E.I.C., Secretary-Treasurer.

In an address before the Saint John Branch of The Engineering Institute of Canada on April 10th, 1930, Major E. M. Slader, commanding officer of the 4th Medium Brigade outlined the history of artillery.

Mr. Slader said that artillery may be described as a missile-throwing weapon which even in the ancient periods was very efficient. Both the balista and catapult were then used with the former more efficient than the latter and more effective. The balista was known to throw a stone of 600 pounds a distance of one-half mile.

Speaking of the general construction of artillery, the speaker said that most guns of today were called wire guns, which was true of practically every type of gun in the British service. He stated that the shells formerly were used in mortars but that in the guns no shells were used. In 1824 General Paixham, of the French army, advised the introduction of shell guns. The shrapnel shell was invented in 1805. The first shell was round and it had a base which was set off. The modern shell differs to this inasmuch as it has powder at the base and the bullets spread out cone-shaped.

Up until the time of Galileo, Mr. Slader continued, the principles of the shell in the air was a complete mystery. Galileo discovered the laws of falling bodies and wrote several articles on trajectory. The first man to apply mathematical reasoning to gunnery was Fastaglia. Alexander Robins in his day tested the effect of air resistance on shell and invented the balistic pendulum for measuring muzzle velocity. Up until 1890 all artillery were direct fire, he said, and in the beginning of the present century the matter of indirect fire began to receive attention.

Quoting the great French Emperor, Napoleon, who said that the man who is clever enough to bring an unexpected battery up is the man who will win the day, Mr. Slader stated that this principle was adopted in the last 100 days of the war and proved effective, showing that the artillery played a great part in bringing about victory for the Allies. He spoke also of the final period with the attack of Cambrai when the artillery came as a complete surprise to the Germans.

A vote of thanks, moved by G. N. Hatfield, A.M.E.I.C., and seconded by J. A. W. Waring, A.M.E.I.C., was tendered the speaker by W. J. Johnston, A.M.E.I.C., who acted as chairman.

Annual Meeting

The annual meeting of the Saint John Branch of The Engineering Institute of Canada was held at the Riverside Golf and Country Club on April 28th, 1930. The Entertainment Committee provided us with a turkey dinner for the occasion and we had as guests, The Hon. John B. M. Baxter, Premier of the Province; R. J. Durley, M.E.I.C., General Secretary of The Institute; Mr. O. J. Fraser, Mr. J. S. Hoyt and Major E. M. Slader.

The meeting, which was largely attended, was presided over by W. J. Johnston, A.M.E.I.C., chairman of the Branch. In addition to the toast to the province, toasts to the guests and to The Engineering Institute of Canada were proposed by H. I. Mulligan, S.E.I.C., and C. C. Langstroth, A.M.E.I.C., respectively. E. M. Slader, J. S. Hoyt, O. J. Fraser and W. H. Swift, Jr., responded to the first, as guests of the Branch, while Mr. Durley honoured that to The Institute. The toast to the press was proposed by J. L. Feeney, A.M.E.I.C.

The election of officers for the ensuing year resulted as follows: Chairman, W. J. Johnston, A.M.E.I.C.; vice-chairman, J. N. Flood, A.M.E.I.C.; secretary-treasurer, A. A. Turnbull, A.M.E.I.C. G. A. Vandervoort, A.M.E.I.C., was made a member of the executive committee.

The annual report of the chairman covered the activities of the local Branch during the past year. He made passing mention of the improved business conditions generally throughout the Maritime provinces, in which he pointed out that building permits issued in Nova Scotia for 1929 amounted to an increase of 86.7 per cent over 1928, while an increase of 61.5 per cent was shown in New Brunswick for the same period, and a small increase registered in Prince Edward Island.

Among the various reports submitted during the business session which followed the address was the report of the auditors, submitted by H. I. Mulligan, S.E.I.C.; the report of the executive submitted by the secretary, E. J. Owens, A.M.E.I.C.; the report of the programme and meetings committee by G. A. Vandervoort, A.M.E.I.C.; the report of the entertainment committee by J. H. McKinney, A.M.E.I.C.; the report of the employment committee by J. D. Garey, A.M.E.I.C.; report of the fuel committee by Professor Stephens; report of the salaries committee by S. R. Weston, M.E.I.C.; the report of the publicity committee by J. M. Lamb; the report of the natural resources and engineering industries committee by C. C. Kirby, M.E.I.C.; and the report of the town planning committee by G. G. Hare, M.E.I.C.

A vote of thanks was tendered to the Board of Trade, the New Brunswick Power Company and the press, on motion of J. L. Holman, Jr.E.I.C., and V. S. Chestnut, A.M.E.I.C.

In reply to the toast to the province, proposed by Charles M. Hare, S.E.I.C., Premier Baxter told of the importance and dependence placed in the members of the engineering profession. In praising the work of the skilled engineer, he held out as examples the plant of the Saint John dry dock, the Grand Falls power plant, and the new mills of the New Brunswick International Paper Company at Dalhousie. He also spoke of the engineering skill that would be brought out in the construction of the proposed bridge across the Saint John harbour.

The bridge across the gorge at the falls was a tribute to the late A. R. Wetmore, he said.

Governments everywhere, said Dr. Baxter, are helping the resources through their administration but they are not able to do it without the training of the skilled intellect, and in this connection they must depend upon the judgment of the engineer first, last and for all time.

In connection with the province, Premier Baxter said that some years ago when the finances of New Brunswick were not in the fair state they are today, he believed that there was mineral wealth under the crust of this part of the country that would prove a big reward for the trouble in mining it, and under his administration during the last few years steps had been taken for the encouragement of the development of this industry. While he expressed the hope that mineral value would be found, he was of the opinion that the basic minerals, rather than gold or silver, would prove more beneficial, as they would result in more real development and more employment.

"It is not the intention of any government to undertake themselves to develop the minerals, but in my view a government can help to encourage and assist others in the development," said the Premier.

In an address which dealt with the administration of the Branches and parent body of The Institute, Mr. Durley told of the organization being first launched in London more than a hundred years ago for the purpose of utilizing the great powers of nature for the use of mankind. Speaking of the Canadian Institute, with Branches from Sydney, N.S., to Victoria, B.C., comprising 5,000 members, he gave credit to the Branch officials for a great deal of the success obtained by the parent body.

In connection with the work accomplished during the last year he told of some 200 members having been placed in positions by the employment bureau of The Institute.

He urged for the unification of the examinations of engineers in the various provinces of the Dominion with the view that the results obtained would be beneficial to all, and in this connection reported that a commission appointed by the council of The Institute had made a study of the legislation governing the registration in the different provinces during the last three years, and have been authorized to determine what steps are necessary for a uniform law.

Following the business meeting, cards and a social evening was enjoyed at the club by the members.

Sault Ste. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting of the Sault Ste. Marie Branch was held in the Y.M.C.A., on April 25th, when Mr. James Govan, registered architect of Toronto, and research engineer for the Gypsum, Lime and Alabastine Company, addressed the meeting on the subject, "Recent Research Studies of Fire, Heat, Sound and Condensation Problems." Previous to the meeting the speaker of the evening and his assistant Mr. Wright were entertained at dinner by the members of the Branch.

In his opening remarks, Mr. Govan gave it as his opinion that we in Canada need to appreciate the influence of our climatic conditions on newcomers to our country. Again, travelling through northern Ontario he was impressed by the number of buildings erected due to some industrial development which had finished and passed on. We should study the probable length of life of a building, for example, the life of a mining town is short and the population not dense. In planning a building, the designer should ask himself how long he wants the building to last. Even in the largest cities where buildings are built of such durable materials as stone, concrete and steel they are soon obsolete. Modern research shows that buildings soon become obsolete and inefficient.

Tests have shown that the most efficient wall in resisting heat flow is one with thin structural material with a thick space filled with a cheap insulating material. The problem then is to make frame materials fireproof. Experiments have been successful in fireproofing with dry material. It has been found that you cannot ignite woodwork behind gypsum until all the water of crystallization has been driven off which requires long and continuous heating at high temperatures. Steel which bends at comparatively low temperatures may be protected by a layer of gypsum.

The speaker showed a number of slides illustrating the efficiency of this heat insulating and fire-proofing which showed that a very great economy in heating may be so obtained.

Experiments in sound-proofing show that the most efficient walls are the stiffest and thickest. A frame wall where material on the side is not in contact with material on the other side even by nailing has proved very efficient.

In concluding Mr. Govan stated that the Gypsum Company deserve great credit for contributing building comfort and safety in Canada.

An interesting discussion followed and a vote of thanks for his instructive talk was tendered Mr. Govan.

Detroit-Windsor Tunnel

On April 30th, at the Y.W.C.A., a special meeting of the Sault Ste. Marie Branch was addressed by Mr. R. B. Value, on the Detroit-Windsor tunnel which is under construction. Mr. Value drew the attention of those present to the special problems and methods of construction in connection with this tunnel which it is expected will be completed about the end of 1930.

Toronto Branch

J. J. Spence, A.M.E.I.C., Secretary-Treasurer.
A. B. Crealock, A.M.E.I.C., Branch News Editor.

It is the usual custom of the Toronto Branch of The Engineering Institute of Canada to close the winter season with the annual meeting, but as a most interesting lecture was available which could not be procured in the fall Mr. Traill, the new Chairman, called an extra meeting for the evening of Thursday, April 24th. The speaker was A. W. K. Billings, M.E.I.C., who gave a very interesting and instructive illustrated address on the water power development of Brazil. He dealt particularly with the south eastern portion which includes Rio de Janeiro, Sao Paulo and Santos which district contains the bulk of Brazil's population and wealth and where Mr. Billing's Company serves all the light, power, tramway, telephone and gas utilities. Mr. Billings also described other remote parts of Brazil where abundant potential power exists but is too far from civilization to be commercially developed.

The most interesting development described was at Serra near Santos, the power house of which is practically on sea level and its storage is on a plateau some 2,400 feet above. The plateau slopes gently inland and is covered with lakes. Dams are being built and pumping equipment is being installed to raise the water from some of the lower inland lakes to the higher ones near the coast. By raising the water 80 feet it becomes available for power under a head of 2,400 feet or a return of nearly 30 times the energy required for pumping.

The meeting was well attended by Institute members and guests, among the latter were several officials of the Brazilian Traction Company and the Mexican Light and Power Company. The lecture was thoroughly enjoyed by all and at the conclusion a hearty vote of thanks was tendered to Mr. Billings.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Wanted

CIVIL AND MECHANICAL ENGINEER, aggressive practical engineer, with background of experience in design, construction, maintenance and operation of pulp and paper mill, desires change. Especially qualified to reduce mill costs. Apply to Box No. 53-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Apply to Box No. 107-W.

Situations Wanted

CIVIL ENGINEER, B.Sc., Jr.E.I.C., with general engineering experience in construction, estimating, draughting, preliminary designing and building maintenance, desires position with opportunities. At present employed as buildings supervisor in public utility company. Available on short notice. Apply to Box No. 173-W.

CIVIL ENGINEER. A.M.E.I.C., graduate, R.P.E.P.Q. Twenty years experience surveying and construction hydro-electric, railways, and paper mills, desires position. Will go anywhere if terms satisfactory. Apply to Box No. 294-W.

Situations Wanted

CIVIL ENGINEER, B.A., B.Sc., with six years experience on surveys; layout and construction of hydro-electric works; design of highway bridges and construction of highways; desires position as assistant engineer on design and construction of reinforced concrete and steel structures. Available on short notice. Location immaterial. Apply to Box No. 301-W.

CIVIL ENGINEER, A.M.E.I.C., Reg. Pro. Eng. Ont. and N.B., age 47, married, twenty years experience in this country; twelve years in Scotland as construction and municipal engineer, specializing in roadway, water and sewer works, desires similar position, available forthwith. Just completed sewer and waterworks schemes for town in Maritime Province. Have also been engaged as engineer and superintendent with contractors on steam shovel excavation, concrete and caisson works for large buildings in Toronto, etc. Apply to Box No. 336-W.

CIVIL ENGINEER, B.Sc., fifteen years experience, including surveying, construction,

Situations Wanted

mining and tunnelling. Available at once. Will go anywhere, but prefer Eastern Canada. Apply to Box No. 346-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., is open for engagement. Twenty-four years general experience both as engineer and as contractor. Has specialized in the construction of wharves, dams, foundations, etc. Apply to Box No. 358-W.

MINING ENGINEER, graduate, age 32, A.M.E.I.C., ten years experience in design, construction, erection and maintenance of paper mill and mine buildings and machinery. Several years on hydro-electric work in charge of surveys and investigation; desires permanent connection with mining or paper company. Apply to Box No. 362-W.

MECHANICAL ENGINEER, B.A.Sc., Univ. of Toronto 21, A.M.E.I.C., married. Pulp and paper mill maintenance experience: draughting, layout of buildings, machinery and piping, mechanical design. Also experienced in reinforced concrete and steel building design and construction work. Desires position of permanency in plant engineering or maintenance work with reliable organization offering opportunities for advancement. Apply to Box No. 370-W.

CONSTRUCTION SUPERINTENDENT, with twenty-five years experience on hydro-power developments, paper mills and general building construction. Apply to Box No. 372-W.

ELECTRICAL ENGINEER, B.Sc. '23, A.M.E.I.C., experience, estimating pole line, cable and wire layouts, supervising estimates, in charge of cost inventory and appraisal work, in charge of draughting, records and budget control work, instructing engineering principles. Seven years with one company. Four years instructing in electrical engineering at evening classes, desires position along the above lines with opportunities. Best of references. Apply to Box No. 376-W.

STRUCTURAL DRAUGHTSMAN, age 31, well educated, with experience in designing and supervision, desires a change of position and location. Preferably north western Canada. Apply to Box No. 378-W.

CONSTRUCTION ENGINEER, Canadian, speaking and writing French and English, A.M.E.I.C., P.E.Q. Twenty years experience in water power development, roadway, water and sewer works, as engineer in charge or superintendent, desires position. Available on short notice. Apply to Box No. 380-W.

GRADUATE ENGINEER, N.S. Tech. Coll., age 25, desires permanent position with industrial concern. Since graduation has spent two years apprenticeship with Can. Westinghouse Co. Apply to Box No. 382-W.

COST ACCOUNTANT, graduate civil engineer who has specialized in construction costs, desires new connection. Especially familiar with hydro-electric and paper mill construction accounting, including preparation of cost statements, installation of stores and time-keeping systems, etc. Apply to Box No. 389-W.

EXECUTIVE, B.Sc. McGill, M.E.I.C., comprehensive experience, with clean and successful record, desires permanent position, preferably in or near Montreal. Experience covers research, design, installation, operation, purchasing, organization and responsible management. Apply to Box No. 401-W.

CIVIL ENGINEER, B.Sc., '24, Jr.E.I.C., C.P.E.Q., Canadian, age 30, married. Experience: Construction power developments, railways, highways, pulp and paper mills, maintenance pulp and paper mills, railways, desires permanent position with opportunity for advancement. Apply to Box No. 402-W.

Situations Wanted

MECHANICAL ENGINEER.—Any organization which can use the services of an aggressive and practical engineer is requested to open negotiations by communicating with the advertiser. Canadian, university graduate, age under 30. Experience as mechanical superintendent, chief draughtsman, estimating, purchasing, construction, costing, stores control, etc. Qualified for engineering, production, purchasing, sales, or in a business capacity. Accustomed to responsibility, proven ability in the industrial field. Apply to Box No. 406-W.

CIVIL ENGINEER, D.L.S., graduate, experience in surveying, calculating and municipal work, and in charge of office and field parties. Best of references. Apply to Box No. 413-W.

Situations Vacant

RECENT GRADUATE, in electrical or mechanical engineering, for general industrial work. Work part in office and part in the plant. Must be competent to do transit work and levelling in connection with laying out new building sites. Location, Northern Quebec. Apply to Box No. 508-V.

DESIGNING DRAUGHTSMAN. — Excellent opening for right man with large newsprint company, centrally located. Apply, stating age, experience and salary expected, to Box No. 527-V.

ELECTRICAL ENGINEER, recent graduate. One who has taken General Electric or Westinghouse students' course. Apply to Box No. 536-V.

MECHANICAL ENGINEER, with four or five years experience for plant maintenance. Canadian, graduate engineer. Apply to Box No. 541-V.

WATERWORKS ENGINEER, with experience on the design of filtration plants. Please state experience and salary expected in first application. Interviews will be arranged with suitable applicants. Apply to Box No. 543-V.

CHEMICAL ENGINEER, experienced man preferably with college training as chemical engineer, desired to form and organize a control department in a large paper mill. This position will offer great opportunities for the right man. Previous training or experience in research work or control essential. Please state particulars of education, experience, together with salary required. Apply to Box 545-V.

STEAM POWER ENGINEER. Young man with college training and experience in handling of steam power desired to fill permanent position with a large and progressive paper company. Previous experience in analysis and investigation of production and distribution of steam essential. Must be agreeable to start at a reasonable salary. This position offers splendid opportunities with favourable chance for advancement. State particulars, history and salary desired. Apply to Box No. 546-V.

DESIGNING DRAUGHTSMAN wanted by a large pulp and paper mill. Should preferably be a graduate with experience in design of structural steel and reinforced concrete, but pulp and paper mill experience not essential. State in detail age, education, experience and salary desired and when could report and other particulars. Apply to Box No. 550-V.

MECHANICAL ENGINEER OR DRAUGHTSMAN, preferably with experience in rolling mills, wire drawing and cabling machinery, for position as draughtsman in plant manufacturing cable. Location eastern Quebec. Apply to Box No. 551-V.

MECHANICAL ENGINEER, with machine shop training, to take charge of the Montreal sales office of a well known company

Situations Vacant

manufacturing gears, speed reducers, flexible couplings, and silent chains. Must be well recommended. Apply to Box No. 552-V.

SALES ENGINEER, with knowledge of and experience in the heating and power plant field. Salary and commission. State age, experience and qualifications to Box No. 553-V.

DRAUGHTSMEN—one or two draughtsmen experienced in general pulp and paper mill work and construction, for a company in the province of Quebec. Apply at once to Box No. 554-V.

MECHANICAL DRAUGHTSMAN AND DESIGNER wanted by large pulp and paper mill. Should have technical education and mechanical experience, but pulp and paper mill experience not essential. State in detail, age, education, experience, and salary desired, and when could report and other particulars. Apply to Box No. 560-V.

ELECTRICAL ENGINEER, preferably graduate Canadian university, with test floor experience. Opening offers permanent employment for right applicant along lines of plant maintenance and with every possibility of considerable new construction work in the near future. Please give complete information in first letter, stating age, experience, and salary expected, to Box No. 561-V.

MECHANICAL ENGINEERS. Two young graduate engineers with sales ability wanted by a well-known Canadian company. Apply, giving full particulars, to Box No. 562-V.

DRAUGHTSMEN, with three or four years experience in design of machine parts and piping layouts, for a company in the province of Quebec. Apply at once giving particulars of experience, to Box No. 563-V.

TOWN ENGINEER, for a town in Maritime Provinces. Electrical and civil engineer, or electrical engineer with sufficient knowledge of civil engineering to take charge of water and sewerage system, building of roads and sidewalks, etc. Must be able to speak French. Apply to Box No. 565-V.

INSTRUCTOR—Wanted for a technical high school, in western Canada, an instructor in electricity, capable of handling either shop work or theory, duties to begin September 1, 1930; Canadian preferred; salary $1,800 to $3,300. State qualifications, including details of academic standing and practical training, also teaching experience, if any, and present position. Applications received up to June 24th, 1930. Apply to Box No. 566-V.

STRUCTURAL ENGINEERS, wanted in B.C. for the positions of structural engineer, structural senior assistant engineer, and structural assistant engineer, experienced in the design of reinforced concrete and steel structures. Applicants not holding a B.C. Engineering Act license will be eligible subject to their qualifying for registration. Apply to Box No. 568-V.

MINING ENGINEERS—Graduate mining engineers. Applications from young mining engineers able to do surveying surface and underground in B.C. Apply to Box No. 569-V.

TECHNICAL GRADUATE, for work in concentrating mill. Applicants will be expected to qualify for intermediate or final registration under terms of the Engineering Act of B.C. Apply to Box No. 570-V.

SQUAD LEADERS—Two or three assistant engineers as squad leaders in making plans for large transoceanic pier in B.C. Should be Canadian college graduates. Expected to carry out such design as may be assigned by designing engineer, and oversee preparations of plans, and well founded in structural mechanics and in particular reinforced concrete and steel design. Apply to Box No. 571-V.

Preliminary Notice

of Applications for Admission and for Transfer

May 22nd, 1930

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in July 1930.

R. J. Durley, *Secretary.*

---

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for a least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ANDERSON—WILLIAM GALLOWAY MACDONALD, of 1194 Mackay St., Montreal, Que., Born at Glasgow, Scotland, Feb. 27th, 1905; Educ., 1921-25, Technical College, Dundee, and St. Andrews Univ.; A.M.I.C.E.; 1921-24, ap'tice engr. to Robert Killie & Son Ltd., Dundee; 1925-29, chief asst. engr., to the Dundee Waterworks Engr.; 1929-30, field engr. on constrn. of alterations and additions to Corner Brook, Nfld., paper mill, by W. I. Bishop Ltd.; Mar. 1930 to date, asst. engr. to W. S. Lea, M.E.I.C., Consltg. Engr., Montreal.
References: A. B. McEwen, S. H. Hawkins, H. A. Morey, W. I. Bishop, R. S. Lea.

ANDERSON—YNGVE RAGNVALD, of Prince Albert, Sask., Born at Kennedy, Minn., U.S.A., Apr. 30th, 1902; Educ., B.E., Univ. of Sask., 1924; 1922, instr'man., Sask. Dept. of Highways; 1923-24, ceramic work, Dominion Fire Brick & Clay Products, Ltd., Claybank, Sask.; 1924-25, ceramic lab. and plant work, Evans & Howard Fire Brick Co., St. Louis, Mo.; 1925-26, foreman in charge of dept. mfg. hand moulded refractory shapes, and 1926-27, engr. on constrn. of modern fire brick plant with railroad tunnel kiln, for same company; 1927-28, ceramic engr. i/c production and new constrn. at plant of The Dominion Fire Brick & Clay Products Ltd., Claybank, Sask.; 1928-29, instr'man. and i/c party on land surveys, mining claim surveys, municipal engrg. and sewerage works with Underwood & McLellan, Consltg. Engrs., Saskatoon, May 1929 to date, ceramic engr. and manager in charge of Prince Albert Branch of The International Clay Products Ltd., of Estevan, Sask.

‡For 1930-31-32

TREASURER
F. P. SHEARWOOD, Montreal, Que.

SECRETARY
R. J. DURLEY, Montreal, Que.

OFFICERS OF BRANCHES

HALIFAX
Chairman, W. P. COPP
Vice-Chair., C. St.J. WILSON
Sec.-Treas., R. R. MURRAY, 87 Cambridge St., Halifax, N.S.
Executive, D. S. WICKWIRE, J. L. ALLAN, G. T. MEDFORTH, L. ALLISON, W. H. NOONAN, J. J. SEARS, L. M. MATHESON, G. S. STAIRS, J. D. FRASER
(Ex-Officio) H. F. BENNETT, F. R. FAULKNER

CAPE BRETON
Chairman, A. L. HAY
Vice-Chair., A. P. THEUERKAUF
Sec.-Treas., S. C. MIFFLEN, Dom. Coal Co. Ltd., Glace Bay, N.S.
Executive, C. M. SMYTHE, J. P. COTTER, J. A. FRASER, Y. C. BARRINGTON, M. DWYER.

SAINT JOHN
Chairman, W. J. JOHNSTON
Vice-Chair., J. N. FLOOD
Sec.-Treas., A. A. TURNBULL, 348 Douglas Ave., Saint John, N.B
Executive, G. A. VANDERVOORT, C. C. LANGSTROTH, H. F. MORRISSEY
(Ex-Officio) E. T. OWENS

MONCTON
Chairman, L. H. ROBINSON
Vice-Chair., G. E. SMITH
Sec.-Treas., V. C. BLACKETT, Eng. Dept., C.N.R., Moncton, N.B.
Executive, E. T. CAIN, T. L. LANDERS, J.G.MacKINNON, C.S.G.ROGERS, A. S. GUNN, A. F. STEWART
(Ex-Officio) M. J. MURPHY

SAGUENAY
Chairman, R. E. PARKS
Vice-Chair., S. J. FISHER
Sec.-Treas., R. LANCTOT, 7 Lafontaine Ave., Chicoutimi, Que.
Executive, H. R. WAKE, G. E. LAMOTHE, J. A. KNIGHT, G. O. VOGAN

QUEBEC
Hon. Chair., A. R. DECARY
Chairman, A. B. NORMANDIN
Vice-Chair., S. L. deCARTERET
Sec.-Treas., P. METHE, Ecole Technique, Blvd. Langelier, Quebec, Que.
Executive, H. CIMON, T. J. F. KING, L. C. DUPUIS, A. LARIVIERE
(Ex-Officio) W. G. MITCHELL

ST. MAURICE VALLEY
Chairman, ELLWOOD WILSON
Sec.-Treas., R. MORRISSETTE, City Engr., Cap de la Madeleine, Que.
Executive, H. DESSAULLES, B. GRANDMONT, A. A. WICKENDEN

MONTREAL
Chairman, D. C. TENNANT
Vice-Chair., A. DUPERRON
Sec.-Treas., C. K. McLEOD, 1440 St. Catherine St., W., Montreal, Que.
Executive, A. COUSINEAU, P. E. JARMAN, W. McG. GARDNER, J. A. LALONDE, N. L. MORGAN, F. NEWELL
Ex-Officio) F. A. COMBE, FRASER S. KEITH, G.R. MacLEOD, O. O. LEFEBVRE, F.P. SHEARWOOD, P. B. MOTLEY, J.A. McCRORY, JULIAN C. SMITH, J. L. BUSFIELD

OTTAWA
Chairman, F. H. PETERS
Sec.-Treas., F. C. C. LYNCH, Nat. Resources Intelligence Service, Dept. of the Interior, Ottawa, Ont.
Executive, G. A. BROWNE, V. M. MEEK, L. L. BOLTON, W. L. CASSELS, W. F. M. BRYCE
(Ex-Officio) N. CAUCHON, C. CAMSELL

PETERBOROUGH
Chairman, W. E. ROSS
Secretary, F. G. A. TARR, 270 Rubidge St., Peterborough, Ont.
Treasurer . A. B. GATES
Executive, A. E. CADDY, B. OTTEWELL, A. L. KILLALY, H. R. SILLS, P. P. WESTBYE, W. F. STEWART
(Ex-Officio) R. L. DOBBIN, R. C. FLITTON, S. O. SHIELDS

KINGSTON
Chairman, D. M. JEMMETT
Vice-Chair., A. JACKSON
Sec.-Treas., L. F. GRANT, Royal Military College, Kingston, Ont.
Executive, A. G. MacLACHLAN, F. R. HENSHAW, L. M. ARKLEY
(Ex-Officio) W. L. MALCOLM

TORONTO
Chairman, J. J. TRAILL
Vice-Chair., C. S. L. HERTZBERG
Sec.-Treas., J. J. SPENCE, Eng. Bldg., University of Toronto, Toronto, Ont.
Executive, F. B. GOEDIKE, J. W. FALKNER, A. B. CREALOCK, G. H. DAVIS, J.R.COCKBURN, C.B.HAMILTON
(Ex-Officio) J. G. R. WAINWRIGHT, R. B. YOUNG, L. W. WYNNE-ROBERTS

HAMILTON
Chairman, W. F. McLAREN,
Vice-Chair., F. P. ADAMS
Sec.-Treas., J. R. DUNBAR, Can. Westinghouse Co., Ltd., Hamilton, Ont.
Executive, J. B. CARSWELL, H. S. PHILLIPS, E. M. COLES, G.A. COLHOUN
(Ex-Officio) H. A. LUMSDEN, E. H. DARLING

LONDON
Chairman, W. G. URE
Vice-Chair., W. R. SMITH
Sec.-Treas., F. C. BALL, City Engr's Dept., London, Ont.
Executive, D. M. BRIGHT, J. FERGUSON, E.V. BUCHANAN, R.W. GARRETT, G. E. MARTIN
(Ex-Officio) W. P. NEAR, W. M. VEITCH

NIAGARA PENINSULA
Chairman, WALTER JACKSON
Vice-Chair., E. P. MURPHY
Sec.-Treas., R. W. DOWNIE, Welland Ship Canal, Thorold, Ont.
Executive, C. W. WEST, F. L. HAVILAND, J. K. WYMAN, J. C. MOYER, W. R. MANNOCK, C. G. CLINE, N. BATES, H. D. DAVISON
(Ex-Officio) A. J. GRANT, C. H. SCHEMAN, M. B. ATKINSON, E. G. CAMERON

BORDER CITIES
Chairman, ORVILLE ROLFSON
Vice-Chair., R. J. DESMARAIS
Sec.-Treas., R. C. LESLIE, 1618 Giles Blvd., Windsor, Ont.
Executive, C. G. R. ARMSTRONG, F. STEVENS, H. J. COULTER
(Ex-Officio) A. E. WEST, L. M. ALLAN

SAULT STE. MARIE
Chairman, C. H. E. ROUNTHWAITE
Vice-Chair., A. H. RUSSELL
Sec.-Treas., A. A. ROSE, 34 The Drive, Sault Ste. Marie
Executive, J. W. LeB. ROSS, J. M. SILLIMAN, R. A. CAMPBELL, J. G. DICKENSON
(Ex-Officio) J. H. JENKINSON, A. E. PICKERING

LAKEHEAD
Chairman, C. B. SYMES
Vice-Chair., D. G. CALVERT
Sec.-Treas., GEO. P. BROPHY, P.O. Box 86, Port Arthur, Ont.
Executive, D. C. CHISHOLM, J. C. MEADER, W. H. SOUBA, G. R. DUNCAN
(Ex-Officio) H. S. HANCOCK, D. G. CALVERT

WINNIPEG
Chairman J. W. PORTER
Sec.-Treas., E. W. M. JAMES, 255 Balfour Ave., Winnipeg, Man.
Executive, A. L. CAVANAGH, F. G. GOODSPEED, R. W. MOFFATT, G. S. ROXBURGH, T. C. MAIN
(Ex-Officio) F. H. MARTIN, C. H. ATTWOOD

SASKATCHEWAN
Chairman, W. G. WORCESTER
Vice-Chair., D. A. R. McCANNEL
Sec.-Treas., R. W. E. LOUCKS, Surveys Br. Land Titles Office, Regina, Sask.
Executive, J. M. CAMPBELL, D. A. SMITH, R. A. SPENCER
(Ex-Officio) H. R. MacKENZIE

LETHBRIDGE
Chairman, C. S. CLENDENING
Vice-Chair., N. MARSHALL
Sec.-Treas., Wm. MELDRUM, Galt Mines. C.P.R., Lethbridge, Alta.
Executive, R.F.P.BOWMAN, N.H.BRADLEY, R. LIVINGSTONE
(Ex-Officio) J. B. deHART, G. S. BROWN, G. N. HOUSTON

EDMONTON
Chairman, JULIAN GARRETT
Vice-Chair., C. A. ROBB
Sec.-Treas., W. E. CORNISH, University of Alberta, Edmonton, Alta.
Executive, T. W. BROWN, R. M. DINGWALL, R. J. GIBB, H. J. MacLEOD
(Ex-Officio) R. W. ROSS, E. STANSFIELD

CALGARY
Chairman, B. RUSSELL
Vice-Chair., R. C. HARRIS
Sec.-Treas., A. W. P. LOWRIE, Dom.Water Power & Reclam. Service, Southam Bldg., Calgary, Alta.
Executive, F. M. STEEL, J. A. SPRECKLEY, L. A. B. HUTTON
(Ex-Officio) F. J. ROBERTSON, T. LEES, J. H. ROSS, W. H. BROUGHTON

VANCOUVER
Chairman, A. D. CREER
Vice-Chair., H. B. MUCKLESTON
Sec.-Treas., J. C. OLIVER, 930 Birks Bldg., Vancouver, B.C.
Executive, C. E. WEBB, A. C. R. YUILL, F. LEE, F. P. V. COWLEY, P. H. BUCHAN, A. S. WOOTTON

VICTORIA
Chairman, F. G. ALDOUS
Vice-Chair., H. F. BOURNE
Sec.-Treas., K. M. CHADWICK, 25 Brown Bldg., Victoria, B.C.
Executive, A. L. CARRUTHERS, F. C. GREEN, L. W. TOMS
(Ex-Officio) F. M. PRESTON

Second World Power Conference

Berlin, Germany, June 1930

Foreword

The World Power Conference, originally inaugurated by Great Britain with a view to improving from technical and commercial aspects the methods of generating and distributing energy in every form and to promoting the use of energy by international collaboration, held its first Plenary Meeting at London in 1924. Since that time sectional meetings have alone been held: the Basle Conference (1926) which dealt with the Utilization of Water Power and Inland Waterways; the London Fuel Conference of 1928; the Barcelona Meeting (May, 1929) on Water Power Utilization, and finally the Tokyo Meeting (October, 1929) on the Development of Power Resources, the latter coinciding with the World Engineering Congress.

Under the auspices of the International Executive Council of the World Power Conference the German National Committee is now organizing the Second Plenary World Power Conference to be held in Berlin, June 16-June 25, 1930. At this meeting the most prominent personalities in engineering science, economics, and industry, in addition to leading statesmen from about fifty different countries, will assemble to participate in a programme of discussions of world wide interest to be followed by a series of carefully organized tours through all parts of Germany.

The Honorary Patron of the 1930 Conference at Berlin is Reichspräsident von Hindenburg, the Honorary President being His Excellency, Dr. Oskar von Miller, the creator of the Deutsches Museum and pioneer of the electrical supply industry, while Dr.-Ing. E.h.C. Köttgen has assumed the duties of Chairman of the Conference. The Members of the Honorary Executive Council include the various German Secretaries-of-State, the political heads of the various German states, as well as leading representatives of science, industry, finance, commerce and of public corporations.

As many as 300 of the most prominent German engineers have been engaged for more than a year in making preparations for the Conference and more than 400 papers have been submitted from the different participating countries. These have been printed and sent out on request to all interested parties in order that the papers may be thoroughly considered and discussions prepared well in advance of the Conference.

Canada took a prominent part in the First Plenary Conference at London in 1924 and just as keen an interest is being taken in the meeting at Berlin. The Honorary Chairman of the Canadian National Committee is the Honourable Charles Stewart, Minister of the Interior, while the Chairman of the Executive Committee having active charge of arrangements for Canadian participation is Dr. Charles Camsell, Deputy Minister of Mines, Ottawa. The Berlin Meeting, like its predecessors, will be an event of the very highest importance to the whole engineering world.

It is gratifying to note that a substantial delegation of Canadian engineers is taking part in the proceedings of the Conference of 1930. The Dominion of Canada has been honoured by the selection of one of these, Dr. O. O. Lefebvre, M.E.I.C., as chairman of Section 13 of the Conference, "Rationalization and the Technical and Economic Problems of Water Power Utilization."

The seven papers presented in this issue of The Engineering Journal form the Canadian contribution to the technical literature of the Conference. All the authors are recognized authorities on their respective subjects, and the papers now published constitute a timely record of engineering progress in Canada since the date of the previous World Power Conference. They are reproduced here by kind consent of the International Executive Council of the World Power Conference and the Canadian National Committee, and with the permission of the respective authors.

— The Editor.

Second World Power Conference

June 16 to June 25, 1930

BERLIN

organized by the German National Committee
under the auspices of the
INTERNATIONAL EXECUTIVE COUNCIL WORLD POWER CONFERENCE

International Executive Council

LONDON

Chairman: D. N. DUNLOP (Great Britain)
Vice-Chairman: ED. TISSOT (Switzerland)

Canadian National Committee

Honorary Chairman: HON. CHARLES STEWART
Minister of the Interior

Honorary Vice-Chairmen

HON. F. P. BURDEN, B.A.
Minister of Lands, British Columbia

HON. HONORE MERCIER, K.C., LL.B.
Minister of Lands and Forests, Quebec

W. W. CORY, C.M.G.
Deputy Minister of the Interior, Ottawa

C. A. MAGRATH, LL.D., F.R.S.C., M.E.I.C.
Chairman, Ontario Hydro-Electric Power Commission; Chairman, Canadian Section International Joint Commission

E. W. BEATTY, K.C., LL.D.
President, Canadian Pacific Railway Company

SIR HENRY W. THORNTON, K.B.E., M.E.I.C.
President, Canadian National Railways

A. J. GRANT, M.E.I.C.
President, Engineering Institute of Canada

P. S. GREGORY, B.A., B.A.Sc., M.E.I.C.
President, Canadian Electrical Association

H. H. VAUGHAN, M.E.I.C.
Chairman, Canadian Engineering Standards Association

C. H. DAHL, B.A.
President, Canadian Electric Railway Association

J. S. DE LURY, B.A., Ph.D.
President, Canadian Institute of Mining and Metallurgy

JOHN MURPHY, M.E.I.C.
Electrical Engineer, Department of Railways and Canals, and Dominion Railway Commission

BRIG. GEN. C. H. MITCHELL, C.B., C.M.G., D.S.O., C.E., LL.D., D.Eng., M.E.I.C.
Immediate Past President, Engineering Institute of Canada

L. A. THORNTON, B.Sc., M.E.I.C.
Commissioner, Saskatchewan Power Commission

Executive Committee

Chairman: CHARLES CAMSELL, B.A., LL.D., F.R.S.C., F.G.S.A., M.E.I.C.
Deputy Minister of Mines, Ottawa

J. B. CHALLIES, C.E., M.E.I.C.
Manager, Water Resources Department, Shawinigan Water and Power Company

F. A. GABY, B.A.Sc., D.Sc., M.E.I.C.
Chief Engineer, Ontario Hydro-Electric Power Commission

O. O. LEFEBVRE, B.A.Sc., D.Sc., C.E., M.E.I.C.
Chief Engineer, Quebec Streams Commission

R. J. DURLEY, Ma.E., M.E.I.C.
General Secretary, Engineering Institute of Canada

J. T. JOHNSTON, B.A.Sc., C.E., M.E.I.C.
Director, Dominion Water Power and Reclamation Service, Department of the Interior

JOHN MURPHY, M.E.I.C.
Electrical Engineer, Department of Railways and Canals, and Dominion Railway Commission

Acting Secretary: NORMAN MARR, B.A.Sc., C.E., M.E.I.C.
Chief Hydraulic Engineer, Dominion Water Power and Reclamation Service, Department of the Interior

Honorary Chairman

Hon. Charles Stewart

Hon. Charles Stewart, Minister of the Interior.

Chairman, Executive Committee

Charles Camsell, M.E.I.C.

Charles Camsell, M.E.I.C., F.R.S.C., F.G.S.A., Deputy Minister of Mines, Department of Mines, Canada.

The Authors

The Hydro-Electric Industry in Canada

G. Gordon Gale, M.E.I.C.

G. Gordon Gale, M.Sc., M.E.I.C., vice-president of the Canadian Hydro-Electric Corporation, Ltd., at Ottawa, Ont., presents a paper on "The Hydro-Electric Industry in Canada." Mr. Gale has had considerable experience in the subject on which he writes, having been at one time vice-president and general manager of the Hull Electric Company and general manager of the Gatineau Power Company.

Fuel Investigations and Research in Canada

B. F. Haanel, M.E.I.C.

B. F. Haanel, B.Sc., M.E.I.C., is the author of the paper on "Fuel Investigations and Research in Canada." He has practically devoted his entire career to the solving of fuel problems, chiefly those of Canada. He is Chief Engineer, Division of Fuels and Fuel Testing Mines Branch, Department of Mines, Ottawa, and as such has been closely associated and in close contact with the development of Canada's fuel resources.

Recent Trends in Water Power Development in Canada

T. H. Hogg, M.E.I.C.

T. H. Hogg, D.Eng., M.E.I.C., Chief Hydraulic Engineer of the Hydro-Electric Power Commission of Ontario, Toronto, is the author of the paper on "Recent Trends in Water Power Development in Canada," a subject on which Mr. Hogg is eminently qualified to write. He was appointed a member of the Lake of the Woods Control Board in 1927, and in the same year received the Honorary Degree of Doctor of Engineering from the University of Toronto.

Storage Reservoirs in Canada

O. O. Lefebvre, M.E.I.C.

O. O. Lefebvre, B.A.Sc., D.Sc., M.E.I.C., Chief Engineer, Quebec Streams Commission, Montreal, is the author of "Storage Reservoirs in Canada." Dr. Lefebvre has been responsible for many outstanding engineering works, notably the large storage works on various rivers in the province of Quebec, for the regulation of the flow of these rivers for power purposes. He is a member of the Joint Board of Engineers appointed by the governments of Canada and the United States to investigate and report on the engineering features of the proposed St. Lawrence river navigation and power project.

Economic Aspects of Electrical Supply in the House and on the Farm

F. A. Gaby, M.E.I.C.

F. A. Gaby, D.Sc., M.E.I.C., is the author of the paper on "Economic Aspects of Electrical Supply in the House and on the Farm." Mr. Gaby presented two papers at the World Power Conference held in London in 1924. As chief engineer of the Hydro-Electric Power Commission of Ontario since 1912, Mr. Gaby has been constantly in touch with the problems presented by the supply of electricity for domestic purposes and for use in rural districts.

Generation, Transmission and Distribution of Electricity in Canada

Julian C. Smith, M.E.I.C.

Julian C. Smith, LL.D., M.E., M.E.I.C., vice-president and general manager of the Shawinigan Water and Power Company, and Professsor C. V. Christie, M.E., M.E.I.C., Professor of Electrical Engineering and Chairman of the Department of Electrical Engineering, McGill University, are joint authors of the paper on the "Generation, Transmission and Distribution of Electricity in Canada."

Mr. Smith has been identified with the development and transmission of hydro-electric power throughout Canada, and particularly in the province of Quebec for more than twenty-five years, notably as hydraulic engineer in charge of the development at Cedar Rapids, Que., as supervising engineer on the development of the Manitoba Power Company at Winnipeg, Man., as well as chief engineer in the developments of the Shawinigan Water and Power Company and allied companies.

Water Power Resources of Canada and Their Development

J. T. Johnston, M.E.I.C.

J. T. Johnston, B.A.Sc., M.E.I.C., Director, Water Power and Reclamation Department of the Interior, Ottawa, has contributed the paper on "Water Power Resources of Canada and Their Development." Mr. Johnston is the originator of the inventory system of water resources compilation and analysis which has been adopted by practically all the provincial power and water administrations in Canada.

C. V. Christie, M.E.I.C.

Professor Christie, M.E., M.E.I.C. is an authority on electrical engineering, and during the course of his career as a consulting engineer has had occasion to study some of the large transmission systems of Canada in detail, so that his knowledge of the subject of electric transmission is an intimate one. His text book on electrical engineering has been widely used by students in the universities in both Canada and the United States.

Water Power Resources of Canada and Their Development

J. T. Johnston, C.E., M.E.I.C.,

Director, Water Power and Reclamation Service, Department of the Interior, Ottawa, Ont.

Paper presented before the Second World Power Conference, Berlin, Germany, June 16-25, 1930.

I. General Outline

Water power during the present century has been and continues to be the most vital force behind Canadian industrial development. With ample resources evenly distributed from coast to coast water power has enabled Canada to develop into a manufacturing country of the first importance. With energy from this source developed, distributed and sold at low cost, industries have been attracted in increasingly large numbers, mines have been developed which would otherwise have remained dormant and a decided betterment in the standard of living has been effected by its widespread use in the homes and on the farms. With the exception of power for transportation and certain restricted areas, principally in the Prairie Mid-West, water power supplies practically the entire energy requirements of the Dominion.

At the First World Power Conference held in London in 1924 a paper entitled "Water Powers of Canada, Their Nature, Extent and Administration," was presented by Mr. J. B. Challies, c.e., m.e.i.c., at that time Director, Dominion Water Power and Reclamation Service, Department of the Interior, in which the fortunate position of Canada with regard to the nature, extent and location of water power resources was reviewed in considerable detail together with an analysis of the development which had been made up to 1924 and a synopsis of water power administration throughout the Dominion. It is the purpose in the present paper to give a re-analysis of the water power situation in Canada bringing the figures up to the beginning of 1930, the year of the Second World Power Conference, as nearly as may be estimated from the information at present available (October 1929) and to deal particularly with the progress which has been made in the period subsequent to 1924.

Available and Developed Water Power

The water power available in Canada according to the most recent estimates totals 20,347,400 twenty-four hour horse power under conditions of ordinary flow or 33,617,200 twenty-four hour horse power ordinarily available for six months of the year. The favourable distribution of these resources in every province of the Dominion is shown in table No. 1 and is also indicated graphically on figure No. 1. On a commercial basis the available water power resources would probably warrant a total installation of about 43,700,000 h.p. so that with the total existing installation of 5,710,802 h.p. it may be said that slightly more than 13 per cent of the at present recorded resources of the Dominion are developed.

In columns 5 and 6 of table No. 1 figures of population and installation per thousand of population are respectively shown. The total installation for the Dominion averages 583 h.p. per thousand population, a figure which places Canada amongst the leading countries of the world in the per capita utilization of water power. In 1924 this figure was 353 h.p. per thousand.

Outline of Development 1924 to 1930

In the six years period which has elapsed since the First World Power Conference, water power installation has exceeded the most optimistic estimate made in 1924. While the population in this period increased about seven per cent water power installation in horse power increased 79 per cent. In 1924 an estimate based on past growth indicated a total for the beginning of 1930 of about 5,200,000 horse power whereas the figures today show an actual total of more than 5,700,000 horse power. In new development practically every province was represented, Quebec taking the lead with more than 1,437,000 horse power, Ontario next with 563,500 horse power followed by British Columbia with 203,900 horse power, Manitoba 149,900 horse power, New Brunswick 69,000 horse power, Nova Scotia 58,000 horse power, and Alberta 37,400 horse power.

An important feature of the past six years has been the extension and interconnection of transmission systems and the consolidation of numerous systems under single control. This is touched upon in the review by provinces which follows in Section II and is shown graphically on the various plates of transmission systems. An advance was

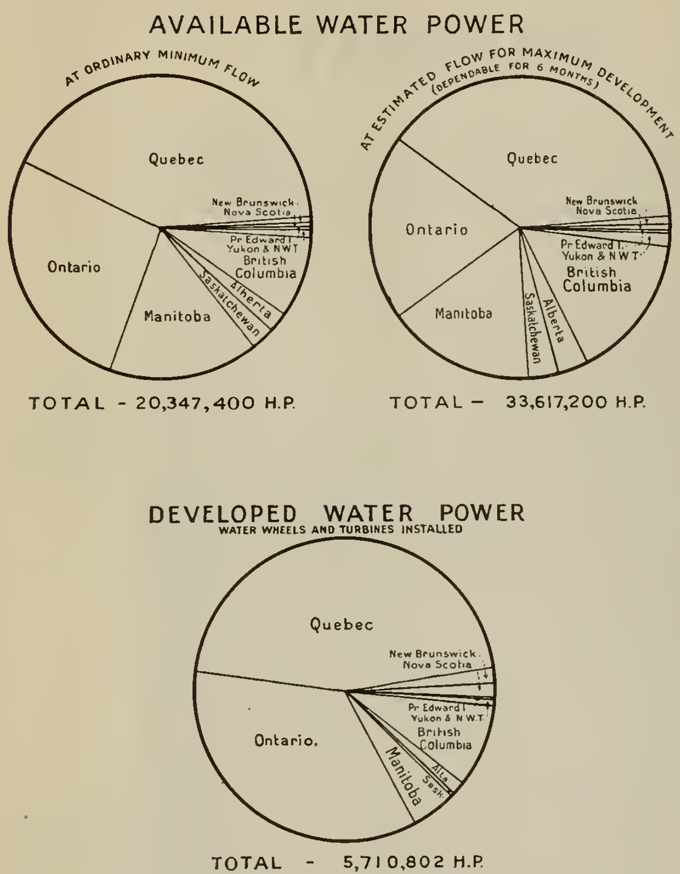

Figure No. 1—Available Water Power in Canada on Basis of 24-Hour Power at 80 Per Cent Efficiency.

also made during the period into higher voltages for long distance transmission. In 1924 lines of 110,000 volts were the highest in operation whereas at the present time there are lines of 134,000, 168,000 and 220,000 volts, thereby considerably extending the availability of hydro-electric energy.

Current Progress

In addition to the large increase in water power installation during the past six years there are a number of undertakings in the course of construction at the present time the total of whose initial installations will amount to 550,000 horse power and when completed to their ultimate designed capacities will add to the Dominion's total more than 2,500,000 horse power. There are, as well, numerous projects in the prospective stage many of which will undoubtedly materialize in the near future and will add very greatly to the programme of development.

Capital Invested in Water Power

The capital invested in water power development in Canada inclusive of that in transmission and distribution systems is estimated to be $1,250,000,000 or more than that for any other single manufacturing industry. The corresponding figure in 1924 was $688,000,000 so that during the past six years an average of about $94,000,000 per year has had to be provided for the purpose of new development. The readiness with which this new capital has been secured is an evidence of the stability of Canadian water power investments. Also the large proportion of such securities held within the country itself affords proof of the confidence Canadians have in this type of investment.

The opportunities for further investment in Canadian water power undertakings are likely to be numerous, the

Table No. 1—Available and Developed Water Power in Canada[1]

Province	Available 24-hour power 80 per cent efficiency		Turbine installation h.p.	Population June 1, 1929	Total installation per 1,000 population
	At ordinary minimum flow h.p.	At ordinary six months flow h.p.

Quebec.........	8,459,000	13,064,000	2,572,418	2,690,400	956
New Brunswick..	68,600	169,100	112,131	419,300	267
Nova Scotia.....	20,800	128,300	108,406	550,400	197
Prince Edward Island........	3,000	5,300	2,439	86,100	28
Yukon and N. W. Territories....	294,000	731,000	13,199	12,400	1,063
	20,347,400	33,617,200	5,710,802	9,796,800	583

[1]The estimates of available power are based upon sites where the head is definitely known or well authenticated. They omit many falls, rapids or possible concentrations, regarding which information is not reasonably definite and reliable. The estimates may therefore be looked upon as representing the minimum power possibilities of the Dominion.

All estimates of available power represent continuous twenty-four hour power at an efficiency of generation of eighty per cent. The figures in column 2 are based on "ordinary minimum flow" which is the average, over all the years for which records are available, of the mean flow for the two lowest seven-day periods in each year. Six-month power in column 3 is based on the "ordinary six-month flow" which is the average over all the years for which records are available, of the mean flow for the lowest seven consecutive days in the lowest of the six high months in each year.

The figures in column 4 represent the rated capacities of all water wheels and turbines installed throughout the Dominion. These figures should not be directly compared with the available power figures in columns 2 and 3. The actual water wheel and turbine installation throughout the Dominion averages about thirty per cent greater than the corresponding ordinary six-month figures calculated as in column 3. On this basis, therefore, the available water power resources of the Dominion as at present recorded would permit of a turbine installation of about 43,700,000 h.p. In other words, the present installation represents about thirteen per cent of the present recorded water power resources.

resources are exceptionally well situated and ample for extensive utilization; labour conditions are relatively stable; total manufactures and the proportion of manufactures exported show rapid and sustained increase while for legitimate power projects governmental co-operation is sympathetic and constructive.

Coal Equivalent of Developed Water Power

The development of water power in Canada has had a direct and very great effect in reducing the consumption of coal. While it is difficult to assign a precise figure of the coal equivalent of developed water power, as numerous assumptions must necessarily be made dependent upon conditions under which the power is developed, nevertheless, taking into account all present conditions surrounding water power development in Canada and comparing them with somewhat similar conditions of fuel power development elsewhere, it is reasonable to state that a saving of coal of six tons per annum is capable of being effected by each installed horse power. This means that the total present water power installation of 5,710,800 horse power is capable of effecting a saving of about 34,000,000 tons of coal per annum. With the marked economies that are continually taking place in the coal

Table No. 2—Developed Water Power in Canada—Distribution by Industries

January 1, 1930

Province	Turbine Installation in Horse Power			
	In central electric stations	In pulp and paper mills	In other industries	Total
1	2	3	4	5
British Columbia	418,210	81,000	60,832	560,042

Saskatchewan	....	....	35	35
Manitoba	311,925	....	....	311,925
Ontario	1,624,393	240,880	94,402	1,959,675
Quebec	2,216,150	220,810	135,458	2,572,418
New Brunswick	83,910	19,278	8,943	112,131
Nova Scotia	76,979	16,008	15,419	108,406
Prince Edward Island	376	....	2,063	2,439
Yukon and Northwest Territories	....	....	13,199	13,199
Canada	4,802,263	577,976	330,563	5,710,802

Column 2 includes only hydro-electric stations which develop power for sale.

" 3 " only water power *actually developed* by pulp and paper companies. In addition to this total, pulp and paper companies, purchase from the hydro power central electric stations totalled in column 2 approximately 860,000 h.p. A considerable amount of off-peak power is also purchased for use in electric boilers.

" 4 " only water power *actually developed* in connection with industries other than the central electric station and pulp and paper industries. These industries also purchase power from the central electric stations totalled in column 2.

" 5 totals all turbines and water wheels installed in Canada.

consumption of fuel power stations it will be necessary from time to time to adjust this figure of coal equivalent but under existing conditions the foregoing estimate is not unreasonable.

Utilization of Developed Water Power

A broad classification of the present turbine installation of 5,710,802 horse power is shown in table No. 2 and graphically on figure No. 2 under the headings, central electric stations, pulp and paper mills and other industries. A more detailed classification of the ultimate use of the power is difficult because of the large proportion which is accounted for by central electric stations from which power is sold for a multitude of uses.

The classification shows that 4,802,263 horse power or 84.1 per cent of the total is installed in central electric stations for general distribution for all purposes, 577,976 horse power or 10.1 per cent is installed in pulp and paper mills in addition to some 860,000 horse power of electrical energy which these mills purchase from central electric stations and 330,563 horse power or 5.8 per cent is installed in other industries among which are included mines, mineral reduction works, electro-chemical plants, saw, grist and grinding mills, machine shops, municipal pumping plants and street railways all of which also purchase power extensively from central electric stations.

Water Power in the Central Electric Station Industry

In the Canadian central electric station industry over 95 per cent of the primary power equipment is energized by falling water while the diversity of use of hydro-electricity induced by moderate prices results in almost 99 per cent of the total kilowatt hour output being generated in the hydraulic stations.

Of recent years there has been an increasing trend in the proportion of water power developed by central electric station organizations. At the present time 84 per cent of the total water power installation in Canada is so operated, as compared with 75 per cent in 1924.

Figures issued by the Dominion Bureau of Statistics indicate that during the year 1928 the large central electric stations in Canada produced 15,931,204,000 kilowatt hours, of which 15,705,271,000 kilowatt hours were generated by hydraulic stations. These large stations account for more than 99 per cent of the output of all central electric stations. Assuming an annual increase of 10 per cent as shown by the figures for the first eight months of 1929 the total output of hydraulic central electric stations for the year 1929 should amount to 17,300,000,000 kilowatt hours. This indicates a utilization of about 1,765 kilowatt hours per capita, a figure more than double that for the year 1922 and one which places Canada in the forefront of power using nations.

It is of interest to record that in 1928 there were eighteen systems, that is, undertakings in the same district that fall under the control of the same financial interests, which had an annual output of 100,000,000 kilowatt hours or more and whose combined total accounted for over 92 per cent of the total units generated by central electric stations. The largest of these, that of the Hydro-Electric

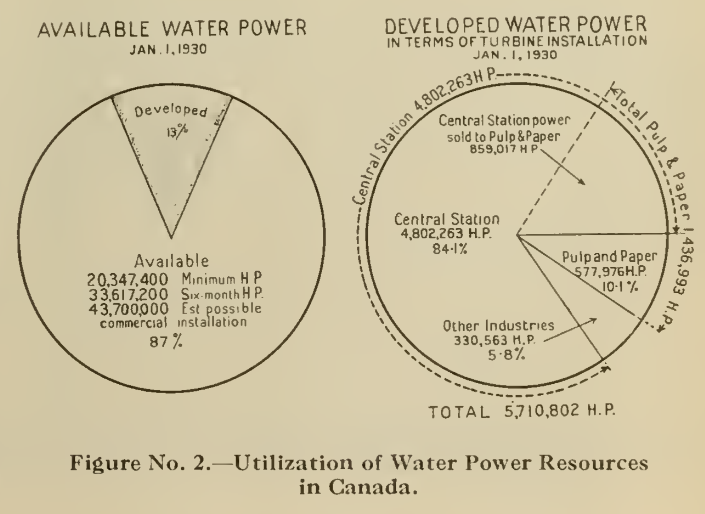

Figure No. 2.—Utilization of Water Power Resources in Canada.

Power Commission of Ontario, generated more than 4,000,000,000 units. In the province of Quebec four systems generated in excess of 1,000,000,000 units each while the remaining systems with lesser outputs were situated in British Columbia, Alberta, Manitoba, Ontario and Quebec. This furnishes direct evidence of the increasing tendency towards the consolidation of systems that is taking place throughout the Dominion.

The extensive economic radius of modern electric transmission combined with the fortunate location of water power in relation to centres of industry removed from supplies of native fuel has led to the development of enormous amounts of hydraulic power for use in manufacturing in established centres where labour is plentiful and of a permanent character and with shipping and distributing facilities readily at hand. The predominance of water power in the industrial life of Canada is indicated by figure No. 3 and table No. 5 which illustrate the sources and character of power for the various industrial centres and districts of the Dominion.

Table No. 3 shows the distribution of hydro-electric generating stations by location and type of ownership. Reference to this table will verify what has been already stated in regard to the effect of lack of indigenous coal supplies upon the location of hydro-electric plants in the provinces of Ontario and Quebec.

Water Power in the Pulp and Paper Industry

The production of pulp and paper is Canada's greatest manufacturing industry, its gross and net values of product and its disbursements for salaries and wages exceed the corresponding figures for those of any of the other manufacturing industries while its output of newsprint for the three last completed census years exceeded that of any other country.

As the production of newsprint requires an installation of approximately 100 h.p. per ton of daily output it is obvious that Canada's supremacy in its manufacture is due no less to her abundant supplies of low priced power than to her extensive forest resources. More than 90 per cent of the motive power in this outstanding industry is derived from water power.

The pulp and paper industry maintains a hydraulic installation of 577,976 h.p. and in addition purchases approximately 860,000 h.p. of electrical energy for power purposes from central electric stations. Considerable off-peak and surplus power is also purchased from central electric stations for use in electric boilers.

The provinces of Ontario and Quebec lead in pulp and paper production and have 240,880 and 220,810 hydraulic horse power respectively installed in connection with the mills and 176,744 h.p. and 622,388 h.p. purchased from hydro-electric central stations, British Columbia being next in order of production, Manitoba and the Maritime provinces also using considerable amounts of hydraulic power for this industry.

Table No. 4 shows in detail the use of hydro-electric power, column 6 being of particular interest as showing the extent to which the electric drive with its uniform speed and possibilities for centralized operation of mills receiving power from a number of different developments, has been adopted by this industry.

Water Power in the Mineral Industries

Canada possesses an active or prospective mineral field covering over three million square miles, comprising over 80 per cent of her total area and mining operations in most of the workings already developed require large amounts of power so that their profitable operation is greatly facilitated by the low cost of hydro-electricity.

Ample power supplies make it possible to conduct large scale operations with consequent lowered cost thereby permitting profitable operation of relatively low grade deposits. Thus the scope of the industry is immensely enlarged and many millions of tons of ore treated which if power were limited and expensive would have no commercial value.

Canada's mineral industries maintain a hydraulic installation of approximately 100,000 h.p. and purchase

Table No. 3—Developed Water Power in Canada—Utilized in the Central Electric Station Industry

Estimated at January 1, 1930

Province	Commercial Stations					Municipal Stations				
	No. of stations	No. of turbines	Total turbine installation h.p.	Average h.p. per station	Average h.p. per turbine	No. of stations	No. of turbines	Total turbine installation h.p.	Average h.p. per station	Average h.p. per turbine

Ontario	69	202	552,358	8,005	2,734	48	140	1,072,035	22,334	7,657
Quebec	90	256	2,189,490	24,328	8,553	14	23	26,660	1,904	1,159
New Brunswick	3	9	71,850	23,950	7,983	3	6	12,060	4,020	2,010
Nova Scotia	13	17	10,166	782	598	21	36	66,813	3,182	1,856
Prince Edward Island	5	6	376	75	63	...	...	......	.....	.....
Yukon and Northwest Territories	...	...	......	.....	.....	...	...	......	.....	.....
Canada	211	576	3,508,515	16,628	6,091	97	235	1,293,748	13,337	5,505

Commercial stations include all privately owned.
Municipal stations include all publicly owned.

Note.—Statistics in this table are based upon a census of the industry made by the Dominion Bureau of Statistics in co-operation with the Dominion Water Power and Reclamation Service. In addition to the central electric station organizations included above certain industrial hydraulic plants sell small amounts of electricity, i.e., the sale of electricity is only incidental to their main industries.

Table No. 4—Developed Water Power Utilized in the Pulp and Paper Industry

January 1, 1930

Province	Installed and Purchased Water Power in Horse Power					
	Turbine installation in the industry			Purchased hydro-electric power	Total hydro-electric power col. 3 and col. 5	Total hydro-power used in the industry col. 4 and col. 5
	Direct drive	Hydro-electric drive	Total			
1	2	3	4	5	6	7
British Columbia	26,155	54,845	81,000	2,550	57,395	83,550

*The pulp and paper mills of Manitoba and New Brunswick purchase hydro-electricity totalling 51,062 h.p.

Column 2 includes all turbines actually installed in the industry directly driving mill equipment.
" 3 includes all turbines actually installed in the industry transmitting power through electric drive.
" 4 totals the turbine capacity actually installed in the industry.
" 5 includes only power purchased from central electric stations for the operation of pulp and paper mills.
" 6 totals the hydro-electric power used in the industry.
" 7 totals the water power used in the industry.

approximately 380,000 h.p. of hydro-electricity from the central electric stations. This power is used for the extraction of ore, crushing, smelting, refining and other processes. The extraction of the mineral requires power for compressing air for drilling, for stripping, hoisting, hauling and conveying; for pumping water supply and drainage; for lighting, heating and ventilating and for machine, blacksmith and framing shops.

The actual extent of Canada's minerals is not known, every extension of transportation facilities renders fresh mineral fields available. It is believed, however, that wherever mineral deposits may be found the same geological formation that provides for their occurrence may also be expected to supply the necessary water power for their development.

Water Power in the Electro-Chemical and Electro-Metallurgical Industries

One of the recent outstanding developments of Canadian industry has been the application of electricity to many chemical and metallurgical processes. New industries have been established in localities where the large amounts of low-cost electricity essential to their successful operation could be developed from adjacent water powers or procured by purchase from plants already in existence. In some cases chemical loads have been developed to convert surplus or off-peak power into marketable products.

Electric energy is used chiefly for the production of heat or to promote chemical actions or reactions, the application of the energy falling into three main classes: the electrolytic refining of those metals which can be produced of greater purity by electric processes, the electrolytic production of chemicals which are more easily and economically produced electrically than by other means and electric furnace processes where exceptionally high temperatures are required.

The principal Canadian plants which depend wholly upon electric power for the operation of their processes are located in the vicinity of low-cost hydro-electricity: in Ontario, at Niagara Falls; in Quebec, at Hull, Shawinigan Falls and Arvida; and in British Columbia at Rossland. Many smaller plants are located at different points throughout the country but all where hydro-electricity is obtainable at low cost. These industries have at the present time a hydraulic turbine installation in their own plants of approximately 60,000 h.p. and purchase about 132,000 h.p. of electrical energy from central electric stations and there are many indications that this is but the beginning of the utilization of water power for this purpose.

While the utilization of off-peak power will afford opportunity for the development of the smaller electro-chemical industries there are many large undeveloped sites in Canada which offer special advantages for the location of large power-using industries requiring continuous power. It is expected that in the future many of these will be utilized for the development of electro-chemical industries.

Past and Future Growth in Water Power Development

The growth of water power development in Canada from 1900 to 1929 is illustrated in figure No. 4 and the growth in the various provinces from 1910 to 1929 in figure No. 5.

The total installed horse power at the end of the year 1900 was 173,300 horse power. Development was active in the years following so that at the end of 1910 the total had grown to 977,000 horse power. A decided increase in the rate of growth then took place and by the end of 1916 a figure of 2,222,000 horse power was reached. From 1916 to 1920, war and post-war conditions had the effect of retarding development with the result that the total at the end of 1920 amounted to only 2,515,000 horse power. Following 1920 an intensive period of development commenced which has continued to the present time. By the end of 1923 the total had grown to 3,192,000 horse power and at the end of 1929 to 5,711,000 horse power.

During the past six years the average annual increase in installation has been about 420,000 horse power. The curve in figure No. 4 has been projected on the basis of this recent growth and shows that in 1940 the total for the Dominion will probably have reached a figure of 10,300,000 horse power.

Table No. 5—Developed Water Power in Canada—Hydro-Electric Stations Serving Industrial Areas Indicated in Figure No. 3

No.	Plant or System	Owner	Installation
1	Anyox plant	Granby Cons. Min., Smelt. & Pwr. Co., Ltd.	13,400

With the undertakings now in process of development and with those at present in active prospect there is every reason to believe that this rate of growth will not only be maintained but will be considerably exceeded. Available resources are more than ample to provide for such an expansion.

The foregoing has summarized the water power situation in Canada sufficiently to show the extent and distribution of the resources, the widespread development that has taken place and the outstanding importance of this development in the industrial, commercial and domestic life of the Dominion. In Part II, which follows, a more detailed account will be given of the situation in each province with particular reference to the developments made in the period from 1924 to date.

Part III will summarize the recent water power legislation and tendencies of administrative policy, both of the Dominion and of the provinces.

II. Review by Provinces

The early history of water power development in Canada was briefly sketched in a paper before the First World Power Conference and need not be repeated here, except to emphasize the point that the development of long distance transmission provided the key to release the power contained in large water power sites for useful work. Sites of several thousands of horse power could not be fully utilized while the application of that power was restricted to the area that could be reached by mechanical or low voltage electrical means. When the radius of application widened, the power that could be produced at a single site increased, until now single developments of several hundred thousand horse power are not only quite feasible, but are advantageous because of the economies incidental to large undertakings and, conversely, transmission and distribution systems are spreading across the country so that nearly everywhere from coast to coast, factories, municipal services and homes are energized efficiently and at low cost by electricity produced in hydro-electric developments possibly many miles distant.

The extent and development of water power in Canada varies in accordance with topographical and climatic changes and is also affected by variations of policy in different administrations; for this reason a more extended discussion of the subject can best be given under provincial divisions with, sometimes, further subdivisions into districts.

British Columbia

British Columbia, the most westerly province of Canada, has an area of approximately 356,000 square miles and being traversed by three distinct mountain ranges is for the most part rugged while the climate and precipitation show wide variations, the latter varying from an average of less than 10 inches per annum over the interior plateau to upwards of 100 inches per annum in the coastal belt.

Available Water Power Resources

The available water power resources of British Columbia are estimated at 1,931,000 h.p. under conditions of ordinary minimum flow and 5,100,000 h.p. for six months of the year. These estimates are most conservative as they are based upon head and flow records for individual streams and take no account of the numerous natural opportunities for storage, or make any allowance for the many excellent natural facilities for storing the flow of several streams in one or more reservoirs and releasing it through a single high head power plant.

Developed Water Power

The total hydraulic turbine installation of British Columbia is now 560,042 h.p. of which 418,210 h.p. is developed by central electric station organizations for general industrial, commercial and domestic use, 81,000 h.p. is installed in pulp and paper mills and 60,832 h.p. in other industries, notably mining and smelting and the production of sawn lumber.

Central Electric Station Developments

The principal central electric station developments are those of the British Columbia Power Corporation serving the Vancouver and Victoria districts, the West Kootenay Power and Light Company serving the Nelson and Southern boundary districts and the East Kootenay Power Company serving the Fernie and Eastern boundary districts and extending a considerable distance into the Crow's Nest Pass mining area of Alberta.

Power for the Vancouver area is received from four plants, two on the north arm of Burrard Inlet, 16 miles from Vancouver, drawing water from Lakes Buntzen and Coquitlam, and two on the Stave river, the first at Stave Falls, 36 miles from Vancouver, and the second 10 miles above Stave Falls on the shore of Stave lake and operated by water drawn through a tunnel from Alouette lake whose natural flow was reversed by damming to provide the necessary power for the upper plant and to augment the power already in use at Stave Falls. The Coquitlam-Buntzen plants operate under an average head of 395 feet and have an aggregate installation of 84,000 h.p. The Stave Falls plant operates under an average head of 113 feet and has an installation of 77,500 h.p. while the Stave lake plant which is automatically controlled from Stave Falls has an average head of 125 feet and an installation of 12,500 h.p. The extensive transmission system serving Vancouver and the surrounding district is shown on figure No. 6.

Power for the Victoria district is generated in three stations, one on the Goldstream river, 12 miles from Victoria where under an average head of 670 feet 3,400 h.p. is installed and two at the mouth of the Jordan river 36 miles from Victoria where under an average head of 1,145 feet 25,000 h.p. is installed in one plant and 2,250 h.p. in a second recently completed automatically controlled plant drawing water from the same diversion dam. Figure No. 7 illustrates the transmission systems serving the Victoria area.

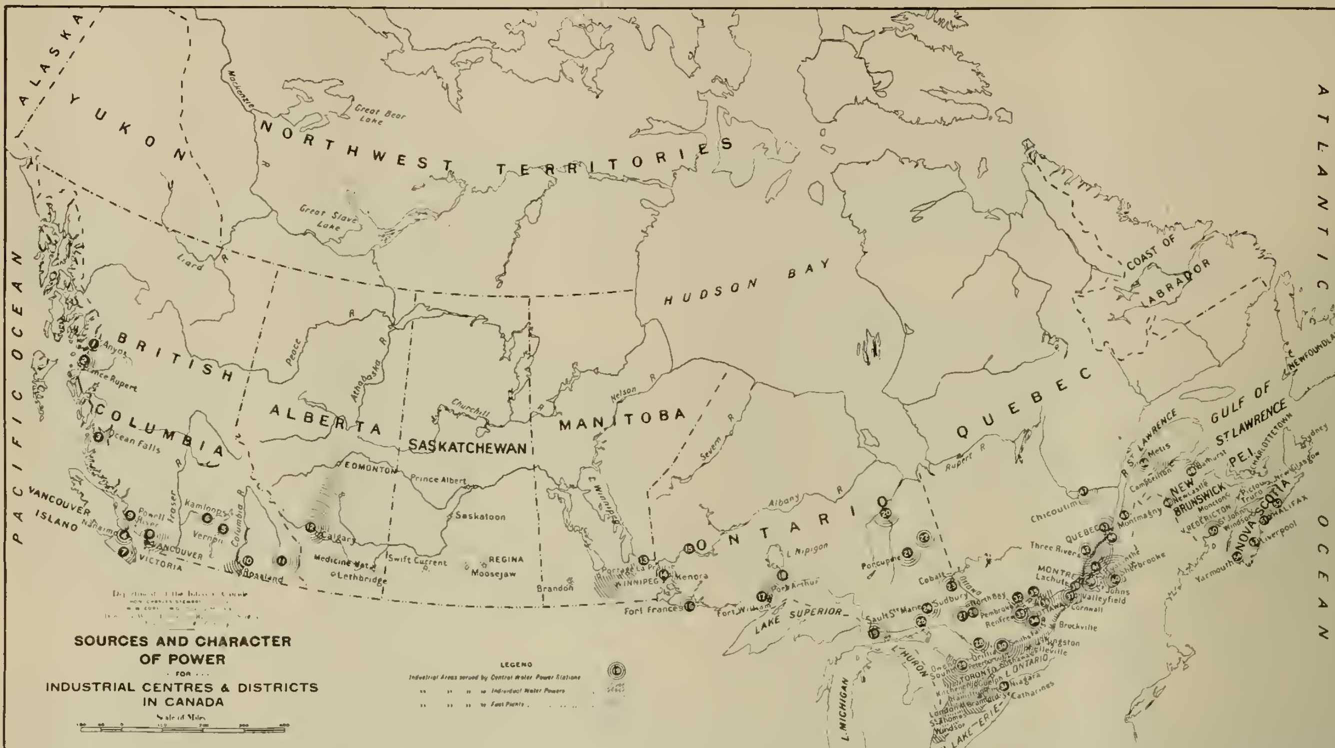

Figure No. 3.
For List of Hydro-Electric Stations serving Industrial Areas Indicated, see Table No. 5.

The British Columbia Power Corporation which controls the above described plants is now engaged upon two extensive developments to augment the supply of power for the Vancouver district. The first of these is a development at Ruskin near the mouth of the Stave river where 42,500 h.p. is being initially installed for operation in the autumn of 1930; the ultimate capacity to be 170,000 h.p. The second project is on the Bridge river where by a series of dams the water is to be diverted through a tunnel 13,200 feet in length and thence through penstocks to a power house on Seton lake where under a head of some 1,300 feet 80,000 h.p. is expected to be in operation by 1932. Further stages involve the construction of additional storage dams, enlargement of tunnel and power house capacity until an ultimate installation of 550,000 to 700,000 h.p. is reached.

Power for the Nelson and southern boundary districts is supplied by the West Kootenay Power and Light Company and more locally by the municipality of Nelson. The former Company operates three plants on the Kootenay river, the first at Upper Bonnington Falls where 34,000 h.p. operates under an average head of 70 feet, the second at Lower Bonnington Falls where the former plant of 4,016 h.p. was replaced in 1925–1926 by one of 60,000 h.p. and the third, completed in the fall of 1928, at South Slocan where 75,000 h.p. is operated under a head of 70 feet. This Company now proposes to develop 80,000 h.p. on the Pend d'Oreille river and is considering another development of 20,000 h.p. on the Adams river.

The municipality of Nelson operates a plant at Upper Bonnington Falls to serve Nelson and some smaller adjacent municipalities. It operates under a head of 60 feet and the installation has recently been increased from 3,570 h.p. to 6,570 h.p.

The Fernie and eastern boundary district receives power from two plants operated by the East Kootenay Power Company, one on the Bull river near Aberfeldie where 7,200 h.p. is operated under an average head of 275 feet and one at Elko on the Elk river where 15,000 h.p. is installed and operates under an 85-foot head. This Company is now investigating the possibilities of a further 15,000 h.p. development on the Elk river at Phillips Canyon.

In addition to the outstanding central electric stations described there are many smaller hydraulic developments utilized for the supply of electricity for public use.

Pulp and Paper Installations

There are seven mills in British Columbia engaged in the pulp and paper industry using hydro-electric power. Two of these operate with purchased power and the remainder produce their own water power to the extent of 81,000 h.p. Amongst the largest is the mill of the Powell River Company Limited on the Powell river which has a total turbine installation of 49,860 h.p., of which 35,460 h.p. is connected to electric generators and the remainder is used directly to drive mill machinery. Another large installation is that of the Pacific Mills Limited on the Link river at Ocean Falls where, of 26,850 h.p. turbine capacity, 9,600 h.p. is directly connected to machinery and the remainder to electric generators. The electric power produced is, in both cases, mainly used in the manufacture of pulp and paper although a small amount is sold for municipal use in their immediate vicinity.

Power for Mining

The mineral industry in British Columbia has large power requirements and furnishes by far the heaviest load in the Nelson-Rossland and Fernie-Cranbrook districts. The Consolidated Mining & Smelting Company of Canada, which operates a number of zinc, lead and copper properties in both the West and East Kootenay areas, is the largest consumer and in addition power is transmitted from the East Kootenay plants for coal mining in the Crow's Nest Pass.

On the Pacific coast the extensive copper and gold areas receive power from a number of important developments, while amongst the water power stations developed solely for mining purposes may be mentioned two owned by the

Granby Consolidated Mining, Smelting and Power Company, with a combined installation of 13,200 h.p. on Falls creek, and two by the Britannia Mining and Smelting Company, totalling 19,070 h.p. on Britannia creek, whilst on Vancouver Island there is a 12,000 h.p. plant on the Puntledge river supplying power to Canadian Collieries Limited for coal mining.

Alberta

Alberta, the most westerly of the Prairie provinces, has a total area of about 225,000 square miles. The southern part of the province is part of the great central plain, the prairie lands extending from the international boundary to approximately the line of the north Saskatchewan river, then follows an area of mixed prairie and woodland succeeded in turn by the northern forests which dense at first thin out towards the northern boundary.

The southern part of the province is drained by the Saskatchewan river system and the northern by the Slave and its main tributaries the Pease and Athabaska. Precipitation is low in southern Alberta but towards the north it increases to about 20 inches per annum.

Available Water Power Resources

The water power resources of the province of Alberta are estimated at 390,000 h.p. under conditions of ordinary minimum flow and 1,049,500 h.p. for six months of the year. The principal power rivers of the southerly portion of the province are the Bow, North Saskatchewan and Brazeau having estimated aggregate power resources of 70,000 h.p. for six months of the year but with advantage taken of natural storage economic capacities it is believed that this figure could be doubled or trebled.

In northern Alberta the Athabaska, Peace and Slave have aggregate power resources estimated at close to 1,000,000 h.p. No power development has yet taken place on these streams, but the rapid northward trend of settlement and mineral discovery is directing attention towards them.

Developed Water Power

The total hydraulic installation of Alberta is 70,532 h.p. all but 212 h.p. of which is installed in central electric stations. With the exception of a 960 h.p. development of the Dominion Parks Branch on the Cascade river and an 800 h.p. installation at Lake Louise the production of hydro-electricity is practically confined to the Bow river developments of the Calgary Power Company which serves a transmission system which covers the whole of the western portion of the province from Edmonton south to the international boundary. The Company owns three developments on the Bow river with 11,600 h.p. installed at Kananaskis Falls, 20,000 h.p. at Horseshoe Falls and 36,000 h.p. at the recently completed Ghost development. This Company also controls the 780 h.p. development formerly operated by the Calgary Water Power Company in Calgary.

Utilization of Developed Power

With the exception of the power used in the Crow's Nest Pass for coal mining and secured from the developments of the East Kootenay Power Company in British Columbia, the power developed is used almost entirely for manufacturing, municipal and domestic use. The Calgary Power Company sells power in bulk to some municipalities and in others has taken over the distribution as well. Many of the municipalities, particularly the larger ones, already possessed fuel power stations and the Company owns or operates some of these or purchases power therefrom to supplement the supply of power to the transmission system when the load is greater than can be met by the hydro-electric supply. Figure No. 8 shows the transmission systems of the province.

Saskatchewan

The province of Saskatchewan has an area of 252,000 square miles and may be divided into the two main divisions of the plain region and the Laurentian plateau. The southern part of the province lies in the great central plain of north America but the northern is of an entirely different character being part of the Laurentian plateau with rocky uneven surface, well wooded and plentifully interspersed with lakes, swamps and muskegs.

The southern portion of the province is drained by the north and south Saskatchewan which unite to form the Saskatchewan while the northern portion is drained easterly by the Churchill and westerly by the Black.

Available Water Power Resources

The water power resources of Saskatchewan are estimated at 542,000 h.p. at ordinary minimum and 1,082,000 h.p. at ordinary six months flow. The water power sites in the southern portion of the province have their values impaired by the low winter flow and summer floods but may possibly be advantageously developed in conjunction with fuel power plants. The more extensive resources of the northerly streams have until recently been too far afield for development but the opening up of new mining fields in Saskatchewan and adjacent portions of Manitoba has already led to the commencement of construction at the Island Falls site on the Churchill river.

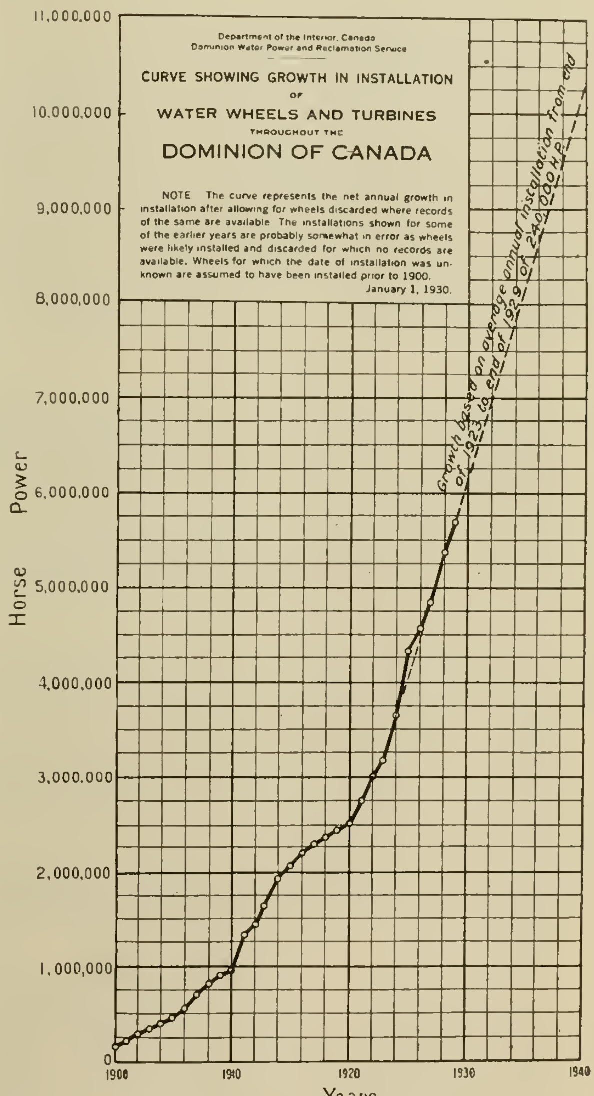

Figure No. 4.

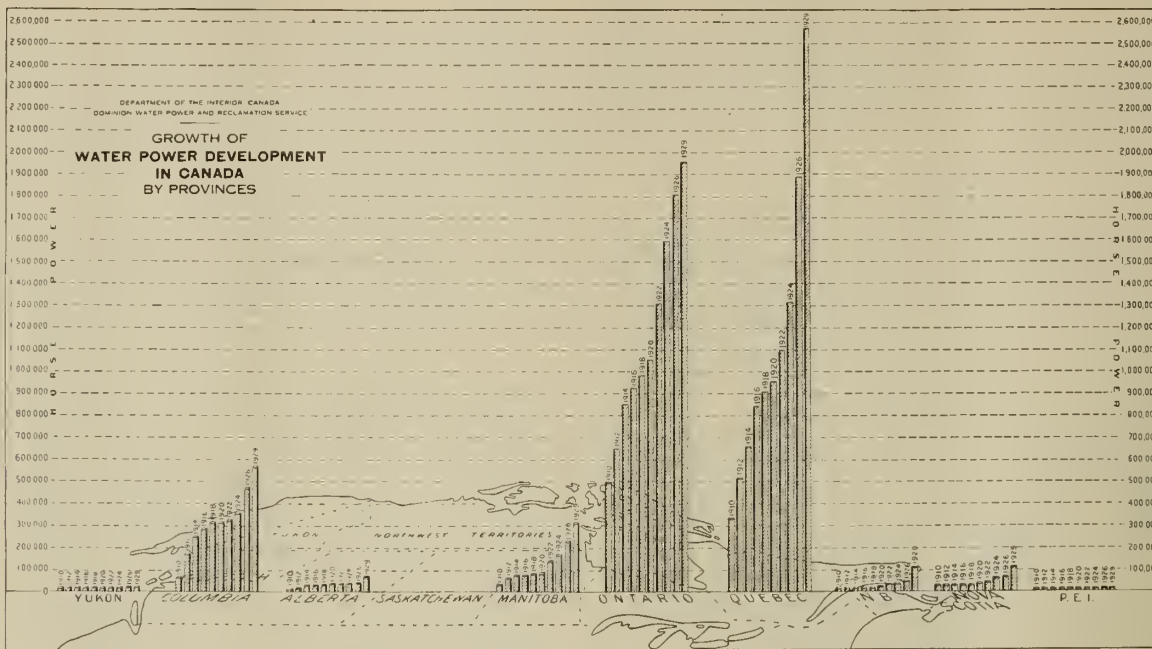

Figure No. 5.

Developed Water Power

Except for a small development of 35 h.p. in connection with an Indian mission the Island Falls site referred to above is the first to be developed in the province. This development which is being made by the Churchill River Power Company will be 84,000 h.p. of which the initial installation of 42,000 h.p. will soon be in place. The power will be transmitted 65 miles to the Flin Flon mine of the Hudson Bay Mining and Smelting Company, the parent company. A stated portion of the power, on requisition of the Government of Saskatchewan, must be made available for public distribution.

Manitoba

The province of Manitoba has a total area of 250,000 square miles and the Nelson river, which lies entirely within its boundaries, drains the vast area which contributes water to Lake Winnipeg. This watershed comprises nearly one-half the area of Alberta and Saskatchewan, a considerable area in western Ontario and northern Minnesota and North Dakota, while about three-fifths of the whole of Manitoba is tributary to the Lake Winnipeg-Nelson river basin.

A line, commencing a few miles west of the Lake of the Woods and extending northward and westward following the east shore of Lake Winnipeg and thence northwesterly to the Saskatchewan boundary, divides the province of Manitoba into two sections. To the west and south of this line is the great central plain of north America, while to the north and east is the great Laurentian plateau, both of which have already been described.

Precipitation in Manitoba ranges from about 18 inches in the south to 15 inches in the north with an average of 20 inches on the watersheds in the eastern part of the province.

Available Water Power Resources

The water power resources of the province of Manitoba are estimated at 3,309,000 h.p. under conditions of ordinary minimum flow and 5,345,000 h.p. for six months of the year. The outstanding power river of the province is the Nelson which, between Lake Winnipeg and Hudson bay has a descent of 710 feet and a power capacity of from two and a half to four million horse power. The most important power river from the point of present utility is the Winnipeg, capable of supporting an installation of about 750,000 turbine horse power and already the chief source of energy for southern Manitoba. Other large power sites exist on the Churchill river and at Grand Rapids on the Saskatchewan river, whilst the smaller rivers possess many sites of a considerable economic value.

Developed Water Power

The total turbine installation in Manitoba is now 311,925 h.p., of which nearly 311,000 h.p. is on the Winnipeg river — 105,000 h.p. at the Point du Bois plant of the City of Winnipeg, 37,800 h.p. at the Pinawa station of the Winnipeg Electric Company and 168,000 h.p. developed by a subsidiary of the same company, the Manitoba Power Company, at Great Falls. Another subsidiary of the Winnipeg Electric Company, the Northwestern Power Company, is now engaged on a 225,000-h.p. undertaking at Seven Sisters Falls, half of which will be shortly brought into operation under reduced head. The Seven Sisters development will bring about the abandonment of the Pinawa development which utilizes water in a side channel, which water will be re-diverted to the main river. The City of Winnipeg has also commenced a development at Slave Falls, on the Winnipeg river, with an ultimate designed capacity of 100,000 h.p. No other power developments in the province can be considered as imminent although a project is under consideration for Whitemud Falls on the Nelson river where a 300,000-h.p. installation has been proposed, whilst a number of smaller sites are being actively considered for the supply of power for mining in the northern sections of the province.

Utilization of Developed Power

The principal use of Winnipeg river power is for transmission to Winnipeg and district for general industrial, municipal and domestic purposes. The transmission systems are illustrated in figure No. 9, which indicates also that is transmitted to the pulp and paper mill of the Manitoba Paper Company, a subsidiary of the Abitibi Power and Paper Company, Limited, at Fort Alexander and for mining in the Central Manitoba area.

Ontario

The province of Ontario has an area of about 407,000 square miles and is divided into two main watersheds, one draining southerly into the Great Lakes and St. Lawrence river and the other northerly into Hudson and James bays. The extreme westerly portion of the province drains to Hudson bay by way of the Winnipeg and Nelson rivers. With the exception of the comparatively small area in the south bounded by lakes Huron, Erie, Ontario and the St. Lawrence and lower Ottawa rivers and an area in the far north comprising the coastal plain, the whole of Ontario lies within the Laurentian plateau and possesses its characteristics which have already been described.

Precipitation in the lower Great Lakes and St. Lawrence basin ranges from 30 to 40 inches per annum, in the upper Great Lakes and northwesterly portions of the province it ranges from 20 to 25 inches and in the far north diminishes to 20 inches or less.

Available Water Power Resources

The water power resources of the province of Ontario are estimated at 5,330,000 h.p. under conditions of ordinary minimum flow and 6,940,000 h.p. for six months of the year. The outstanding resources are situated on the Niagara and St. Lawrence rivers. On the Niagara, the power of which is shared with the United States, the complete power capacity is from five to six million horse power, but by international treaty Canada is restricted to a total diversion of 36,000 and the United States to 20,000 cubic feet per second and the figures given above for the extent of available power resources in Ontario takes account of this restriction. The available power on the St. Lawrence where it forms the boundary is from one and a half to two million horse power. These also are shared with the United States. Another river, the Ottawa, which forms the boundary between Ontario and Quebec, possesses large power resources estimated at from 600,000 to 1,000,000 h.p. which would be shared between the two provinces. To specify every river possessing considerable power capacity would require considerable space and it will suffice to state here that throughout the whole Laurentian area many power rivers are to be found ranging in capacity from the Abitibi of from 230,000 to 335,000 h.p. downwards to those having a capacity of 1,000 h.p. or less.

Developed Water Power

The present total turbine installation in Ontario is 1,959,675 h.p. and virtually the entire energy requirements of the province for industry and for municipal and domestic uses is supplied by this development supplemented by power purchased in bulk from hydro-electric stations on the Gatineau and Quinze rivers in Quebec. Consideration of this development can best be made by treating it under the sub-headings of Central Stations, Pulp and Paper, and Mining.

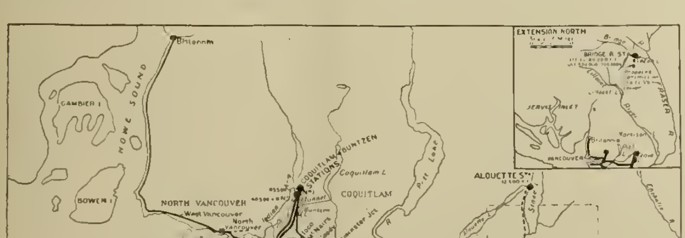

Figure No. 6.

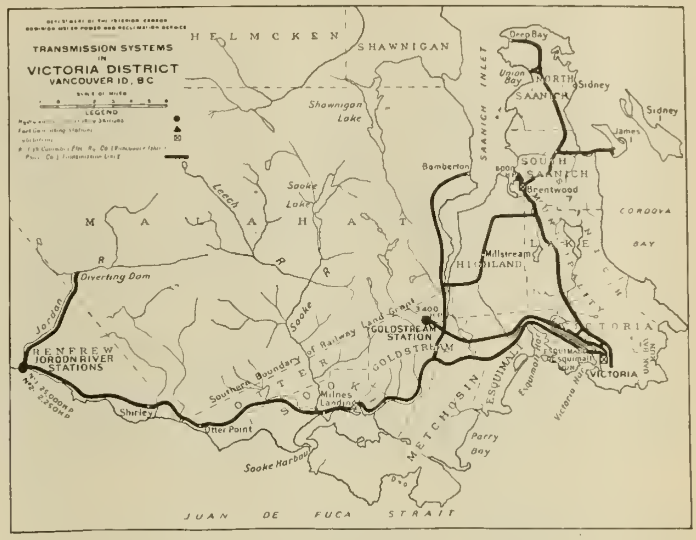

Figure No. 7.

Central Station Developments

By far the largest organization for the production and distribution of central station power is the Hydro-Electric Power Commission of Ontario. The Commission operates eight systems through which it sells power to some 550 municipalities and owns and operates 25 power stations with an aggregate installation of 1,047,879 h.p. In addition it purchases power from the Gatineau Power Company for its Niagara and three eastern Ontario systems. The largest system is the Niagara which serves the whole southwestern peninsula from east of Toronto as far west as Windsor and is supplied by the Commission's Queenston development of 502,000 h.p., the Ontario power station of 208,200 h.p., and the Toronto power station of 164,000 h.p., all three at Niagara Falls. In addition to this installation, totalling 874,200 h.p., the Commission purchases power from the Gatineau Power Company under a contract for the supply of 230,000 to 260,000 h.p. Delivery of this power is taken at the Ottawa river to which the Company transmits it and is conveyed from there over the Commission's own 220,000-volt line to Toronto. The Georgian bay system is served by six stations with an aggregate capacity of 25,050 h.p.; the Nipissing system by three stations totalling 57,000 h.p.; the Ottawa system by power purchased in bulk; the Thunder bay system by a 75,000-h.p. plant on the Nipigon river; the central Ontario and Trent systems by nine plants on the Trent Canal with an aggregate capacity of 57,980 h.p.; the St. Lawrence system by purchased power and the Rideau system by two stations aggregating about 4,500 h.p. and by purchased power.

The Commission is at present providing for the growing demand for power by recent purchases of developed and undeveloped sites, by installing a tenth unit, 58,000 h.p. in its Queenston plant and by a new station of 54,000 h.p. at Alexander Landing on the Nipigon river. A contract has also been made recently with the Beauharnois Light, Heat & Power Company in Quebec, whereby the Commission will purchase 250,000 h.p. at $15.00 per h.p. year, delivery to commence in 1932.

While the Commission operates slightly more than three-fifths of the total central electric station installation of Ontario there are a number of outstanding instances of distribution under joint stock company ownership, particularly of power developed for specific uses such as mining or pulp and paper manufacturing. The largest of

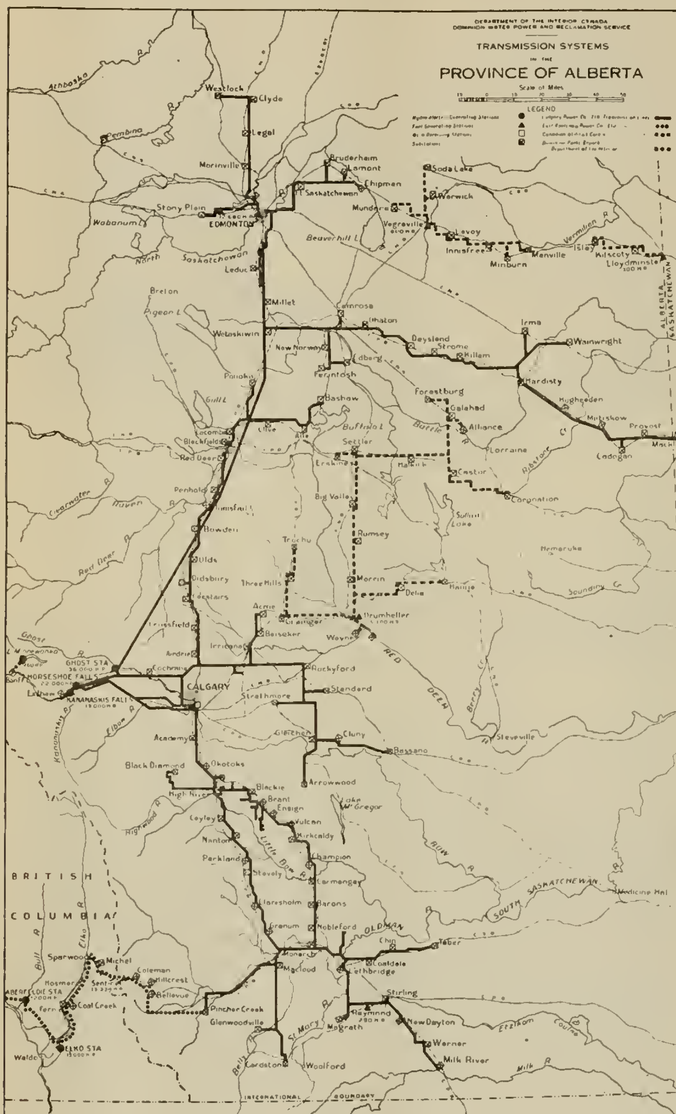

Figure No. 8.

these systems, the Canada Northern Power Corporation, serves the gold and silver mining areas in northern Ontario and north western Quebec from seven stations in Ontario with an aggregate installation of 53,340 h.p. and one in Quebec of 40,000 h.p. This Company has also commenced the construction of a plant on the Montreal river, its fourth on that stream, where 13,000 h.p. will be installed. The International Nickel Company of Canada operates through subsidiary companies five plants on the Vermilion and Spanish rivers with an aggregate installation of 62,500 h.p. much of the output being used in the mining and smelting plants of the parent company although a considerable portion is sold for general industrial and domestic use. The Abitibi Electrical Development Company, a subsidiary of the Abitibi Power and Paper Company, operates a 48,000-h.p. plant at Island Falls on the Abitibi river from which power is sold for general distribution and the remainder used to supplement the supply for the parent Company's Iroquois Falls mills where 58,000 h.p. additional is installed. The Keewatin Power Company has two plants totalling 30,875 h.p. at the outlets of the Lake of the Woods, developed for general distribution and for supplying the mills of its parent company, Kenora Paper Mills Limited. The Ontario and Minnesota Power Company operates four plants totalling 51,850 h.p. on the Seine and Rainy rivers, for general distribution and pulp and paper mill supply. Among the privately owned plants doing a purely central station business may be mentioned that of the Dominion Power and Transmission Company at Decew Falls where 45,000 h.p. is developed for distribution in Hamilton and vicinity, the Great Lakes Power Company's 28,000-h.p. plant at Sault Ste. Marie, the Kaministikwia Power Company's 35,000-h.p. plant at Kakabeka Falls, near Fort William, and the Ottawa Electric Company's three stations on the Ottawa river at Ottawa which have an aggregate installation of 13,100 h.p. Figure No. 10 shows the transmission systems operated in the province.

Pulp and Paper Installations

There are 48 pulp and paper mills in Ontario operated by hydraulic power over half of which develop all or part of the power used in operating them. The mills producing their own power have an aggregate installation of 238,880 h.p. of which approximately 60 per cent is hydro-electric and the remainder direct connected to the mill machinery while much of the power purchased is secured from central electric stations developed under the aegis of the pulp and paper companies supplied. Among the larger installations not specifically referred to in the preceding section may be mentioned those of the Abitibi Power and Paper Company at Smooth Rock Falls, Sault Ste. Marie, Espanola and Sturgeon Falls which total to 68,340 h.p., those of the Spruce Falls Power and Paper Company of Kapuskasing totalling 58,750 h.p. and that of J. R. Booth Limited at Ottawa, 29,000 h.p.

Power for Mining

The province of Ontario ranks first amongst the provinces in diversity and value of mineral production and the mineral industry secures practically all its power requirements from water power. Here again much of the power is developed by central station organizations under the control of the mining companies, the principal producers being the Canada Northern Power Corporation and International Nickel Company of Canada already referred to. In addition the Wahnapitae Power Company which has been recently acquired by the Hydro-Electric Power Commission of Ontario operates three stations in the Sudbury district aggregating 16,900 h.p., the Algoma district is served from two stations aggregating 21,170 h.p. and the Red Lake district by a recently completed plant of an initial installation of 5,000 h.p.

Quebec

The province of Quebec with a total area of some 600,000 square miles is comprised in two main drainage basins, the St. Lawrence river and gulf and James and Hudson bays. There are also smaller areas which drain respectively into the Bay of Chaleur, into the St. John river and thence through New Brunswick and a third, the Koksoak, which flows into Ungava bay.

North of the St. Lawrence practically the whole territory is part of the Laurentian plateau which, as has already been stated, is favourable to the widespread location of water powers both great and small. South of the St. Lawrence and west of a line from the City of Quebec to the foot of Lake Champlain the country is a comparatively flat plain broken only by hills rising abruptly to heights of about 1,000 feet. East of this line the territory becomes more rugged being part of the Appalachian highlands.

Throughout the St. Lawrence basin precipitation ranges from 30 to 40 inches annually while towards the Hudson bay it diminishes to 25 inches or less.

Available Water Power Resources

The total available resources of the province of Quebec are estimated to be 8,459,000 h.p under conditions of ordinary minimum flow or 13,064,000 h.p. ordinarily available for six months of the year.

There are a great many rivers in the province with large power resources — the St. Lawrence with from two to two and a half million h.p., the Saguenay with from one and a quarter to one and a half million and the St. Maurice with upwards of a million h.p., are the largest with many others having capacities of from 100,000 to 1,000,000 h.p., in fact, there is no section of the province far removed from available water power.

Developed Water Power

The present turbine installation in the province is 2,572,418 h.p., more than double what it was at the time of the First World Power Conference, while there is no abatement in construction operations. A 260,000-h.p. initial development is expected to be completed on the Saguenay in 1931 and expanded later to an ultimate installation of 1,000,000 h.p.; another development on the Lievre of 90,000 h.p. initial and 120,000 h.p. ultimate installation is under construction; a 500,000-h.p. development at Beauharnois on the St. Lawrence has recently been commenced and many others are in active prospect.

Utilization of Developed Power

As in Ontario, the use of power is most easily treated under the sub-headings of Central Station, Pulp and Paper, and Mining, bearing in mind that many central stations provide power for the manufacture of paper and for the mining industry, whilst other power plants which were developed primarily for these industries also do a central station business.

Central Electric Station Development

The more notable central electric station developments are those of the Gatineau Power Company which operates 6 plants aggregating well over half a million horse power on the Gatineau and Ottawa rivers in the Hull-Ottawa district and 12 smaller stations serving the district along the north shore of the Ottawa river between Hull and Montreal; the Montreal Light, Heat and Power Consolidated serving the city and district of Montreal from three stations totalling 229,500 h.p. on the St. Lawrence and one of 21,600 h.p. on the Richelieu river; the Southern Canada Power Company serving the district south of Montreal to the International boundary from five stations totalling 58,580 h.p.; the Shawinigan Water and Power Company and subsidiaries serving the districts along the north shore of the St. Lawrence from Montreal to Murray bay east of Quebec City and between the St. Lawrence and the International and New Brunswick boundaries from sixteen stations with a total installation of 647,850 h.p. and the Duke-Price Power Company operating a 495,000 h.p. station at Isle Maligne on the Saguenay river. This latter station serves large pulp and paper and aluminum industries as well as other local demands. The transmission systems of all of the above mentioned organizations are interconnected for the exchange of power. The generating stations and transmission systems of the populated section of Quebec are illustrated on figure No. 11 which serves to show that hydro-electric energy is everywhere available in ample quantity to meet the industrial and domestic demands of the province.

Pulp and Paper Installations

In the province of Quebec there are 53 mills utilizing hydro-electricity in the production of pulp and paper. The mills maintaining and developing their own power have an aggregate turbine installation of 215,736 h.p. of which 145,296 h.p. is direct connected to mill machinery and 70,440 h.p. to electric generators. In addition to the mills purchasing all their power requirements many of the mills developing power supplement it by purchased power. The supply of power for industry will shortly be increased by the completing of a 90,000-h.p. development on the Lievre river to supply a pulp and paper mill being built near Buckingham.

Power for Mining

Under this heading should also be included power used in the production of aluminum and in electro-chemical industries. Comparatively recently the Rouyn mining area has been opened up and is supplied by a development on the Quinze river which has already been mentioned as furnishing power for mining in Ontario. This plant is operating under 70-foot head with an installation of 40,000 h.p. It is proposed to increase the capacity to 56,000 h.p. by raising the head to 90 feet. At Shawinigan Falls on the St. Maurice river there is a substantial electro-chemical industry obtaining power from the St. Maurice river

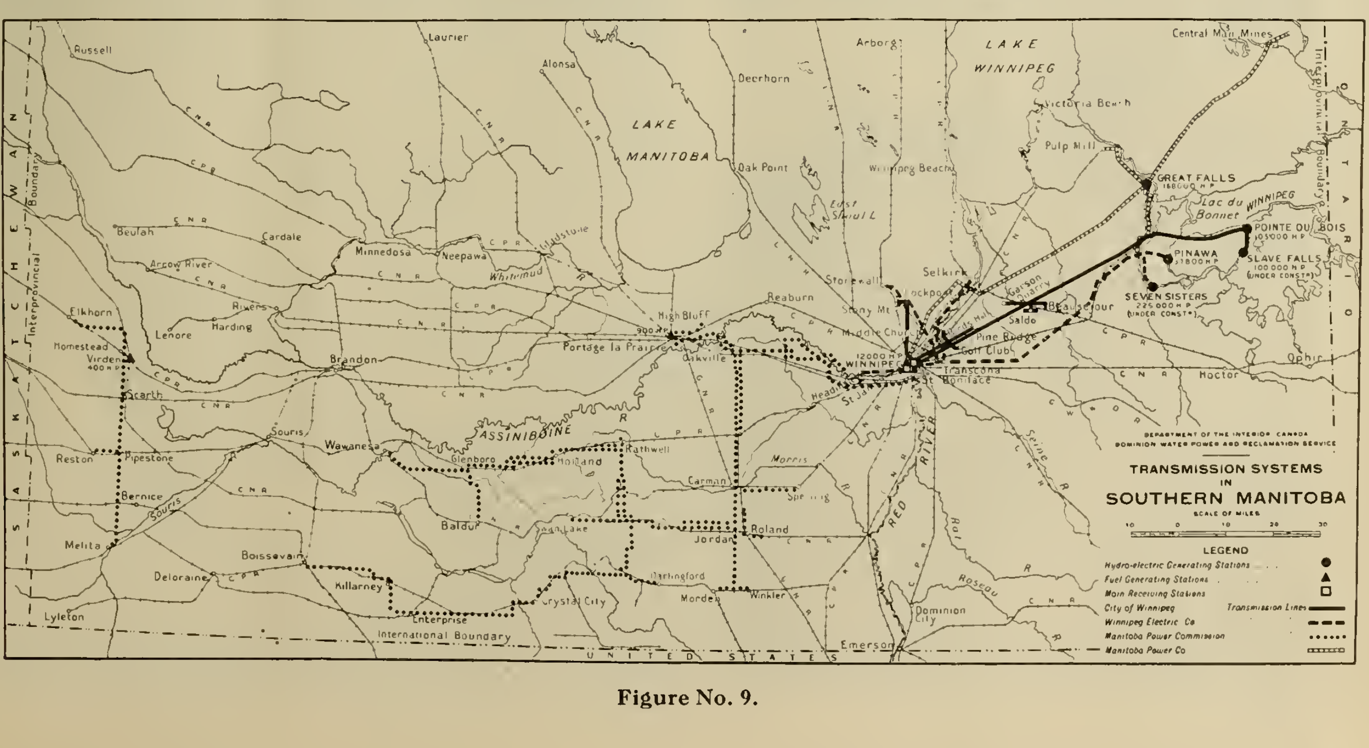

Figure No. 9.

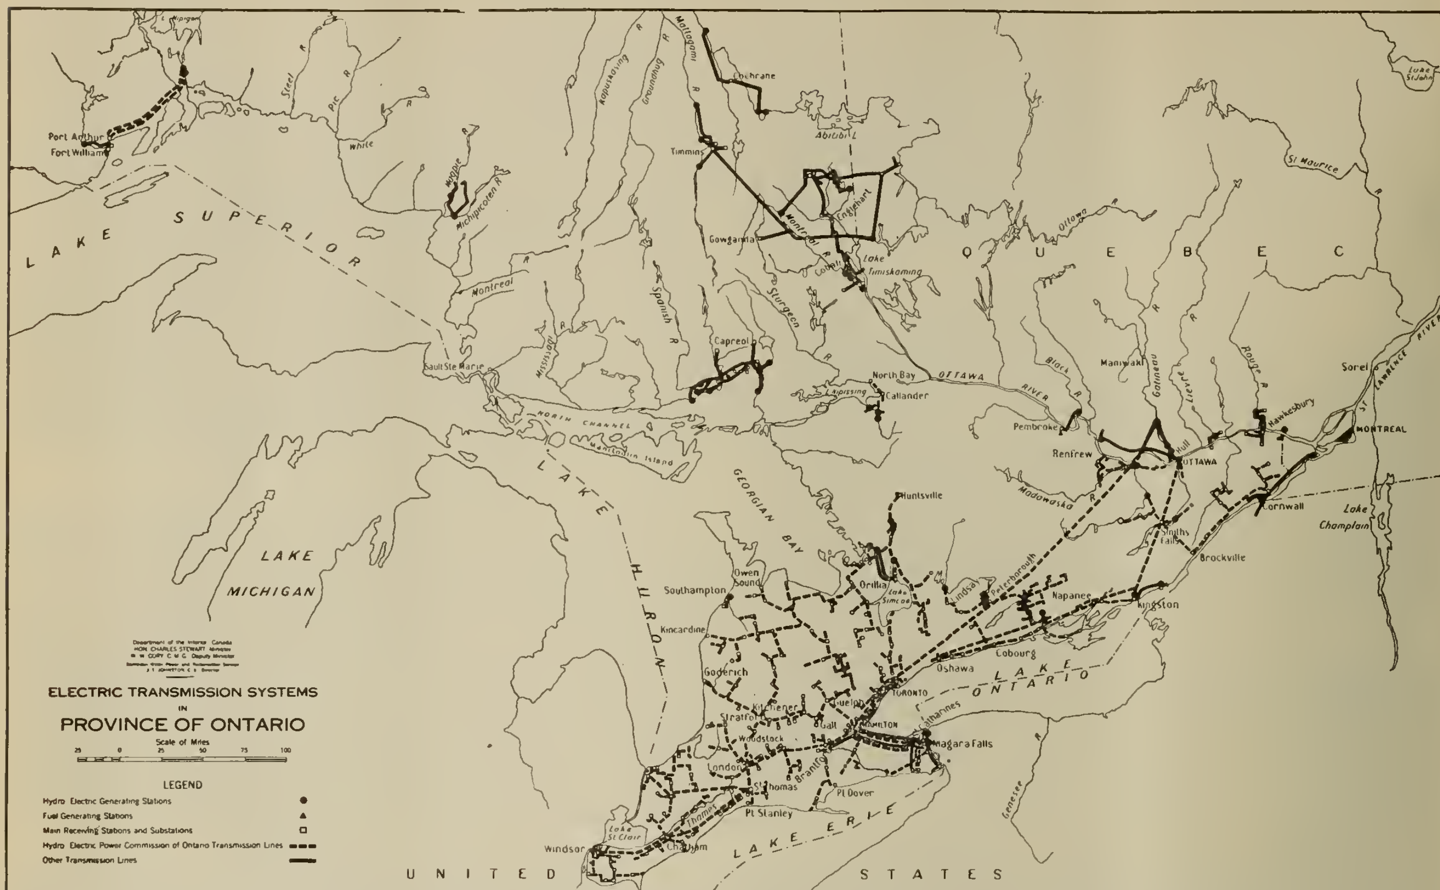

Figure No. 10.

stations. Recently the Aluminum Corporation of Canada established a plant for the production of aluminum at Alcoa. This industry at present secures power from the Isle Maligne development, though a subsidiary the Alcoa Power Company has commenced a hydro-electric development at Chute-a-Caron on the Saguenay river which, as already stated, will have an initial installation of four 65,000 h.p. units to be completed in 1931 and an ultimate capacity of about one million horse power.

Storage Developments

An outstanding feature of power development in the province of Quebec has been the construction by or under the control of the Quebec Streams Commission of storage dams to regulate and augment the flow of streams so as to greatly increase their available power. Such dams have been constructed on the St. Maurice, St. Francois, Ste. Anne-de-Beaupre, Metis and Gatineau rivers and on Lake Kenogami. The most recently completed storage project, that on the Upper Gatineau river, was commenced in 1926 with the construction of the Mercier dam and has just been brought to a successful conclusion by the completion of the Cabonga dam. It provides two reservoirs for the regulation of the Gatineau river, the Baskatong of 96,000,000,000 cubic feet and the Cabonga of 45,000,000,000 cubic feet. The Commission has an extensive storage project under way at the present time to regulate the flow of the Lievre river by a reservoir of 25,000,000,000 cubic feet at Cedars rapids while it has recently been announced that the Shawinigan Water and Power Company under the authority of the Commission will construct a reservoir on the Mattawin river which will warrant an addition of 100,000 h.p. to the company's plants at Grand'Mere, Shawinigan Falls and La Gabelle.

Maritime Provinces

The provinces of New Brunswick, Nova Scotia and Prince Edward Island, with a total area of about 51,000 square miles, are known collectively as the Maritime provinces and both geographically and geologically differ completely from Ontario and Quebec. The Laurentian plateau does not extend into these provinces, the climate is more moderate, the precipitation greater and the watersheds are smaller. The ample precipitation of from 40 to 55 inches annually, comparatively high altitudes approaching to the seashore and many natural reservoir sites, all contribute to the making of a number of attractive power sites. These sites when compared to those already discussed are relatively small but are nevertheless of considerable aggregate capacity and constitute a valuable economic natural resource.

Available Water Power Resources

The aggregate resources of these provinces is 82,400 h.p. under conditions of ordinary minimum flow and 302,900 h.p. for six months of the year, but with storage will justify a turbine installation considerably in excess of the larger figure, in fact the installed capacity is already 223,076 h.p.

Developed Water Power

The present installation in New Brunswick is 112,131 h.p., in Nova Scotia 108,406 h.p. and in Prince Edward Island 2,439 h.p. In New Brunswick there is one large development, that of the St. John River Power Company at Grand Falls on the St. John river where 60,000 h.p. is installed of an ultimate 80,000 h.p. capacity. Other substantial developments are 14,000 h.p. on the Nipisiguit river and 11,400 h.p., on the Aroostook river. The New Brunswick Electric Power Commission has now been in operation for about 10 years and distributes power in a number of districts. This power is produced in the Commission's own 11,100-h.p. station on the Musquash river, supplemented by power produced in privately owned stations. In Nova Scotia recent power development has been largely due to the Nova Scotia Power Commission which has developed a number of sites to supply power for both general distribution and for sale in bulk for industries. The number of the Commission's installations is now ten and the aggregate installation 60,905 h.p. or over 56 per cent of the total for the province. Water power development in Prince Edward Island is limited by the small extent of the power resources which consist of a number of mill-sites on small streams in the main only large enough to supply energy for a mill or small community. The most recent development was of 160 h.p. completed in 1927.

Utilization of Developed Water Power

Approximately 75 per cent of the developed power in New Brunswick is distributed by central electric stations, reference to figure No. 12 showing the considerable areas enjoying such service. Pulp and paper mills of which there are six operating on hydraulic power either developed as part of the mill project or purchased from central stations maintain an installation of 13,728 h.p. of which all but 1,900 h.p. is converted to electricity.

In Nova Scotia approximately the same conditions obtain as in New Brunswick. Almost 71 per cent of the power is installed in central electric stations and the pulp and paper mills of which there are eight operating and one under construction have an installation of 16,008 h.p. all directly connected to mill machines and also purchase considerable electric power from the central stations.

The Yukon and Northwest Territories

These territories have a total area of one and a half million square miles and aggregate power resources estimated at 294,000 h.p. under conditions of ordinary minimum flow and 731,000 h.p. for six months. These estimates are based, in the main, on the reports of members of the geological survey and other explorers and not upon actual measurements of flow and fall, although some reconnaissance measurements have been taken in the Yukon. The development of power is so far restricted to the Yukon and amounts to 13,199 h.p. used for the supply of Dawson and to supply power for gold dredging operations in that area. It is possible that the development of silver-lead properties in the Mayo district will require water power development, whilst a number of sites in the Great Slave lake areas are being spoken of to supply power for the working of recent mineral discoveries to the south of that lake. It is possible, therefore, that with the opening up of northern Canada there will be in time a considerable amount of water power development in the Northwest Territories.

III. Administration

Recent Water Power Legislation and Tendencies of Administrative Policy

Introduction

The third section of the paper on Canada's water power resources presented at the First World Power Conference in 1924 contained a description of the administrative policies and procedures adopted in the various parts of Canada for the control of water power development and a synopsis of the basic laws in force in each province. No important changes have been made in these policies and laws since 1924 and the great increase in development already described has taken place in accordance with administrative principles now well established which have proved sound and adequate to meet the conditions of an expanding and highly specialized industry.

The two main principles on which water power development is based throughout Canada may be described

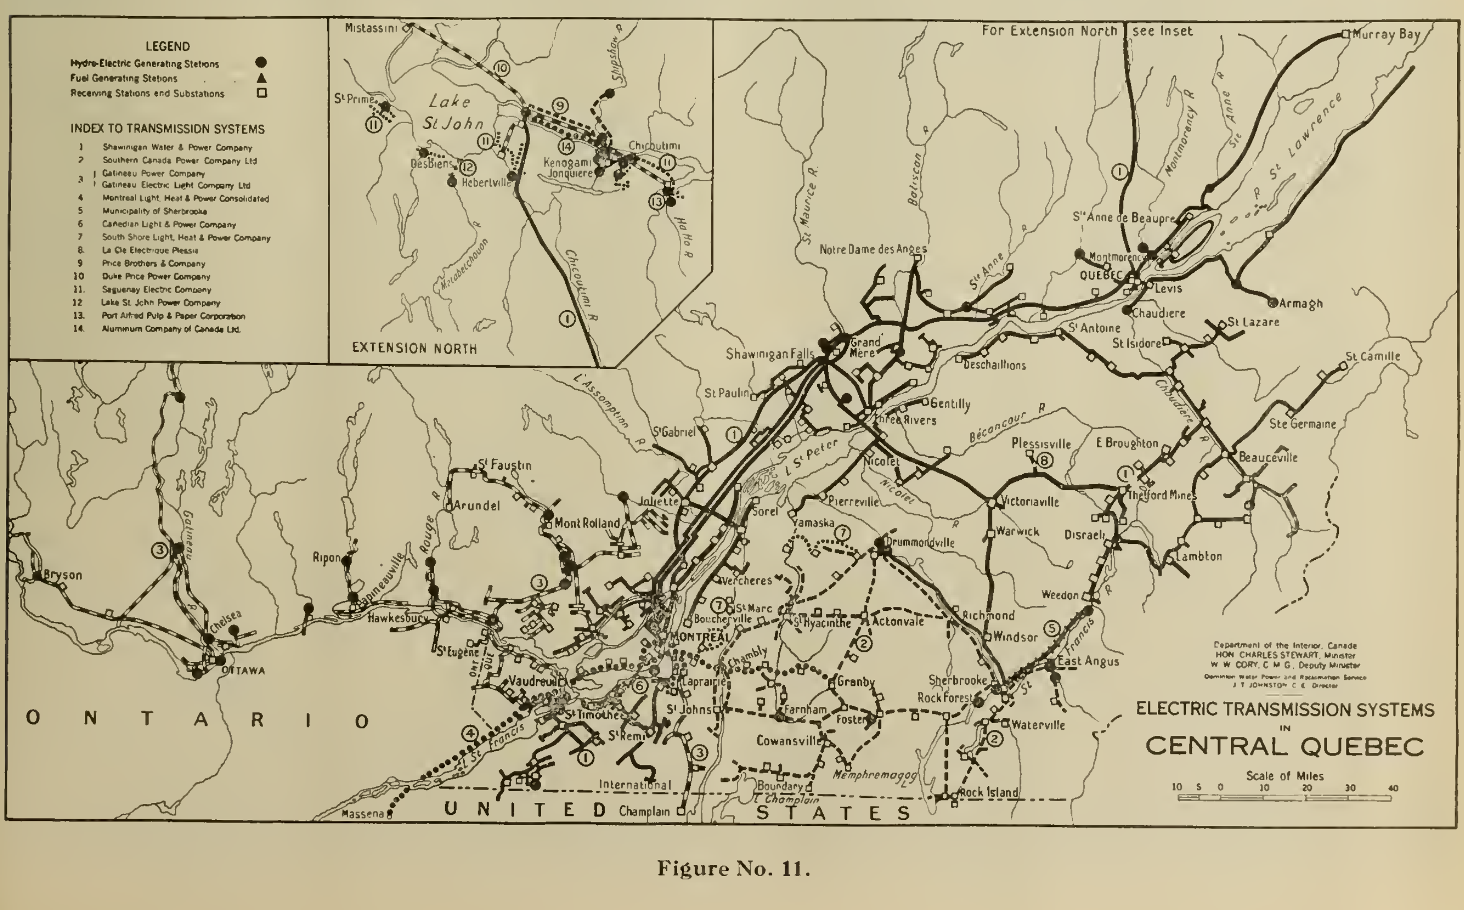

Figure No. 11.

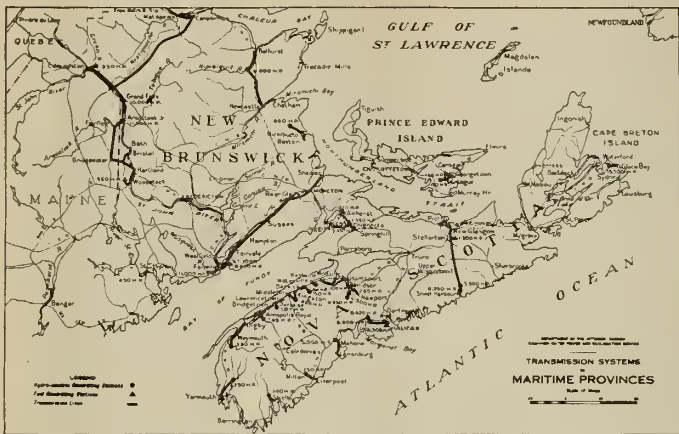

Figure No. 12.

as public ownership and operation under government agency and private ownership and operation under controlled conditions, or more specifically,—

(1) Development of power sites and transmission and sale of power at cost by a commission appointed by a provincial government, acting under legislative authority and financially supported by the credit of the province;

(2) Granting of power privileges to municipalities, companies or individuals by lease or license for a definite term, under government control of rates and service and subject to charges for the privilege granted

Power sites privately owned may also be developed upon complying with the Dominion and provincial laws in regard to works in water, but subject, in the cases of public utilities, to control of rates and service.

Public ownership with the supply of power at cost is general throughout the greater part of Ontario, and has been adopted on a smaller scale in New Brunswick, Nova Scotia, Manitoba and Saskatchewan. In Manitoba, the Power Commission operates an extensive system of transmission but buys nearly all the power which it distributes. In Saskatchewan, a Power Commission was appointed in 1929 under authority of an act of the Legislature passed early in that year and based on the similar acts already in force in Ontario and other provinces. The Commission has begun its operations by acquiring the municipal fuel-power plants in Saskatoon and some of the neighbouring towns; and by making suitable interconnections has thus begun to build up a power system.

Privately owned developments play an important part in supplying the power requirements of all the provinces and, in some cases, the outstanding or major part. Power companies operating sites leased from the Crown have built up great undertakings in Quebec, northern Ontario, Manitoba, Alberta and British Columbia which form the basis of the industrial and domestic well-being of these areas. The sale of blocks of power at economic rates from privately owned developments to the public ownership commissions constitutes an important factor in balancing power supplies with the demand in several important areas and jointly and beneficially meets the purposes and requirements of the two types of development.

Public ownership and municipal and private enterprise are thus to be found side by side throughout Canada either in the same or in neighbouring provinces and the two policies, so different in principle, are alike in the great results which they have achieved. The outstanding example in Canada of public ownership is the Hydro-Electric Power Commission of Ontario which has become the world's largest power producing and distributing agency. The group of power companies serving the metropolitan district of Montreal and adjacent areas and those supplying similar facilities in other provinces show the possibilities of private enterprise. The descriptions of these developments in the earlier part of this paper bear testimony to the great progress which has been made in hydro-electric practice under both administrative policies.

The reader is referred to the previous paper of 1924 for a general survey of water power legislation in Canada and of the policies which have been adopted to aid in the production of low-cost power, but it may be repeated, in order to make clear what follows, that under the plan of self-government which has been adopted for the Dominion of Canada, those provinces which in a general sense own their natural resources have, through their legislative assemblies, the exclusive right to determine the conditions under which the water powers within their territorial boundaries may be developed and used, while in those provinces wherein the natural resources are still vested in the Crown in the right of the Dominion, the water powers are administered by the Parliament of Canada.

The provinces which directly control their water power resources are Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. In the others, Manitoba, Saskatchewan and Alberta, the water power resources are administered under Dominion legislation, as also in the parts of Canada lying outside the provinces, namely, the Yukon and Northwest Territories. In the railway belt of British Columbia, which is a strip of land twenty miles in width on either side of the main line of the Canadian Pacific Railway across the province, transferred by the province to the Dominion as an aid towards the construction of the railway, the water powers belong to the Dominion but their administration has been entrusted to the province, to be dealt with under the general water power laws of the province, for economic reasons.

Dominion Control of Navigable Waters

The absolute right of those provinces which own their natural resources to deal with the water powers within their boundaries is limited by the control of the Dominion over all works in navigable waters. "The Dominion Parliament, which has authority to legislate for the conservancy of navigation, has, beyond doubt, a right to declare what shall be deemed an interference with navigation, and to control all works erected in navigable waters." (Chief Justice Strong, 26 S. C. R. at 538.) In pursuance of this right the Dominion Parliament has enacted that,—

"No work (subject to certain minor exceptions) shall be built or placed in, upon, over, through or across any navigable water unless the site thereof has been approved by the Governor in Council, nor unless such work is built, placed and maintained in accordance with plans and regulations approved or made by the Governor in Council." (R. S. C. 1927 c. 140 s. 4.)

The nature and extent of the Dominion's control over navigable waters have been freely discussed in recent years and the subject is one which is full of difficulty and of much concern to the provinces. In order to define the respective rights of the Dominion and the provinces with regard to water powers in navigable rivers, especially those which are interprovincial and international in character, the Dominion Government, after consulting with the provincial governments, drew up a series of questions which were submitted for elucidation to the Supreme Court of Canada in October 1928. The questions, however, proved to be of too hypothetical a character, and the court declined to answer them in categorical terms. The decision of the court upon these questions leaves the whole subject much as it was before, but the general conclusion as expressed in this judgment is that a province has the right to control or use the waters in provincial rivers and to develop or authorize the development of water powers within the province, provided that in so doing navigation is not prejudiced and that the province complies with Dominion requirements as to navigation, and provided further that there is no valid conflicting legislation by the Dominion under an overriding power, such, for example, as the Dominion jurisdiction with respect to canals connecting a province with any other or others of the provinces or extending beyond the limits of the province. (See Re Water Powers Reference, Canada Law Reports, 1929.)

Exportation of Hydro-Electric Power

In 1907 the Parliament of Canada passed the Electricity and Fluid Exportation Act which prohibits the exportation from Canada of electrical power or energy together with petroleum, natural gas, water or other fluid except under license to be granted by the Governor in Council upon such conditions as he thinks proper. Under authority of this act, regulations were established by the Governor in Council on November 4, 1907, setting out the conditions for the granting of export licenses. The principal features of these licenses are that they must be renewed annually and are revocable at will by the Governor in Council if the licensee refuses or neglects to comply with any of the conditions from time to time imposed by the Governor in Council under the act.

Section 10 of the act of 1907 provides that the Governor in Council may impose export duties not exceeding ten dollars per annum per horse power upon power exported from Canada. In accordance with this provision, an export duty of three one-hundredths of one cent per kilowatt hour upon power exported from Canada became effective on April 1, 1925. This duty is payable monthly by the licensee and is in addition to the yearly license fee of from $25 to $50 per annum. During the fiscal year ending March 31, 1928, the duty paid on power exported amounted to $373,676.21.

Dominion Water Power Legislation

The Dominion Water Power Act remains unchanged since its passage in 1919. The regulations of 1921 under that act have been amended only by an Order in Council of September 10, 1928, which broadens the discretion of a regulating authority in determining the fair rate of return which a water power licensee may be permitted to earn and introduces the principle that current rates of wages must be paid to all those engaged in the construction, operation and maintenance of developments authorized by the act. The act and regulations, which were prepared with the greatest care, have proved eminently satisfactory as a means of encouraging water power development and protecting both public and private interests. Although the rights granted are for a definite term of years only, and the Crown reserves the right of recapture, more than $80,000,000 have already been invested by private and municipal enterprise in undertakings based upon these regulations.

The only recent legislation dealing with Dominion water powers is an act entitled An Act Respecting Water Power in the Provinces of Alberta, Saskatchewan and Manitoba, passed in 1929, which authorizes the Government of Canada to enter into agreements with the governments of the three provinces named, or any of them, for the transfer to the provincial governments of the administration of the ungranted water powers on Dominion lands in these provinces. The water powers are then to be administered under provincial laws in a manner similar to that in which the province of British Columbia administers the water powers in the railway belt of that province. Up to the present time no agreements have been made under this act, but Alberta early in 1929 passed legislation to provide for the administration of their water powers in the event of the transfer taking place.

Provincial Power Commission Acts

The provincial acts governing the operations of the power commissions in New Brunswick, Nova Scotia, Ontario and Manitoba remain substantially unchanged since 1924, although many amendments on minor points have been made as experience has shown to be desirable. Important additions have been made to the Ontario and Manitoba acts for assisting in the supply of power in rural districts. The Saskatchewan Power Commission Act of 1929, by means of which that province has now entered on the field of public ownership of power supplies, is very similar to the other corresponding provincial acts and provides adequate authority for the development, distribution and supply of power throughout the province by government agency. As a means of regulating the operations of privately owned supplies of power, public utility commissions have now been established in every province. The most recent act of this nature which provides for the establishment of a public utility commission in Prince Edward Island is described in the section below dealing with that province.

Water Power Legislation in British Columbia

The Water Act, 1924. The basic water power legislation in British Columbia, the Water Act, was consolidated in 1924 but the administrative system remains unchanged. In 1929, however, an important division was added by which the Board of Investigation became the Water Board and its duties were extended so as to make it a public utility commission with all necessary powers to enquire into and fix rates or tolls and conditions of service for all power companies in the province. There is a right of appeal from orders of the board to the courts. The act provides that every power company shall be entitled to earn a fair return on property used or reasonably held for use in service and that the Water Board in fixing rates must take this into consideration, but the act gives no indication of what constitutes a fair return. The regulations under the Water Act also remain unchanged.

Water Power Legislation in Ontario

In Ontario there has been no change in the regulations for leasing water powers on Crown lands, although the rental charged in new leases is usually one dollar per horsepower-year instead of fifty cents as formerly, the amount of the rental being at the discretion of the Minister of Lands and Forests.

The Water Powers Regulation Act which controls the use of rivers for power purposes also remains unchanged, but the Water Privileges Act and the Rivers and Streams Act, together with the Saw Logs Driving Act and the Timber Slide Companies Act, have been consolidated to form the Lakes and Rivers Improvement Act, R. S. O. 1927 c. 43.

Lakes and Rivers Improvement Act. The general purpose of the Lakes and Rivers Improvement Act is to specify the conditions under which lakes and rivers and their waters may be used for all purposes, to afford means for harmonizing conflicting interests making use of the waters of any particular stream and to regulate works in water. The provisions which particularly affect the owners or developers of water power sites are Parts I, II, and VII.

Part I provides for the approval by the Lieutenant-Governor in Council of dams or other structures for impounding water on all lakes and rivers to which the act applies. Dams already constructed may also be made subject to the act and the owner may be required to make repairs or improvements considered necessary for the protection of public or private interests. Officers may also be appointed to regulate the use of streams, including alterations in the flow and water levels. Part II corresponds to Part I of the Rivers and Streams Act and authorizes the Minister of Lands and Forests to determine without right of appeal the respective rights of users of any particular stream to which this part of the act is made to apply by proclamation. Part VII is the Water Privileges Act in revised form and enables the owner of a water privilege to obtain possession of the lands required for its effective utilization, including necessary transmission lines, subject to payment of compensation.

Power Commission Act. The operations of the Hydro-Electric Power Commission of Ontario, which have been described in Section II of this paper, are conducted in accordance with the Power Commission Act, consolidated in 1927 and now forming Chapter 57 of the Revised Statutes of Ontario 1927. No important changes have been made in the constitution or functions of the commission.

Water Power Legislation in Quebec

No change has been made in the policy by which the Quebec water powers are granted under the form of an emphyteutic lease, and the principal conditions of the standard form of lease are also unchanged. As regards legislation affecting private developments, this also remains practically unchanged, but while the substance of the legislation remains the same, the form of arrangement has been altered by the revision of the statutes adopted in 1925. In this revision the previous system of compiling the statutes as a whole in the form of a code has been abandoned and the statutes are now divided into separate chapters. For example, the reserve of three chains along the banks of non-navigable rivers and lakes, Crown granted since June 1, 1884, is now section 7 of the Quebec Fisheries Act.

The Water-Course Act. The legislation which most directly affects the owners or developers of water power sites in Quebec is the Water-Course Act which collects together in one act a number of the provisions previously scattered through different articles of the code. Of the seven parts into which this act is divided, Divisions I, II, III and VI relate to water power development. Division I affirms the right of the administrative authority to alienate or lease the beds and banks of navigable rivers and lakes, subject to certain conditions. Division II deals with the right of riparian owners to improve water-courses for power and other purposes. Division III authorizes the expropriation of lands required for the utilization of privately owned power sites and Division VI sets out the conditions governing the construction and maintenance of storage reservoirs.

Quebec Streams Commission. The legislation governing the operations of the Quebec Streams Commission, already described in Section II of this paper, was originally passed in 1911 and now forms Division VII of the Water-Course Act.

Prohibition of Exportation of Power. Water power development by private and municipal enterprise continues to be general in Quebec, but in recent years close attention has been given to the conservation of water power resources and their utilization in the best interests of the province. To this end, the exportation of power in which the Crown has an interest was prohibited by an act passed in 1926. The first two sections of this act as follows,—

(1) Every sale, lease or grant whatsoever of water powers, belonging to the province or in which it has rights of ownership or other rights, made on or after the 24th of March, 1926, shall contain a clause prohibiting the exportation, outside of Canada, of the electric power which may be developed in this province.

(2) Every contract, permit or grant authorizing, from and after the same date, the installation or passage of transmission lines, in or over the Crown domain, shall likewise contain a similar prohibitive clause.

The same prohibitions apply to existing contracts unless reported to the Minister of Lands and Forests within three months after the coming into force of the act and to renewals of such contracts. This act does not prohibit the export of power from Quebec to another province, and large contracts have been made in recent years for the export of power from Quebec to Ontario.

Water Power Legislation in New Brunswick

Since 1924, the chief interest in water power development in New Brunswick has centred in the operations of the New Brunswick Electric Power Commission and the development of Grand Falls by the St. John River Power Company.

The latter was incorporated by act of the provincial legislature in 1926 and authorized to develop power at Grand Falls and for that purpose to divert and regulate the flow of the St. John river, to develop storage in New Brunswick and beyond its borders and to transmit and distribute power anywhere in New Brunswick and beyond its borders. The power company, which is a subsidiary of International Power and Paper Company, Limited, acquired the rights and property of Grand Falls Company, previously incorporated with a provincial charter, and was also granted certain property and storage rights belonging to the province. In connection with the development of storage, the act provides that the owners of other power developments on the St. John river are to contribute to the cost, by payments to the power company for benefits derived from the company's storage "based on the ratio of the respective increases of dependable continuous power at each site created by such storage."

Water Power Legislation in Nova Scotia

The Nova Scotia Water Act, which vests in the Crown the right to the use of water and water-courses in the province, has not been amended since 1920 and is now Chapter 26 of the Revised Statutes of Nova Scotia, 1923. In 1926 the Chairman of the Nova Scotia Power Commission was appointed the Minister to have charge of the administration of the Water Act and the Regulations under it. These Regulations are still substantially in the form in which they were approved by the Minister of Public Works and Mines in 1922.

Water Power Legislation in Prince Edward Island

In 1929 Prince Edward Island fell in line with the other provinces of Canada by passing a Public Utilities Act providing for the appointment of a commission of three members by the Lieutenant-Governor in Council to deal with motor bus services, telephones, light, heat and power companies, and municipal undertakings of a like nature. The commission is given the usual powers to regulate effectively the rates charged and service rendered by public utilities and an appeal may be taken from any of its decisions to the provincial Court of Appeal. The annual expenses of the commission are to be borne by the several public utilities under its jurisdiction in proportion of their gross earnings.

Recent Trends in Water Power Development in Canada

T. H. Hogg, D.Eng., M.E.I.C.,
Chief Hydraulic Engineer, Hydro-Electric Power Commission, Toronto, Ont.

Paper presented before the Second World Power Conference, Berlin, Germany, June 16-25, 1930.

The activity in hydro-electric development in Canada, during the past five years, has been phenomenal. The demands of domestic, commercial and industrial load in the communities throughout the country have exerted a steady and increasing pressure in the fields of design and construction. At the end of 1923, turbine installations had a capacity of 3,200,000 horse power, and at the end of 1928, 5,350,000 horse power. Furthermore, new developments under construction at present will have an additional aggregate capacity in excess of 1,000,000 horse power.

Particular industries have, on their own initiative, been responsible for some of the outstanding developments in Canada today, and the co-ordination of the water power resources with those of the mines and forests has resulted in the establishment of communities in areas which, a few years ago, were known to few, other than prospectors and surveyors. These new industrial centres, which are growing on the frontiers of our provinces, are the future markets for power, creating a further stimulus to manufacture. This development brings sharply into relief the realization that cheap power, such as abounds in Canada's water power resources, is destined, more than any other single contributory factor, to lay the foundations of the country's future industrial growth.

In recording the immense increase in the utilization of hydro-electric power throughout the Dominion, reference should be made to the systematic investigations carried out by the Dominion Water Power and Reclamation Service of the Department of the Interior from coast to coast. Through the agencies of this organization there have been co-ordinated the stream measurement studies of all the provinces, with the result that the financier and the engineer interested in the development of hydro-electric energy are in a position to plan their undertakings upon dependable stream flow data secured by uniform methods and with standardized equipment.

The above named organization has supplemented its stream flow studies in the territory of western Canada, over which it has administrative jurisdiction, with detailed power and storage surveys of all the power rivers within the reach of early commercial exploitation. All these data are made available without cost to those interested in the development of the Dominion's water resources.

Water power development in Canada is governed, in general, more than ever before, by the consideration of economy. This has always played a prominent part in the design and construction of plants, in conformity with the conditions existing at the time of their inception; but the possibility, and, in some cases, the actuality of restriction in water supply, head and convenient and cheap power sites, have brought into prominence methods of design and details of construction which were foreign to the field of water power development a decade ago.

With the exploitation of the cheaper and more easily developed water powers, the increasing power demand has turned attention to the more remote, and more costly, sources of supply. While the regions in which the great majority of water powers abound have no known native fuel resources, the rapid advances that have been made in recent years, and the promise of further advances in the low cost production of electrical energy from coal, bring closer the day when steam plants will challenge the present supremacy of hydro-electric power, even in these districts. This has called into play a tremendous effort to offset, in whole or in part, the additional cost of these more expensive developments by devices to increase the efficiency of the component parts of the plants, to the end that as large a proportion as possible of the potential energy of the stream may be converted into usable power. The reduction of loss of head in hydraulic structures, and the increased average efficiency of water wheels over their range of loads is of paramount importance. To increase the output and reduce the cost of investment are the primary objectives in power plant design at present, and indications point to the increasing stress on these aspects, as time passes. Further, economy is at times exercised in the reduction of operating costs, where the installation of automatic or semi-automatic plants can justifiably be made. For isolated plants, the curtailment of cost and increase in net revenue are dependent entirely on refinements in design and construction, details of which are illustrated below in the examples cited.

Simplified layouts are becoming numerous, with the rejection of all but essentials; conservation of water is more carefully considered, and storage of impounded water, together with reduction of leakage or diversion, is being carried to a further degree than ever before.

The structures conveying the water to and from the turbine, which are subjected to the closest scrutiny with a view to efficient design, are the intake works, canal, tunnel or pipe line, distributors and draft tube.

In the case of the mechanical equipment, steady progress has been made in turbines, governors and their appurtenances. The relief valve is being dispensed with where pipe line conditions warrant its omission and the governor be allowed to reduce pressure rise by adequate adjustment. These, and similar modifications when possible, are effecting substantial savings in development costs.

Simplification of generator design and an increasing use of outdoor transformer and switching stations are becoming evident.

The salient features in which methods of design and construction have progressed are discussed below, and illustrated by examples drawn from a number of developments built recently, or at present under construction.

Intakes

Among the important changes in the design of intakes is the omission of the superstructure for the same. The provision of special devices to perform the usual duties of a crane in the handling of the racks and headgates, and the proper consideration of the particular conditions for each development have permitted satisfactory operation in latitudes having most severe winter climates. The use of self-contained rack structures supported in checks in the headworks walls is another feature offering considerable advantage by permitting the easy and quick removal of the same when necessary. The heating of racks by low voltage electric current has been of considerable assistance in plants where frazil offers difficulties in operation.

Headgates, with roller trains rigidly attached to the body of the gate, are now being used to overcome the difficulties in operation of gates having loose roller trains. Where operation under high heads is necessary, the gates

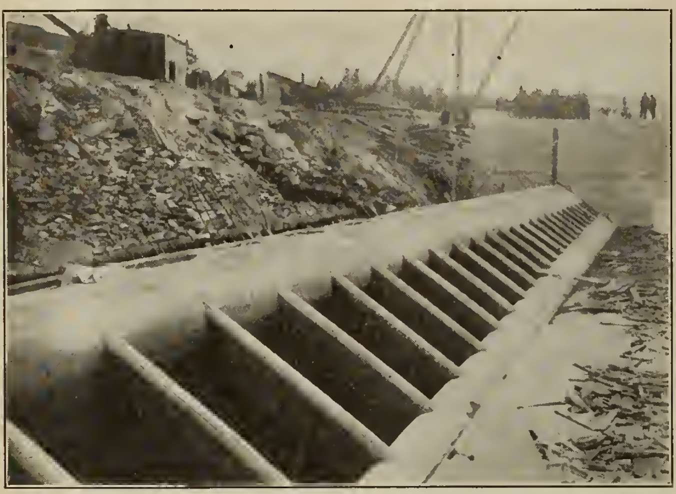

Figure No. 1.—Exterior of Intake Tube at Grand Falls Development. These Tubes, Two in Number, are 17½ feet in Diameter. The Vanes in the Intake Slot are set at Angles and Spaces Varied from End to End to Effect the Desired Distribution of the Draft throughout the Length of the Tube.

are now being built with a continuous roller train and fitted to rest on an inclined seat when in the closed position. New forms of sealing devices are also being introduced, and in this connection the use of a flexible brass sealing strip has proven very satisfactory.

The draft distributor proposed by Messrs. Johnson and Wahlman, for the Queenston development on the Niagara river, was described at the former conference. The feature of this design is that a uniform draft is secured through the full length of the distributor. This same type has been built in several installations since then, where reduction of intake loss and protection from floating debris or ice were imperative, and its use in the future will probably be more general. It offers particular advantage where the water supply is to be drawn from a shallow head pond, by materially reducing excavation necessary to secure the required depth as compared with the more conventional type. An intake of this type, which went into service recently, is that at the Grand Falls development on the St. John river in New Brunswick. This will be called upon to deliver 7,500 cubic feet per second to a tunnel 24½ feet in diameter.

Dams

In the development of water powers, it is to be expected that those sites offering the greatest natural head and requiring the least construction in the way of dams would be developed first. In consequence, an increasing number of plants are being constructed which involve the use of large dams to create the desired head. Such dams are usually higher and frequently of much greater length than those whose principal function is to maintain a head pond and to provide a proper seal for the intake to the water passages.

Several developments, in which dams of large proportions concentrate the river gradient, have been completed recently, or are at present under construction. Among these are the Ghost development on the Bow river in Alberta, the Seven Sisters development on the Winnipeg river in Manitoba, and the Alexander development on the Nipigon river in Ontario. As a result of the increased volume in such structures, there is presented a greater opportunity than heretofore for the economical use of the earth fill type of dam, although this type has been used in Canada for many years. Two examples are included in the above mentioned developments now under construction, namely, the Ghost and the Alexander plants.

At the present time there are two favoured methods being used in the construction of large earth fill structures, namely, the hydraulic fill and semi-hydraulic fill. The dam at the Ghost development is being constructed by the hydraulic fill method. In this case the material is handled by dredge pumps to pipes having outlets at suitable points for distributing material along the dam. As a result of the method of distribution employed, the finer material is carried to the centre of the structure to form an impervious core, and the coarser material is deposited in the outer section of the dam.

The dam which is being constructed for the Alexander development is of the semi-hydraulic fill type. In this instance the material is transported to, and deposited in, the sides of the dam by train and other mechanical means. By the use of hydraulic monitors, located on scows floating in a central pool, the finer material is segregated from the coarse, and is washed into the centre of the structure, forming a watertight core.

Both the above mentioned methods have proved satisfactory, and each has its advantages, depending on the conditions obtaining at the particular site.

In the case of masonry dams, no important changes have been made in the design or construction, except in the case of dams with steel gates, where more positive means are now being provided for the heating of the gate checks and of the gates themselves to prevent the freezing of the gate to the checks and the accumulation of ice on the face of the gate. Such provision makes it possible to operate the gates during the winter season, without danger of damage to the operating mechanism or without delays during times of emergency.

In the design of steel sluice gates, changes similar to those mentioned under headgates are being made to overcome the difficulties resulting from the breakages of roller train cables.

The use of fixed rollers on sluice gates of such large dimensions as are now used, required heavier operating

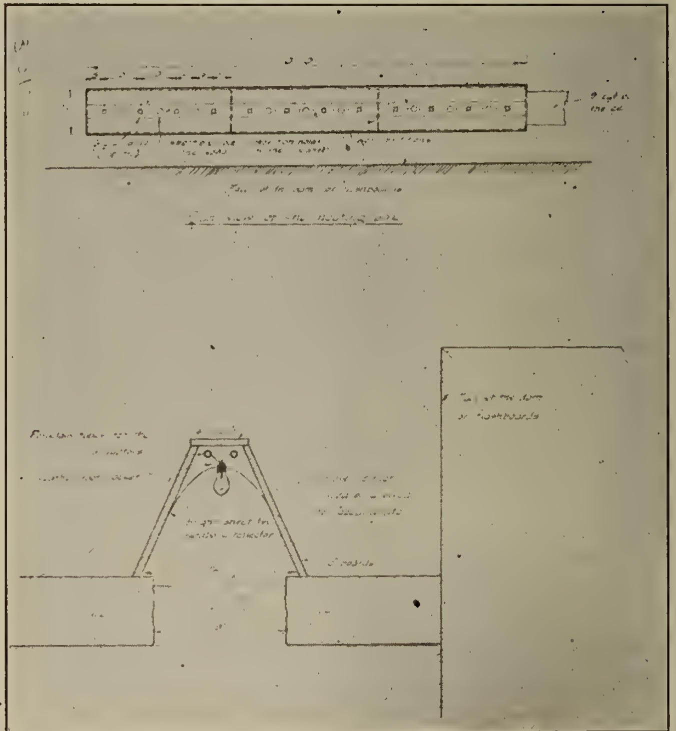

Figure No. 2.—To Relieve Ice Pressure on Dams, Reflectors of the Type Here Illustrated are used by the City of Winnipeg System to Maintain an Open Channel Close to the Face of the Dam.

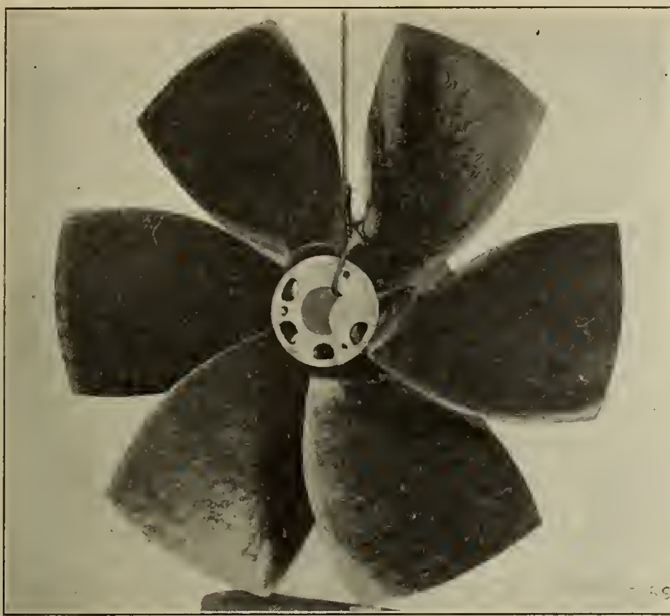

Figure No. 3.—Propeller Type Runner with Fixed Blades. The Turbine Runners at La Gabelle in Quebec and at Great Falls, Manitoba, are Identical with the One Illustrated. The Former have a Capacity of 30,000 Horse Power under a Head of 60 feet, and are 15′ 9½″ in Diameter, and the Latter have a Capacity of 28,000 Horse Power.

mechanism and heavier supporting structures for the same, without resulting increase in cost.

Where heavy ice forms on the head ponds of power plants, considerable attention has been given to securing protection against the ice action on the head walls, gates, dams and flashboards, particularly when the forebay is subject to much variation in level. Generally, the protection is secured by maintaining an open channel along the face of the structures by one of several methods, the most common of which are, cutting by hand or steam saw, by agitation of the water with compressed air, and by the use of heat reflectors mounted along the face of the structure.

Owing to the nature of the terrain over the greater part of Canada, very few examples of arch dams are to be found, but these are now making their appearance in the development of water powers in British Columbia, where the deep valleys of the Rocky mountains offer opportunities for the economical use of this type of structure.

Tunnels

In tunnel construction, considerable advance has been made in the case of large sections. Several well known examples exist where the cross-sections have greatly exceeded those used in former works. The Niagara Falls Power Company's pressure tunnel is mentioned, because of its great size, although situated in the United States on the Canadian border. It has a horseshoe section of cross-sectional area equivalent to a circle of 32 feet in diameter, with a concrete lining 18 to 24 inches in thickness.

The largest pressure tunnel in Canada is that of the Grand Falls plant in New Brunswick. The section is also of horseshoe shape, and equivalent to a circle of 24½ feet in diameter. It is lined with 18 inches of concrete.

The extension to the Shawinigan Falls plant, Quebec, includes a 20-foot diameter tunnel, lined with concrete.

In all of these, the greatest care was taken in design to obtain a channel of correct economic size, and, by construction methods, to have an alignment and a smooth surface finish that would reduce losses to a minimum.

Draft Tubes

Difference of opinion still exists regarding the respective merits of the various designs of draft tubes, with considerable favour going to the concentric type. While many of these have been constructed with satisfactory results, the increased cost of installation and the questionable advantage of this type in practical results, over its competitors, may result in a reversion to the cheaper, and withal efficient, elbow type of draft tube. Concentric draft tubes have been found to have a decided advantage, in many cases, in improving the part gate efficiency and in reduction of vibration and shock, due to variation of the draft-tube vacuum. There appears to be, however, a structural weakness in the high central cone used with certain types of concentric draft tubes, a number of cases having been reported where failure has taken place, probably due to repeated shock stresses. From the record of the performance of this central cone, it would appear advisable to have the cone built with a complete steel sheath filled with concrete. This steel cover acts both as reinforcement for the cone and also as the form work for the construction of the same. The limitation of the height of the cone to a point where the loosening of any part of the same would not permit its coming in contact with the runner, also appears as an advisable safeguard against serious damage as a result of any failure of this portion of the draft tube.

With runners having high specific speeds, pitting of the upper portion of the draft tube has been the experience in many instances. To assure quick and inexpensive repairs, renewable steel plates have been provided where the conditions were such that pitting was anticipated.

In low-head plants, the design of the draft tube becomes of greater importance, particularly with turbines of high specific speed, owing to the greater proportion of the total head represented by the draft head on the unit.

A recent development in connection with draft tubes is the use of ejectors, or underwater sluices, connecting directly from the intake to the draft tube chamber. These ejectors are controlled by submerged sluice-gates, which, when opened, permit of a heavy discharge into the draft chamber, thereby increasing the draft head and the capacity of the units. These are, of course, operated only during periods of high flow, when the tailwater is above normal level, and in conjunction with movable blade runners, they add materially to the output of the units at this time.

Water Wheels

Water wheels, for use in low head installations, are passing through a period of rapid development. The demand for increased efficiency in the use of water and for

Figure No. 4.—Runner for Back River Development. The Runner Illustrated is Rated at 8,800 Horse Power under a Head of 27 feet. Vanes may be adjusted Manually to Suit the Prolonged Reduction in Head, down to 18 feet, that is experienced in the Spring and Early Summer.

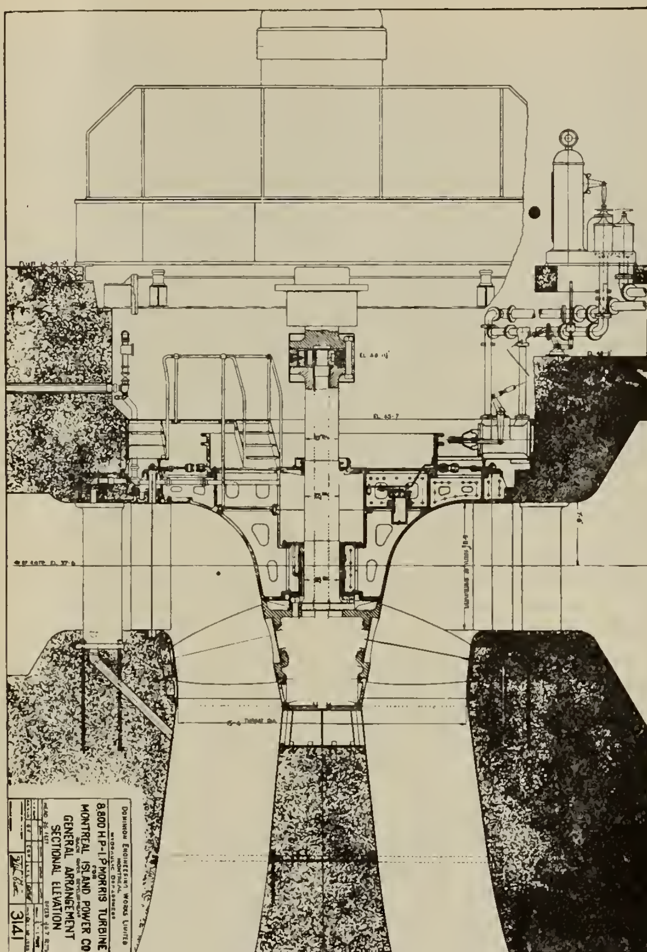

Figure No. 5.—Section Through One of the Back River Development Units. The Vanes are Adjustable, the Adjustment being effected at the Coupling Through the Hollow Shaft.

reduction in dimensions and number of units, has focussed the efforts of designers on the work of producing a high speed wheel to fulfil these requirements, with the result that the propeller wheel is rapidly dominating the low head field. This wheel has, until recently, been used in Canada with fixed vanes, but there are indications that movable vane type, or Kaplan turbine, may be employed more widely for such installations.

The earlier predictions regarding the limiting value of head under which propeller wheels could be justifiably selected, have been discounted. Actual installations of this type have been successfully made under heads up to 60 feet, with the probability of their use under higher heads. It is regarded in some quarters, with no little confidence, that successful use of the propeller wheel will shortly be made with heads in excess of 100 feet. Experiments are at the present time being conducted with this end in view.

A digression, to explain a condition common to many parts of the country that permits the efficient use of single unit plants with propeller type runners, may prove of interest at this point. There are large areas in various parts of the Dominion in which transmission networks, supplying hundreds of municipalities, draw energy from many different developments. By having centralized control of operation of a group of plants, it is possible to use all units at maximum efficiency, one or the other plant being shut down entirely, or run at maximum efficiency, as the load in the system varies from hour to hour. Propeller turbines, with fixed vanes, reach their maximum efficiency at or near full gate opening, and are usually inefficient at fractional gate openings. In large interconnected systems, it is possible to limit the operation of such turbines to loads at which they will be highly efficient. High maximum efficiency thus becomes of importance, and low part gate efficiency of less significance. In such cases, the advantage in part gate efficiency, possessed by the propeller turbine with governor controlled vanes, is discounted. The propeller turbine with fixed vanes is thus able, in large systems, to give efficient service, and, being less expensive and less complicated, has found frequent application.

These same conditions have prompted the use of plants in which the whole capacity of the site is developed in a single unit and, in general, in the use of as few units as the state of the art will permit. The consequent increase in unit capacity has enlarged the field of application of propeller and other high specific speed wheels.

In many low head plants there are periods, more or less protracted, during which the head available is reduced considerably below normal. The period of reduced head is usually coincident with a period of ample water supply. For these conditions, the fixed blade propeller unit is at a disadvantage and, in some cases, has been supplanted by turbines with manually adjustable vanes. An example of the installation of these turbines is found in the Back river development, about eight miles from Montreal. The Back river is one of the channels through which the Ottawa river reaches its outlet into the St. Lawrence. The average regulated flow is 20,000 cubic feet per second, for which condition the head is 26 to 27 feet. When the flow reaches a flood stage of 90,000 cubic feet per second, the head is reduced to 18 feet. There are six units installed at present, with an ultimate installation of ten. Three of the runners are 192 inches in diameter and have four vanes, and three are 185 inches in diameter with six vanes. The vanes are adjustable to suit the varying head and flow conditions, the adjustment being made manually and requiring that the unit be shut down. The adjustment will require only

Figure No. 6.—Francis Runner for West Kootenay Plant in British Columbia, Typical of Many Large Runners used Elsewhere Throughout the Country.

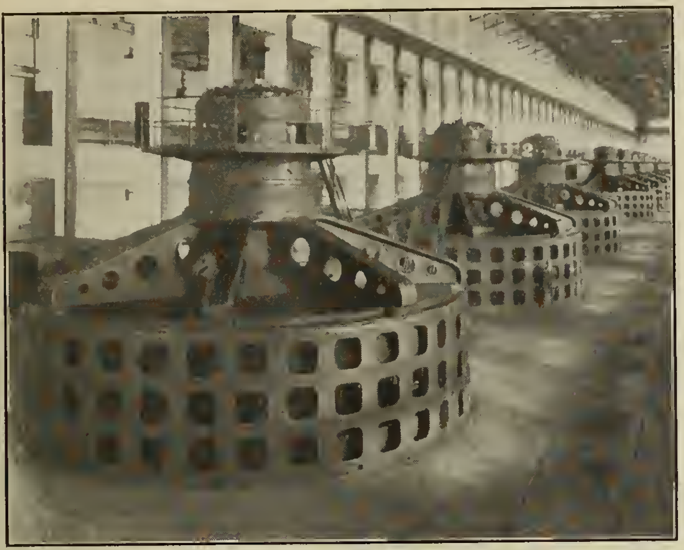

Figure No. 7.—Interior View of the Generator Room at Isle Maligne on the Saguenay River, Quebec. This Station contains Eleven Turbine Units Rated at 45,000 Horse Power under a Head of 110 feet. The Generators are rated at 30,000 Kv.-a.

a few minutes, and as the period of low head is of considerable duration, this is not a serious disadvantage, as compared with the resulting gain in power.

Among the typical Canadian installations in which propeller type runners of the fixed vane type are used, are those at La Gabelle in Quebec, and Great Falls and Seven Sisters in Manitoba. At La Gabelle the turbines are of 30,000 horse power capacity under a 60-foot head. At Great Falls, on the Winnipeg river, there are six 28,000 horse power units operating under a 56-foot head, and at Seven Sisters, on the same river, the installation now in progress will have runners with a capacity of 37,500 horse power under a head of 66 feet. In connection with the last, it is interesting to note that these units will operate at a speed of 138.5 r.p.m.

One installation of three Kaplan turbines is in progress in Nova Scotia at present, the first of this type to be used in Canada.

The quest for units of greater capacity and high speeds has produced runners (of the Francis type) having blades of decreased width or having a smaller number of blades. Both tendencies shorten the channel and guide the water less definitely and less positively. They also tend to increase the discharge. The combination of lack of guidance and the use of higher velocities result in a greater tendency towards pitting than is found with the original types of design. This shortening of the passages usually results in higher efficiency, offsetting the disadvantage of increased liability of pitting. Much attention has been given to means of overcoming this weakness, and, among others, reduction of the draft head and the coating of the runner with special alloys have been resorted to. While various degrees of success have attended these methods, it would appear that, if certain limiting relations of specific speed and head, and limiting values of draft head are exceeded, pitting may be expected. These facts have long been given consideration in connection with the fixing of speeds and setting for Francis turbines, but there appears to be a tendency to overlook the specific speed-head relation in dealing with propeller type units.

There are many plants where the periodic repair of pitted runners is considered as necessary maintenance. In many of these plants the saving in first cost, resulting from the higher speed, more than justifies the increased annual expenditure. Repair of pitted runners by electric welding is the universally adopted method. On plants having a number of units installed, it is a common practice to have a spare runner, in order that the time the unit is out of service is limited to that necessary to change the runners. In other plants, particularly with runners of large physical dimensions, the runners are welded in place at a considerable saving in time and expenditure.

Governors

Changes have taken place, and are in progress, in the flyball drive, governor control and governor pumping systems.

As between the arrangement of all the parts of the system in one housing containing actuator, servomotor and pumping system, and the arrangement of these parts separately from each other, the latter method has found greatest favour in Canadian practice.

The use of vertical units and development of automatic stations have focussed attention on the reliability of the driving power for the governor flyballs. Failure and slipping of governor belts have been experienced frequently, especially with vertical units. Electric motor drive for the flyballs has therefore been used to a great extent in new plants, and has replaced belt drives in a number of other cases. The motor drive assures reliability of service, gives finer speed control, and eliminates slippage and friction.

On certain governors the flyballs are of small size and require very little power to drive them. For these, ordinary instrument transformers connected to the generator leads, are sufficient. Numerous installations of this type are in service. For large flyballs, more driving power is required. In such cases, service transformers, or auxiliary generators, must be used. It is proposed to use auxiliary generators of small capacity, mounted on the main generator shaft, for

Figure No. 8.—Woodward Actuator Type Governor. This Type of Governor is used at the Cameron Falls Plant on the Nipigon River, and at the Paugan, Chelsea and Farmers Plants on the Gatineau River. In All of These Plants the Flyballs are Motor Driven.

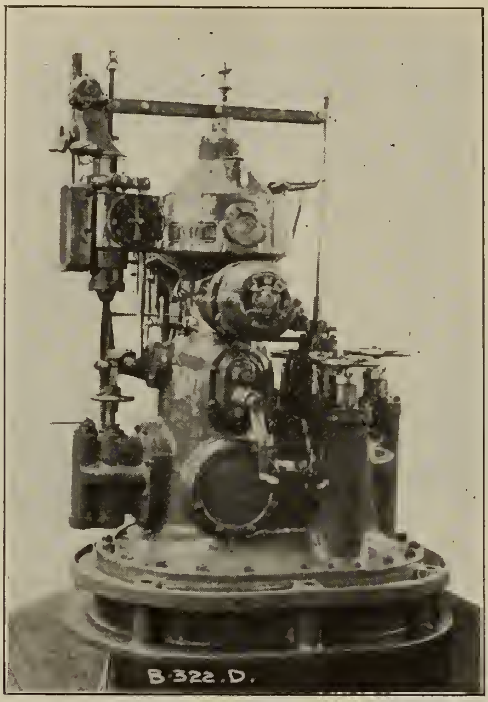

Figure No. 9. — Allis-Chalmers Governor with Motor-driven Flyballs.

new installations. No such arrangement is as yet in service in Canada, but a large development now under construction is to use this source of power for the governor drive.

Although electric flyball drives are generally considered more reliable than belt or gear drives, the practice is to equip the governors with sufficient safety devices to prevent overspeed, or other accidents, due to failure of power supply to the motor. As a further improvement, manufacturers are now equipping actuators with automatic load limiting devices, automatic synchronizing devices and locking devices for turbine gates and generator brakes.

Electric flyball drives are being used at the Back river development, the tenth unit in the Queenston development, at the Gatineau river plants, to name only a few, and generally on automatic plants.

As power stations with a number of large units came into use, there was departure from the practice of using oil as the governor fluid. Water, with sufficient potassium bichromate in solution to prevent rusting and to improve its lubricating quality, was substituted. At present, the largest power stations in Canada are operated with this governor fluid, and sufficient experience has been obtained to compare it with oil. It has been found to operate satisfactorily, if the system is kept clean. Otherwise, slimy matter tends to clog the more delicate parts of the governor mechanism. Constant care must be exercised to keep the correct percentage of bichromate in solution to prevent rusting.

Centrifugal pumping units of large capacity were found necessary in order to reduce heating of the governor fluid. Duplication of the pumping units was also necessary to assure continuous service. The centrifugal pump is at a disadvantage in the event of a drop in frequency, as the governor pressure is then reduced, crippling the whole system.

The unit system, however, still finds much favour, using small high speed pumps of the gear-rotary type, with oil as the transmitting medium. Flexibility and reliability are secured by interconnecting the pressure and return mains of the several unit systems.

Surge Tanks

While the surge tank has been necessary in many power plants, to afford relief for excess pressure due to sudden stoppage of flow in pipe lines, and to afford speedy acceleration of the water column on sudden demand, there are conditions developing in the field of power distribution that may permit its omission from some plants where formerly it might fairly have been considered indispensable.

In the case of isolated plants, the standpipe still offers the best means of furnishing extra flow in the event of sudden demand of load, but, in an interconnected system, the flywheel effect of all the rotating machinery exerts its influence on the speed regulation when load changes occur. In such cases the large available inertia is sufficient to maintain the system speed until the water column in the conduit is accelerated sufficiently.

The conditions arising from rejection of load on such a system are met by increasing the time of the governor stroke to such a degree that the pressure rise is kept within limits that may be provided for by reasonable structural design, the speed rise of the unit being controlled by the inertia of the connecting lines and the load of the whole system.

The above must not be read as meaning that the surge tank may be eliminated in all cases. As already pointed out, in isolated plants with long conduits and in large plants with long conduits, the surge tank is a very necessary part of the installation. The differential surge tank is generally preferred as having distinct advantages over the simple tank.

Bearings

Considerable interest has been aroused by the employment of rubber in the mechanical details of power plants, more particularly in the case of guide bearings and valve seats.

Marked success has attended the attempts to decrease leakage through large control valves by the use of rubber sealing rings. The experience with water lubricated, rubber guide bearings has been most encouraging; so much so, that they have beeen substituted for lignum vitae or oil

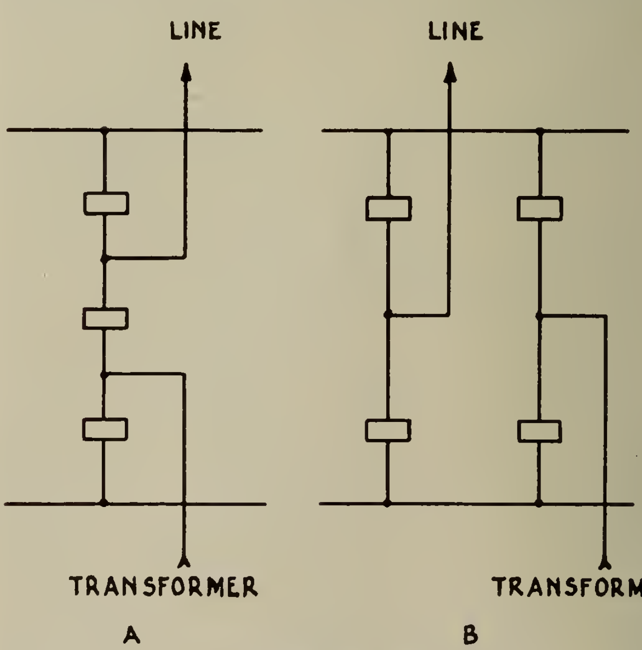

Figure No. 10.—The Arrangement of High Voltage Switching, illustrated in Figure (a), is referred to as the 1.5 Basis. As Compared with the Layout Illustrated by Figure (b), which it has Superseded in Some Instances, it effects a Saving of Some Moment. In a Station of 200,000 Horse Power Transformed at 220 Kv., with Four Banks of Transformers and Four Outgoing Lines, it effects a Saving of about $240,000 in Oil Switches Alone.

Figure No. 11.—Paugan Falls Development, Gatineau River. This Plant contains Eight Units, Rated at 34,000 Horse Power Each, at 125 r.p.m., under a Head of 132 feet. The Cooling Air for these Generators is Drawn Directly from the Power House, and Warm Air is Discharged from Generators through the Tailrace Wall. Part of the Power Generated here is Transmitted at 220 Kv. to Leaside, 230 Miles Distant.

bearings, with superior results. They appear to be particularly applicable with sediment-bearing water, where the lignum vitae bearings are subject to excessive wear, but particular attention must be paid to insure continuous water supply.

In the case of large butterfly valves, where it is necessary to reduce leakage to a minimum, such as would occur when a unit is used only to carry peak load, and will remain shut down for comparatively long periods, successful attempts have been made to secure a practically watertight valve by the introduction of a rubber seal. The valves used for this purpose are of standard butterfly type, with the sealing effect supplied by a hollow rubber ring, mounted in the periphery of the housing, and pressing against the outside of the wicket when closed. The pressure of the sealing ring against the disc is developed by water pressure within the sealing ring. Later designs have provided for the seal to be placed around the wicket itself, thus avoiding the collection of silt in the recess formerly necessary in the valve housing. Careful experiments were necessary to determine the best pressure and design of this sealing device, and the tests which took place found the leakage, in at least two installations of valves of approximately 20 feet in diameter, to be less than one-half second foot.

Attempts have been made to decrease leakage around guide vanes by the use of rubber, but do not seem to have met with sufficient success to induce its inclusion in design.

Automatic Plants

The successful operation of automatic plants has enabled the development of small water powers, where the cost of operation would formerly have been a deciding factor against their exploitation.

With simplicity of layout, economy of design, and reduction of operating costs, these plants are becoming more in evidence, and these small additional sources of power are making themselves felt, in the aggregate, particularly in those systems which do not contain any of the great power concentrations such as exist on the greater rivers of the country. The result is that electric power is available over much wider sections of the more sparsely settled country than would have been considered economically feasible a few years ago.

Control systems may be described as fully automatic, remote or supervisory, although these terms lack definiteness of application. In the fully automatic plant, starting and synchronizing, or stopping the unit, according to load demands, water level or water supply conditions, may be carried out by the equipment, without the intervention of an operator. With supervisory control, the operator at a remote station may take no active part in bringing a unit into service, but obtains signals advising him how each piece of equipment is functioning. Remote control permits the operator in the master station to start the unit, adjust speed, synchronize, adjust load, etc., in the automatic plant.

There are numerous automatic plants throughout the Dominion, among which might be mentioned those at Meyersburg and Hagues Reach, on the Trent river in Ontario, two fully automatic plants, the former having three units of 2,200 horse power each, and the latter three of 1,600 horse power each. A number of others in Ontario are designed for remote control.

The outstanding automatic plant in point of size is the Alouette generating station in British Columbia. This plant has a single vertical unit of 12,500 horse power under 125.5-foot head. The control equipment is fully automatic, the starting signal being given by the operator at Stave Falls ten miles distant. The starting signal being given, the main valve admitting water from the penstock to the turbine opens very slightly, and then pauses while water pressure is built up in the turbine, after which it continues its movement until fully open. The motor driven governor pump commences operation, as also does a motor driven lubricating oil pump, the latter continuing until a gear-driven pump operating from the main turbine shaft takes over its duty. In sequence, and as suitable conditions

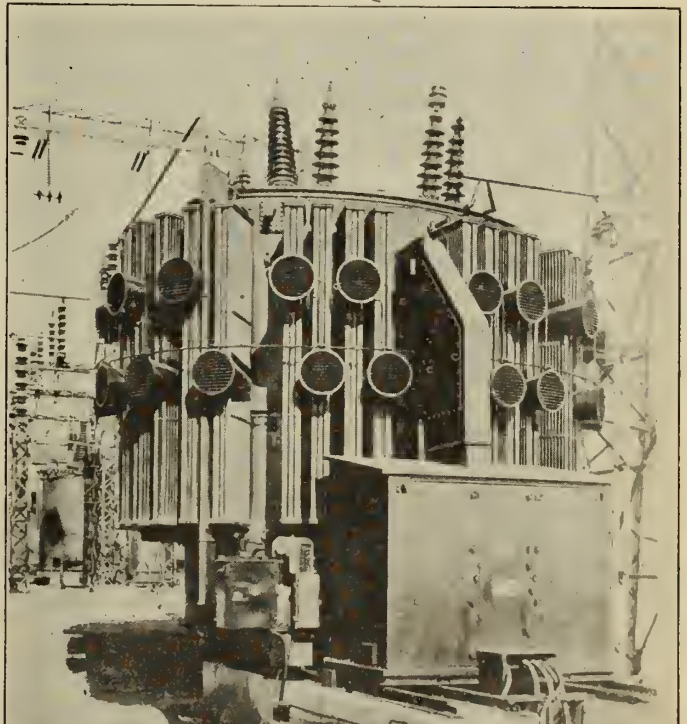

Figure No. 12.—Air-cooled Transformer equipped with Air Blowers. The Air-cooled Transformer is Frequently Preferred in Locations where Extremely Cold Weather is Experienced, as it Eliminates the Great Expense of Maintaining a Water Cooling System in Such Situations. By the Addition of Blowers, the Rating of the Transformer May Be Increased Materially.

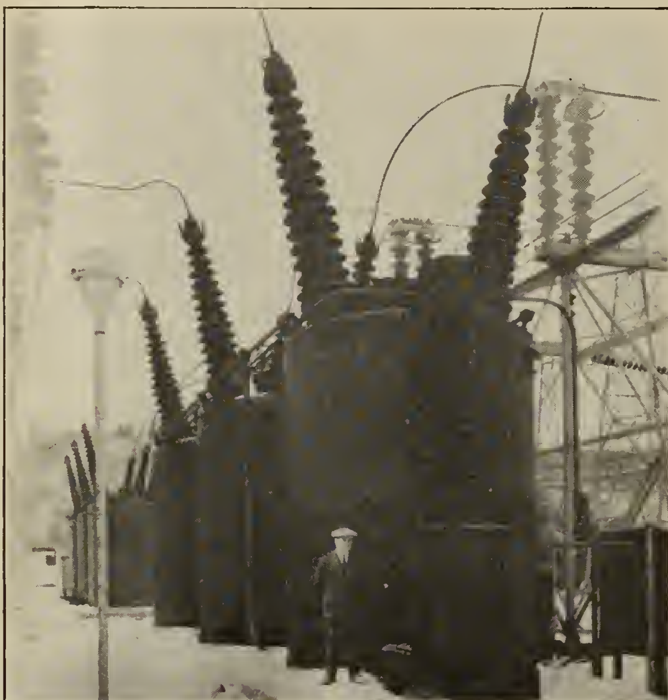

Figure No. 13.—Outdoor Installation of 220 Kv. Circuit Breakers at Leaside.

obtain, the turbine gates are opened, exciter voltage built up and applied to the alternator, the latter brought to synchronous speed, and the low tension breaker closed.

The element of time involved in the performance of these various functions depends on such conditions as head, amount of load, condition of the transmission system, etc. From the instant the starting signal is given, about seventy seconds elapse until the main valve is completely opened, synchronization requires 3½ minutes, and full load may be reached by the unit in 10 minutes.

In the first year of operation at Alouette there were fifteen emergency, and six automatic, shutdowns. Thirteen of the emergency shutdowns were due to governor driving belt trouble, all of which occured in the first four months of operation, and two were due to broken links on turbine gates. The automatic shutdowns were those caused by protective equipment coming into action. In no case was an emergency or automatic shutdown attributable to improper functioning of any of the automatic equipment.

Some of the earlier plants with supervisory control have given considerable trouble, and have not met the expectations of their designers. The experience in the Alouette plant, and in a number of others, indicates the tremendous advance in successful design and operation of automatic equipment. In general, a certain amount of attendance is necessary in plants. With this in mind, it is possible greatly to simplify the design of supervisory systems.

General Layout of Electrical Equipment

There are few avenues along which progress is possible in reduction of capital cost of electrical equipment of hydro-electric stations. Generator efficiencies leave no room for improvement, and adequate switching must be provided to meet the growth in interconnection. Extreme care is used in planning, to the end that operating labour and equipment will be reduced. There is a tendency to eliminate generator voltage equipment, except in cases where the transmission voltage is very high, when just sufficient low voltage equipment for synchronizing, or for local loads, is installed. When the transmission voltage is 110 kv. or less, a considerable amount of switching is done on the high voltage side of the transformers. An arrangement of high voltage oil switches, referred to as the "1.5 basis," is gaining favour. By the usual arrangement of transformers and lines, four switches are required per bay. On the 1.5 basis only three switches are required, effecting very considerable economy.

Economy in operation is effected by automatic plants in some cases, and in others by the use of a single operating floor, from which the operator may supervise the governors, oiling system, generators and turbines.

Switching equipment for 110 kv. and upward is generally placed outdoors. For lower transmission voltages, about one-half the installations are so arranged. Proposals to use outdoor generators have received some consideration on the score of reduction in capital cost, but, as the cost of the superstructure of the plant is such a small part of the total cost of development, and the saving by its omission is offset by the difficulty and high cost of repairs in bad weather, it has so far not been greatly favoured. Various schemes, however, are being studied to reduce building costs and, at the same time, meet this objection to outdoor generating station. In one case, a group of 25,000 kv.-a. vertical shaft outdoor type condensers is being installed, with arrangements for lowering the rotor so that repairs may be made on rotor or stator without dismantling the condenser or removing the weatherproof housing over the units.

Greater intensity of artificial illumination is now provided in generating stations than formerly, making working conditions in the plant immensely better. The decorative treatment is also given more attention, thereby improving the general appearance, assisting the lighting, and adding to the morale of the operating staff.

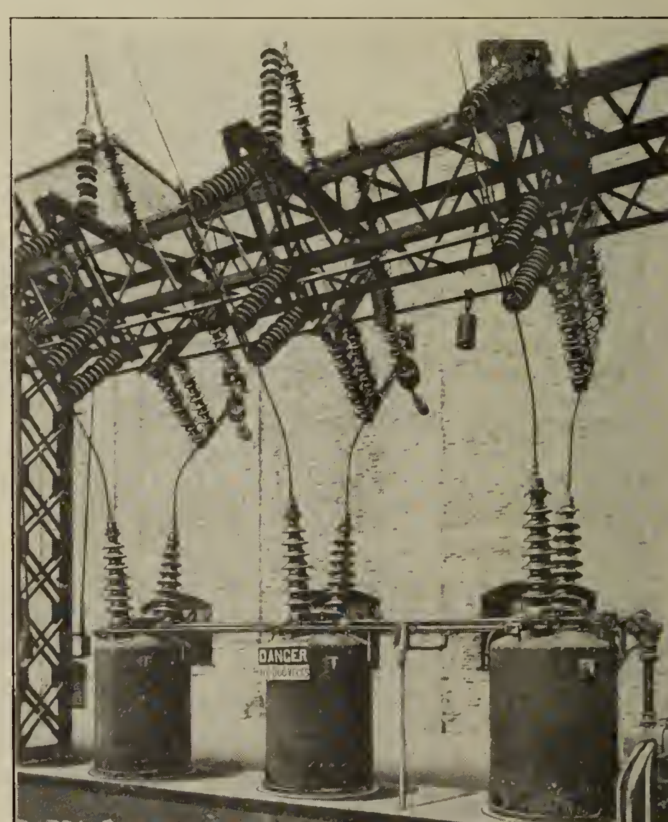

Figure No. 14.—Outdoor Installation of 110 Kv. Circuit Breakers. On Top of the Steel Structure is shown a Short Circuiting Air Break Switch to Permit the Oil Breaker to be inspected and Overhauled without an Interruption of Power.

Generators

Generator designs, in which structural steel replaces castings, are finding favour, because of lower cost, quicker delivery and reduction of head room required for handling rotating parts by crane. The umbrella type of generator is also growing in favour, principally because of reduction of head room required and ease of handling when dismantling for repairs. This last mentioned advantage is illustrated by design for a plant containing two 5,400 kv.-a. generators, in which a saving of 8 feet 6 inches in head room was effected. An order was placed recently for a 41,500 kv.-a. machine of the umbrella type. Generators self-enclosed for cooling are meeting approval, because of decreased dust accumulation and fire risk. Furthermore, the arrangement lends itself very readily to fire protection by the use of carbon dioxide. This method of fire protection has been used to some extent, but fire protection by means of water is frequently installed.

The use of hydrogen for cooling generators has not been seriously considered, due to the general low speed of this type of machine, but the increased output for a given generator, due to the use of this gas, combined with other advantages, may change the present viewpoint.

Generator lubricating systems are of the unit type in plants with few units, but where there are five or more units the tendency is to use a central system.

Transformers

In localities where very severe winter weather is experienced, self-cooled transformers are preferred, as the low cost of the water-cooled type is offset by the great expense of maintaining a water-cooled system. Furthermore, the rating of the self-cooled unit may be increased by the use of air blowers.

The choice between three-phase and single-phase transformers depends upon the system layout, but, in general, the single-phase unit is preferred. The shielded transformer for high voltage is receiving considerable attention.

Most large transformers are being ordered with tap changers, tap changing to be effected in some cases under load, and in others when not under load. The difficulty of transporting large transformers of this type is overcome by placing the assembled core in tanks on specially designed cars for shipment.

Switching

The minimum possible number of oil breakers are now used, and diagrams and connections simplified as far as possible, especially with voltages of 110 kv. and upward. Breakers having a rupturing capacity of 2,500,000 kv.-a. are now obtainable from reputable manufacturers.

Figure No. 15.

Practically all outdoor oil breakers are now equipped with bushing type current transformers for relay operation. Electric heaters are installed in the oil and in the operating mechanism housing to maintain good operating conditions during winter. Special circuit breaker oil is usually required with a cold test of —40° F. for use in outdoor breakers to assure satisfactory operation under the most severe climatic conditions.

Storage

Extensive storage and regulation schemes have been undertaken in various parts of Canada. On the Gatineau river, a tributary of the Ottawa, almost complete regulation of the upper reaches is effected by the Lake Bascatong storage basin. Four concrete dams and three small earth embankments were used to create this reservoir which impounds 93,000,000,000 cubic feet of water. There are at present, three large power developments on the river, and at the lowest of these the catchment area is 9,600 square miles; the catchment area of the reservoir is 6,200 square miles; regulation is thus fairly complete, and is being improved by the construction of another storage basin located at Cabonga.

Mention should be made here of the regulation works on the St. Maurice river, where the Gouin dam creates a storage basin with a capacity of 160,000,000,000 cubic feet. This, however, is not a recent development, and therefore, although of great magnitude, does not come within the scope of this paper.

In a number of instances, large lake expanses have been used as storage basins, notably on the Nipigon, English and Winnipeg rivers. On the first named, Lake Nipigon has an area of 1,500 square miles, and has been developed as a storage basin to benefit power sites on the Nipigon river, by which it is drained to Lake Superior. A range of 7 feet is used for storage here, but with the large lake area the impounded water amounts to 290,000,000,000 cubic feet. Lake of the Woods, also with an area of 1,500 square miles, and a storage range of 4 feet, has been used for some years to regulate the flow of the Winnipeg river. During the past year, a control dam has been built at the outlet of Lac Seul on the English river, which is an important tributary of the Winnipeg. Here it is possible to use a greater storage range than is usual on a natural water surface, as the country around the lake is undeveloped. The area of the lake is 420 square miles, and in a storage range of 12.5 feet it will impound 145,000,000,000 cubic feet, and provide a continuous outflow of 6,000 cubic feet per second, almost three times the low water flow under natural conditions.

To give scale to these storage developments, they may be compared with some of the other outstanding storage basins at present in use.

Storage Reservoir	Capacity of Basin (Cubic Feet)
Gatun (Panama)	183,000,000,000
Gouin (Quebec)	160,000,000,000
Assuan (Egypt)	78,000,000,000
American Falls (United States)	75,000,000,000
Lake Nipigon (Ontario)	290,000,000,000
Lac Seul (Ontario)	145,000,000,000

Aerial Surveys

The use of aerial surveys has been very rare in connection with water power development, but the last few years have seen some very important and interesting applications of this method.

The rapidity with which large areas can be photographed, and the remarkable truth of the resulting pictures, when studied through the medium of the stereoscope, place at the disposal of the investigator the means of quickly deciding the main features of a project, and localizing the field work to the bare necessities of the situation, with an assured saving of time and expense.

This would apply more particularly to those sites which are in regions which have not already been surveyed, and for which maps are not available, although, in certain cases where the country has been mapped, aerial surveys may still be justified.

Aerial surveys were used for the location of the transmission line delivering power from plants on the Gatineau river to Toronto, Ontario. This line was determined by means of aerial photography, and some idea of the importance of the time factor may be drawn from the fact that a flight for the purpose of photographing the proposed route, with fifty per cent overlap of the individual exposures, would occupy, with suitable weather conditions, an actual working period of about three hours, for the entire distance of 202 miles.

Applying the stereoscope to the photographic prints secured from the flight, permitted the rapid selection and final determination of the route in the office. The aerial survey was also a great time saver, since, by its use, many physical features were shown which did not appear on the available maps. Accurate information regarding topographic details was supplied, and the final field work in connection with the actual location and construction of the line was greatly facilitated.

Another specific example of the application of aerial survey methods is found in the delimitation of the area around Lac Seul that will be flooded at maximum lake level after completion of the storage dam at the lake outlet. Aerial photographs were taken of the shore of the lake, careful record being made of the time at which each photograph was taken. These photographs, along with data as to lake levels at the time of exposure, allowed the ground survey party to select those locations along the shore where the flood contour was any distance from the water's edge, and only at such places was the ground survey used to define the flood contour.

Conclusion

It is obvious that in a general paper of the length desired for such a conference as this, only a brief outline of the trend of such a widespread activity as power development can be given. The topographical features of Canada are so varied, and the uses of electric power so diverse that conditions encountered embrace almost every known circumstance. The foregoing description is an attempt to portray how the various requirements are being met. With such rapid and material progress as has been made in the immediate past, one hesitates to pass opinion as to the future. It would appear, however, that the coming years will see considerable development in pumping-storage schemes for peak load plants, and in the use of automatic devices for the starting up and synchronizing of large units.

The closer study of the allied problems of cavitation and pitting in turbine runners and draft tubes offers a field for much useful and beneficial research.

Consideration might also be given to the possibility of further simplifying plants having a considerable number of units. This may be done by equipping only a few of the units with governors, the other units being always run at full load, perhaps not even being equipped with wicket gates. The use of much simplified governors for large interconnected systems offers favourable possibilities also, in which case normal regulation of individual units, such as is needed, might be largely secured by frequency control.

Generation, Transmission and Distribution of Electricity in Canada

Current Practice in the Design and Operation of Electrical Generation, Transmission and Distribution Systems in Canada

Julian C. Smith, LL.D., M.E.I.C.,
Vice-President and General Manager, Shawinigan Water & Power Company, Montreal, Que.,
and
C. V. Christie, M.E.I.C.,
Professor of Electrical Engineering, McGill University, Montreal, Que.

Paper presented before the Second World Power Conference, Berlin, Germany, June 16-25, 1930.

Introduction

The paper will describe current practice in the design and operation of electrical generation, transmission and distribution systems in Canada.

The authors presented a general paper on this subject at the World Power Conference in London in 1924 and with that paper as a background the changes and developments since that date will be discussed.

In the period under review, 1924 to 1929, the development of electric power in Canada has been very rapid and the installed h.p. per 1,000 population for the whole of Canada is now over 580, while in the provinces of Quebec and British Columbia, the two provinces which definitely favour private ownership, the installed capacity is approximately one h.p. per capita.

The following table shows approximately the water power resources of the various provinces of Canada as estimated at the beginning of the year 1930.

Available and Developed Water Power in Canada
October 1st, 1929.

Province	Available 24-hour power at 80 per cent efficiency based on ordinary 6 months flow h.p.	Turbine Installation h.p.	Population June 1, 1929	Total Installation per 1,000 population
British Columbia	5,103,500	560,042	591,000	948
Alberta	1,049,500	70,532	646,000	109
Saskatchewan	1,082,000	35	866,700	...
Manitoba	5,344,500	311,925	663,200	470
Ontario	6,940,000	1,939,675	3,271,300	599
Quebec	13,064,000	2,572,418	2,690,400	956
New Brunswick	169,100	112,131	419,300	267
Nova Scotia	128,300	108,406	550,400	197
Prince Edward Island	5,300	2,439	86,100	28
Yukon and Northwest Territories	731,000	13,199	12,400	1,063
Canada	33,617,200	5,710,802	9,796,800	583

The figures in this table have been taken from the records of the Department of the Interior.

The construction of storage dams and reservoirs above the power developments has made it economical to develop many rivers beyond the capacity estimated under ordinary six months flow and conditions will tend to improve in this respect. The total of 33,617,200 h.p. is very conservative as an estimate of the total resources of Canada and when the numerous large and at present almost unknown rapids and falls are surveyed and the necessary storage reservoirs are constructed this total may well be doubled.

The installation for the whole of Canada averages 583 h.p. per 1,000 population, Quebec leads the other provinces with 956 h.p. per 1,000, British Columbia is second with 948, Ontario is third with 599 and Manitoba is fourth with 470 h.p. per 1,000. Nova Scotia has developed 85 per cent of the recorded power available while Quebec has developed only 20 per cent of h.p.

The installed turbine capacity in Canadian hydro-electric generating stations in November 1924 was 3,900,000 h.p. while in 1929 five years later it was 5,700,000 representing an average increase of 360,000 h.p. per year. This average rate of installation will probably be increased in the next five year period and plants now under construction or definitely projected will bring the total installation in 1934 above 7,500,000 h.p.

That steam plants play a relatively unimportant part in the supply of electricity throughout Canada in general may be seen from the fact that their combined capacity is less than 5 per cent of the capacity of the hydro-electric plants and they supply less than 1½ per cent of the kw.hrs. consumed in the country.

Capital Invested and Revenue per Horse Power

The total outstanding capital invested in water power development including transmission and distribution, from reports of the Department of Trade and Commerce is $1,172,600,000 which is an average of $219 per h.p. installed. This amount may be subdivided as follows:

Generation	69.5 per cent	.....	$152.00 per h.p.
Transmission	16.0 " "	.....	35.00 " "
Distribution	9.0 " "	.....	20.00 " "
General	5.5 " "	.....	12.00 " "

Generation includes investment in storage and regulating dams, power houses and sites including all equipment up to the step-up transformers.

Transmission includes investment in step-up transformer stations, transmission lines and receiving stations but does not include step-down transformers.

Distribution includes step-down transformers in receiving stations, distribution lines, substations, line transformers and meters.

General includes investments in office, buildings, stores, working capital, etc.

These figures which are obtained for the industry as a whole cannot be applied to particular properties. The figure of $152 per h.p. for power generation including all equipment up to the generator terminals is representative of medium capacity plants but many plants of large capacity favourably situated have been developed below $120 per h.p. for operation at from 60 to 70 per cent load factor. Such development costs must not be exceeded if power is to be sold in large blocks at figures equivalent to $12 to $15 per h.p. at the generator bus bar as has been done in many instances during the last five years.

It must also be remembered that probably less than 50 per cent of the developed h.p. is transmitted more than a very short distance and the figure of $35 per h.p. given above for transmission should be at least $70 per h.p. when applied to the power which is transmitted.

The percentage of the developed power which is distributed to small power users and for domestic purposes is probably less than 20 per cent of the whole and the cost per h.p. of distributed power should therefore be $100 instead of $20 as given above.

The same government department gives for 1927 the average revenue per h.p. of primary power as $24.93 for all Canada while in Quebec it is $19.26 and the revenue per kw.hr. generated as 0.72 cents for all Canada and 0.52 cents for Quebec, which has a large number of industries using large amounts of power at high load factor such as the paper mills and large chemical industries.

How far the developments of hydro-electric properties will continue and when steam-electric stations of large size will enter the field in Canada, depends on a great variety of conditions such as location of possible hydro-electric stations with respect to the load, cost of constructing the stations and the necessary transmission systems, quality of service demanded and finally on the capital cost of high efficiency steam-electric stations and on the cost of coal.

The steam electric station has already made its appearance in British Columbia where there is an abundant supply of coal and such stations will doubtless be constructed as stand-by and peak load stations in some of the large hydro-electric systems but probably not before Canada's present hydro-electric installation is doubled.

Analysis of the Cost of Power Generation and Transmission in a Typical Case

Assume that 250,000 kw. is to be delivered at 220,000 volts, 60 cycles, 90 per cent power factor at 250 miles from the generating station.

Two single circuit transmission lines will be required and synchronous condensers will be installed in the receiving station of sufficient capacity to raise the line power factor to unity.

Receiving Station

The receiving station will cost complete about $4,000,000 or $16 per kw.

The annual costs will be

Interest	6.0 per cent	$240,000
Depreciation	3.0 " "	120,000
Taxes and insurance	1.0 " "	40,000
Contingencies	1.0 " "	40,000
Operation and maintenance		80,000
Power losses, 5,000 kw.		100,000
Total annual cost		$620,000

This is equivalent to $2.48 per kw. per year or $1.86 per h.p. per year.

At 80 per cent load factor the cost is 0.352 mils per kw.hr. and at 60 per cent load factor is 0.472 mils per kw.hr.

Transmission Lines

Cost of two lines at $20,000 per circuit mile = $10,000,000 = $40 per kw.

Annual costs.

Interest	6.0 per cent	$600,000
Depreciation	2.0 " "	200,000
Taxes and insurance	0.5 " "	50,000
Contingencies	0.5 " "	50,000
Operation and maintenance $200 per circuit mile per year		100,000
Losses, 25,000 kw.		500,000
Total annual cost		$1,500,000

This is equivalent to $6 per kw. per year or $4.50 per h.p. per year and to 0.86 mils per kw.hr. at 80 per cent load factor or 1.14 mils per kw.hr. at 60 per cent load factor.

Step-Up Transformer Station

300,000 kv.-a. at $6.70 per kv.-a. = $2,000,000.

Annual costs.

Interest	6.0 per cent	$120,000
Depreciation	3.0 " "	60,000
Taxes and insurance	0.5 " "	10,000
Contingencies	0.5 " "	10,000
Operation and maintenance		40,000
Power losses, 3,000 kw.		60,000
Total annual cost		$300,000

Generating Station

280,000 kw. at $160 per kw. = $4,500,000.

Annual costs.

Interest	6.0 per cent	$2,700,000
Depreciation	1.0 " "	450,000
Taxes and insurance	0.5 " "	225,000
Contingencies	0.5 " "	225,000
Water rentals		400,000
Operation and maintenance		300,000
Total annual cost		$4,300,000

This is equivalent to $17.20 per kw. per year delivered to the load or $12.90 per h.p., 2.46 mils per kw.hr. at 80 per cent load factor and to 3.28 mils per kw.hr. at 60 per cent load factor.

	Generation	Step-up transformer station	Transmission 250 miles	Step-down transformer station	Total cost up to low voltage side of step-down transformers
Capital cost per kw. delivered to load	$160.00	$ 8.00	$ 40.00	$ 16.00	$224.00
Capital cost per h.p. delivered to load	120.00	6.00	30.00	12.00	168.00
Annual cost per kw. delivered to load	17.20	1.20	6.00	2.48	26.88
Annual cost per h.p. delivered to load	12.90	0.90	4.50	1.86	20.16
Cost per kw.hr. delivered to load at 80 per cent load factor	mils 2.46	mils 0.17	mils 0.86	mils 0.35	mils 3.84
Cost per kw.hr. delivered to load at 60 per cent load factor	3.28	0.27	1.14	0.47	5.12

The cost per kw.hr. delivered to the load may be subdivided 64.25 per cent generation, 4.35 per cent step-up transformers, 22.40 per cent transmission, 250 mils and 9.00 per cent step-down transformer station.

Generation of Power

The major additions to the generating stations in the various provinces of Canada since 1924 are briefly outlined below.

British Columbia

The British Columbia Power Corporation has a series of three developments on the water-way consisting of the upper and lower Alouette lakes, Stave lake and the Stave river. The first development of the system, the Stave Falls plant, has a capacity of 77,500 h.p. The Alouette plant was constructed at the Stave lake end of a tunnel discharging the waters of Alouette lake into Stave lake. It has a capacity of 12,500 h.p. in one unit and is designed for full automatic operation from the Stave Falls station. The Ruskin development below the Stave Falls plant is at present in the early construction stage. The first 42,500 h.p. unit is expected to be in operation in the autumn of 1930 and the second unit will be installed during the following year. The Stave Falls watershed will at that time be fully developed with a capacity of 175,000 h.p.

The West Kootenay Power and Light Company, controlled by the Consolidated Mining and Smelting Company of Canada, in 1926 completed the installation of a 60,000-h.p. plant at Lower Bonnington Falls on the Kootenay river. A 75,000-h.p. development at South Slocan on the same river was completed in 1929 and they have applied for the right to develop 80,000 h.p. on the Pend d'Oreille river.

Other power companies in British Columbia are making similar additions to their generating plants to cope with the increasing demand for power. During the last ten years the developed power has been increasing at a rate in excess of 30,000 h.p. per year.

Alberta

In Alberta a site is now being developed on the Bow river which will have an ultimate capacity of 36,000 h.p.

Saskatchewan

In Saskatchewan the population is concentrated in the prairie district where no water power sites of economic value exist and this has delayed the development of hydro-electric power in this province.

The Churchill River Power Company has started work on a development at Island Falls on the Churchill river to provide power for mining developments. The ultimate capacity of this plant will be 84,000 h.p. of which 42,000 h.p. will be installed in 1930.

Manitoba

The development of power in Manitoba is proceeding at a rapid rate.

The municipal plant of the City of Winnipeg at Point du Bois Falls on the Winnipeg river reached its ultimate capacity of 105,000 h.p. in 1926 and the city then purchased power from the Winnipeg Electric Company. The city has now started work on a development at Slave Falls on the Winnipeg river which will have an ultimate capacity of 100,000 h.p. in eight units.

The Winnipeg Electric Company through its subsidiary company the Manitoba Power Company has constructed at Great Falls on the Winnipeg river a plant of 168,000 h.p. capacity in 6 units of 28,000 h.p. each. This plant was completed in 1928 and work has already started on a plant at Seven Sisters Falls on the Winnipeg river, designed for six units of 37,500 h.p. each. It is expected that three of these units will be installed in 1930.

Ontario

The Hydro-Electric Power Commission of Ontario operates 25 hydro-electric stations with a combined turbine capacity of about 1,100,000 h.p. This load is growing rapidly but they are to a large extent meeting the growth by purchasing power from privately owned companies in the province of Quebec. The most important generating station owned by the Commission is the Queenston station on the Niagara river which has an installed turbine capacity of 502,000 h.p. in nine units. The turbines are vertical, single runner, Francis type, rated at 58,000 h.p. at 187½ r.p.m. The generators are 25 cycle, 12,000 volt, 54,000 kv.-a. and are at present the largest capacity machines in Canada. A tenth unit of 58,000 h.p. is now being installed.

The Commission in 1926 entered into a contract with the Gatineau Power Company to purchase 260,000 h.p. of 25 cycle power from the generating stations on the Gatineau river and later entered into a second contract with the same company for the supply of up to 100,000 h.p. at 60 cycles for the Eastern Ontario system.

In the fall of 1929 the Commission contracted to buy 250,000 h.p. of 25 cycle power from the Beauharnois Light, Heat & Power Company at Beauharnois, Quebec. This power will be transmitted over 300 miles into the Niagara system.

Of the developed power in Ontario about two thirds is controlled by the Commission and one third located mainly in the newer portions of the province is owned by private companies.

Quebec

In the province of Quebec new hydro-electric power developments are being made at a rate exceeding 250,000 h.p. per year and this rate will be increased during the next five years. The greater part of this power is required by industries in the province of Quebec but a very considerable amount will be delivered to the Hydro-electric Power Commission of Ontario to take care of the growth of their load.

The major additions to the generating stations in Quebec since 1924 are briefly described below.

The Duke-Price Power Company

First may be mentioned the great plant of the Duke-Price Power Company at Isle Maligne on the Saguenay river.

The Saguenay, one of the great tributaries of the St. Lawrence, flows out of Lake St. John by two channels, the Grand Discharge and the Little Discharge. These two channels unite at a point nine miles below the lake outlet and thirteen miles further down stream the river reaches tidewater at Chicoutimi.

Lake St. John is located about 100 miles north of the city of Quebec. Its normal water level is 310 feet above mean sea level and the drainage area of the lake is estimated to be 30,000 square miles. The Duke-Price Power Company by a grant of the provincial government is permitted to use the storage capacity of Lake St. John between ordinary low water and ordinary high water, a range of 17.5 feet giving a storage capacity of 187.1 billion cubic feet.

The power development at Isle Maligne has at present a capacity of 495,000 h.p. in eleven units of 45,000 h.p. each and a twelfth unit will later be installed bringing the capacity up to 540,000 h.p.

The head available ranges from 100 to 120 feet.

The turbines are 166½-inch, vertical shaft, single runner, Francis type units operating at 112.5 r.p.m.

The generators have a full load rating of 30,000 kv.-a. or 24,000 kw. at 80 per cent power factor, 13,200 volts, three phase, 60 cycle, 112.5 r.p.m. with a temperature rise not exceeding 55 deg. cent. but each generator will carry 35,000 kv.-a. continuously at normal voltage and 80 per cent power factor with a temperature rise not exceeding 70 deg. cent.

Between Isle Maligne and Chicoutimi the Saguenay has a fall of about 210 feet at Chute-a-Caron. The necessary rights to develop power in this section are held by the Alcoa Power Company a subsidiary of the Aluminum Company of America and construction work is well advanced on the site. The turbine capacity which can economically be installed is estimated to be 1,030,000 but it was found that the best economy in construction would be obtained by diverting part of the available water and building a temporary power plant developing 260,000 h.p. at a head of 150 feet in four units of 65,000 h.p. each. Construction of this plant will be completed in July 1930. The construction equipment and organization will then be used to carry out the final step which will give a combined capacity of 1,030,000 h.p. The first plant will be kept in operating condition and will be utilized when the river flow conditions warrant it.

The Shawinigan Water & Power Company

The St. Maurice river is the largest source of power in the province of Quebec at the present time, with a developed capacity of 650,000 turbine h.p. of which 580,000 h.p. is controlled by the Shawinigan Water & Power Company.

The St. Maurice river drains an area of approximately 16,200 square miles which consists entirely of forest cover and lakes. About 4,800 square miles of this area is above the storage reservoirs which have been constructed on the upper reaches of the river.

The main storage reservoir is the Gouin dam which has formed a lake about 300 square miles in area and stores all the spring run-off from an area of 3,650 square miles. The reservoir is capable of storing 180×10^9 cubic feet and through its construction the regulated flow of the St. Maurice river has been increased from 6,000 cubic feet per second to 16,000 cubic feet per second. Other storage reservoirs now under construction on tributaries to the St. Maurice will eventually increase the regulated flow at Shawinigan Falls to 19,000 cubic feet per second.

During 1928 and 1929 two 43,000 h.p. units were installed in the power house at Shawinigan Falls. The turbines are vertical units operating at 138.5 r.p.m. under an average head of 150 feet. The generators are three phase, 60 cycle, 11,000-volt machines of 40,000 kv.-a. capacity. An additional machine of 30,000 h.p. capacity will be installed in 1930 in each of the two remaining plants on the river.

The Shawinigan Water & Power Company has been granted the right to develop the rapids and falls on the upper part of the St. Maurice river and it is estimated that over 1,200,000 h.p. can be developed in this area. Work has already commenced on the first of these developments and a 220,000-volt transmission line is being constructed to carry the power into the Shawinigan network.

The Shawinigan Company has also purchased 100,000 h.p. from the Duke-Price Power Company at Isle Maligne for the supply of industries in the Quebec district.

The Gatineau Power Company

The Gatineau river enters the Ottawa river two miles below the city of Ottawa. Its drainage area is about 9,600 square miles. It is subject to great fluctuations in volume decreasing at times in the summer months to 2,500 cubic feet per second.

To improve the regulation of the river the Mercier storage dam was built about 100 miles above Ottawa. It has created a lake with an area of over 100 square miles capable of impounding 95×10^9 cubic feet of water for use during the low flow season. It is estimated that this reservoir in conjunction with other smaller reservoirs on the watershed will enable a regulated flow of 10,000 to 11,000 cubic feet per second to be obtained. The reservoir above the Mercier dam is the third largest artificial storage reservoir in the world.

The Gatineau Power Company a subsidiary of the International Paper Company has developed three sites on the Gatineau river in the province of Quebec.

The first at Farmers Rapids 4½ miles from the mouth of the river where a head of 66 feet is available.

Three vertical 162-inch, single-runner, Francis turbines 24,000 h.p. each are at present installed giving a capacity of 72,000 h.p. The ultimate capacity is 120,000 h.p. in five units.

Two of the generators are three phase, 60 cycle, 6,600 volt, 90 r.p.m. 25,000 kv.-a. and the third is 25 cycle, 6,600 volt, 90 r.p.m. 22,500 kv.-a.

The Chelsea station is 1½ miles above the Farmers station and operates under an average head of 96 feet.

Three vertical 162-inch single-runner, Francis turbines 34,000 h.p. each are at present installed giving a capacity of 102,000 h.p. The ultimate capacity is five units developing a total of 170,000 h.p.

Two of the generators are 60 cycle, 6,600 volt, 100 r.p.m. 36,000 kv.-a. and the third is 35 cycle, 6,600 volt, 100 r.p.m. 32,000 kv.-a.

The Paugan station is 26 miles above the Chelsea station. It operates under an average head of 130 feet. The power house is designed for eight 35,000 h.p. units of which six are installed. The plant may ultimately be extended to contain sixteen similar units. The present installed capacity is 204,000 h.p. and the ultimate capacity will be 544,000 h.p.

The turbines are vertical 140½ inch, single-runner, Francis type rated at 34,000 h.p. at 125 r.p.m.; the generators are 3 phase, 25 cycle, 6,600 volt, 125r. p.m. 28,500 kv.-a.

These three plants have a present installed capacity of 378,000 h.p. and an ultimate capacity of 834,000 h.p.

Of the power developed on the Gatineau river 260,000 h.p. at 25 cycles has been sold to the Hydro-Electric Power Commission of Ontario for their Niagara system and up to 100,000 h.p. at 60 cycles is reserved for the Commission to supply its contracts in the eastern part of Ontario.

The 25 cycle power is delivered at 220,000 volts at the interprovincial boundary and is transmitted to Toronto, a distance of 230 miles over the first 220 kv. lines to be constructed in Canada.

The Gatineau Power Company has also during the last year added a second 25,000 h.p. unit to the 60 cycle generating station at Bryson on the Ottawa river.

The Montreal Island Power Company

An interesting plant which is now rapidly approaching completion is that of the Montreal Island Power Company on Riviere des Prairies eight miles from the centre of Montreal. The operating head varies during the year from 18 to 26 feet and propeller type turbines are being installed with vanes that may moved by mechanical means. A shut down of about five minutes is required to adjust the blades. Two units rated at 9,000 to 10,000 h.p. are now in operation and four more will be installed to complete the initial stage of this development. The generators are 60 cycle, 12,000 volt, 10,000 kv.-a., 85.5 r.p.m. units designed to operate as low as 75 per cent power factor.

The James MacLaren Company

At High Falls on the Lievre river, a tributary of the Ottawa river, the James MacLaren Company is completing a 60 cycle power development with an initial capacity of 90,000 h.p. in three units and an ultimate capacity of 120,000 h.p. The head available is 180 feet.

The complete project includes a storage reservoir with a capacity of 25,000,000,000 cubic feet at Cedars Rapids and a 250-ton pulp and paper mill near the town of Buckingham.

The Beauharnois Light, Heat and Power Company

The Beauharnois Light Heat and Power Company have been granted the right to divert 40,000 cubic feet per second from Lake St. Francis on the St. Lawrence river and to return it lower down at Lake St. Louis. They will develop 500,000 h.p., half at 25 cycles to be delivered to the Hydro-electric Power Commission of Ontario and the remainder at 60 cycles, for the supply of industries in and around the city of Montreal.

Two million h.p. can be developed in this stretch of the St. Lawrence river.

The Maritime Provinces

In the Maritime provinces, New Brunswick, Nova Scotia and Prince Edward Island, while the total water power resources are limited, a number of important developments have been made.

The Grand Falls Development

The Grand Falls development on the St. John River in New Brunswick is the largest development in the Maritime provinces.

The station is designed for an ultimate capacity of 80,000 h.p., but at present three units only with a total capacity of 60,000 h.p. are installed. The operating head is 125 feet.

The generators are three phase, 60 cycle, 6,600 volt, 163.6 r.p.m. 17,500 kv.-a.

Mersey River System

Three developments have been made on the Mersey river in Nova Scotia and combined into one system of 20,000 h.p. to supply power to a paper mill.

At Upper Lake Falls the head varies from 42 feet to 22 feet depending on the level in the storage pond. Two 2,350 h.p. turbines are installed, they are of the propeller type and the blades are adjustable by hand for changes of head. The two generators are 3,000 kv.-a., 60 cycle, 6,600 volt, and the plant is arranged for automatic control from the main station.

At Lower Lake Falls a constant head of 49 feet is available and two 5,300 h.p. turbines and two 4,100 kv.-a, 60 cycle, 6,600 volt generators are installed, equipped for automatic operation.

At Big Falls, two 6,350 h.p., Francis type, turbines are installed and two 5,000 kv.-a., 60 cycle, 6,600 volt generators. The power from the three plants is brought to the bus bars in this station.

Design Tendencies

There has been no increase in the maximum size of hydro-electric generators during the last five years and the 54,000 kv.-a., 25 cycle units in the Queenston plant in Ontario are the largest capacity units in Canada. These will however soon be surpassed by the 65,000 kv.-a. 60 cycle units of the Alcoa Power Company at Chute-a-Caron on the Saguenay.

In the electrical design of generators considerations of stability have had an important effect on design. In the case of generators installed in power houses located at considerable distances from the load centres and where therefore long transmission lines are required, the generator reactance should be kept as low as economy will allow and the short-circuit ratio should be kept high or else the generator should be provided with quick response excitation. On the other hand when the power house is situated close to the load the reactance may be kept high and the short circuit ratio low resulting in a less expensive machine with lower fault currents.

There is a general tendency in the later developments towards a generator voltage of 13,000 volts instead of 6,600 volts.

Slight reductions in losses have been obtained by the use of better iron, transposition of armature windings and by improvements in the ventilating systems.

In synchronous condensers there has been a tendency towards higher speeds which has resulted in a reduction in both losses and costs.

The principal improvements in mechanical design have resulted from the general use of fabricated construction in both the stator and rotor. This development has made possible some reduction in weight and a great reduction in pattern costs and has removed very serious limitations to economic generator design and construction.

Transmission of Power

Transmission of electric power in Canada has not undergone any radical change during the last five years. In 1925 the highest transmission voltage in Canada was 132 kv., while to day one double circuit 165 kv. line has been in service for three years and one 220 kv. has been in service for over a year. Two other 220 kv. lines are under construction and many more will be built during the next three years.

Transmission at 220 kv. may now be considered standard practice where large blocks of power are to be transmitted over great distances of 150 to 300 miles. Loads up to 125,000 kw. per circuit can be handled efficiently at this voltage and it is doubtful if more than this amount of power should be carried normally over a single circuit.

When it is necessary to bring power over longer distances as, for instance, from the rivers flowing into James bay or Hudson bay where transmission distances may be as great as 500 miles, it is probable that 330 kv. will be used and no serious difficulty is anticipated.

Where distances of transmission over 300 miles are under consideration the principle of constant voltage transmission will probably be applied, that is, the voltage at both ends of the line will be maintained constant and of the same value. Synchronous condensers will be required not only in the receiving station but also at one or more points along the line to regulate the voltage.

The greatest distance to which power has been transmitted in Canada is 230 miles from Paugan Falls to Toronto to supply the 25 cycle system of the Hydro-Electric Power Commission of Ontario.

Within three years the Commission will have one or two 220 kv. lines over 300 miles in length carrying power from the new development of the Beauharnois Light Heat & Power Company on the St. Lawrence river to Toronto.

The transmission of power over long distances is somewhat easier at 25 cycles than at 60 cycles because of the lower line reactance and the smaller charging current but the cost of the line and the efficiency of transmission are not changed.

Although double circuit towers have been employed on many important transmission lines, there is a decided tendency to construct new lines with single-circuit towers with horizontal spacing of conductors to reduce the lightning hazard. This type of construction has been used on a number of important 60 kv. lines.

For tower foundations either the concrete block or the structural steel grillage type of footing may be used and both appear to be satisfactory.

Aluminum cable with steel reinforcing is used as the conductor material for almost all transmission lines in Canada. For 220 kv. lines a 795,000 circuit mil cable is used with an outside diameter of 1.093 in., while conductors up to 1,590,000 circuit mils have been installed to supply large electric steam generator loads delivered at generator voltage.

Two transmission lines of outstanding importance are briefly described below, the Quebec-Isle Maligne line and the Toronto-Paugan Falls line.

The Quebec-Isle Maligne Line

The Quebec-Isle Maligne transmission line of The Shawinigan Water & Power Company connects the industrial area around the city of Quebec with the great hydro-electric power reservoir of the Saguenay valley and the lake St. John district where over two million h.p. can be economically developed.

The line is 135 miles in length and crosses a country covered with virgin forest without inhabitants or roads. The maximum elevation reached was 2,900 feet.

The distance was not great enough to require 220 kv. and the importance of the service made it imperative to install two circuits.

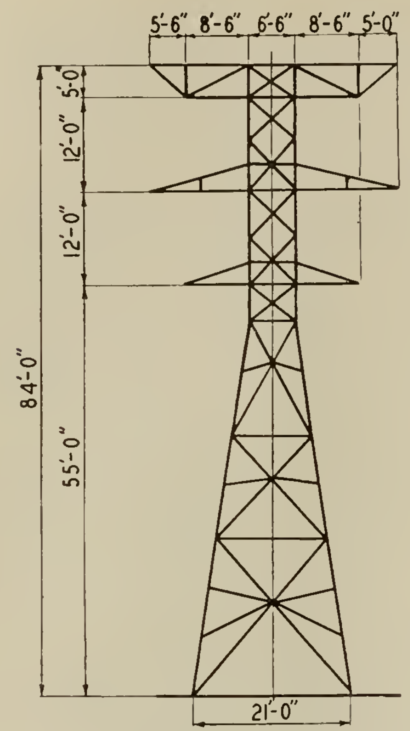

Figure No. 1—Standard Light Tower, Quebec-Isle Maligne 165-Kv. Line.

A delivery voltage of 165 kv. was adopted and a sending voltage of 180 kv. and provision was made in the transformers to vary these voltages by 10 per cent.

The line was required to carry 100,000 h.p. of 60 cycle power and it was necessary that one circuit should be capable of carrying the total load in case of failure of the other circuit.

A synchronous condenser designed to supply 30,000 kv.-a. either lead or lag has been installed in the terminal station at Quebec to control the voltage.

Figure No. 1 shows the tower dimensions and figure No. 2 the suspension insulator assembly for this line. Further details of the line are given in table No. 1.

The Toronto-Paugan Falls Line

The Toronto-Paugan Falls line of the Hydro-Electric Power Commission of Ontario is the first of a series of lines designed to carry up to one million h.p. of 25 cycle power from plants near the western borders of the province of Quebec into the industrial area surrounding the city of Toronto. It was designed to carry 125,000 h.p. on one circuit over a distance of 230 miles and was the first 220 kv. line to be constructed in Canada. The first of the two single circuit lines was put into service in 1928 and the second line is rapidly approaching completion. The conductor used was 795,000 circuit mils aluminum cable with steel reinforcing and the conductors were strung on a horizontal plane with a separation of 25.25 ft. Two ground wires were installed on each circuit.

The tower foundations are of the steel grillage type. Two 25,000 kv.-a. synchronous condensers have been installed in the Leaside receiving station at Toronto to regulate the voltage of these lines. In figure No. 3 is shown the outline drawing of the standard light tower and in figure No. 4 the suspension insulator assembly.

Some details of the line are shown in table No. 1.

Table No. 1—Comparative Characteristics of the 165 kv. Double Circuit and 220 kv. Single Circuit Lines

Item	Isle Maligne Line	Paugan Falls Line
Conductor..........	397,500 circ. mils A.C. S.R., 30 strands Al., 7 strands steel.	795,000 circ. mils A.C. S.R., 54 strands Al., 7 strands steel.
Spacing............	13 ft., 13 ft., 24 ft.	25.25 ft., 25.25 ft., 50.5 ft.
Average span.......	900 ft.	1,100 ft.
Weight of light tower	10,400 lbs. (Two circuit)	8,895 lbs. (Single Circuit)
Type and weight of footing...........	Concrete block, 2 cu.yd. = 8,100 lbs. per leg, 8 reinforcing bars. ½ in. by 5 ft.	Steel grillage 1,891 lbs.
Insulators..........	10 units suspension 4.75 in. per unit.	16 to 18 units suspension 5 in. per unit.
Types of towers.....	Light, semi-anchor, anchor, transposition	Light, light angle semi-anchor, anchor, transposition.

The Leaside Transformer Station at Toronto

The Leaside transformer station of the Hydro-Electric Power Commission of Ontario at Toronto was the first 220 kv. substation built in Canada. It receives power from the 220 kv., 25 cycle lines from the Paugan Falls station of the Gatineau Power Company and through two banks of three-winding transformers connects this system to the

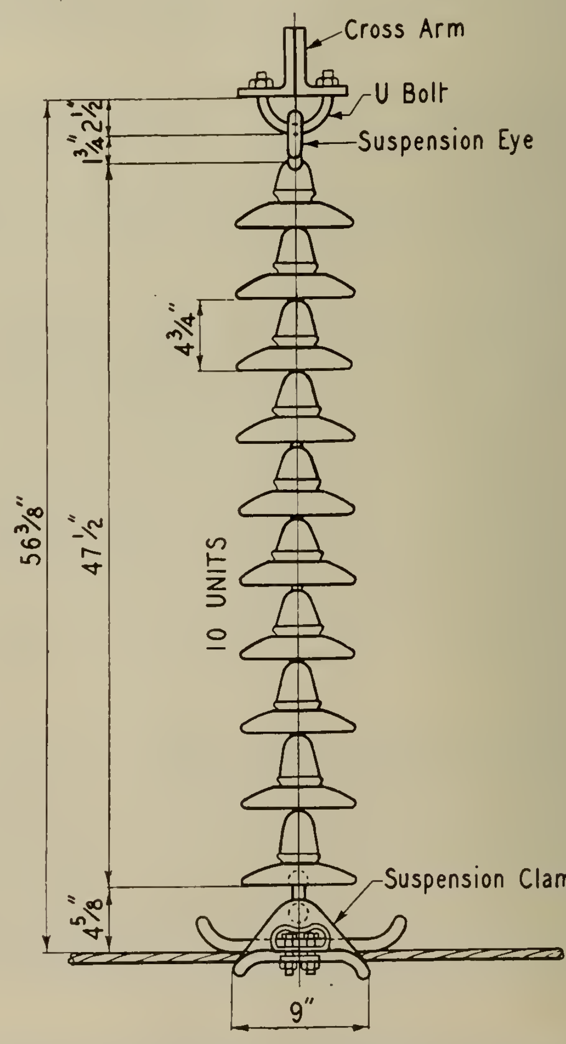

Figure No. 2—Suspension Insulator Assembly, Quebec-Isle Maligne 165-Kv. Line.

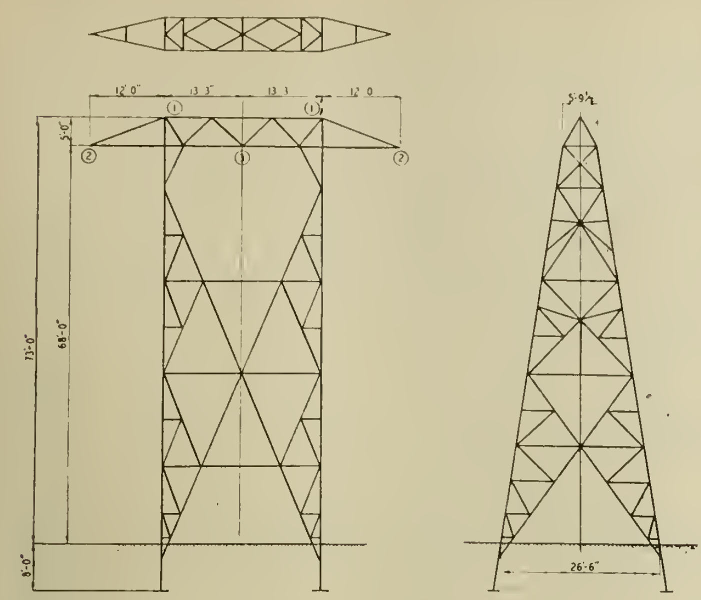

Figure No. 3.—Standard Light Tower, Toronto-Paugan Falls 220-Kv. Line.

110 kv. system fed from the Queenston generating station and to the 13.2 kv. local distributing system in Toronto.

The 220 kv. bus and switching equipment between the incoming lines and the transformers was laid out on a basis of 12 feet minimum clearance between phases and 7 feet 6 inches minimum clearance to ground.

The insulation for the disconnecting switches and on the bus supported by post insulators consists of six 14.5 inch high units. For the strain bus twenty 10-inch diameter standard 5-inch suspension discs are used and for the suspension bus 18 similar units are used. Hollow conductor copper cable with I-beam core is used for strain busses and for jumpers between busses. This conductor has the conductivity of 750,000 circuit mils copper cable and has an outside diameter of 1.249 in.

The 220 kv. oil circuit breakers have a current rating of 800 amp. and a rupturing capacity of 2,500,000 kv.-a. They are of the outdoor type with oil filled bushing.

Although low freezing oil is used in the breakers two 1,000-watt immersion heaters are placed in each tank to prevent the oil from thickening due to low temperature. A 500-watt heater is installed in the motor mechanism housing.

Two bushing type current transformers are mounted on each bushing for relay operation and for metering.

On test with the breaker not on load the complete opening stroke time was 0.7 second and the closing time 0.9 second. The time interval between the operation of the controller and the parting of the contacts was 0.15 second.

The 220 kv. disconnection switches are of the high pressure contact type and are rated 1,000-amp. The 220 kv. switches make the complete opening or closing operation in sixteen seconds.

Main Transformers

Two banks of transformers, each bank consisting of three 15,000 kv.-a. single phase, 25 cycle, 118,000/65,000/13,200-volt oil insulated water cooled, three-winding outdoor transformers and one spare have been installed. The banks are connected in star on the high voltage winding with the neutral point positively grounded. On the medium voltage winding they are connected in star and operated in parallel with the Commission's 110,000-volt system and the neutral is grounded through a resistance. The low voltage windings are connected in delta.

Each of the three windings has a continuous rating of 15,000 kv.-a.

The high voltage winding has a tap changer which can only be operated when the transformer is not energized. Taps are 215-kv., 205-kv., and 195-kv. No operating taps are provided on the medium voltage winding but the voltage of this winding can be changed under load by a special transformer which is connected in series to boost or buck the terminal voltage 7½ per cent in 2½ per cent taps. This special transformer is energized from the low voltage winding of the main transformers.

Synchronous Condensers

Two 25,000-kv.-a., 500 r.p.m. condensers are being installed one on each 45,000-kv.-a. bank of transformers. They are of the vertical outdoor type with the thrust bearing below the rotor and the exciters direct connected below the thrust bearing. They will be equipped with quick response excitation and automatic starting equipment with remote control. Carbon dioxide fire fighting equipment will be installed.

These machines are required to control the 13.2-volt bus voltage and in conjunction with the under-load tap changers on the 110-kv. systems windings of the transformers give flexibility to the distribution of the reactive kv.-a. between the 220- and 110-kv. systems besides increasing the efficiency of the system by making it possible to operate near unity power factor when desirable.

System Stability

By stability is meant the ability of rotating machines, such as generators, synchronous condensers and synchronous motors, to remain in synchronism under extreme changes in load whether caused by normal or abnormal system conditions.

This characteristic of stability has become a controlling factor in system design affecting as it does the design and

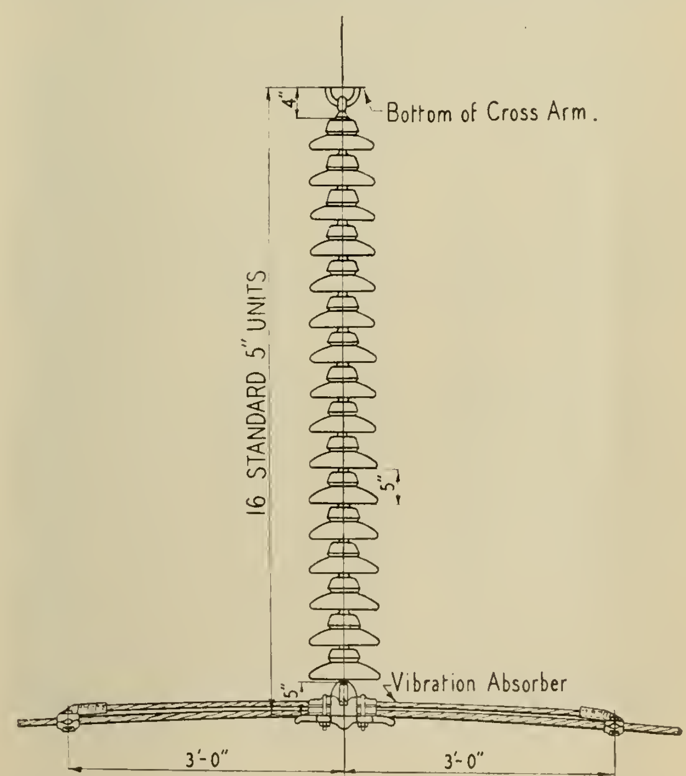

Figure No. 4.—Suspension Insulator Assembly, Toronto-Paugan Falls 220-Kv. Line.

application of all synchronous machinery on the system and also the choice of the operating voltage and the number and interconnection of circuits in the system.

This condition has been a gradual development brought about by the increasing importance of long distance transmission of power and the desire to obtain the maximum power capacity for a given investment in the transmission system.

The factors in generator design which particularly affect stability are transient reactance, synchronous impedance, short circuit ratio and the speed of exciter response. The moment of inertia of the generator rotor has sometimes an important influence on stability but the speed control exercised by the governors of the prime movers is too slow to affect the stability.

The per cent transient reactance of a generator is defined in the Standards of the A.I.E.E. as 100 times the ratio of the voltage produced by the combined armature and field leakage fluxes to the rated voltage, on the basis of rated armature current and with the axes of the armature and field magnetomotive forces coinciding.

The per cent synchronous impedance is 100 times the ratio of the field ampere turns required to produce rated armature current on sustained short circuit to the air gap ampere turns corresponding to rated voltage at no-load and at rated frequency.

The short circuit ratio is the ratio of the field ampere turns required to produce rated voltage at no-load and at rated frequency to the field ampere turns required to produce rated armature current at sustained short circuit.

Low transient reactance is desirable from the standpoint of system stability because it causes a small instantaneous drop in voltage and change in voltage phase when system short-circuits occur.

The per cent transient reactance of modern water wheel driven generators varies from 25 per cent to 50 per cent. As shown in the following table, it is usually about 50 per cent greater than the armature leakage reactance.

Modern Canadian Water Wheel Generators

Kv.-a.	R.p.m.	Cycles	Per cent syn. react.	Per cent trans. react.	S. C. ratio	WR^2 Lb.-Ft.^{2}

12,000	128.5	60	113.6	50	0.99	6,400,000
10,600	120	60	100	39	1.1	7,900,000
11,000	128.6	60	102	34	1.06	4,725,000
10,000	180	60	92	39	1.19	2,400,000
10,000	85.7	60	116	43.8	1.0	9,000,000
54,000	187.5	25	115.6	30.1	1.0	21,600,000
45,000	187.5	25	130.1	25.1	0.91	21,500,000
32,000	100	25	94	24	1.32	26,800,000
28,500	125	25	91	27	1.27	26,000,000
22,500	88.3	25	82.1	19.6	1.39	31,500,000
12,000	125	25	107.5	31	1.08	5,000,000

The lower values of transient reactance are difficult to obtain in 60 cycle generators and increase the cost of the machines.

A high short-circuit ratio is obtained by making the generator field strong in comparison with the armature, this results in less armature demagnetizing effect and in a smaller decrease of flux and voltage with increase of armature current. Such a condition tends to decrease the likelihood of system instability and for this reason the purchaser frequently specifies high short-circuit ratio.

However, the condition desired to promote stability is not a minimum reduction in flux, or flux interlinkages, but no reduction in flux and this can only be obtained by a quick response voltage regulator and excitation system and when these are supplied, the high short-circuit ratio becomes of less importance.

Short circuit ratios of modern Canadian generator range from 0.8 to 1.25. Where higher values are required the size and cost of the generators or synchronous condensers are increased.

When a single generator is to be used to charge a long transmission line a high short-circuit ratio is desirable to prevent excessive voltage rise. For this purpose machines with short-circuit ratios up to 2.0 have been designed.

The most effective method of improving the stability of generators and synchronous condensers is to accelerate the flux increase in the machine by improving the excitation and voltage regulating system. Rapid flux control has been assisted by improvements in the design of exciters, laminated stator frames are used to reduce the retarding effects of eddy currents during flux change; compensating windings are placed in the pole faces to neutralize armature reaction; the field windings are divided into a number of circuits to reduce self-inductive effects and the maximum voltage of the exciter may be increased up to about four times that required by the main field at normal load, giving a large forcing effect during system disturbances.

By making these improvements in design and providing a pilot exciter to excite the main exciter a sufficiently rapid voltage response can be secured in large low speed direct connected exciters and it is not necessary to provide the more expensive motor-driven exciters.

Where an exciter of ordinary design may be capable of increasing its armature voltage at the rate of 50 volts per second, low speed exciters for direct connection to large vertical generators have been built with a rate of voltage increase of 200 to 350 volts per second. This is a sufficiently rapid response for any except the most sensitive systems. High speed exciters for synchronous condensers can be built with a rate of control of 2,500-volts per second or over but such a rate is not required in the majority of installations.

The decrease of transient reactance and the speeding up of the exciter response, while they improve stability, both tend to increase the currents flowing when a fault occurs on the system and it is imperative that the faulty section be taken off the system with a minimum delay. The rupturing duty of circuit breakers is, therefore, increased and at the same time it is important that their operating time should be reduced.

The rating of oil circuit breakers has increased to 2,500,000 kv.-a. and this should be sufficient to protect any system where care has been taken to limit the possible power concentration. High voltage circuit breakers have up to the present time been rather slow in operation requiring with their control relays a total rupturing time of 0.4 to 0.6 seconds. It seems probable that this can be reduced to 0.2 or even 0.1 seconds but only at a considerable increase in cost.

For rapid and economical clearance of faulty lines it may be advisable to break the circuit on the low voltage side of the line transformers. The expensive high voltage oil circuit breakers may, in some cases, be entirely omitted and the transformers included as part of the line.

Lightning

Lightning presents a still unsolved problem for the transmission engineer. Extensive service experience, laboratory tests and calculations have given much valuable information as to the voltage and wave shape of induced lightning surges on transmission lines but the lightning proof line has not yet become a reality.

To protect lines from lightning the following measures are of value:

(1) Lines should where possible be kept away from locations where lightning is known to be especially prevalent.

(2) Overhead ground wires should be installed to reduce the induced lightning voltages. In addition to reducing the induced voltage the ground wire increases the attenuation of the wave as it travels along the line.

(3) Extra line insulation makes the line more nearly lightning-proof but transfers the danger of breakdown to terminal apparatus and only increases the need of lightning arresters to protect the terminal transformers.

(4) Grading rings may increase the insulator spark-over voltage for lightning waves of very steep wave front and will at the same time decrease the 60-cycle insulation value. This is not serious as the factor of safety is still high. Grading rings have not been installed on the 220 kv. lines in Canada as it was felt that their value had not been sufficiently demonstrated.

(5) The value of wood as an insulator against lightning voltage is being more and more appreciated and wood cross arms are being used in many cases even on steel structures. The insulation strength of wood poles wet or dry is 100 to 300 kv. per foot and 180 kv. is considered a good average value to assume.

Some engineers feel that too much money should not be spent in trying to eliminate entirely the lightning flash-over of a line but rather that instantaneous protection should be provided to clear the line, in case the power arc follows the lightning flash, before any permanent damage is done to the insulators. If the system consists of a number of parallel lines and is properly designed from the point of view of stability, the flashover and instantaneous clearance of one line will not result in loss of synchronism.

Lightning Arresters

A number of 220 kv. systems have been operated for a period without lightning arresters but the experience has not been satisfactory and it is now considered that for highly insulated lines lightning arresters are of sufficient value in protecting terminal apparatus to warrant the expense of their installation.

Only if the line insulation against lightning is reduced to a point where it is below the impulse voltage strength of the transformers is it safe to operate without lightning arresters.

The majority of switching surges are less than three times normal (normal being the crest value of the line to line voltage). Switching loads on and off produces relatively mild surges, but energizing or de-energizing unloaded lines produces a more serious shock. Six or seven times normal represents the order of the highest switching surge. This magnitude occurs with the de-energizing of an unloaded line.

Lightning voltages to which arresters may be subjected may be of any value up to the flashover value of the line insulation.

For 66-kv. lines with steel towers the r.m.s. 60-cycle dry flashover value averages 3.8 times the system voltage or 6.5 times the line to neutral voltage. But with wood poles and cross-arms in series the flashover limit is raised by an indefinite amount.

The lightning flashover with steel towers will be about 10 to 12 times normal with a fairly steep wave front but may be much higher with wood cross-arms.

Voltages to which lightning arresters may be subjected during operation should be studied very carefully. The highest voltages usually occur at light load or after load has been dropped suddenly and the generators are running at excessive speed.

Inductive Co-ordination of Power and Signal Systems

The problem of co-ordinating power transmission and distribution systems with neighbouring signal systems has become more complex as the power systems have increased in capacity and in extent.

Properly designed and co-ordinated transposition schemes will usually reduce the voltage induced in the signal system by the balanced components of current and voltage in the power system to such small values that they will not interfere with operation.

Induction from residual currents and voltages which are present in power systems under normal operating conditions is still serious in some cases. Transposition of the power conductors does not directly reduce such induction, but if the residual voltage is mainly due to differences in the capacities to ground of the various power conductors, transpositions in the power circuit will reduce the residual voltage. Transposing the signal circuit conductors results in equalizing the voltages induced in them by the power circuit residuals, and so eliminates the voltage between conductors, except insofar as impedance unbalances in the signal circuit may interfere with such equalization. Excessive residuals on the power circuit can usually be avoided without violating any principle of economic design.

Slot harmonics in generator voltage waves may be eliminated by sloping the slots relative to the axis of the machine either uniformly or in steps: or they may be reduced by using fractional values of slots per pole.

Harmonics due to the non-sinusoidal distribution of the excitation flux relative to the peripheral length of the pole pitch may be eliminated in salient pole machines by suitable shaping of the pole surfaces and in non-salient pole machines by the proper distiibution of the excitation winding.

Sixty cycle generators can now be made with a telephone interference factor (t.i.f.) as low as 11 in large size machines and from 15 to 25 in medium size machines without appreciable increase in cost. In 25-cycle generators the t.i.f. may be obtained as low as 3.5 in large size machines and from 5 to 10 in medium size machines.

Distortion of wave form may also be caused by transformers, particularly when operated with high flux densities which results in the production of harmonics in the magnetizing current waves. In a star-star connected bank of transformers the third harmonic magnetizing current and its multiples cannot flow and as a result third and higher harmonic residual voltages to ground are produced and result in interference. A delta connected tertiary winding or a change the star-delta connection will eliminate these residual voltages.

Arc furnaces introduce harmonics which are difficult to eliminate. Mercury arc rectifiers on electric traction circuits sometimes introduce residual currents and voltage of high frequency. A filter is in many cases necessary to reduce this effect.

When induction due to normal operating conditions had been studied and remedies developed, the abnormal or fault conditions remained and these present the real problem to day.

Abnormal conditions in the power system generally produce large residual currents and voltages and the inductions from these residuals may, in the case of a very severe exposure, amount to several thousand volts.

The electrostatic induction from abnormal residual voltages may be calculated by the method of images based on the hypothesis that the earth is a perfect conductor and may be replaced by a perfectly conducting plane at the surface of the earth.

When the method of images was applied to the calculation of induction from residual currents and the calculations were checked by tests it was immediately apparent that the surface of the earth could not be used as the equivalent conducting plane and many tests were made in different parts of the country to determine the proper location of such a plane. It was found that the proper depth for the equivalent plane varied widely with the nature of the ground and also with the distance between the two circuits. This method of calculating induction from residual currents has therefore been abandoned.

As a third approximation the earth is assumed to be a uniformly conducting body. The results calculated on this basis agree much more closely with the facts as determined by experiment but since the conductivity of the ground varies irregularly at different places and at different depths the most carefully calculated results cannot be taken as correct until their accuracy is demonstrated by test.

The ratio of maximum to minimum specific resistance of the earth met with in practice is about one hundred to one and the corresponding ratio of maximum induction to minimum induction varies with the distance between the circuits, being only about two to one for roadway separations but increasing rapidly as the separation increases. It is therefore very important to know the earth conductivity when calculating the induction to be expected in exposures especially with wide separation of circuits.

The abnormal conditions which give the greatest amount of trouble are (a) short-circuits; (b) grounds and (c) switching of loads or lines.

Short Circuits

Short circuit currents flowing in many modern systems are very large since the combined capacity of generators and synchronous motors connected to the system is large. It is to the advantage of the power company as well as of the signal company that short circuit currents should be limited, as the oil switches must be able to clear the worst short circuits without injury.

Three phase short circuits are not usually very troublesome as the currents and voltages in the three phases are more or less balanced. Single phase short circuits are however very serious as they are both electrostatically and electromagnetically unbalanced.

Grounds

When a system is connected star with grounded neutral, a ground on any phase constitutes a short circuit which is cleared by the overload protection but in the meantime the single phase short-circuit has caused a disturbance in the neighbouring signal system.

The magnitude of the fault currents can be reduced by inserting resistance or reactance in the neutral connection to ground. There has been however some difficulty in adopting this method as it has been found that the neutral impedance required to adequately limit the fault currents are, in the majority of cases, of such magnitude that the power transformers must be insulated for full line voltage and their cost is therefore increased.

There seems to be a growing tendency to standardize the star connection with neutral connected to ground through a medium resistance or reactance. The Peterson grounding coil has not as yet been applied in Canada.

When an isolated system is grounded at one point it can still operate but it is electrostatically unbalanced and will cause some electrostatic interference in neighbouring communication systems. If, however, a second ground on another phase occurs at some distance away, a fault current will flow out on the phase wire and back through ground. This will cause serious electromagnetic induction.

If a ground wire is installed it will carry part of the ground current and so will reduce the interference. High resistance steel ground wires will reduce the magnetic field created by the fault about 10 per cent. High conductivity ground wires may be expected to reduce the field by 35 to 40 per cent but to be effective they must extend over the whole distance affected by the fault and must be grounded through low resistance grounds.

The signal companies are in some cases asking the power companies to install high conductivity ground wires practically equivalent to the phase wires but this expenditure can only be justified in very exceptional cases.

Switching

Switching on and off of loads does not cause serious interference, but switching lines on and off may induce high voltages. Switching an unloaded line off is one of the most troublesome cases.

If under transient fault conditions the voltage induced along the two wires of a signal system in parallel does not exceed 400 or 500 volts no serious interference with the operation of the signal system should result unless the impedances to ground of the two sides of the system are unbalanced.

The exact limits of magnitude of induced voltages which can be effectually handled by acoustic shock preventing devices have not been definitely determined up to the present and they depend to a considerable extent on the impedance of the circuit through which the voltage operates. Currents up to 10 amp. have been discharged without causing severe acoustic shock.

Acoustic shock absorbing devices have been developed for the purpose of protecting telephone operators from such shocks but they cause appreciable losses in the circuits and are not applicable to substations and therefore cannot protect the public from these shocks.

The Common Neutral System

When the primary distribution system grows beyond the economic limits of the 2,000 volt delta network, it is the usual practice to change the voltage to 4,000 volt star retaining the same transformers as before. A fourth wire is installed to carry residual currents. This neutral wire may be connected to ground at the substation only or a number of grounds may be installed at different parts of the system. The primary distribution with multiple grounds gives a better voltage regulation for the power system but the residual current cannot be confined to the neutral wire and often more than 50 per cent of it will flow through the ground. This stray current gives trouble to the telephone companies particularly to the two-party lines which use the ground as part of the ringing circuit. However comparatively slight modifications of the telephone systems enable them to operate satisfactorily and it seems probable that the multiple grounded primary neutral should be accepted as standard. With underground systems no trouble is experienced.

When a secondary grounded network is provided including the water system it is common practice to connect the primary neutral system to the secondary ground network and this gives the common neutral system which appears to be the system which will be employed almost universally, but the power companies must take all precautions to maintain a good wave shape.

Hydro-Electric Industry of Canada

Some Economic Aspects

G. Gordon Gale, M.E.I.C.,

Vice-President, Canadian Hydro-Electric Corp. Ltd., Ottawa, Ont.

Paper presented before the Second World Power Conference, Berlin, Germany, June 16-25, 1930.

The phenomenal expansion of recent years has established the hydro-electric industry as one of the foremost activities in Canada. The rapid development of many new power sites and the widespread extension of transmission lines have created conditions which present certain economic aspects of particular interest.

It is first necessary to review briefly the situation with regard to all the available power resources throughout the Dominion in order to appreciate the predominance of water power as a source of energy.

Fuels as a source of power are found in abundance in the east in the bituminous coal deposits of Nova Scotia and in the west in Alberta and southeastern British Columbia and on Vancouver Island. Lignites are found in southern Saskatchewan, oil and natural gas in Alberta and to a limited extent in the southwestern peninsula of Ontario. In the central part of the Dominion, notably in the provinces of Ontario and Quebec, native fuels are almost entirely lacking but compensation is afforded by the widespread occurrence of ample water powers fortunately situated with regard to both the centres of population and to the other great natural resources of forests and minerals.

Fuels are used almost exclusively as a source of power for rail transportation in Canada, the exceptions being urban and suburban electric railways which in the main are operated by hydro-electricity purchased from central electric stations. Fuels are also used to a limited extent in general manufacturing and to a much more limited extent in the central electric station industry, the latter use being largely confined to Saskatchewan and parts of Alberta, Manitoba and the Maritime provinces. Due to its availability and the advantageous rates at which it is sold, hydro-electric power produces over 98 per cent of the electricity used by the public.

A comprehensive review of the water power resources of the Dominion and their development is being presented to the Conference by Mr. J. T. Johnston, M.E.I.C., Director, Dominion Water Power and Reclamation Service, Department of the Interior, so that it is only necessary to repeat here the estimates of total resources and present development in order to better understand the discussion which follows.

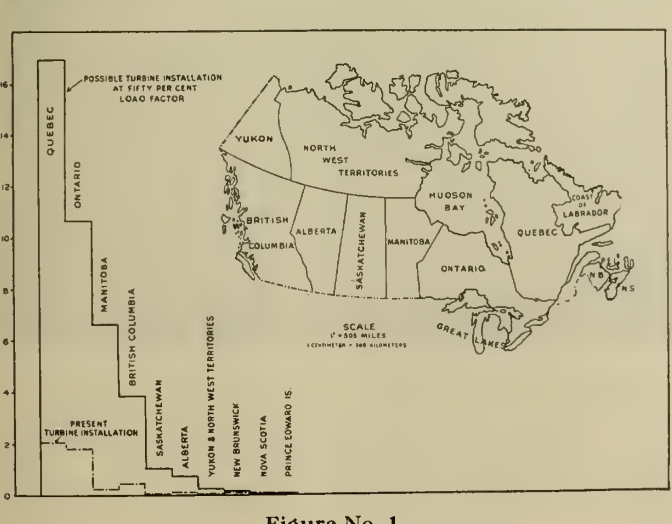

Figure No. 1.

Figure No. 1 presents graphically the possible turbine installation at approximately 50 per cent load factor and the total turbine installation at January 1st, 1930. This provides an interesting basis of comparison between developed and undeveloped water power in each of the provinces of the Dominion while table No. 1 lists for each province and for the Dominion as a whole, the total estimated water power resources and the total turbine installation in horse power at January 1st, 1930. The turbine installation is further divided to show the totals utilized by central electric stations and by other industries. These figures indicate that more than 84 per cent of Canada's total water power installation is in central electric stations and while definite figures are not available as to what part of the turbines in the "other industries" group is connected to electric generators, the best possible estimate leads to the conclusion that not less than 40 per cent is so connected.

Historical—Early Hydro-Electric Development and the First High Voltage Transmission

The utilization of water power for the generation of electricity started some forty years ago when certain

Table No. 1—Available and Developed Water Power in Canada

Canada......	20,347,400	33,617,200	5,710,802	4,802,263	908,539

The figures in columns 2 and 3 represent 24 hr. power and are based upon rapids, falls and power sites of which the actual existent drop or the head possible of concentration is definitely known or at least well established. Many rapids and falls are scattered on streams from coast to coast which are not yet recorded.

The figures of column 4 represent the actual water wheels installed throughout the Dominion and average 30 per cent greater than the corresponding available power as calculated in column 3. The figures quoted above therefore indicate that the *at present recorded water power resources* of the Dominion will permit of a turbine installation of about 43,000,000 h.p., i.e., the present turbine installation represents only *slightly more than 13 per cent* of the present recorded water power resources.

Columns 5 and 6 divide the total hydraulic installation into that used for the public distribution of electricity and that installed for industrial purposes.

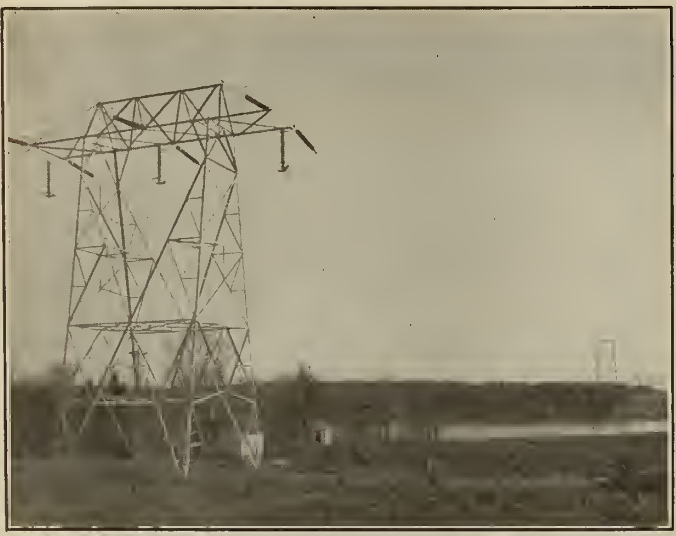

Figure No. 2.—Gatineau-Toronto Transmission Line Crossing the Ottawa River.

The first 220,000-volt line in the British Empire. A patrolman's house with telephone booth may be seen. A telephone line, built for operating purposes, parallels the power line 60 feet (18.3 m.) from the centre line of the towers except at the river crossing where it is carried on the steel towers below the power wires.

developments were established from which electricity was generated and distributed at generator voltage to immediately adjacent communities. The city of Ottawa is a case in point, hydro-electricity being produced for use within the city as early as 1890 from a plant at Chaudiere Falls on the Ottawa river. Such developments were the direct result of the then recent introduction of the incandescent electric lamp. The real impetus to hydro-electric development came, however, with the introduction of high voltage transmission which, in Canada, dates from 1895 when power was transmitted from a 1,200-h.p. plant on the Batiscan river to the city of Three Rivers, Quebec, over an 11,000-volt line, 17 miles in length. This was reputed to be the first high voltage transmission line in the British Empire.

The feasibility of remote utilization being thus established, similar developments rapidly followed at widespread points, Montreal receiving power from Lachine; Quebec City from Montmorency Falls; Hamilton, Ontario, from DeCew Falls; Victoria, British Columbia, from the Goldstream river and Nelson, British Columbia, from the Kootenay, all in 1898.

Advances in Transmission

Improvements in transforming equipment developed rapidly, leading to higher transmission voltages and correspondingly longer transmission lines. To supplement the supply of power to Montreal, an eighty-five mile, 50,000-volt transmission line was built from Shawinigan Falls in 1903, this being the longest and highest voltage transmission line in America at that time. It is interesting to note that by 1911, an additional double circuit line operating at 100,000 volts was provided to supplement this service. In 1906 power was first received in Toronto from Niagara Falls, 90 miles distant, at 60,000 volts, while in the same year Winnipeg river power was first transmitted to the city of Winnipeg over a 60,000-volt line 65 miles in length.

The next outstanding achievement in the transmission of hydro-electricity in Canada followed the creation of the Hydro-Electric Power Commission of Ontario which in 1910 commenced the transmission of power purchased at Niagara Falls to 12 municipalities in western Ontario at 110,000 volts. This system was gradually extended until by October 31, 1928, 833½ miles were operated by the Commission at that voltage.

While many improvements in conductors, insulators, switching and transforming equipment were developed, 110,000 volts remained the highest Canadian transmission voltage until 1927 when the Shawinigan Water and Power Company completed a 168,000-volt line 135 miles in length to transmit power from the great Saguenay river development of the Duke-Price Power Company to Quebec City. This achievement was followed in 1928 by the building of a 220,000-volt line from the Paugan station of the Gatineau Power Company to Toronto, a distance of 230 miles. A second line at the same voltage on the same right of way is scheduled to go into operation in August, 1930, to complete the delivery of 260,000 h.p. purchased by the Hydro-Electric Power Commission of Ontario. These lines are illustrated by figures Nos. 2 and 3.

The extension of transmission systems has led to widespread distribution of power and a gradual reduction in the number of the fuel power stations serving individual municipalities. The most outstanding instance has occurred in Ontario where over one hundred fuel stations serving as many municipalities have been replaced by hydro power distributed by the Hydro-Electric Power Commission. To a lesser extent similar replacement of fuel stations has occurred in the other provinces and is most marked at the present time in Alberta where the extension of the Calgary Power Company's distribution has brought hydro-electricity within the reach of a large number of communities formerly dependent on small steam or internal combustion plants. The widespread distribution of electricity has had a very marked effect upon living conditions in Canada. It is estimated that approximately 62 per cent of Canadian homes are wired for electricity, an outstanding proportion when due consideration is given to the fact that 45 per cent of the population dwell in rural areas.

In the domestic field not only are all the more common electrical appliances such as irons, washing machines, toasters, cooking ranges and small heaters in general use but newer devices including electric refrigerators, ironers, household water supply plants, dishwashers, and radio receiving sets are being constantly introduced and are meeting a growing demand. In the larger power field the electrification of the manufacturing industries is rapidly progressing, practically all operating either partially or wholly by electricity most of which is purchased from central electric stations.

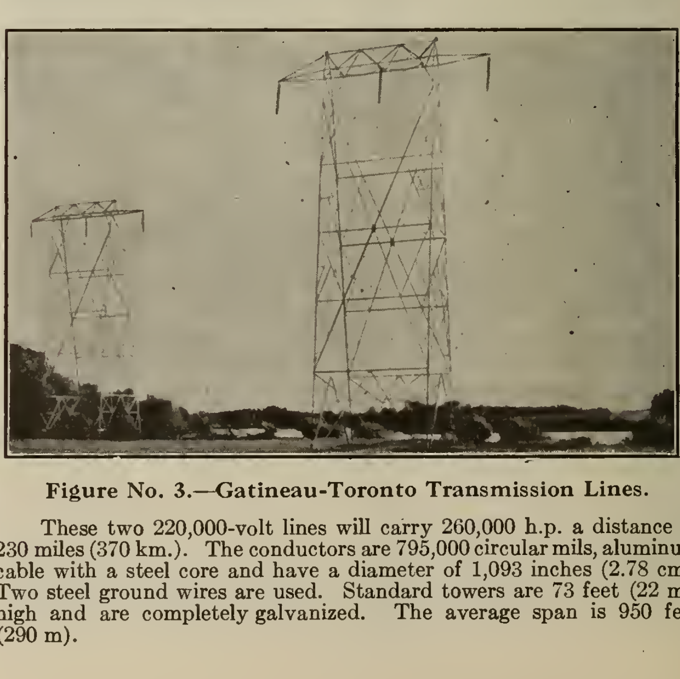

Figure No. 3.—Gatineau-Toronto Transmission Lines.

These two 220,000-volt lines will carry 260,000 h.p. a distance of 230 miles (370 km.). The conductors are 795,000 circular mils, aluminum cable with a steel core and have a diameter of 1,093 inches (2.78 cm). Two steel ground wires are used. Standard towers are 73 feet (22 m.) high and are completely galvanized. The average span is 950 feet (290 m).

Figure No. 4.—Aeroplane View of the Paugan Development of the Gatineau Power Company.

Showing the sluiceways on the right, the power house in the centre and 202,000-volt switching station on the left. In the river above the power house may be seen pulpwood logs being directed towards the log chute which is situated just left of the sluiceways. At the extreme left of the intake to the power house is the by-pass through which the river was diverted during the construction period. Six 34,000-h.p. generators are now installed in the power house which is designed for eight machines. The dam is built for six additional units, making an ultimate installation of fourteen.

Intensive study in connection with the design, installation and operation of central electric station equipment has resulted in such high operating efficiencies that not much room remains for improvement in these particular fields. Further economies in the industry are dependent upon such major processes as the interconnection of stations and systems giving the fullest utilization of stream flow, head and storage and providing a diversity of use producing highly efficient operation; the consolidation of controlling and operating companies with its accompanying opportunities for low cost financing and widely experienced executive and engineering management, and, the standardization of equipment of well considered and satisfactory design.

The Interconnection of Stations and Systems

As the demand for power increases, the problem of the complete utilization of stream flow becomes of increasing importance. One factor in solving this problem is the establishment of a series of interconnected installations on the same stream so designed as to correlate the heads and storage to produce the greatest output at the least capital expenditure.

The development of a number of plants on a stream under centralized control or of one large plant while possessing great economic advantages for the maximum production of power, involves such heavy capital expenditures that it becomes necessary to produce and market the fullest possible output with the least possible delay.

If a market for the power is not already available, it becomes necessary to create one even if this initial load does not provide an adequate return on the capital invested. This initial load may be and often is, provided by the establishment of some industry where steam for use in the manufacturing process may be generated in electric steam boilers until a more advantageous market can be found for the power while even after the development of a market at ordinary commercial rates, the low capital expenditure involved in an electric steam boiler installation warrants its retention for the use of any surplus or off-peak power.

Field for Electric Steam Boilers

It is well recognized that steam cannot be produced by electricity as ordinarily sold on the kilowatt hour basis, in direct competition with coal, except in cases where surplus power is available which can be contracted for at a low rate.

In estimating the possible revenue from the sale of electricity for the production of steam the relationship existing between the energy in a kilowatt hour and in a pound of steam must be considered. One kilowatt hour will produce in an electric boiler approximately three pounds of steam. One ton of coal will produce about 15,000 pounds of steam, i.e. 5,000 kw.h. of electricity will produce the same amount of steam as a ton of coal. The price of electricity for steam generation is, therefore, determined by the cost of coal.

While the revenue obtained from the sale of power for steam is generally insufficient to pay the fixed charges on the development, it is sufficient to permit many large installations being brought into operation when only a comparatively small proportion of their output can be sold at ordinary commercial rates.

Examples of Centralized Control

A recent notable instance of the development of a river under single control is afforded by the construction programme of the Gatineau Power Company on the Gatineau river in the province of Quebec.

Like most of the rivers draining the northern slope of the St. Lawrence valley, the Gatineau was subject to periods of very low flow, consequently power development on a large scale was uneconomic without extensive storage. No single development could be made to carry the high annual charges involved in adequate storage. To justify any development it was necessary to contemplate the construction of three plants and the storage of at least 100,000 million cubic feet of water.

These three plants were designed and constructed for a total installation of 562,000 h.p. with an initial installation of 378,000 h.p. which has since been increased to 436,000 h.p. One of the developments, the Paugan station, is so designed that a further 204,000 h.p. may be installed in an extension to the present power house if interconnection with other systems where navigation or other considerations preclude the storage of water, warrants low load factor operation on the Gatineau river.

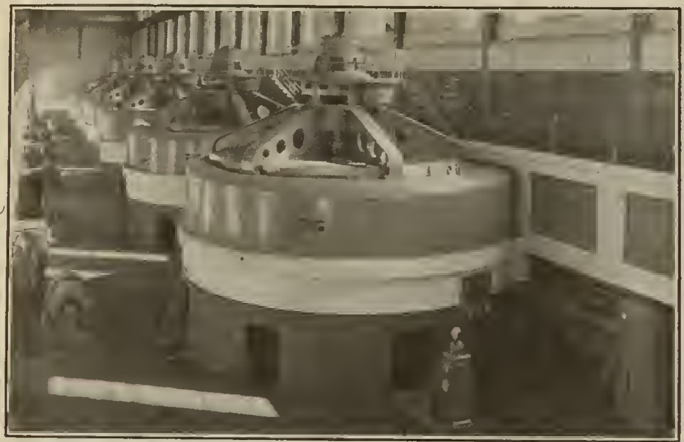

Figure No. 5.—Interior of the Generator Room, Paugan Station of the Gatineau Power Company.

The generator ventilating system is of the totally enclosed type and is controlled by the louvres at the right of these machines. The motor-generator sets at the left and the auxiliary generator which may be seen just below the railing around the direct connected exciters are part of the high speed excitation system used for maintaining the stability of the 220,000-volt system through which Paugan is tied in with Niagara 310 miles (500 km.) away.

The initial storage of 100,000 million cubic feet originally provided under the aegis of the Quebec Streams Commission in the Baskatong reservoir has been supplemented by the creation of the Cabonga reservoir where more than 45,000 million cubic feet of water are impounded.

The generation of the tremendous amount of power attendant upon such development necessitated the finding or creating of new markets for the output. These markets were provided by the building by an associated company of the world's second largest pulp and paper mill to which energy was sold not only to meet its heavy power demands but also for the generation of steam in electric boilers, and by the completion of contracts with the Hydro-Electric Power Commission of Ontario for the sale of some 360,000 h.p. of electrical energy to supplement the supply to the Niagara, Rideau, St .Lawrence and central Ontario systems.

The economic development of the Gatineau river on such a magnificent scale within a period of a few years is an event of outstanding importance in the field of hydro-electric undertakings. It was followed by the acquisition by the same company of three plants controlled by another organization on the Ottawa river, a stream of very limited regulation. These plants have been interconnected with those on the Gatineau river and are used to the maximum capacity of the water available (which on account of lack of regulation would have been wasted if not used) with a corresponding saving in water on the Gatineau river where regulation provides for the storing of water until load conditions warrants its use. The improvement in operating conditions in the Ottawa river plants is strikingly illustrated in figure No. 7 which shows representative weekly load curves for the three plants before and after interconnection with the Gatineau river stations.

The lower load curve on figure No. 7 is that for a typical week in October 1928 before interconnection was effected and the upper that for the corresponding week in October 1929, after interconnection. Not only were the operating conditions of the Ottawa river plants improved but it became possible to effect economies by the doubling of the equipment in one of them to achieve fuller utilization of the available water.

A somewhat similar instance of the development of a stream by a single company in order to take the fullest advantage of the flow and storage occurs on the St. Maurice river. The Shawinigan Water and Power Company has acquired practically complete control of this river by new construction, the acquisition of plants operated by other organizations and by the leasing of undeveloped sites to provide for future power demands.

The first undertaking by this company was the building of headworks at Shawinigan Falls to provide power for its own power house and those of two manufacturing companies. Delivery of electrical power commenced in 1902 and the installation steadily increased until 280,000 h.p. was in operation. The completion of the Gouin storage dam by the Quebec Streams Commission in 1917 increased the amount of power available at Shawinigan Falls in low water periods by 100,000 h.p. This dam is located at La Loutre about two hundred miles from the mouth of the river and impounds approximately 175,000 million cubic feet of water. Further storage is provided on the Manouan river, a tributary of the St. Maurice, where 17,000 million cubic feet of water are impounded. The Gouin and Manouan dams store sufficient water in their reservoirs to generate one thousand and ninety million kilowatt hours when utilized in the company's power houses at Shawinigan Falls, La Gabelle and Grand'Mere. The recent purchase of the latter brought the company's total installation on the St. Maurice to 576,000 h.p. The local storage ponds at these three plants are under such control due to the efficient regulation of the stream that a balance of the electrical loads of each is maintained with the result that the water is utilized to its fullest value in its passage to the St. Lawrence.

By the acquisition of the remaining undeveloped water powers on the St. Maurice the company has placed itself in a position to take the fullest economic advantage of the storage provided. The sites so acquired have an estimated capacity at commercial load factors of 600,000 h.p.

Many similar cases of interconnected developments occur throughout Canada. In British Columbia by the erection of a dam at the outlet of Alouette lake into the Alouette river the level of the lake was raised 45 feet and its water diverted through a tunnel into Stave lake. By the construction of a power plant at the mouth of the tunnel 12,500 h.p. is developed, the water being again used at the Stave Falls plant while a third development at Ruskin near the mouth will utilize the water of Stave lake for the second and that of Alouette lake for the third time. The increased flow in the Stave river due to the diversion

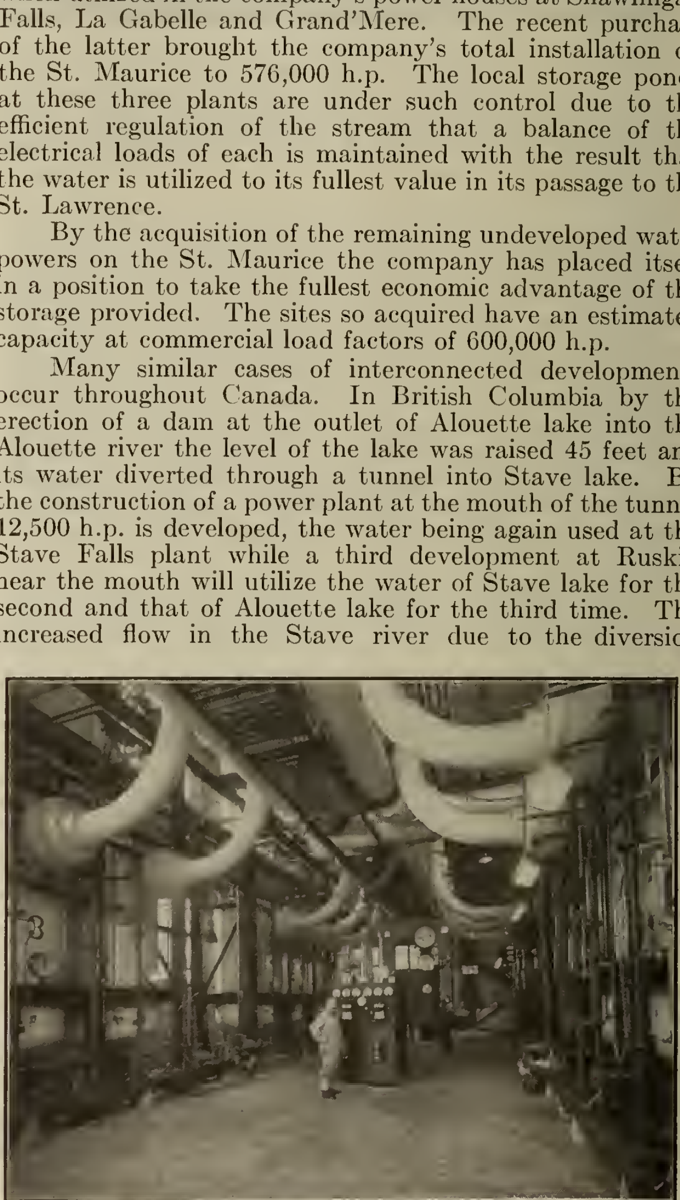

Figure No. 6.—Interior of Gatineau Pulp and Paper Mill Boiler Room.

This is the largest single installation of electric steam generators in the world. The four generators in this comparatively small room use 150,000 kw.

thereinto of the waters of Alouette lake provided power for the installation of an additional unit at Stave Falls and rendered economic the raising of the head at that plant with its attendant provision of additional storage. The net result of the scheme was that the installation of the Stave Falls plant was raised from 52,000 h.p. to 77,500 h.p., the new plant at Alouette dam produces 12,500 h.p. and additional water and more uniform flow is provided for the plant now under construction at Ruskin. The ultimate designed capacity of this plant is 170,000 h.p.

In Alberta the development of the Bow river is in the hands of the Calgary Power Company which operates two plants totalling 31,600 h.p. near Seebe, and a recently completed station at Ghost Falls where 36,000 h.p. is installed. The three stations are interconnected and the flow of the stream is regulated by the Minnewanka storage dam 30 miles upstream which impounds over one thousand, nine hundred million cubic feet of water in Minnewanka lake for use in each of the three plants in turn. The Ghost development, the furthest down stream, is a combined power and storage scheme and provides pondage for an additional three thousand, two hundred and ten million cubic feet of water.

In Ontario, the Hydro-Electric Power Commission wherever practicable has interconnected its plants. On the Nipigon river the Commission operates a 75,000 h.p. plant at Cameron Falls and is constructing another 54,000 h.p. at Alexander Landing while the remaining power sites on the river are also marked for development by the same organization.

As the amount of water available for the operation of the Niagara stations of the Commission is fixed by International Treaty, the three plants, Queenston of 502,000 h.p., Ontario Power of 208,200 h.p. and the Toronto power station 164,500 h.p. are interconnected and operated to obtain the maximum power. As water used at the Queenston generating station will develop more than double the power that it would develop if used at the other stations, this station is operated to carry the maximum load possible at all times. The efficient operation due to this apportionment of the available water is evidenced by the peak load figures of the plants for the year ended October 31, 1928, viz., 529,469 h.p. for the Queenston station, 182,574 h.p. for the Ontario power station and 141,019 h.p. for the Toronto power station.

The Commission's Georgian bay system is supplied with power by six interconnected stations of the Severn, Eugenia, Wasdells and Muskoka divisions and notwithstanding the fact that this system operates at 60 cycles and the Niagara system at 25 cycles the two are interconnected through frequency changing equipment at Mount Forest. The Commission's central Ontario and Trent systems include nine generating stations on the Trent canal waterways and these are all interconnected for efficiency in operation while the system is tied in to the St. Lawrence Rideau and Ottawa systems which also receive a substantial supply of power from the Gatineau Power Company's plants on the Ottawa and Gatineau rivers.

The Nova Scotia Power Commission operates three combined power and storage schemes. One of these, the St. Margarets bay system, includes three generating stations on the North East river. These stations have an aggregate installation of 15,820 h.p., are interconnected and utilize not only the waters of the North East river but also those of the Indian river which is diverted into the North East by damming. Four storage reservoirs have been created in connection with the system, Five Mile and Big Indian lakes reservoirs on the Indian river and Pockwack and Wrights lakes reservoirs on the North East river. These impound three thousand, five hundred and seventy-two million cubic feet of water.

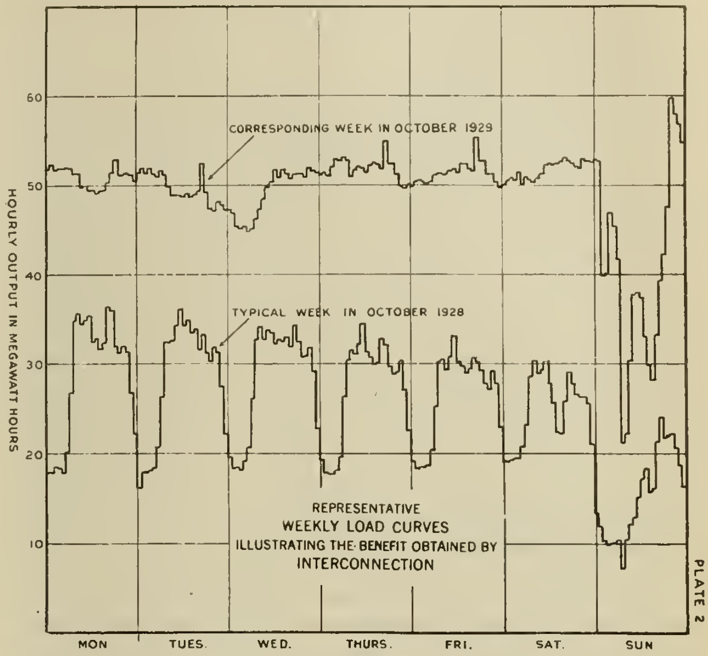

Figure No. 7.

The Sheet Harbour system has at present two interconnected generating stations on the East River Sheet Harbour of an aggregate capacity of 11,849 h.p. and a very extensive system of storage reservoirs throughout the drainage basin of the river which impound four thousand and sixty-two million cubic feet of water, equivalent to eight million, nine hundred and forty-two kilowatt hours when used in the two plants.

The third system, the Mersey, includes three generating plants totalling 31,050 h.p. on the Mersey river. These plants are interconnected and extensive storage is provided on the upper reaches of the river.

Many other instances of interconnection of Canadian generating stations leading to economies in the use of water could be quoted and considerable as are the advantages so derived they are perhaps secondary to those accruing from the interconnection of the transmission systems of related or independent organizations.

The Interconnection of Transmission Systems

The interconnection of transmission systems has many advantages in Canada where the widespread application of electricity to domestic, commercial and industrial utilization produces a diversity of load characteristics in different areas which permits of high load factor operation when the systems supplying these areas are interconnected.

In the cities, for example, the heaviest load usually occurs in the winter just before the factories cease operations for the day. The lighting load is then at its peak and the street car load is heavy. In small towns and villages the peak load occurs later in the evening. Construction and mining loads are usually high during the summer months and help to balance the winter lighting and heating peaks. Even in the field of purely domestic supply the existence of rates low enough to bring electric ranges, water heaters and the numerous other appliances available into every day use in large numbers of homes has done much to provide diversity in a load in which the average consumption was formerly very low and the period of maximum utilization short. The sum of these various loads in different areas ensures much higher load factor operation of interconnected systems than if the individual loads were carried by isolated systems. The selling of any off-peak or surplus power for the generation of steam, the smelting or casting of metals or for electro-chemical processes does much to increase the already high average load of such interconnected systems.

In the generation of hydraulic power the fullest use of the generating equipment at high load factor results in the lowest cost of the electrical energy so produced.

The saving effected in installation by the interconnection of systems is also very great in that it obviates necessity for large reserves of generating machinery. Isolated stations which must rely on their own resources to ensure continuity of service are practically compelled to install sufficient spare generating equipment to carry their peak loads with their largest units out of operation. The effect of interconnection in this respect is to pool the spare equipment, the amount required by the interconnected systems being very little greater than that which would have been necessary for the system with the largest individual load if interconnection had not obtained. Interconnection has helped to eliminate on practically all Canadian systems the necessity of maintaining auxiliary fuel power equipment.

Economies in the installation of new equipment are also effected by the installation of the larger, lower unit cost and more efficient equipment which is rendered possible by the stagering of construction operations by the different members of the interconnection. For example, if two interconnected loads are each growing at the rate of say 10,000 h.p. per year, it is possible for one organization to install a 20,000 h.p. unit to provide for the growth in the two systems to be followed later by the installation of a similar unit by the second constituent member.

Great economies in the utilization of water are also effected by the interconnection of systems generating power on watersheds of different regimen, the heavy flow from seasonal or abnormal weather conditions occurring at different times provides for the use of the maximum amount of water which cannot be stored, while conditions of abnormal low flow on some watersheds are frequently compensated for by satisfactory water conditions on others.

Most of the larger Canadian organizations generating electricity for public use have their transmission systems interconnected with at least one other system for the interchange of power. The most outstanding instance of this occurs in the province of Quebec where five organizations generating over 90 per cent of the total central station output of the province are so interconnected. These are the Gatineau Power Company which operates 6 plants aggregating well over half a million horse power on the Gatineau and Ottawa rivers in the Hull-Ottawa district and 12 smaller stations serving the district along the north shore of the Ottawa river between Hull and Montreal, the Montreal Light, Heat and Power Consolidated serving the city and district of Montreal from three stations totalling 229,500 h.p. on the St. Lawrence and one of 21,600 h.p. on the Richelieu river; the Shawinigan Water and Power Company and subsidiaries serving the districts along the north shore of the St. Lawrence from Montreal to Murray bay and between the St. Lawrence and the International and New Brunswick boundaries from sixteen stations with a total installation of 647,850 h.p.; the Southern Canada Power Company serving the district south of Montreal to the international boundary from five stations totalling 58,000 h.p. and the Duke-Price Power Company operating a 495,000 h.p. station at Isle Maligne on the Saguenay river.

In the province of Ontario the Hydro-Electric Power Commission has interconnections with a number of privately or municipally owned systems. The Niagara system receives power from the Canadian Niagara Power Company, from its own Georgian bay system, and from the Gatineau Power Company. The Georgian bay system in turn receives power as required from the Niagara system, from the municipality of Orillia's 6,360 h.p. plant on the Severn river which is operated in parallel with the six hydraulic plants of that system and from two steam power plants, one operated by the municipality of Owen Sound and the other by the Canadian Pacific Railway Company in Port McNicoll. The central Ontario and Trent systems secure power from the Gatineau Power Company while reciprocal arrangements for the exchange of power exists with the Peterborough Hydraulic Company, the Campbellford Water and Light Commission, the Canadian General Electric Company and the municipality of Fenelon Falls which organizations operate hydraulic plants with an aggregate installation of 12,770 h.p. The Rideau system receives power from the Gatineau Power Company and the Rideau Power Company while the St. Lawrence system also receives power from the Gatineau Power Company.

The Dominion Power and Transmission Company which operates a 45,000 h.p. hydro-electric generating station at DeCew Falls, near St. Catharines, and a 29,500 h.p. steam auxiliary plant in Hamilton is interconnected with the Canadian Niagara Power Company's 121,000 h.p. plant at Niagara Falls which as already stated is in turn connected with the Hydro-Electric Power Commission's generating stations at Niagara Falls.

In the province of Manitoba, the three large systems now in operation, that of the city of Winnipeg, 105,000 h.p., the Winnipeg Electric Company, 37,800 h.p., and the Manitoba Power Company, 168,000 h.p., are all interconnected for the exchange of power as required.

In New Brunswick a reciprocal arrangement for the exchange of power exists between the New Brunswick Electric Power Commission and the New Brunswick Power Company which operates a 6,600 h.p. fuel power plant in the city of Saint John.

In addition to the existing interconnections in the provinces of Quebec and Ontario, the Beauharnois Light, Heat and Power Company, recently formed, has started construction on the Beauharnois development, the first link in the much talked of St. Lawrence Waterways scheme. The initial development will be 500,000 horse power and power will be supplied to both the Hydro-Electric Power Commission in Ontario and the Montreal Light, Heat and Power Consolidated in Quebec thus providing a further interconnection between the power resources of the country's two leading provinces.

Commencing with the simple form of interconnection between the generating stations controlled by one organization, the practice has developed rapidly and will by force of circumstances be an increasingly important factor in the expansion of the hydro-electric industry. In interconnection between independent systems the making of contracts is one of the major problems. The numberless conditions of load division, segregation of losses, pooling of reserves and the allocation of fixed charges tend to make the necessary working agreements deeply involved but the advantages in operation are so outstanding that every year sees new interconnections effected.

There are necessarily economic limits to the interconnection of electrical systems and when no further improvement can be obtained in diversity, load factor and service and the cost of transmission due to distance becomes too great these limits have been reached.

The Consolidation of Operating and Controlling Organizations

Quantity production of electricity as of manufactured products leads to lowered unit costs and the consolidation of operating organizations has done much to provide more extended service at more advantageous rates. Consolidation has frequently resulted in taking electric utilities out of the hands of local capitalists of limited financial and

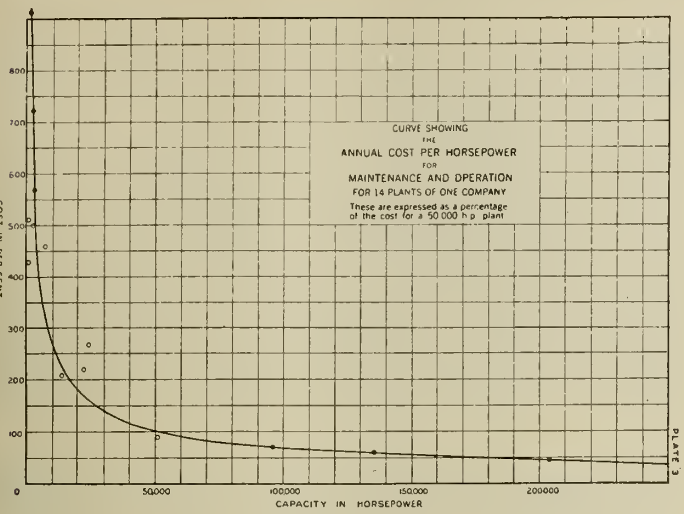

Figure No. 8.

managerial ability combining them with others where ample finances and expert executive and engineering management have led to their rapid development. In many cases plants developed to meet local needs but too small for economical operation have been dismantled and their markets supplied by the larger plants while plants capable of enlargement have been extended to capacity.

The economic advantages of replacing these small plants is very great as is illustrated in figure No. 8 which shows comparative costs for maintenance and operation of fourteen representative stations of different size expressed as a percentage of the cost for a 50,000-h.p. plant. As will be noted the disparity in costs in favour of the larger plants is very marked.

Practically all the larger systems in Canada are the result of a combined policy of the construction of new stations and the acquisition of existing ones with their appurtenant markets for power.

The Hydro-Electric Power Commission of Ontario, the world's largest distributor of electricity, which operates thirty generating stations has purchased eighteen of them of a totalled combined capacity of 450,309 h.p. These eighteen stations vary considerably in size the largest being the plant of the Ontario Power Company at Niagara Falls which at the time of its acquisition had an installation of 228,200 h.p. and the smallest that of the municipality of Gravenhurst at South Falls on the Muskoka river where 750 h.p. was installed. Only one of these (purchased during the past year) is operated as an independent unit.

The Shawinigan Water and Power Company has also done much to extend the sphere of its operations by the purchase of plants and distribution systems operated by other organizations. Beginning with the acquisition of the North Shore Power Company in 1907, numerous purchases have been made until the company now owns eight central electric station companies. The company also controls by stock ownership the Quebec Power Company and has substantial stock interests in other important central station organizations.

The Gatineau Power Company has also followed a policy of acquiring stations within its area of operation. The company was incorporated in 1925 to take over the developed and undeveloped water power sites acquired by the International Paper Company. The operation of the existing plant at Kipawa was at once assumed and the development of three sites on the Gatineau river commenced. During the period 1925 to 1928 the Company acquired sixteen central station Companies operating in the Ottawa and the Gatineau river valleys. The interconnections effected between the stations acquired by this company have had a most marked effect upon the distribution of electricity in the very extensive area served. Certain of the smaller stations which have proved unsatisfactory in service and operating costs have been closed or dismantled while operation by remote control from other stations will provide for more economical operation of others.

The Montreal Light, Heat and Power Consolidated which provides the electric power distribution in Montreal, Canada's largest city, had its beginning in 1902 and is now made up of ten consolidated companies.

The Southern Canada Power Company was incorporated in 1913 as a merger of several then existing companies and later acquired seven municipally owned and fourteen privately owned generating stations or distribution systems. Several of the generating stations acquired proving too inefficient and costly to operate were dismantled or replaced.

The principle of consolidation of operating companies as described above is general throughout Canada and numerous other instances of such consolidation might be cited. Another factor of more recent adoption in the Canadian central electric station field is the formation of holding companies; i.e., companies organized to acquire and hold the securities of operating companies and frequently to operate, manage and act as fiscal agents for the companies so controlled.

The holding companies afford to the operating companies under their control many economies and advantages by the centralization of expert executive and engineering personnel. The services of highly skilled engineers such as would scarcely be available to individual companies are retained and a breadth of experience and technical knowledge in design, management and operation is available to the constituent companies.

Among the more important Canadian holding companies may be included the Power Corporation of Canada which controls through stock ownership East Kootenay Power Company, Limited, and Canada Northern Power Corporation which in turn controls Northern Canada Power Company, Limited, Northern Quebec Power Company, Limited, Great Northern Power Corporation, Limited, and Northern Ontario Light and Power Company, Limited. In addition to its controlling interest in the foregoing companies, Power Corporation of Canada has a substantial interest in some twelve other prominent Canadian central station organizations.

The Canadian Hydro-Electric Corporation, Limited, was organized in 1927 to acquire and control Gatineau Power Company, Gatineau Electric Light Company, Limited, and Saint John River Power Company.

Many of the larger operating companies also function as holding companies for the smaller organizations which they own or control and much of the successful operation of these subsidiary companies is due to the financial, executive and engineering connection with the larger companies.

Standardization of Electrical Equipment

The economic advantages of standardization of electrical equipment are so great that in spite of the occasional criticisms of suppression of individuality and artistic instinct in design, it has become accepted in principle and is in general being adhered to in practice.

Standardization in Canada had its inception in 1917 with the issuance of Letters Patent to The Canadian Engineering Standards Association. The main object of this Association is to promote the establishment of industrial standards by providing an organization to receive requests for standardization, investigate their desirability and arrange for the formation of committees comprising representatives of both manufacturers and users to determine standards acceptable to all interests concerned.

The Association is not concerned with, nor does it take any active part in the preparation of the specifications but it reviews the findings of the committees to satisfy itself that the standards have been properly prepared, and finally it arranges for their publication and issue.

Other objects of the Association as enumerated in its charter include the co-ordination of the efforts of producers and consumers for the improvement and standardization of engineering products and the promotion of the general adoption of engineering standards and the revision and amendment of such standards when necessary.

The Association endeavours to follow as closely as possible the standards prepared by the British Engineering Standards Association with which it is closely allied but in many cases on account of established business interests it has been found advisable to follow other standards already generally adopted in Canada. In all cases the specifications prepared are drafted to meet the requirements of and to operate in the best interests of Canadian industry.

The budget of the Association is guaranteed by the National Research Council of Canada with the understanding that special efforts be made to obtain financial support from Canadian industry. The ready response to this suggestion gives tangible evidence of industry's appreciation of the economic value of the work undertaken.

One of the outstanding achievements of the Association has been the compilation of the Canadian Electrical Code which has been officially adopted in the provinces of British Columbia, Nova Scotia, Ontario, Quebec and Saskatchewan. This code has also been officially adopted in the Bahamas, British West Indies.

The standardization projects now under consideration include a revision of Part I of the Electrical Code; the preparation of Part II of the code which will indicate suitable standards for electrical apparatus and materials which must be complied with in order to obtain approval for their sale or use in Canada and also of Part III of the code which will deal with outside wiring rules covering minimum requirements which may prove acceptable to all provincial authorities. Standardization of distribution type transformers, power transformers, and of oil for transformers and oil switches is also under way.

Conclusion

In the foregoing summary of three of the main economic aspects of the Canadian central electric station industry it has only been possible to touch on the highlights of each.

The expansion which is taking place in Canada in general industry, the transition from agricultural to industrial supremacy and the rapid development of our natural resources of forest and mine all combine to create a demand for power under conditions constantly varying and each involving some special economic problem. Great as has been hydro-electric development in the past the future will witness even more rapid and far reaching progress and there is no reason to fear that the problems arising therefrom cannot be successfully solved.

Economic Aspects of Electrical Supply in the House and on the Farm

F. A. Gaby, D.Sc., M.E.I.C.,
Chief Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ont.

Paper presented before the Second World Power Conference, Berlin, Germany, June 16-25, 1930.

The economic results of the rate policies followed by the co-operative municipal undertaking administered by the Hydro-Electric Power Commission of Ontario, Canada, will, it is believed, be of special interest to delegates attending the World Power Conference, with respect to a number of outstanding features.

In the first place, as regards the magnitude of its operations in the supply of electrical energy, the Ontario undertaking occupies a preeminent place among the electrical organizations of the world; second, the careful records necessitated in carrying out the Commission's fundamental policy of service *at cost* afford a body of data respecting the economic results of its policies which is unusually comprehensive and informative; finally, the success which has been achieved over an extensive territory with respect to the provision of service to consumers at low unit costs, is, when judged by the standard of results in many other territories, to be characterized as almost phenomenal, and has been the subject of widespread comment.

Scope of Discussion

Five years ago — at the time of the First World Power Conference — a good deal of information was presented dealing descriptively with various aspects of Ontario's municipal electrical undertaking, and no attempt is made to recanvass ground thus already covered. In the present discussion, attention will be focussed upon certain economic aspects of the undertaking, and, to limit the consideration to reasonable dimensions, these economic results will be especially illustrated with reference to service to urban residential consumers, and to agriculturists.

In order to give the economic features of electrical service in Ontario their proper setting so that they may rightly be interpreted in their relationships to electrical service elsewhere, the general circumstances appertaining to the province and its people, and to their unique electrical undertaking, will first of all be indicated summarily, with special reference to progress made since 1924. The economic structure of the enterprise will be outlined, the principles followed in designing the tariffs will be referred to, and the domestic rates or tariffs(1) themselves will be described in a general and comprehensive way. The economic results attained by the application of these tariffs will then be cited, having regard to the two principal aspects — the results from the standpoint of the consumer, and the results from the standpoint of the utility.

The Province of Ontario

Of the total land area of Ontario — some 365,000 square miles(2) — much the greater part is underlain by the rocky formation of the Laurentian plateau, geologically known as the "pre-Cambrian shield." This northern territory possesses immense forest wealth, and has mineral resources of which the present developments — though of substantial magnitude — are believed to be only a beginning. It, however, supports directly a relatively small part of the province's population of 3,200,000. The

(1) The term "Rates" is used in Ontario and in this discussion with the significance of "tariff" and carries no idea of "taxes."

(2) The total area of the province is about 407,000 square miles and includes about 41,000 square miles of water area—chiefly Canada's portion of the Great Lakes.

southerly part of the province, comprising an area of about 40,000 square miles, is a fertile agricultural territory, and is also admirably adapted by reason of an advantageous climate, abundant natural resources, good transportation facilities, a central situation in the Dominion, and ample supplies of low-priced hydro-electric power, to continue to have a remarkable industrial and commercial development. About sixty per cent of the people of the province live in urban communities, and the other forty per cent are occupied with agriculture, including fruit-growing.

Industrial development has proceeded along modern lines; expanding use of power-driven machinery has continuously increased the productivity of the workers, and the relatively high wage levels thus made possible have permitted the masses of the people to attain an unusually high standard of living.

Central station power supply in Ontario is almost entirely based upon the water powers. The commercially available potential water powers are conservatively estimated to exceed 6,000,000 h.p., nearly 2,000,000 h.p. having now been installed in developed power sites. The climatic, geological and topographical characteristics of the province are such as to favour the economical development of water powers to a degree which exceeds that in many other territories.

It should be emphasized, however, that as regards ease and inherent cheapness of development, the water powers of Ontario are in no sense phenomenal, and the low costs of service to consumers which prevail in the province cannot be attributed solely, or even principally, to low costs of generation, *per se*. However, insofar as the province may have an advantage over some other territories as regards the cost of generation of power, this is partly offset by the costs of widespread transmission from the power sites to the centres of consumption. Even in the relatively closely settled southern Ontario, the density of population is not high, averaging, for example, about one-eighth that of England. The central electric stations of the province have provided more than 5,000 miles of high-tension transmission lines, many of which are of large capacity, as well as over 9,000 miles of distribution lines. Transmission distances range up to a maximum of about 450 miles. In some of the smaller and more remote municipalities, therefore, the delivered costs of bulk power are comparable with those of larger cities served by steam-electric plants, in other countries.

It is believed that the exceptional economic results obtained in Ontario municipalities under the operations of their Hydro-Electric Power Commission, which serves about 75 per cent of the population of the province, will be of interest and of value to the delegates to this conference even though many of their own undertakings may not be served by hydro-electric developments of low or moderate cost.

Extent of Operations and Recent Progress

As indicative of the scope of the Ontario Hydro-Electric enterprise and of progress made in recent years, the statistical data presented in table No. 1 will be of value.

Economic Structure of Ontario Undertaking

Although the undertaking of the Ontario Hydro-Electric Power Commission is a business enterprise which, in many respects, is similar to electrical undertakings elsewhere, yet important differences exist of which account must be taken in order correctly to appraise the economic results which are the subject of this discussion.

The "hydro" electrical undertaking of Ontario, serving over 75 per cent of the population of the province, is an organization of a large number of partner municipalities, co-ordinated into groups or systems for securing common action with respect to power supplies, through the medium of the Hydro-Electric Power Commission which under the Power Commission Act functions as their trustee.

Table No. 1—Extent of Operations and Four Years Progress

	1924	1928
Number of municipalities served		
Cities	25	26
Towns	82	86
Villages	102	110
Police Villages[3]	78	113
Townships[3]	131	257
Total	418	592
Miles of primary transmission lines constructed		
High-tension lines (12 to 220 kv.)	3,616	4,039
Low-tension lines[4]	548	583
Rural low-tension lines (4 and 8 kv.)	909	4,651
Total	5,073	9,273
Growth of load		
Total available capacity including power contracted for	h.p. 864,690	h.p. 1,443,780
December peak load distributed	780,789	1,070,742
Number of consumers served		
Domestic service	332,999	410,655
Commercial light service	57,272	68,435
Power service	10,744	12,097
Rural power districts	14,907	31,583
Total	415,922	522,770
Revenues		
Combined revenue of Commission and municipal electric utilities	$ 24,855,056.01	$ 36,388,391.98
Reserves		
Of Commission for sinking fund, renewals, contingencies and insurance	$ 13,440,810.50	$ 37,545,583.86
Of municipal electric utilities	24,267,977.17	38,802,723.82
Total reserves	$ 37,708,787.67	$ 76,348,307.68
Capital investments		
Investments of Commission	$178,900,000.00	$211,200,000.00
Assets of Municipalities in "Hydro" undertaking	72,700,000.00	98,300,000.00
Total capital investment	$251,600,000.00	$309,500,000.00

(3) Most of the townships and smaller police villages are served as parts of rural power districts.
(4) Exclusive of local distribution.

The undertaking, embracing all the operations from the provision of the power down to its final delivery to the ultimate consumer, involves two distinct phases of operations. The first is the providing of the electrical power — either by generation or purchase—and its transformation, transmission and delivery in *wholesale* quantities to individual municipal utilities, to large industrial consumers, and to rural power districts. This phase of the operation is performed by the Hydro-Electric Power Commission of Ontario as trustee for the municipalities acting *collectively* in groups or "systems." The second is the *retail* distribution of the electrical energy to domestic, commercial and industrial consumers within the limits of the areas served by the various municipal utilities and rural power districts. This phase of the operations is performed by the municipalities acting *individually* in one of two ways. In the case of the cities, towns and larger municipalities it is performed by municipal utility commissions which, however, operate under the general supervision of the Hydro-Electric Power Commission. In the case of rural power districts the Commission itself — on behalf of the corporations of the individual municipalities — operates the rural power district, and distributes electrical energy to the customers of the corporations in any such rural power district.

The rates at which power is supplied by the Commission to the various municipalities vary with the amounts of power used, the distances from the sources of supply, and other factors. The entire capital cost of the various power developments and transmission systems is allocated to the connected municipalities and adjusted according to the relative use made of the lines and equipment. The entire annual direct expenses such as operation, maintenance, interest and administration, together with reserves for sinking fund, depreciation, contingencies and obsolescence, are paid out of revenue collected from the municipal "hydro" utilities and other consumers through the medium of power bills rendered by the Commission. Power bills to municipal utilities are rendered at an interim estimated rate each month during the year, and credit or debit adjustment is made at the end of the year when the Commission's books are closed and the actual cost determined.

The balance of the revenue of the municipal utilities is retained by them and is used to defray the expenses incurred in distributing to the ultimate consumers the electrical energy provided by the Commission. These include operating, maintenance and administration expenses, interest on the capital investment, sinking fund or principal payments on debentures, and depreciation charges. Concurrently, therefore, with the creation of funds to liquidate their debt to the Commission and provide reserves for renewals, contingencies and obsolescence on the generating, transforming and transmitting systems, the municipalities make similar financial provisions with respect to their local "hydro" utilities.

From the foregoing it will be seen that in the charges for electrical service, the consumers in the municipalities are paying year by year, not only all the costs of providing the service and keeping the physical plant in an up-to-date and efficient condition, but in addition, are providing sums which are used to retire the capital outlays. Thus the municipalities are progressively becoming the owners of a fully paid-up plant. With respect to the local distribution systems, many municipal "hydro" utilities have already reached the point where their quick assets, such as securities and investments, bank and cash balances, and accounts receivable, exceed their total liabilities.

From the above description it will be understood how the principle of service *at cost* is carried out with respect to the wholesale service given to the municipal utilities. We now come to a more detailed consideration of the means by which the same principle of service *at cost* is, under the Commission's direction, carried out in connection with the local individual consumers.

Basic to the design of rate schedules is a knowledge of the costs incurred in providing service and the Commission, as part of its service to the co-operating municipalities, has designed a uniform accounting system and requires that detailed cost records be kept for each municipal "hydro" utility. It also exercises a continuous supervision over the rates charged to consumers, and their relation to the economic status of the local utility.

It has long been conceded that the scientific methods of ratemaking outlined by Dr. John Hopkinson and his successors are correct in principle, in that they seek to make a rate for charging for electrical energy which shall cause each consumer to pay for his service at the rate of its cost to the vendor plus a definite percentage for profit. Such rates have been applied — although to a relatively limited extent — in many parts of the world.

In the case of Ontario's undertaking the principle of service "at cost" embodied in the legislation governing the Commission made it necessary to design and apply rate schedules which, for each class of service, most nearly interpreted in a practicable way the principle of service *at cost* to all consumers.

Now, before coming to a consideration of the economic effect of rate schedules or tariffs designed to give service at cost, it will be profitable to discuss, briefly, the principal factors which have influenced the design of the Commission's rate schedules, and to describe the rate schedules themselves. It will be of assistance to an understanding of this discussion if it is kept continuously in mind that what is being sold by an electrical utility, is not kilowatt-hours *per se* but *electrical service.* The cost of providing electrical service may be divided broadly into (a) customer costs, such as meter-reading, billing and collecting, etc.; (b) demand costs, i.e., costs incurred so that the undertaking is in a position to serve the customer at any time with the service he requires up to the limit of his maximum demand; (c) energy costs.

Now, in the case of electrical service based upon water-power development, the demand cost is the most important element. In the matter of equitable rate determination and application, however, energy consumption — an easily measured quantity — is valuable as an indirect aid to measurement of effective demand, owing to the fact that as the individual load factor is raised the probable diversity between consumers is reduced; and also owing to the fact that in the case of certain classifications and groups of consumers there is a general constancy of relation between energy consumption and station demand.

In the classification of costs for the purpose of designing an equitable rate structure it is not contended that all the costs incurred in supplying service can definitely be allocated to one or other of these three divisions, but it is evident that an equitable rate schedule must take account both of the demand and the consumption, and the readiness to serve.

It will be appreciated that theoretical principles and considerations are of value more particularly as representing an ideal to be striven for, and as a general guide in shaping the main elements of the tariffs. The final test of the validity of principles followed in rate design is, of course, the results obtained in practice.

On account of several factors, including the great elasticity or variation possible in consumption, the large numerical preponderance of consumers and the universal interest which attaches to electrical service in the home, the class of domestic or residential service is especially suited to illustrate the economic results achieved and the conclusions to be derived from the experiences of Ontario in the application of rate schedules designed to apply the principle of service "at cost."

Rate Schedules or Tariffs for Domestic Service

In Ontario, domestic rates apply to electrical service in residences, for all household purposes, including lighting, cooking and the operation of all domestic appliances.

When the Commission started operation in 1910, the recognized domestic use of electricity was for lighting only, and the floor area was considered as indicative of the demand. A service charge was therefore established based on the floor area of the house, which was combined with a consumption or kilowatt-hour rate much lower than generally obtained elsewhere. The development of electrical household appliances was encouraged by the moderate consumption rate, and with the accumulation of cost data secured by the Commission it became evident that to maintain service at cost still lower rates must be given for additional consumption. Consequently, a second or follow-on energy rate, of one-half of the first energy rate, was estab-

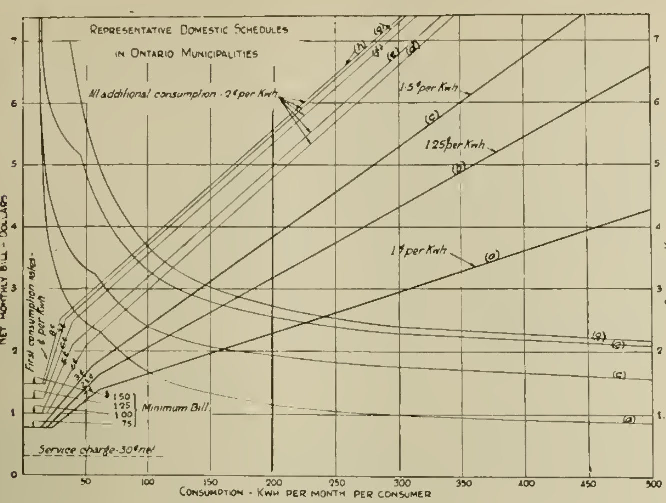

Figure No. 1.

lished for domestic service, and this was applied to all consumption over a certain amount each month, dependent upon the floor area. This form of rate naturally encouraged a greater use of household appliances, and electrical cooking gradually became popular.

Conditions respecting domestic consumption and use in many municipalities have been rapidly changing, and in recognition of this fact a new and somewhat simpler form of rate schedule was devised which has now been very generally adopted for use by the municipal utilities. Under present-day conditions in Ontario, domestic consumers may be grouped into three main types whose average characteristics are known and do not vary greatly in any one municipality. These types are (1) consumers using electrical service for lighting only, (2) consumers using lighting and appliances, not including electric ranges, and (3) consumers using lighting, appliances and electric ranges. Now, a general domestic rate schedule based upon cost must secure from each type of consumer an adequate but not excessive revenue, and the form of domestic rate schedules used in Ontario has been designed with this object.

The present standard schedules therefore consist of (1) a fixed uniform service charge of 33 cents gross per month and an additional amount of 33 cents gross is charged for three-wire or range service, or to consumers having more than 2,000 watts permanently installed, (2) a first consumption rate applicable to energy consumed up to a certain number of kilowatt-hours per month, and (3) a follow-up or secondary rate applicable to all additional energy used. Minimum charges and prompt payment discounts — as in the earlier form of rate — are also employed.

Broadly, the *service charge* may be considered as covering certain costs common to all users of this class, such as meter reading, billing, and a part of the demand costs appertaining to the local distribution system. The consumption or kilowatt-hour rates cover the cost of bulk power delivered to the municipal utility, and any costs of distribution not obtained by the service charge. The first kilowatt-hour rate and the rate for all additional energy are so adjusted as to ensure that in each municipality domestic consumers of each of the three prevailing types — lighting; lighting and appliances; lighting, appliances and ranges — will, as far as practicable, contribute revenues commensurate with the cost as ascertained from known characteristics of these types.

The standard domestic rate schedules may, therefore, representatively be given as in table No. 2 and are graphically shown in figure No. 1. The first three schedules, *a*, *b* and *c*, may be considered as typical of the rates in

Table No. 2.

	Service charge gross	First consumption charge per kw.hr.	No. of kw.hrs. to which it applies	All additional per kw.hr.	Discount prompt payment	Usual minimum bill
	cents	cents		cents	%	\$ c \$ c
a	33	2	60	1	10	0.75 —
b	33	2.5	60	1.25	10	0.75 or 1.00
c	33	3	55	1.5	10	0.75 or 1.00
d	33	4	50	2	10	1.00 or 1.25
e	33	5	45	2	10	1.00 or 1.25
f	33	6	40	2	10	1.25 or 1.50
g	33	7	35	2	10	1.50 or 2.00
h	33	8	30	2	10	1.50 or 2.00

Ontario municipalities. Less than 5 per cent of domestic energy consumption is sold at higher rates than these.

In order to meet special conditions in certain municipalities, variations may be made in any one or more of these factors — except the 10 per cent prompt payment discount which is everywhere employed. The scheme has proved to be a well-graded and flexible one, and has already been adopted for general use in the municipalities served by the Commission.

Table No. 3 representatively shows, for various consumptions, the net monthly bills which are rendered to domestic consumers in Ontario municipalities under the standard rate schedules described above. The first three lines *a*, *b* and *c* may be considered as truly typical of charges to Ontario consumers, as less than five per cent of domestic electrical energy is sold at rates higher than these.

The general circumstances appertaining to the province and to the Commission's undertaking having been reviewed, the basic principles followed in designing rate schedules having been discussed and the domestic rates themselves having been described, it is now in order to deal with actual economic results that have been achieved through the application of the Commission's tariff policies to domestic service under the circumstances existing in Ontario. In this connection two aspects present themselves for consideration — the economic results from the standpoint of the consumer and the economic results from the standpoint of the utility. It will be shown that the policies followed have enabled the consumers to take advantage of the comforts and economies attending the

g	7	35	2	1.87	2.57	2.95	4.75	7.27	10.87
h	8	30	2	2.10	2.64	3.00	4.80	7.32	10.92

[5] The minimum charge varies in different municipalities. It would become the charge where it exceeded the figure shown.

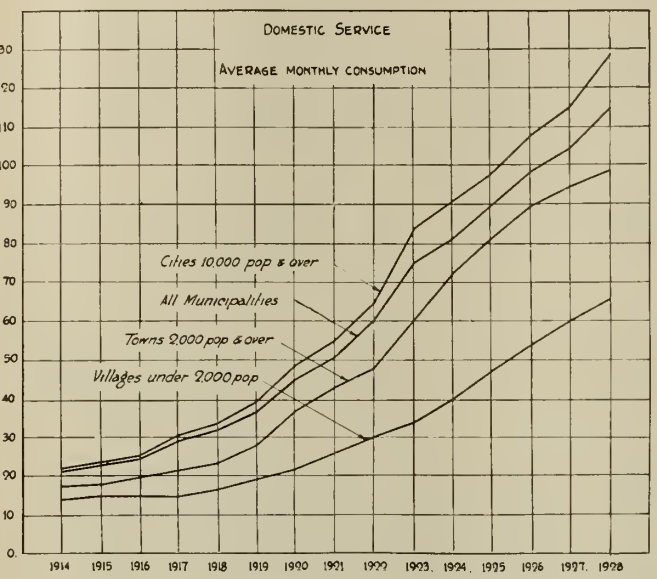

Figure No. 2.—Average Monthly Consumption per Consumer—All Municipalities, showing Growth.

liberal use of electrical energy, to an unusual extent, and that the average unit costs of electrical energy to the consumer have been reduced to a very low point. It will also be shown that this desirable result has been accomplished without impairing the ability of the utilities to earn from domestic service adequate net returns on the capital employed, and without departing from the principles of sound finance.

Economic Effect of Ontario Domestic Rates from the Consumer's Standpoint

From the foregoing summary description of the rate schedules used in Ontario municipalities for domestic service, it will be observed that by incorporating a low follow-on rate they take the form commonly known as "inducement rates." It should be emphasized, however, that while they are inducement rates in form and also in effect, they are not inducement rates in the sense that their primary purpose is to promote consumption, or that they contemplate the assumption of initial losses which will later be recovered through enhanced profits. The primary object in mind in designing the rate schedules is to apportion charges to all consumers as nearly as is practicable according to the costs of the utilities to provide the service. The inducement form of the rates is simply a result of this object — a result, however, which has been of great economic benefit to the consumers of the Ontario undertaking. Rates of the inducement form have enabled Ontario domestic consumers to utilize labour-saving and comfort-giving electrical appliances to a much greater extent than would otherwise have been possible. The increase in average domestic consumption has been exceptionally rapid, and has been a major factor in making possible the provision of electrical service to Ontario domestic consumers at average costs to the consumer, per kilowatt-hour, which are probably lower than in any other comparable territory.

Statistics relating to the consumption of electrical energy in Ontario municipalities served by the Hydro-Electric Power Commission are compiled and published in the Commission's annual reports. There are presented herewith diagrams and curves giving derived statistics relating to certain phases of "hydro" electrical service.

Before presenting these diagrams, however, a word of caution is necessary. Certain of the diagrams present data respecting the "average cost per kilowatt-hour" to the consumer, and are derived from statistics of revenues and kilowatt-hour sales of the utilities, by simple division. Such average costs and revenues per kilowatt-hour have frequently been assumed to be a reliable criterion of the relative rates or prices for electrical service in one municipality or territory as compared with another. Such an assumption involves a serious statistical fallacy and is productive of very misleading results. Particularly is this the case when revenues and consumptions of all classes of service are indiscriminately lumped together in order to deduce a so-called "average cost or rate per kilowatt-hour" for all services; a lower average for one utility than for another is more likely to be due to a preponderance of sales under the industrial and other low-cost classifications than it is to be due to a lower general scale of tariffs.

Even where the utilities compared have similar forms of tariff and where one classification only is considered, the average cost or revenue per kilowatt-hour is no criterion of comparative rates to consumers. It will be observed, for example, from figure No. 4, that in the last twelve years since 1916 there has been a reduction in the average cost or revenue per kilowatt-hour for domestic service in hydro municipalities of approximately 50 per cent. It would be quite incorrect, however, to assume that domestic tariffs have been reduced on the average by 50 per cent in the period. By 1916 the rates in most of the cities and towns had become well-established on a low cost basis with low follow-on rate, and since that time domestic schedules of rates in force have for the majority of customers remained notably free from important upward or downward revision. In general, the charge to the majority of consumers for a specified monthly consumption was not materially different in 1928 from what it was in 1916. The lower average cost to the consumer in 1928 is principally due to the higher average consumption per consumer — see figures No. 2 and No. 3 — and to the form of the tariffs.

Unless this feature of the data presented is fully appreciated, they will fail to convey a useful understanding of the economic results of the Commission's tariff policies. The Commission's tariffs for domestic service are low, but they are not by any means as low in relation to domestic tariffs elsewhere, as would be indicated by indiscriminate comparison of revenues per kilowatt-hour for domestic service.

If it is desired to appraise the Commission's tariffs for domestic service in Ontario in relation to those used else-

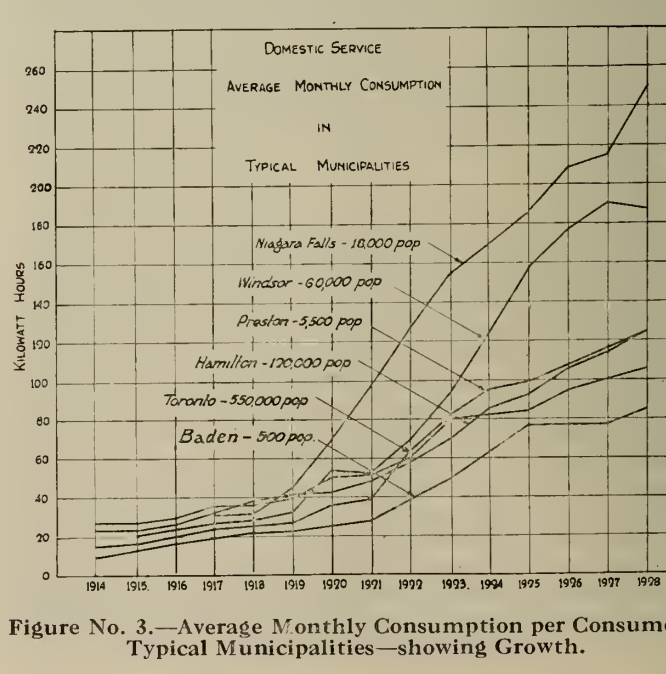

Figure No. 3.—Average Monthly Consumption per Consumer in Typical Municipalities—showing Growth.

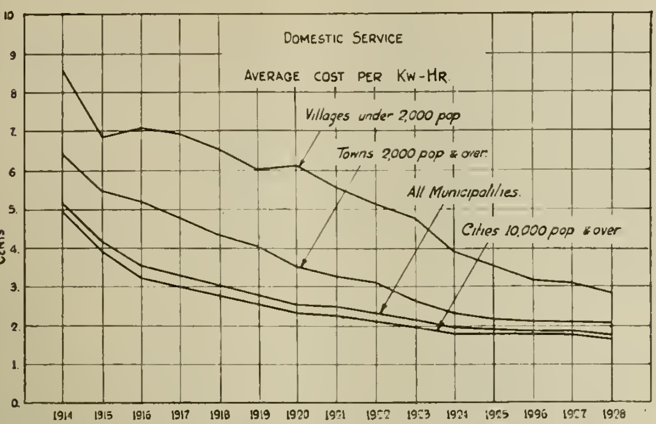

Figure No. 4.—Average Net Cost to the Consumer per Kilowatt-hour Inclusive of all Charges—All Municipalities, showing Decrease.

where, valid conclusions can only be reached by comparing the cost of a month's service to a typical consumer, or series of consumers, taking service under identical conditions as regards energy consumed and other relevant circumstances in the two territories.

Figures Nos. 2 to 6 indicate the rapid growth in consumption, decline in unit cost and other trends respecting domestic service as it has developed under tariffs designed to give service at cost.

The data basic to these diagrams have been published in the annual reports of the Commission. The totals of the principal items are presented in table No. 4.

The curves are shown from 1914 to 1928, but for the present study special attention should be directed to the portion from 1916 on, for the following reasons: The period prior to 1916 was one of exceptionally rapid growth with respect to the number of municipalities of larger size in which "hydro" service was being inaugurated; subsequent to 1916 there has been a steady increase in the number of municipalities served, but those added in recent years have been of smaller size individually. Prior to 1916 was also a period of adjustment of rates among many of the larger municipalities. Substantial reductions in rates were being made affecting a large proportion of the consumers. This is reflected in the decided drop between 1914 and 1916 in the average monthly bill for all municipalities, notwithstanding a substantial increase in average consumption. In the case of a municipal utility newly-established, there are usually substantial reductions in rates during the first few years of service, but in a short time the rate becomes fairly well stabilized and future adjustments of rates, if any, are small. Except in some of the smaller communities this point is reached with a rate schedule equivalent to or approximating the rate schedules *a*, *b*, or *c*, referred to above, depending upon the usual factors of distance, size of load, etc. Data for municipalities whose domestic tariffs had not reached comparative stabilization by 1916 or shortly after exert in the aggregate little influence upon the statistical results of the system as a whole, which are shown in figures Nos. 2, 4 and 5.

Considering, therefore, the portions of the diagrams for the years 1916 to 1928, it is seen that the effect of the Commission's tariff policies and of its sales efforts in merchandizing appliances, has been to induce a steady and consistent growth in average monthly consumption from about 25 kilowatt-hours to 115 kilowatt-hours or a 366 per cent increase. The average monthly bill has increased from $0.84 to $1.97 or 135 per cent. The average cost per kilowatt-hour has dropped from 3.5 cents in 1916 to 1.71 cents in 1928; and this has occurred notwithstanding the fact that the cost of wholesale power — owing to advancing costs of generation and transmission, etc. consequent upon economic adjustments due to the Great War — has increased.

Figure No. 3 relating to certain individual municipalities has been included in order to assist appraisal of the degree to which on the one hand the inclusion from time to time of new municipalities with initially higher rates, and on the other hand the reduction of tariffs in certain of the newer and smaller municipalities after the initial period of operation, have affected the statistical results for the system as a whole. In the case of Niagara Falls and Toronto there have been no changes in domestic rates from 1916 to 1928, and in the case of the other municipalities, such changes as have been made have been in the nature of minor adjustments. The results in these municipalities give, therefore, an indication of the effect of the tariff policies that is comparatively free from complicating factors and serve to confirm the general results from the curves derived by including statistics from all municipalities.

Dealing with the period from 1914 to 1928 and summarizing the results presented in table No. 4 for all municipalities, it is seen that the number of municipalities has increased from 49 to 268, the revenue from $730,168 to $9,411,812, or 13 times, the consumption from 14,359,000 to 551,010,000 kilowatt-hours, or 38 times, the number of consumers from 64,866 to 408,071, or 6.3 times, the average monthly consumption from 21 to 115 kilowatt-hours or 5½ times, the average monthly bill from $1.06 to $1.97, or less than twice, and that the average cost per kilowatt-hour has decreased from 5.08 cents — which it may be noted was even in 1914 a lower figure than was common elsewhere — to 1.71 cents in 1928 or to about one-third.

The last diagram presented, figure No. 6, shows the average cost of electrical service in municipalities served by the Hydro-Electric Power Commission of Ontario. And although for purposes of simplicity we are considering the economic results chiefly as illustrated by the domestic consumer, there have been included in this diagram statistics relating to the commercial lighting service and to the power service. It will be seen that the favourable economic effects of the policy of providing service *at cost* are by no means confined to domestic service but that similarly low-cost service is given both to commercial lighting consumers and to power consumers. With respect to power service supplied by the municipal utilities, the statistics for which are incorporated in the diagram, it should be pointed out that the average load per consumer is about 30 h.p. The Commission serves certain large power consumers direct on behalf of the various systems of municipalities.

Use of Domestic Electrical Appliances by Ontario Citizens

The form of tariff or rate schedule which is necessitated by the principle of service at cost, by incorporating a low follow-on rate promotes a liberal use of the service for electrical appliances and at the present time the major factor in domestic consumption in most Ontario municipalities is the energy consumed for domestic cooking, water heating and labour-saving devices.

During the past five or six years statistics have been collected in most of the municipalities served by the Commission, respecting the number of appliances in use by domestic consumers. The results of the surveys made each year show that there has been a steady growth in the number of appliances in use and also in the percentage saturation of the possible number which might be used.

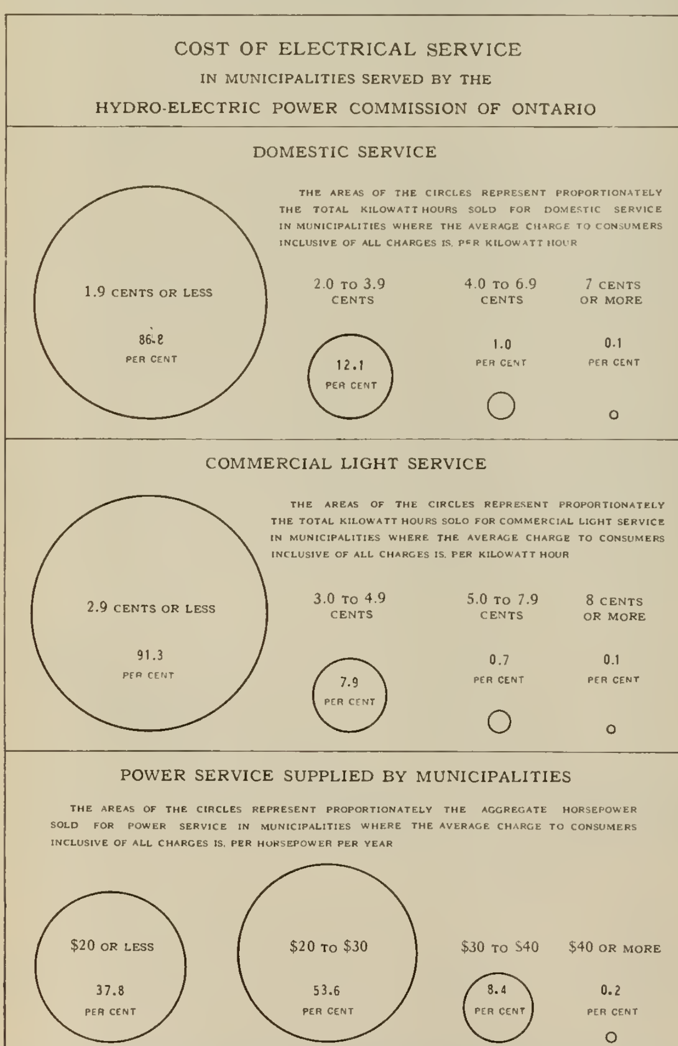

Figure No. 6.—Cost of Electrical Service in Hydro Municipalities —Domestic, Commercial Light, Power Service.

Table No. 5 presents in summary form this information for the years indicated up to January 1st, 1929.

Financial Results of Ontario Tariff Policy

It is pertinent at this point to consider the economic results under the Commission's tariff policies, from the standpoint of the relation of net earnings of the utility to capital investment. Such a consideration will, it is believed, show that the Commission's tariff policies have been quite as successful from the standpoint of the utility as from that of the consumer.

Since domestic service has been selected as the classification which most strikingly illustrates the principles and results under discussion, the economic results for the other classifications of service need not be treated in detail. It suffices to emphasize that the same general tariff policies and methods of cost accounting are pursued for all classifications, except for a minor modification with respect to power supplied by the utilities to the municipal corporations themselves for such purposes as street lighting and waterworks pumping. Tariffs in general are conservatively designed to yield a moderate surplus over all costs; municipal power is supplied strictly at cost.

Now, if it were to be attempted to present consolidated revenues, costs and earnings of capital for the domestic service in all municipalities, or even in a series of representative municipalities, such a presentation would become unduly involved. Where consumers of various classifications of a utility utilize in common important parts of the plant, segregation of costs becomes necessary, and before an intelligent appreciation of such data could be conveyed, a detailed discussion of the methods of assigning and segregating costs would be required, — a discussion which could not adequately here be presented. Moreover, the point at issue — whether the extremely low costs to domestic consumers in Ontario municipalities have been attained without violating the requirement of adequate net earnings on the capital employed — can be settled simply and conclusively without reference to a multiplicity of detailed data.

Results Under Lowest Tariffs

Obviously, if it can be shown that, in the municipality where the lowest domestic tariffs are employed, the resulting revenues are sufficient to produce adequate net earnings on the capital employed, which cannot wholly be attributed to any source other than domestic service, then it will follow *a fortiori* that in the other municipalities, using higher tariffs, even more favourable results are possible of attainment by the utilities. The city in Ontario where the charges for domestic service are lower than in any other municipality is Ottawa, and the circumstance that, in this residential city, the business of the municipal electrical utility is predominently a lighting service, makes it possible to show directly from the audited financial results of the utility, that domestic service and commercial service, at what would be regarded in many quarters as phenomenally low unit costs to the consumer, are nevertheless by themselves productive of a substantial surplus of revenues over all costs.

Owing to unusually favourable costs of bulk power, domestic tariffs in Ottawa are lower even than rate "*a*" of the standard system. A typical domestic lighting and cooking consumer, using say 400 kilowatt-hours per month, pays a monthly charge of $2.94. The domestic consumers in Ottawa use electrical appliances very extensively, and the average monthly consumption is 231 kilowatt-hours per consumer, a condition which results in average cost per kilowatt-hour to domestic consumers of but 0.87 cents.

The pertinent financial results of the Ottawa "hydro" utility for the year 1928 are presented below, in summary form:

Capital invested in distribution system		
Plant, original cost	$1,989,288.40	
Less depreciation reserve	670,670.91	
		$1,318,617.49
Working capital (all other assets except sinking funds, $446,736.36) [5]		242,387.59
Total depreciated capital investment		$1,561,005.08
Funded debt outstanding		953,374.17
Equity of municipal corporation		[5]$ 607,630.91
Revenues of the utility		
Domestic service	$ 278,094.78	
Commercial service	133,523.10	
Total, domestic and commercial	411,617.88	
Street lighting and municipal power (at cost)	94,949.84	
Industrial power and miscellaneous	63,415.87	
Total revenues of the utility		$ 569,983.59
Expenses of the utility		
Cost of bulk power	$ 211,309.52	
Operation and maintenance of distribution system	181,787.82	
Total operating expense		$ 393,097.34
Net earnings before depreciation		$ 176,886.25
Per cent on total capital investment	11.3%	
Depreciation		51,291.00
Net earnings after depreciation		$ 125,595.25
Per cent on total capital investment	8.0%	
Bond interest paid		43,463.44
Total surplus		$ 82,131.81
Per cent on municipal equity	13.5%	
Surplus applied to retire capital	$ 19,673.51	
Free, operating surplus	62,458.30	
	$ 82,131.81	

[5] The Ottawa municipal utility has invested sinking funds in the amount of $446,736.36 which will be used to acquire additional equity in the local system as the bond issues mature.

The surplus earnings reflect the conservative policy which is followed, in order to ensure that the financial status of the undertaking will always be of unquestionable soundness. These earnings, according to the practice in the Ontario undertaking, will be used to lower costs of service in the future, by paying off indebtedness, by extending plant and by investment in trustee securities, or will be returned to the consumers in cash.

A feature of the results in Ottawa which influenced its selection for purpose of illustration — aside from the fact that the costs to consumers are lower there than elsewhere — was the predominence of the lighting services over all other classifications. In the case of Ottawa, reference to the financial statement shows that the bulk of the free operating surplus of $62,000 must have come from the lighting services, including the service to domestic consumers. Services rendered the municipal corporation are by law required to be on a strict cost basis, and the revenues from this source — $95,000 — can thus have contributed no part of the surplus. Industrial power and miscellaneous revenues aggregate but $63,000, and could thus under no circumstances have provided more than a modest proportion of the total of $62,000 surplus. In other words, the utility could have given away the industrial power service it sold — which yielded a revenue of $55,253 — and still have had a surplus from supplying domestic and commercial consumers at the low rates charged.

It is true that the Ottawa utility enjoys a more than usually favourable position in some respects — notably in that the Commission has been able to furnish the local utility with bulk supplies of power at a rate that is lower than is found elsewhere in the province. It will be appropriate, therefore, to cite the results in one other utility, a comparatively small community situated remote from the source of power supply, in order to afford an indication of the economic results of the Commission's tariff policies under circumstances which more closely approximate those generally encountered in territories outside of Ontario.

Results Under Unfavourable Conditions

Selection of a municipality for purpose of illustration has in this case, as in that of Ottawa, been made with a view to simplicity of analysis, and the town chosen is therefore one where service is predominently residential. The town of Sandwich, in the extreme west of southern Ontario, is

Table No. 5—Tabulation Showing the Number of the Larger Electrical Appliances Reported to be in Use Among Hydro Domestic Consumers in Ontario at the End of 1928 and the Number Calculated to be in Use Deduced from Figures Reported[6] Also the Totals Estimated for 1924 and 1926 for Comparison

[6] In some instances estimates or actual figures showing the number of appliances in use were not supplied by the smaller municipalities. Estimates for these missing figures were supplied by averaging the figures which were received from other municipalities.

of moderately small size, with population of 9,400; it is remote from the source of power supply, with transmission distance of 245 miles, and has electric revenues that are predominently derived from domestic service.

Even under these unfavourable circumstances, the Commission's tariff policies have enabled the 2,700 domestic consumers of the Sandwich utility in the fifth year of operation to utilize an annual consumption of 5,700,000 kilowatt-hours, at a total cost to them of $105,000. The average monthly consumption per consumer is thus 180 kilowatt-hours, and the average cost to the domestic consumer is but 1.83 cents per kilowatt-hour. Cost of service to other classifications is similarly low, commercial consumers paying an average of 2.1 cents per kilowatt-hour, and the few industrial consumers the town has paying on the average but $31.25 per horse power per year. Notwithstanding these low costs to the consumers, the utility is in a flourishing financial condition, as will be observed from the financial statement for 1928 which follows:

Municipal Electrical Utility, Town of Sandwich, Ont.

Capital invested in distribution system		
Plant, original cost	$ 251,851.42	
Less depreciation reserve	20,626.42	
		$ 231,225.00
Other assets (except equity in Commission's plant, $52,795.16)		43,659.61
Total depreciated investment		$ 274,884.61
Funded debt outstanding		126,758.74
Equity of municipal corporation		$ 148,125.87
Revenues of the utility		
Domestic service	$ 104 647.25	
Commercial light service	20,069.40	
Total domestic and commercial	$ 124,716.65	
Street lighting (at cost)	8,318.15	
Industrial power and miscellaneous	28,346.75	
Total revenues of the utility		$ 161,381.55
Expenses of the utility		
Cost of bulk power	$ 99,128.08	
Operation and maintenance of distribution system (all classes of service)	16,362.78	
Total operating expense		$ 115,490.86
Net earnings before depreciation		45,890.69
Depreciation		4,220.00
Net earnings after depreciation		$ 41,670.69
Interest payable on bonds outstanding		6,700.88
Total surplus		$ 34,969.81
(Applied to retire capital $ 4,865.12)		
(Free operating surplus 30,104.69)		

From the above data, taken from the audited financial statements of the Sandwich "hydro" utility, it will be observed that the net earnings on the total capital for the year were at the rate of 16.7 per cent before depreciation, and 15.2 per cent after depreciation. The net annual surplus earnings, after payment of interest, were at the rate of 23.7 per cent on the municipality's equity in the undertaking.

The figures speak for themselves. The conclusion cannot be escaped that the tariff policy of the Commission has been eminently successful from the standpoint of the utility, even in small communities handicapped by the costs of long-distance transmission. They establish the fact that service can be given to domestic consumers at average charges per kilowatt-hour of less than two cents, and yet produce net earnings on capital at a rate which would constitute a very attractive return to the owners of the utility even were it privately owned.

There is nothing exceptional about the two financial statements selected for purpose of illustration except the features noted, of preponderating domestic service in both cases, of extremely low consumer's unit costs in Ottawa, and of adverse circumstances in Sandwich. In these two municipalities, results for the year 1928 are entirely consistent with those for previous years.

Taking the municipalities of the system all together, the revenues of the local utilities aggregated in 1928 some $26,000,000 and yielded, above all operating and depreciation costs, interest payments of $2,100,000, surplus applicable to capital retirement, $1,600,000, and additional free surplus of $2,000,000. The investment in plant was $70,000,000, less depreciation reserve of $11,000,000 and additional assets, except sinking funds and equity in the Commission's plant, totalled some $9,000,000. The net earnings of the local capital, after depreciation, were thus approximately 8 per cent, taking all the utilities together, and the net surplus earnings were 14 per cent on the municipal corporations' equities.

Load Characteristics of Domestic Appliances

In view of the already extensive use of electrical appliances in Ontario municipalities, and the rapidity with which, under the stimulus of the inducement form of rate, their use is being extended, the load characteristics to which these appliances give rise have been a subject of special study by the Commission. The surveys made and other relevant data available indicate that, in general, the load characteristics of these appliances are not such as to give rise to high costs.

In Ontario municipalities, the use of electrical service for lighting may be said to be practically universal. The use of electrical appliances of small capacity and intermittent or irregular use — such as flat irons, vacuum cleaners, electric toasters, and washing machines — is also very general among Ontario domestic consumers. The favourable load characteristics of these appliances are so well known that they do not call for extensive discussion at this time. The use of electrical cooking ranges, however, is a feature with respect to which the extensive experience of the Commission will be of interest, and in this connection, the load characteristics of other electrical appliances of large capacity and energy consumption, such as water heaters, ironing machines, air heaters, etc., will also be discussed.

With respect to the influence of load characteristics on costs of supply, it is to be noted that, since lighting and the use of smaller appliances by a domestic consumer usually precedes, and nearly always accompanies, the use of the larger appliances, the utility, from the economic standpoint, is concerned principally with the *additional* costs, consumption and demands appertaining to electrical service used for cooking and lighting and small appliances, over those appertaining to the use of the service for lighting and small appliances only.

Under Ontario conditions, it is found in general that the costs of bulk power to municipal utilities materially exceed the costs for distribution within the municipality, and consequently the factor of principal importance from the economic standpoint, is the extent to which the installation of ranges increases the peak load of the municipality. A factor of hardly less importance is the influence of the electric range upon the load factor of the municipality. Factors of secondary — but not of negligible — importance, are the individual demands of range consumers. Individual demands exert practically no influence upon such costs as meter reading, billing and collecting and office overhead, nor do increased individual demands on the part of the domestic consumers tend appreciably to increase the costs appertaining to such important items of distribution plant as poles, hardware, etc. Large increase in individual demands does, however, increase total costs with respect to such items as copper for distribution conductors, and distribution transformers and substations.

That very large diversity exists among Ontario domestic consumers' demands is indicated by the smallness of the resulting station demand in relation to the sum of the individual demands of the consumers. The diversity is particularly good in the moderately large cities where the distances from employment, hours of work and other factors bring about a large variation in time of day when the electric cooking appliances are used. In certain smaller and highly industrialized municipalities, however, a tendency is found for nearly all of the inhabitants to cook the heavy meal of the day at approximately the same hour, with the result that, in such municipalities, the diversity is somewhat less favourable, and costs attributable to electric ranges are relatively higher than is found in general throughout the province. The experience of the Commission, however, has demonstrated that even under the least favourable circumstances, the costs occasioned by the use of electric ranges are decidedly moderate, and service can be given to consumers at rates low enough to be attractive to the consumer without loss to the utility or disadvantage to consumers of other classifications.

Results with High Electric Range Saturation

As illustrative of load conditions obtaining in a city of some 60,000 population where — notwithstanding a transmission distance of 240 miles and tariffs, in consequence, somewhat higher than those in more advantageously situated Ontario municipalities — the electric range saturation among domestic consumers is the remarkably high figure of approximately 78 per cent, the following results may be cited. The average monthly peak load of the municipality, incurred in serving consumers of all classes, was 17,550 kw. The industrial consumers had aggregate demands, averaged over the year, of 6,530 kw.; the 2,200 commercial consumers had aggregate demands of approximately 6,200 kw; the 3,300 residential consumers not using the service for cooking had aggregate demands estimated at 3,300 kw., and there were served, in addition, approximately 11,500 domestic consumers using electric ranges in conjunction with lighting and other appliances.

Having regard to the diversity, one with another, of consumers within a group, and also equitable apportionment of diversity of one group with the others, as deduced from load records and other data, it is estimated that, of the maximum coincident station load for all groups — 17,550 kw. — between 9,500 kw. and 10,500 kw. is assignable to the 11,500 domestic range consumers, and between 7,000 kw. and 8,000 kw. is assignable to the domestic consumers without ranges, the commercial lighting consumers, the power consumers and the municipal street lighting service. The assignable station demand per range consumer is thus, on the average in this municipality, between .83 kw. and .91 kw.

The annual consumption of electrical energy by domestic consumers in this municipality is approximately 32,000,000 kilowatt-hours measured at the consumers' meters, from which, making allowance for distribution losses, it appears that the municipal station load arising from domestic service, with 78 per cent range saturation, and a slightly restricted energy consumption due to tariff somewhat higher than usual in large Ontario cities, has an average monthly load factor in excess of 40 per cent. The average *daily* load factor would of course be materially higher than this figure.

Results With Relatively Unfavourable Diversity

As representative of load characteristics in a municipality where diversity is relatively unfavourable, the results of a special study made in a municipality with some 6,000 domestic consumers may be cited. In this municipality, a sharp peak had been observed to occur between the hours of eleven-thirty and twelve o'clock, which, although the range saturation was but 33 per cent, was obviously attributable to unusually poor diversity of use of electric ranges. Special study was made of characteristics of individual consumers' loads, and the domestic service was definitely segregated from other classifications of service during the period covered by the survey. The cost of bulk power in this municipality was less, per horsepower, than that in the larger municipality cited above, and the domestic tariff was also lower; in consequence, the average domestic consumption, per range consumer and per lighting consumer, was materially higher than in the larger city.

Typical daily load curves for domestic service in this city, over a period of six months, showed an average maximum demand of approximately 3,800 kw. arising from 2,000 consumers having ranges and 4,000 consumers without ranges. The portion of the domestic peak load assignable to range consumers was approximately 2,700 kw., or 1.35 kw. per consumer, and that to lighting consumers, 1,100 kw., or 0.28 kw. per consumer. The analysis in this city having been directed more particularly to the ascertaining of the characteristics of the domestic load by itself, these figures do not, as in the case of the larger city, include apportionment of diversity existing between the various classifications of service, and are thus somewhat higher than the resulting assignable station demands. Even when appropriate allowance is made for this difference in the basis of the two sets of data, however, the results indicate clearly that diversity among the range consumers in the smaller, industrialized municipality, though good, was materially less than in the first city.

Respecting load factor in the smaller city, the actual typical daily load factor of the domestic load — again without allowance for diversity between classes — was high, the higher average consumption per consumer having offset the poorer diversity. For the month of December, the measured typical daily system load factor was nearly 50 per cent for domestic load by itself, and, if based upon assignable contribution to the aggregate municipal station load, would be a still higher figure.

Thus, even under relatively poor conditions of diversity, the Commission's extensive experience — of which the above data cited are representative — indicates that the load characteristics of domestic appliances are essentially good, and are such as to justify from the economic standpoint the provision of a supply of electrical energy to cooking consumers at low tariffs.

With respect to the load characteristics of the individual consumer, it should be noted that the electrical cookers in general use in Ontario are of the high-capacity type, with insulated oven, but without any special provision for heat accumulation, and no special measures have been taken to encourage limitation of individual peak demands. For consumers using ranges, lights and small appliances, the average installed capacity is about 11,000 watts per consumer, and the average monthly ten-minute integrated peak of the individual consumer is approximately 5,500 watts. Among domestic consumers using the service for lighting and small appliances, but not for cooking, the installed capacity averages about 2,200 watts, and the individual monthly peak demand averages 1,000 watts. As has been noted, however, the high individual peaks of range customers, and the resulting low individual load factors are of comparatively minor import to the utility from the economic standpoint.

In the course of the detailed survey to which reference has been made above, data were also secured respecting the load characteristics of the heavy appliances other than electrical cooking ranges, which are used to a considerable extent by domestic consumers in Ontario municipalities.

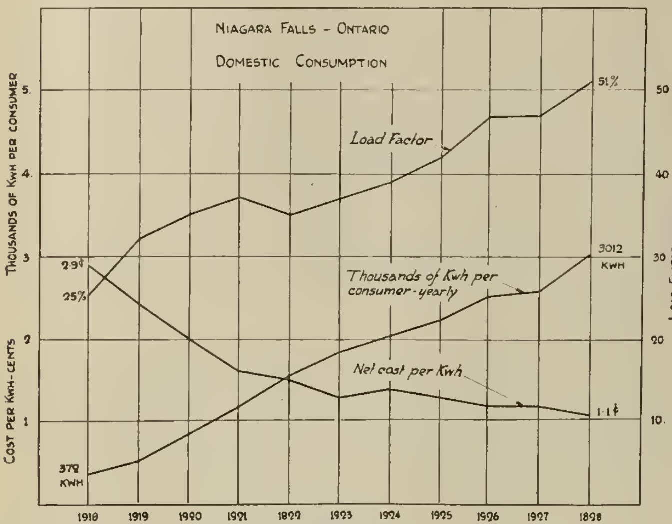

Figure No. 7

Among a group of consumers using both electric ranges and other appliances of large capacity and energy consumption, it was found that the average installed capacity was some 16,000 watts per consumer, about 5,000 watts more than the average installation for range consumers not using such heavy appliances. The average of individual demands, however, was but 5,700 watts, as compared with 5,500 watts, and the average annual consumption showed an increase of 1,860 kilowatt-hours. The large increase in energy consumption with trifling increase in individual demands, is evidence of the very favourable load characteristics of such appliances as regards diversity and improvement of load factor. Inspection of the load curves of the municipalities indicates that air heaters have less desirable diversity characteristics than the other heavy-duty appliances.

Influence on Load Factor of Rapid Growth in Consumption

Figure No. 7, relating to a third city — Niagara Falls, Ontario — shows the domestic consumption for the years 1918 and 1928 inclusive, in kilowatt-hours used per consumer per annum. It will be noted that for 1918 the average was 372 kilowatt-hours whereas for 1928 an average of 3,012 kilowatt-hours was consumed. The curve also shows the effect on the net cost per kilowatt-hour, which varied from 2.9 cents in 1918 to 1.1 cents in 1928. With this curve is also shown the average load factor for domestic purposes during that period. It is interesting here to note that the load factor during this period has increased from 25 per cent to 51 per cent — an increase in load factor which, undoubtedly, is largely responsible for the drop in the net cost per kilowatt-hour.

There has been remarkable development during this ten-year period in the use of electrical appliances. For instance, in domestic service in 1918 the use of electricity was almost wholly confined to lighting. With the beginning of 1919 and following through to 1922, the first major use of the electric range took place, until it was found that in 1921 the daily peak established by ranges equalled the lighting peak created in the evening. This gave the highest possible load factor with respect to the two peaks established. In 1922, the cooking load became greater than the evening lighting load, with a consequent reduction in the load factor. This was compensated for in 1923 by the gradual increase in the use of other appliances, a growth which has been steadily felt during the following years. A fact of interest is also observable about the years 1925 and 1926 when a large number of flat-rate water heaters were installed by domestic consumers. These flat-rate water heaters tended very materially to increase the load factor to the present, which now approximates an average of 51 per cent throughout the year. It is interesting also to note that during this period there has not been any change in the rate structure[7] for the city of Niagara Falls, and that the results have been brought about entirely through the increased use of appliance loads other than for lighting. Although the information is not fully available, yet it appears probable that this load factor will be still higher for the year 1929.

The results just presented clearly demonstrate what may be expected from a proper application of 'inducement' rates to domestic uses in conjunction, of course, with the development of the art.

The results under review were brought about under the most unsettled conditions the industry has probably had, namely, the period following the Great War, when prices, labour charges, etc., went through great changes and when, under normal conditions, a marked advance in the net cost of electric service might have been expected. During this period, the cost of power to the municipality under discussion had been substantially advanced. The cost of distribution material also was considerably higher, but in spite of all such features, the improvement in load factor, and greater use of energy per consumer, have manifestly resulted in a gradual drop in the cost per kilowatt-hour to the consumer.

Thus, in conclusion, it may be remarked that the economic results that have attended the application of the form of tariffs used by the Commission — results that have been shown, in an earlier section of this discussion, to be decidedly favourable from the standpoints of both consumer and utility — are in large measure due to the very advantageous load characteristics which appertain to the use of domestic appliances by the consumers of the Ontario undertaking, even under the less favourable conditions as regards diversity.

Rural Electrical Service

The data that have been presented for domestic service are representative of, and adequately illustrate, the economic results of the Commission's policies as they concern the operations of the Commission in their major aspect of supply to urban consumers. Rural electrical service, though of comparatively minor importance as regards the quantity of power supplied, is nevertheless of special interest because of the intensive efforts that have been directed in recent years and in many parts of the world, upon the problems of solving the difficulties inherent in rural distribution, and also because of the very great economic benefit which accrues to the rural consumer and to the general welfare of the citizens, from the provision of adequate supplies of electrical energy for agricultural consumers at low cost. The results of the Commission's methods and policies in this field will therefore be briefly indicated.

Electrical Service in Rural Districts of Ontario

A number of the outstanding features of rural electrical service in the province of Ontario were described at some length in the paper presented five years ago before the First World Power Conference. This earlier paper[8] was published in the proceedings of the conference, and is thus available for reference. In the present discussion it is

(7) The domestic rates in Niagara Falls throughout the years 1918 to 1929 have been as follows:

Monthly service charge......	3 cents per 100 square feet of floor area.
Energy charges..............	2 cents per kw.hr. for first 3 kw.hr. per 100 square feet.
	1 cent per kw.hr. for all additional energy per month.
Discount for prompt payment	10 per cent on whole bill.

proposed to direct attention specifically to some of the economic aspects of rural supply, and to indicate the results that have been attained through the application of the Commission's methods and policies, notwithstanding the general difficulties inherent in rural electrification, and the special difficulties encountered, even in the 40,000 square miles of "old Ontario," by reason of the relative sparseness of population and absence of the need for irrigation and of other large power demands.

The last five years have been a period of rapid expansion in rural electrical supply in Ontario. The number of rural power districts in operation has increased from 52 to 131. The number of miles of rural distribution line in service has increased from 600 miles to 3,800 miles. The number of consumers served in the rural power districts has increased from 4,200 to 30,000. The bulk power supplied to rural power districts has increased from 2,000 h.p. to 17,000 h.p.

(8) In the former paper a description was given of the Commission's pioneer work in the evolution of practical methods whereby handicaps to rural electrical service in Ontario were successfully overcome; and the legislation under which rural operations were promoted by efficient organization into rural power districts was presented in detail. The special design features whereby the Commission had been able to effect satisfactory overhead and underground rural distribution at low capital costs were described, and average costs per mile were given. The uniform classifications applicable to consumers of the various types found in agricultural areas were set forth, and the basis of estimating the respective costs and designing rate schedules in accordance therewith was discussed. The demand rating, average monthly consumption, and the service charge required to cover distribution costs at that time were stated for each class of service, and the annual consumption charges and total costs of service appertaining to consumers in typical rural power districts were enumerated. The results that had been attained up to 1923 were reported, with respect to the number of consumers, the mileage of distribution lines, and the capital expenditure. The uses made of the service by farm consumers were enumerated, and the energy consumptions appertaining to various types of farm equipment and to various agricultural operations were stated. The favourable influence of rural electrical supply upon the economic status of the agricultural population of Ontario, and its importance with respect to the economic life of the Province in general were discussed, and the powerful stimulus that had been afforded to rural industries was noted.

Since 1923 the modifications of practice found of value in reducing costs of distribution under present conditions have for the most part been of a relatively minor character. Increased loads and wider separation of feed points have rendered a primary voltage of 8,000/4,600 volts more economical than the former standard of 4,000/2,300 volts. The higher voltage is now standard for new construction, and 500 miles of line have been constructed for this potential. For service to small loads at outlying points, it has been found of advantage to extend the phase wires only of the 4,000/2,300 volt grounded circuit, using a 4,000 volt transformer connected across the phases. This procedure extends the possible distance of service, having regard to load and voltage drop, to three times that permissible when using 2,300 volts.

The former standard primary distribution line, which had a pole spacing of 160 feet and employed hard drawn copper conductors, has been found less economical than the present standard line, which has pole spacings of 200 feet and 250 feet — depending on the nature of the territory — and uses steel-reinforced stranded aluminum conductors, with minimum size of No. 4 B. and S. gauge. Copper is still used, however, for secondary conductors. Underground cable construction, which, in the period immediately following the War, had been the means of effecting economies in certain circumstances, has now, as the result of price changes, become less economical than overhead construction in nearly all circumstances.

Capital costs of overhead rural primary distribution lines, constructed according to present standards, using 200 foot spacing and aluminum stranded conductor, steel-reinforced, are approximately four per cent lower than the figure reported in 1924. A mile of single-phase line, installed complete, now costs, including supervision and overhead charges, $1,020, and the corresponding cost for a mile of three-phase line is $1,257. The cost per mile for single-phase No. 6 paper-insulated lead-covered underground cable laid in earth, however, has increased as the result of price changes, and is now approximately $1,266.

The classifications under which rural electrical service is supplied have been found in general to be satisfactory, and minor changes only have been made. In the case of hamlet service, no restriction is now made with respect to number of lighting outlets or use of small appliances, and service is given to shops under this classification. Former classes 1-A and 1-B are thus combined in the present class 1-B. Sub-classifications have been provided in the case of heavy farm service and special farm service, distinguishing between users of single-phase and three-phase power. The class demand ratings are unchanged.

The "grant-in-aid" which the government of the province had made toward the initial capital cost of primary rural distribution lines, as part of its general policy of aiding agriculture was, in 1924, extended to cover 50 per cent of secondary equipment, such as transformers and meters.

Economic Results from Consumer's Standpoint

Respecting the economic results of rural electrical service from the standpoint of the consumers, possibly the best evidence of the benefits derived is the rapidity with which the number of consumers taking advantage of the service has increased. Agriculturists, as a class, exhibit a tendency to form their conclusions respecting the economic benefits of electrical service on the farm from personal observation of the results derived by their neighbours. In the 52 rural power districts that had come into operation up to 1923, the favourable experience of the 4,169 consumers served at that time had by 1928 induced no fewer than 15,741 of the immediate neighbours of these farmers to take advantage of the service, and in addition had encouraged 10,059 rural residents in other parts of the province to take service from 79 rural power districts that had not been served up to 1923.

The average annual consumption and cost to all users in rural power districts is submitted in table No. 6 by classes.

Table No. 6.

Class	Service	Average annual consumption kw.hr.	Class demand rating kw.	Annual net cost to consumer
				$ c.
1 B	Hamlet lighting........	388	0.75	24.56
1 C	" "	1,627	2	56.62

8	Syndicate outfits.......	14,157	..	396.40

As a measure of increase in use of the service by the consumer, and reduction in average cost, the value of average statistics is for rural service largely nullified by the rapidity with which the number of consumers served has increased. Owing to the large increases in consumers served in recent years, the *average* length of time the 29,867 consumers served at the end of 1928 had been using the service is but little greater than the average time of service appertaining in 1923 to the 4,169 consumers then served. Having regard to this limitation of the statistics, however, it is of interest to note that, in the 52 rural power districts served throughout the five-year period, the increase of 375 per cent in number of consumers has been accompanied by an increase in bulk power supplied of 420 per cent. It may be concluded, therefore, that the average use of the service by individual consumers shows a tendency to increase with time that is comparable with the results found among urban consumers.

With respect to the cost of service to the consumer, it should be noted that the increase in number of consumers served has necessitated the construction of distribution lines almost to a proportionate extent The addition of new consumers to existing lines has been offset by the lower density in the new districts and in the portions of older districts more recently served. The 605 miles of line in service in 1923 had increased at the end of 1928 to 3,791 miles, by the addition of 1,815 miles in the 52 districts served up to 1923, and 1,371 miles in the 79 newer rural power districts.

Representative Results to Farm Consumers and Rural Industries

The results of using hydro-electric power service from the consumer's point of view may, however, representatively be illustrated by the information respecting installation, energy consumption and costs submitted below in detail with respect to two dairy farms, one chicken farm and two dairy industries. Data are given by billing periods, showing costs for two separated years in the three farm services, as well as total for a five-year period in one. Satisfaction to users is the final test of success and it is believed that rural hydro consumers are convinced of the merit of the service by seeing their reasonable bills.

The records for the rural industries are submitted in order to illustrate how such industries can be served by hydro-electric power advantageously, at relatively low cost, having regard to the somewhat adverse circumstances of rural electrical distribution.

Dairy Farm — Using Milking Machine
In Woodstock R.P.D.

Discount — 10 per cent.

Reduced Charges to Consumers

As a result of continued search for means of effecting economies in rural distribution costs, and of the additional assistance[12] afforded by the extension of the agricultural "grant-in-aid," it has been found possible to make a notable reduction in the charges to consumers, in respect both of the initial rates applicable in newly-formed rural power districts, and of the average rates charged in the rural areas of the province. The extent of the reduction in service charges from 1923 to 1928 is indicated by table No. 7.

Table No. 7—Reductions in Service Charges, 1923–1928

Classification of service	Annual service charges		
	Maximum for initial 25-cycle operation		Average paid by rural consumers of Ontario
	1923	1928	1928
1 B Hamlet lighting	$ 20.50	$ 19.44	$ 14.53
1 C Hamlet lighting and cooking	36.44	35.64	26.91
2 A House lighting	30.00	24.30	18.30
2 B Small farm service	47.40	37.26	27.99
3 Light farm service	60.82	49.14	36.61
4 Medium farm service	66.94	51.30	38.22
5 " " "	84.50	62.10	46.30
6 A Heavy " "	130.97	79.38	58.15
6 B " " "		89.64	67.30
7 A Special " "	188.90	117.72	87.24
7 B " " "		142.56	106.61

The maximum service charge for initial operation, both in 1923 and 1928, is based on the minimum requirement of three farm contracts or equivalent per mile of distribution line. Class 3 — light farm service — is the classification under which the great majority of farm consumers are served. Taking this class as representative, it will be observed that by 1928 the maximum service charge had been reduced nearly 20 per cent. The average paid by the consumers of the rural power districts of the province—including some 13.5 per cent of consumers served at the 1928 maximum rate, and the remainder at rates ranging from about ninety-five per cent to less than 50 per cent of the maximum — was in 1928 approximately 40 per cent less than the maximum service charge applicable in 1923. These averages take no account of cash rebates made to consumers in rural power districts amounting to some $230,000 during the past two years representing the accumulated excess of revenues produced by the charges made in previous years over costs of service and moderate surplus required to assure financial stability.

[12] See footnote 8.

With respect to reductions in rural service charges, it may be stated that reductions and adjustments are being made from time to time, and at the end of 1929, further reduction has been made to all rural classes as a result of the provincial government's active policy to assist agriculture as far as possible. The basis upon which this adjustment was made was that the net service charge to a farmer for Class 3 service should not be greater than $30 per year — this contrasts with the $36.61 in the table above — and adjustments in all other rural classes were made on a corresponding basis. From the consumer's standpoint, therefore, the economic results of the Commission's policies, as indicated by progressively lowered charges for service, may be said to have been eminently satisfactory.

Use of Electrical Equipment on Ontario Farms

In rural electrical service, even more markedly than in service to urban consumers, the economic results to the consumer are dependent upon the degree to which use is made of electrical equipment. Power-driven farm equipment is capable of effecting substantial economies in agricultural operations, and household appliances relieve the farm women of much drudgery.

In order to ascertain the extent to which electrical equipment and appliances are being installed in the homes and in the barns of farmers receiving service from the Commission's rural power districts, a survey was conducted among farm consumers as distinct from hamlet consumers. Returns have been received from nearly 60 per cent of all farm consumers in the province, the results of which are presented in table No. 8.

It will be noted that some pieces of equipment, particularly those which are intended to be belt driven by an electric motor, are not reported as very numerous. This may be accounted for by the fact that in making returns the consumers have not indicated the equipment which they drive with the motors which are installed and it may be safe to assume that there are more of these pieces of apparatus in operation than are indicated in the table.

Table No. 8—Electrical Equipment in Use by 7,074 Farm Consumers Reporting

	Number	Per cent saturation
Barn Equipment		
Electric motors	1,877	26.5%
" pump systems	1,610	22.7
" milk coolers	22	0.3

" percolators	143	2.0
" fans	136	1.9
" pumping systems	138	1.9
" sewing machines	18	0.2

In the case of electric motors and electric pumping equipment a large percentage of farmers are making use of the facilities of electric service.

The most interesting feature of this table, however, is the extent to which some of the household appliances are being employed. Electric ranges and hotplates have reached a degree of saturation almost equal to that existing in the urban municipalities of the province, while washing machines have been installed to a very much greater extent on the farm than is the case in urban municipalities. Data respecting other electrical appliances show that their popularity and usefulness are spreading in the rural districts. There are a number of rural power districts in the province where the farmers have shown an exceptional inclination to complete electrification of the barn and the home; among these are the districts of Brant, Preston and Woodstock. Table No. 9 shows the equipment installed in each district with the corresponding number of consumers involved.

Table No. 9—Summary of Equipment and Appliances in Use by Farm Customers in Three Well-Developed Agricultural Districts Supplied by Hydro Rural Electrical Service

	Brant	Preston	Woodstock
Number of consumers	212	175	241

" pumps	...	6	...
" grinders	...	2	...
" blankets	...	1	...

The effect of the installation of the more modern appliances is well illustrated in the average consumption of electricity by all consumers in these districts. In Brant, for instance, the average consumption among Class 3 customers is 1,649 kilowatt-hours per annum, in Preston 1,332 kilowatt-hours per annum and in Woodstock 1,430 kilowatt-hours per annum. These figures are materially higher than the average consumption among all Class 3 consumers in the province of 833 kilowatt-hours per annum. There are corresponding differences in the consumption among other classes of farm consumers and the general effect of the extensive use of electricity in these districts has been to materially reduce the average cost per kilowatt-hour to consumers in these districts over the general average. It is hoped that, as the farm consumers throughout the province reach the position where they are able to finance additional power-using equipment, the standard of electrical utilization now set by specific districts will be equalled and even surpassed, in all districts of Ontario.

Financial Results to the Utility

Respecting the economic results of rural electrical service to the utility, it can be stated that, notwithstanding the fact that on the average the consumers have been served but for a short time, the revenues yielded by the charges to consumers have been adequate. The results of operation in 1928 are as follows:

Rural Power Districts — Revenues and Expenses for 1928

Total capital investment in operation		$7,054,654.00
Revenues from consumers		1,342,624.86
Expenses		
Cost of bulk power	$472,594.56	
Cost of operation, etc	342,686.71	
Total operating expenses		815,281.27
Net return before depreciation		$ 527,343.59
Depreciation		123,666.45
Net return after depreciation		$ 403,677.14
Per cent return on total investment 5.7 per cent interest		146,919.58
Surplus		$ 256,757.56
Applied to capital retirement	31,380.07	
Reserved for obsolescence and contingencies	173,252.39	
Other free surplus	52,125.10	
	$256,757.56	

In interpreting the above results of operation, the effect of the government agricultural bonus should be taken into account. Nearly one-half of the $7,000,000 of capital investment for rural distribution having been granted by the province as part of its general policy of aiding agriculture, the charges to consumers are relieved of interest and sinking fund in respect of some $3,500,000, and the net return of 5.7 per cent after depreciation, figured on the total capital investment, — including the government "grant-in-aid" — is thus ample to ensure the financial soundness of this portion of the Commission's activities.

It is of interest to note that the total revenues of one and one-third million dollars represent the sum of the charges paid by nearly 30,000 rural consumers — an average charge per consumer per month of less than $4.00, for service which in the case of a large proportion of the consumers covers lighting of farm residences, lighting of out-buildings, electrical cooking and power for operation of agricultural machinery. The general conclusion to be drawn, therefore, respecting the economic results of the Commission's policies in the field of rural electrical supply is that, having regard to the circumstances in Ontario, these policies have been the means whereby service can be extended on a large scale to rural consumers at relatively low costs without detriment to the financial status of the undertaking, and with great economic benefit to the province as a whole.

In accordance with the suggestion that the greatest weight at the Second World Power Conference should be given to the distribution and utilization of electricity, and that reports were desired respecting experience with domestic and agricultural electricity tariff systems, in their relation to the use of electrical appliances, and also respecting experience as to the influence of these appliances on the load characteristics of the supply stations, the endeavour has been made to present as comprehensively as could be done within the limits of space assigned, a description of the results that have been achieved in the province of Ontario. It is hoped that the information that has been given respecting these important aspects of electrical supply, based on the experience of the Hydro-Electric Power Commission of Ontario in serving several hundred municipalities over a period of nearly twenty years, will be found to be of assistance to those who have to deal with the problems which arise in connection with modern electricity supply undertakings.

Storage Reservoirs in Canada

Dr. O. O. Lefebvre, M.E.I.C.,
Chief Engineer, Quebec Streams Commission.

Paper presented before the Second World Power Conference, Berlin, Germany, June 16-25, 1930.

Statistics respecting the possibilities of the rivers in Canada for producing power have been compiled by the Dominion Water Power and Reclamation Service, Department of the Interior, Ottawa. The last figures given out show that at low water about 20,000,000 h.p. might be generated, but on the basis of the flow available six months in the year or 50 per cent of the time, the amount of power possible would be 33,000,000 h.p. or one and two-thirds the possibility at low water.

The amount of power available in each province of the Dominion is given in table No. 1 for both the ordinary minimum flow and the ordinary six months flow.

To this table No. 1 has been added a column which shows the relation of the ordinary flow available six months in the year to the ordinary minimum.

In the western provinces of British Columbia and Alberta the ratio is 2.6 and 2.7 respectively, while for Ontario and Quebec the ratio is 1.3 and 1.5 respectively. This would seem to show that to increase the low water flow to the six months figures much more storage is required in British Columbia than is required in the central provinces

Table No. 1

Province	Available 24-hour power at 80 per cent efficiency		Relation six months flow to ordinary minimum
	At ordinary min. flow h.p.	At ordinary six months flow h.p.	
1	2	3	4
British Columbia	1,931,000	5,103,500	2.6
Alberta	390,000	1,049,500	2.7
Saskatchewan	542,000	1,082,000	2.0
Manitoba	3,309,000	5,344,500	1.6
Ontario	5,330,000	6,940,000	1.3
Quebec	8,459,000	13,064,000	1.5
New Brunswick	87,000	120,800	1.4
Nova Scotia	20,800	128,300	6.4
Prince Edward Island	3,000	5,300	1.8
Yukon and Northwest Territories	125,200	275,300	2.2
Canada	20,197,000	33,113,200	1.64

of Ontario and Quebec. The ratio may indicate also that the streams in the mountainous country of western Alberta and British Columbia have a longer period of relatively high water.

The amount of power which has been generated in the different provinces up to January 1st, 1930, has been computed as follows:

British Columbia	588,600 h.p.
Alberta	70,500
Manitoba	312,000
Saskatchewan	35,000
Ontario	1,952,400
Quebec	2,595,000
New Brunswick	112,600
Nova Scotia	109,100
Prince Edward Island	2,440
Yukon Territory	13,200
Total	5,790,840 h.p.

This tabulation has been derived from the statistics issued by the Department of the Interior, Ottawa, for January 1st, 1929, to which has been added the amount of power installed during 1929, as given out lately in trade publications, financial reviews and general summaries of power activities during the past year.

The improvement of the rivers for the production of power, if limited to the low water possibility, would mean in the majority of cases a prohibitive cost. The increase in the amount of water available during the low water periods can be obtained only by changing the distribution of the water from one season to another, that is holding the water into large storage basins during the excessive water supply. The increase in the low water flow means a proportionate increase in the amount of primary power which can be generated under a given head. In some cases, where such control has been realized, the low water flow has been increased to a figure higher than the flow available for six months of the year. It is not contended here that the regulation or control of the flow of all power streams is possible, however desirable it may be.

Storage reservoirs have been built quite extensively in all of the provinces where hydro-electric power is generated. In fact, it may be fair to state that all the important power developments have their supply of water assured by storage reservoirs.

With the increasing demand for power and cheap power, dependable power, the question of increasing the low water flow came very much to the front, more specially with respect to the most accessible sources of power. Comprehensive studies have been made throughout Canada of the quantity of water flowing into the principal streams. The initiative in this field of investigation was taken by the Water Power and Reclamation Service of the Department of the Interior at Ottawa. It is true that scattered and very limited investigations of individual streams had been made previously by private power interests, but the above-mentioned branch of the Dominion government has the merit of having organized the hydro-electric survey on a large and comprehensive scale, and properly coordinated the data made available. To this work, the provincial organizations have heartily co-operated, and the Water Resources papers which are issued from time to time form a most valuable guide for the proper and economic improvement of the power streams.

Seasonal Flow

The flow of the rivers is very variable. In the central provinces and the Maritime Provinces, it is generally at its maximum during the spring flood. On the Pacific coast, and more particularly in Vancouver island, the high water occurs in the winter, say November, December and January; in the rocky mountain streams of British Columbia the high water occurs in summer, say in May, June and July,—the streams being fed by the melting ice and snows of the high hills.

The minimum flow, except as above-mentioned, generally occurs during the winter months, in February or March. Generally speaking, the ordinary minimum flow reaches one-third of a cubic foot per square mile of drainage area in all of the eastern provinces. The maximum flow reaches up to ten cubic feet per second per square mile of watershed for the large basins, and from twenty-five to thirty for the smaller basins.

The streams draining the western plains of Alberta and Saskatchewan, and part of Manitoba, such as the Saskatchewan and Assiniboine rivers, have a very low minimum discharge, something of the order of one hundredth of one cubic foot per second, but these are not rated as power streams.

Practicability of Reservoirs

The only method by which the low water of the streams may be increased is by the construction of large reservoirs in which the flood waters, or part of them, are held back by control dams, and distributed during the low water periods.

At the time of spring floods, water flows in excessive volume, always causing inconvenience, and sometimes heavy damage to the riparian proprietors. The surplus water, which is thus stored, constitutes an improvement in the spring flood situation. The reservoirs, therefore, improve both the high water and low water conditions.

A complete control whereby a uniform flow would be available throughout the year is almost impossible to realize. In considering this question, one must bear in mind the fact that the amount of water flowing down a stream is quite different from one year to another,—there being high water years and low water years. Under those conditions, complete control is almost beyond hope.

It may be stated that the average yearly flow on the St. Maurice river, for example, is about 1.7 second-feet per square mile of drainage area. The low average yearly flow is about 1.2 cubic feet per second per square mile. With the present storage facilities, the flow of the stream is regulated to 1.06 second-feet per square mile.

Reservoirs

The construction of reservoirs has been carried out in most of the provinces, and a general outline of the extent to which they have been built in each province is given below.

No details as to cost, or as to the resulting improvement in the flow of the streams regulated are given, except in the case of the rivers in the province of Quebec, when they are controlled by the Quebec Streams Commission.

British Columbia

In British Columbia the principal power developments are those of the British Columbia Electric Power Company, located on Vancouver island, to serve the district of Victoria and vicinity, and the power plants of the same company supplying the city of Vancouver and surrounding district. On Vancouver island, no large amount of storage has been developed beyond the capacity of the ponds resulting from the construction of power dams. On the mainland, storage reservoirs have been created such as: Coquitlam lake, seven or eight miles northeast of Vancouver, with a capacity of 160,000 acre-feet to supply water to the Buntzen plant. The same company built a storage dam controlling the water from Alouette lake,— a reservoir with a capacity of 173,000 acre-feet. This water is diverted into Stave lake through a tunnel and a power plant under a head of about 160 feet. The tailrace of that plant is Stave lake, which has a capacity of 471,000 acre-feet. Stave lake discharges through the Stave falls power plant into the Stave river. On the same stream the Ruskin falls are now being developed. This system is known as the Alouette-Stave-Ruskin development and is located about twenty-five miles northeast of the city of Vancouver, — the system being tributary to the Fraser river.

A third power unit on a large scale is that of the Bridge river, also a tributary to the Fraser. The water of that stream will be diverted through a tunnel into Seton lake, which lies about 1,200 feet lower than the river at the point of diversion. This development is now under construction and, when completed in the next few years, will involve storage reservoirs having an aggregate capacity of 1,293,000 acre-feet. The power plant will be located on the shore of Seton lake about fifty miles north from the city of Vancouver.

Another district in the province of British Columbia, which is remarkable for the amount of power generated, lies in the southeast part of the province,—the Kootenay district, where are rich deposits of copper minerals, which are being extracted on a large scale. A certain amount of storage is available from the Kootenay lakes.

Alberta

In the province of Alberta, the power developed to this date is practically limited to plants on the Bow river, which rises in the Rocky mountains in the Banff district, and flows past the city of Calgary. The Calgary Power Company serves the city of Calgary and district with power generated at two sites on the Bow river. Storage reservoirs have been created in the Minnewanka lakes, with a capacity of 44,000 acre-feet. Lately the Ghost development has been completed and involves a reservoir with a capacity of 73,000 acre-feet.

Saskatchewan

In the province of Saskatchewan, practically no water power had been developed until the year 1929, when work was commenced on the Island falls power site on the Churchill river. This power is intended for the mining industry, more particularly the Flin Flon mine in the northwest section of the province of Manitoba. It may eventually be transmitted to the northern centres of population in Saskatchewan. No storage is mentioned in connection with this development,—the minimum flow of the Churchill river being, no doubt, sufficient for the present power requirements.

Manitoba

The principal power streams in this province are the Winnipeg and the Nelson rivers. The winnipeg has its source into Lake of the Woods, an international body of water located between the state of Minnesota and the province of Ontario, near its western boundary, and flows into Lake Winnipeg. The total fall between the two lakes is about 340 feet, of which 265 feet are within the limits of Manitoba. Power is developed on a large scale on the Winnipeg river by both the city of Winnipeg and the Winnipeg Electric Company, or subsidiaries.

The flow of the Winnipeg river is regulated to about 20,000 second-feet by a control of the discharge of Lake of the Woods and Lac Seul, on the English river, tributary to the Winnipeg. This control is performed by what is called "The Lake of the Woods control board" for lake elevations 1,056.0 to 1,061.25. The capacity of the lake between these limits is 5,000,000 acre-feet,—its area being 1,485 square miles. When the lake level reaches an elevation beyond these limits, control passes to an international board with a Canadian and a United States representative.

The Lac Seul reservoir has a capacity of 3,210,000 acre-feet,— the lake area being 421 square miles.

The Nelson river is the outlet of Lake Winnipeg, 715 feet above sea level, and flows into Hudson bay. Lake Winnipeg is supplied from the Saskatchewan and the Rouge, in addition to the Winnipeg river. No power has yet been developed on the Nelson.

Figure No. 1.—Reservoirs in Canada—British Columbia and Alberta.

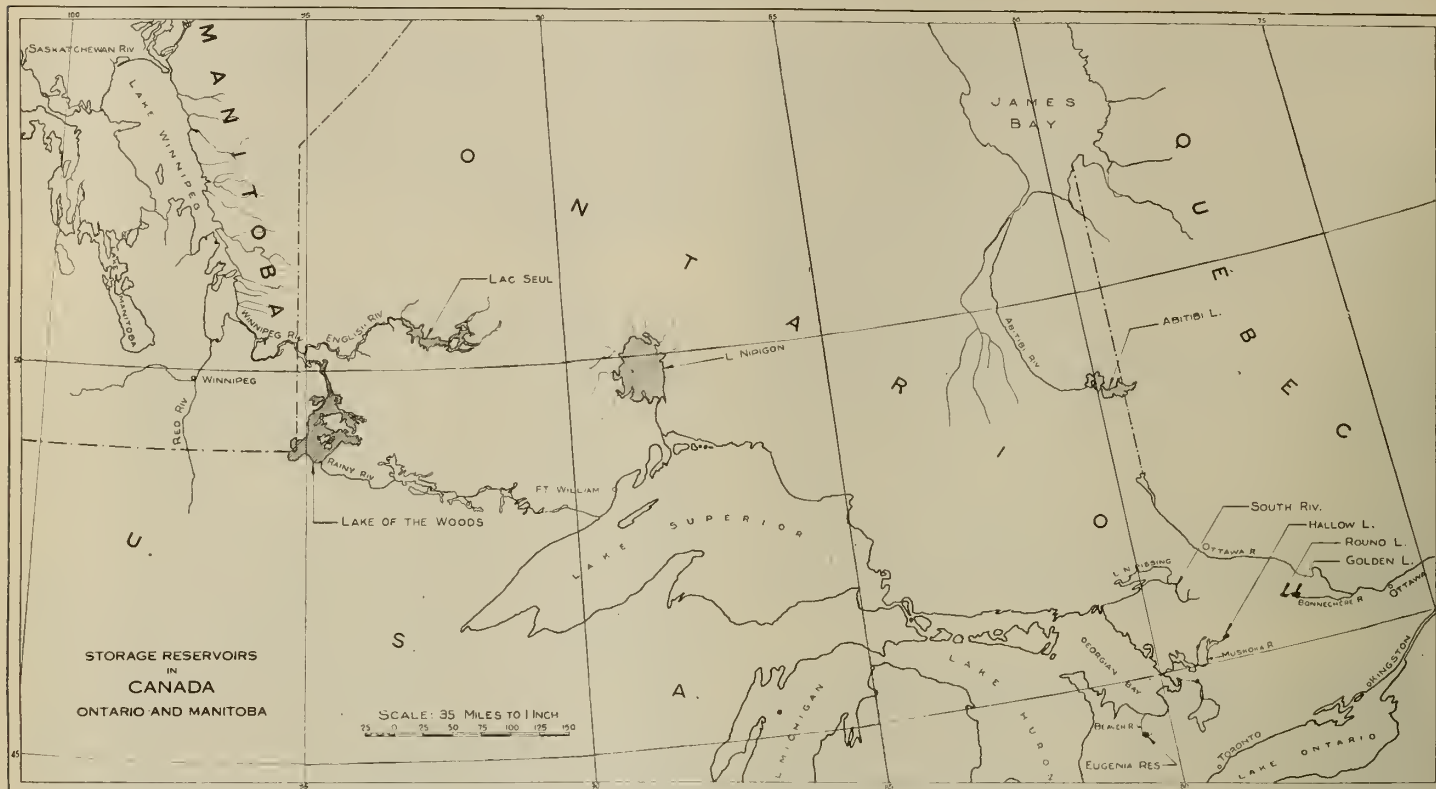

Figure No. 2.—Reservoirs in Canada—Manitoba and Ontario.

Ontario

In the province of Ontario, except in the northeast section, almost all the power is generated and distributed by the Hydro-Electric Power Commission of Ontario, acting as a trustee for the different municipalities it serves with power. The principal reservoirs owned and operated by the Commission are:

Lake Nipigon on the Nipigon river, north of Lake Superior. The capacity of that reservoir is 5,720,000 acre-feet. The minimum flow at the dam is 7,620 second-feet.

Hollow lake reservoir on the Muskoka river, district of Parry Sound. The reservoir capacity is 75,000 acre-feet; minimum flow 500 second-feet.

Eugenia falls on the Beaver river. Capacity of the reservoir 16,000 acre-feet; minimum flow 58 second-feet. This is a combined storage and power.

Round lake and Golden lake on Bonnechere river, a tributary to the Ottawa, and flowing through the town of Renfrew. Combined capacity of the two reservoirs 80,700 acre-feet; minimum flow at Renfrew 300 second-feet.

Five small reservoirs on the south river, district of Nipissing. Capacity 35,000 acre-feet; flow at Nipissing 200 second-feet.

Besides the above reservoirs, private companies have built some storage dams in the northern part of the province, namely:

The storage dam on the Spanish river at Turbine, built and owned by the International Nickel Company, to increase the flow of the Spanish river. Also control by the Abitibi Power and Paper Company of the flow from Lake Abitibi, a large body of water, 875 feet above mean sea level, lying partly in the province of Ontario and partly in the province of Quebec, and forming the source of the Abitibi river. It is controlled between high and low water limits,—a margin of six feet. The storage capacity between these limits is 1,340,000 acre-feet. Water is used to regulate the flow of the Abitibi river, from which power is generated by the Abitibi Power and Paper Company.

Ottawa River

The Ottawa river forms the boundary between the provinces of Ontario and Quebec.

Storage reservoirs have been built some years ago by the Dominion government in view of improving navigation. These reservoirs are located in Quinze lake and Kipawa lake, both completely in the province of Quebec, and into Lake Temiscamingue which is on the interprovincial boundary.

The flow of the Ottawa river is increased to 20,000 second-feet during low water periods, as against a minimum of 12,000 second-feet under natural conditions. These dams are operated and maintained by the Dominion government, and up to this time, no charge has been made to the power interests who benefit by the additional flow.

Province of Quebec

In the province of Quebec, storage reservoirs have been built by the Quebec Streams Commission and by private companies. These will form the text of a special chapter and need not be considered further at this stage.

New Brunswick

In New Brunswick, power is being produced by private companies and by the New Brunswick Power Commission, a governmental organization. This commission has developed on the Musquash river, about fifteen miles southwest of the city of St. John, a power plant where about 11,000 h.p. have been installed. Storage dams have been built in the Musquash valley and lakes. The capacity of the storage is 600,000 acre-feet.

Power has been developed lately at Grand falls on the St. John river. Storage is being provided on the tributaries of this stream,—said tributaries being located partly in the province of Quebec and partly into the state of Maine.

In the province of Quebec, a storage reservoir is being built into Lake Temiscouata, source of the Madawaska river. The water from that lake will be controlled on a depth of about seven feet above low water,—the natural high water not being raised.

Nova Scotia

In Nova Scotia, power is being generated and distributed by the Nova Scotia Power Commission, a governmental organization, and by private companies. This commission has reservoirs in connection with its St. Margaret's bay power, Sheet Harbour and Mersey river developments. Storage dams are located on the Tusket river at Carleton lake, Great Barren lake and Stoney Creek lake,—the aggregate capacity of the reservoirs being 50,000 acre-feet. Power is supplied at Yarmouth.

In the Sheet Harbour system on the East river, seven reservoirs have been built. These are scattered in the basins of the East river and supply water to the power stations of this system.

There has recently been completed on the Mersey river a combined power and storage dam at Upper Lake falls,—the storage being in Rossignol lake, and the capacity of the reservoir about 512,000 acre-feet. Power will be supplied to the Mersey Paper Company at Liverpool, N.S.

St. Lawrence System

Mention should be made here of the natural regulation of the St. Lawrence river due to the Great Lakes system. These Great Lakes form the most effective series of reservoirs, making the St. Lawrence the most regular stream known to the writer. The drainage area of these Great Lakes is 275,000 square miles. The combined area of the lakes themselves is about 95,000 square miles. The average flow out of this system for the period from 1860 to date has been about 241,000 second-feet,—the minimum flow being 180,000 second-feet and the average maximum 290,000 second-feet, a ratio better than two to one.

Mention is made of this natural advantage of the St. Lawrence because that river may be developed to produce about 5,000,000 h.p. in the section between Lake Ontario and Montreal,—Canada being entitled to 4,000,000 and the United States to 1,000,000 h.p., but the storage above-mentioned is provided by nature. There is no control of the flow from the lakes, and many studies of further improvements have shown that it would be very costly and even dangerous to interfere with natural conditions.

Reservoirs in Quebec

The writer now comes to the consideration of the storage reservoirs which have been built in the province of Quebec. They may be divided into three classes:

Those built and operated by the Quebec Streams Commission. These reservoirs are listed as follows:—

The Gouin storage and the Manouane system on the St. Maurice river;

Lake St. François and Lake Aylmer on the St. François river;

Three small reservoirs on the North river, north of Montreal;

Lake Kenogami reservoir in the Saguenay district;

Lake Brûlé and River Savane reservoirs in the Ste. Anne de Beaupré river, below the city of Quebec;

Lake Metis reservoir on the Metis river, in the district of Rimouski.

In the second class are the reservoirs built by power companies and operated by the Quebec Streams Commission:

The reservoirs on the Gatineau river, north of the city of Ottawa, namely the *Baskatong and Lake Cabonga*, the *Cedar Rapids reservoir* on river du Lièvre,—a work soon to be completed, and the *Mattawin storage dam* on the Mattawin river, a tributary to the St. Maurice river,—work now under construction.

In the third class are the storage dams built and operated by private companies. They are as follows:

On the Shipshaw river, reservoirs in lake Onatchiway and Pamascachiou, owned by Price Brothers and Company, Ltd., permit the regulation of the flow to about 1,000 second-feet.

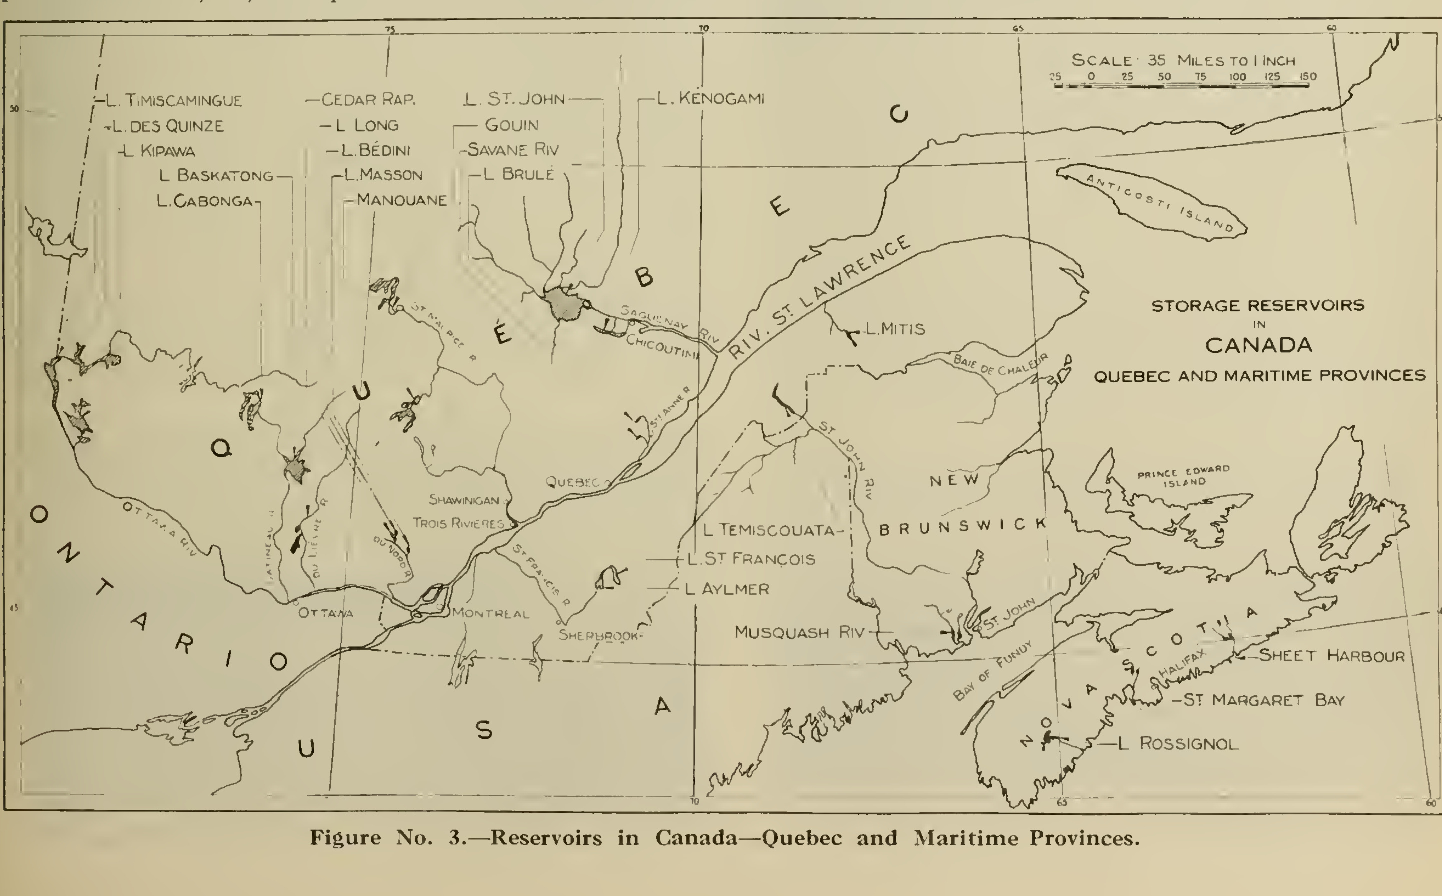

Figure No. 3.—Reservoirs in Canada—Quebec and Maritime Provinces.

Figure No. 4.—Gouin Dam—St. Maurice River—Quebec.

Lake St. John, head of the Saguenay river, is controlled between natural high and low water by a combined power and storage dam at Isle Maligne. The storage capacity is 3,850,000 acre-feet, and the flow of the Saguenay is regulated to 28,000 second-feet.

Three reservoirs on the Jacques-Cartier river, northwest of the city of Quebec, owned and operated by the Donnacona Paper Company.

Combined power and storage dam at the outlet of Lake Memphremagog, west of the city of Sherbrooke, on the Magog river, owned by the Dominion Textile Company, regulating the Magog river to 600 second-feet.

A combined power and storage dam at Megantic, at the outlet of Lake Megantic, at the head of the Chaudiere river, south of the city of Quebec.

Practicability of Reservoirs

The practicability of storage reservoirs in the province of Quebec was demonstrated in 1910 and 1911, through the initiative of the Shawinigan Water and Power Company, by the construction of relatively small reservoirs on the Manouane river, a tributary to the St. Maurice. This company had developed the famous Shawinigan falls on the St. Maurice and soon found that the amount of power it could generate from these falls could be increased very substantially and cheapened by increasing the low water flow. Uncertainty as to the quantity of water which would reach the plant under winter conditions, when let out of reservoirs located more than two hundred miles from the plant, was dissipated by the experiment with the Manouane reservoirs. It was found that the water let out from these dams reached the plant with no appreciable loss. This experiment was followed by attempts to regulate the flow on a much larger scale.

Reservoirs Built by the Quebec Streams Commission

The Quebec government, in 1912, authorized the Quebec Streams Commission to undertake the regulation of the flow of the St. Maurice river. In 1915, the same policy was followed in the case of the St. François river on the south shore of the St. Lawrence, and later extended to the Chicoutimi district with the control of Lake Kenogami; also the St. Anne de Beaupré river, the Metis river in the lower St. Lawrence, and river du Nord, northwest of of Montreal.

On the St. Maurice river, the Gouin dam controls a reservoir that has a capacity of 3,662,000 acre-feet. It is claimed to be the largest artificial reservoir in the world. The discharge of the St. Maurice has been increased from a minimum of 6,000 second-feet to 17,000 second-feet at Shawinigan,—practically three times as much primary power being made available.

On the St. François river, two storage dams were built, forming two reservoirs: Lake St. François with a capacity of 276,500 acre-feet, and Lake Aylmer with a capacity of 64,000 acre-feet. The low water flow of the stream is increased by 900 to 1,200 second-feet.

Lake Kenogami reservoir has a capacity of 312,000 acre-feet and supplies two streams, both highly developed for power, and upon which are located the principal pulp and paper mills of the Saguenay district, in the towns of Chicoutimi, Jonquière and Kenogami.

On the St. Anne de Beaupré river, two relatively small reservoirs have been built and water is supplied to the Laurentian Power Company's plant at Seven falls,—plant operated under a head of 410 feet. These reservoirs have a capacity of 12,000 acre-feet.

On the Metis river, one reservoir is operated to supply water to the Lower St. Lawrence Power Company, operating a power plant at Metis falls,—the minimum flow of the stream being regulated to 350 cubic feet per second. The capacity of the reservoir is 70,400 acre-feet.

On the North river, northwest of Montreal, three small reservoirs are operated by the commission and serve to increase the low water flow of the river which is highly developed for power. Capacity of the reservoirs 17,500 acre-feet.

The Quebec Streams Commission has spent to date in the vicinity of $10,000,000 to build the storage reservoirs above-mentioned. The cost of these reservoirs has been met by the commission with money advanced by the provincial government. All expenditures of the commission are duly accounted for and must be approved by order of the Lieutenant-Governor-in-Council.

Annual Charges

The power companies benefiting from the additional flow provided by the storage dams have to pay for the benefits which they derive. The unit price upon which each benefiting company or individual must pay is the same for all interests on the one stream, but varies considerably as between one stream to another. Each regulation project has to be considered separately when it comes to assessing the benefiting parties. Capital cost is the determining factor. The commission bases its charge on the amount required yearly to meet the interest on the capital invested in a reservoir, the amount required for the amortization of that capital in thirty years, and the cost of operation and maintenance of the works.

On the St. Maurice river for example, the charge agreed upon between the benefiting companies and the commission is equivalent to $3.65 per h.p.-year of the additional power produced with the additional flow.

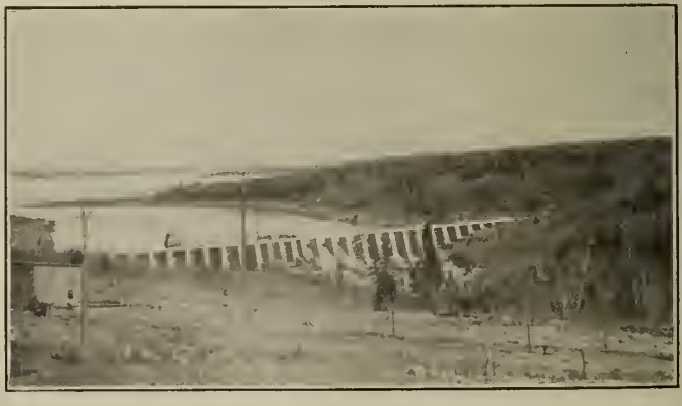

Figure No. 5.—Allard Dam—St. François River—Quebec.

Figure No. 6.—Taschereau Dam—Lake Kenogami Reservoir—Quebec.

On the St. François river, the charge is equivalent to $7.50 per h.p.-year of additional power.

The revenues, which the commission derives from the storage reservoirs it operates, were $751,993.92 in 1928-1929.

Legislation

Whenever, after duly investigating a storage proposition, the commission asked for authority to undertake the regulation of a particular stream, a special act of the legislature was passed for that particular proposal. A separate act of the legislature was passed for each of the streams which the commission has under control. The commission is not authorized by a general law. All these individual acts are practically similar in wording: authority is given to the commission to spend a sum not to exceed an amount mentioned in the act. Plans and specifications of the works must be approved by the Lieutenant-Governor-in-Council. The works must be advertised for tenders and a contract awarded to the lowest tenderer,—provided he can show proper qualifications. The commission is also authorized to acquire properties which may be affected by the proposed works; to build roads which may be required to replace flooded roads, bridges, dykes, telephone lines, etc. The commission is authorized also to negotiate contracts with the benefiting companies, and to impose a tariff in the case of companies refusing to accept the terms of the contract set out by the commission. The contract mutually agreed upon, as well as the tariff determined by the commission, must be approved by Order-in-Council.

Operation of Dams

The commission operates the storage dams to the best advantage of the interests using the water. While criticisms may have been heard in the first years that storage dams were operated, these were due to misconception as to the purpose for which these storage works were built, and their limited possibilities. It is realized from all quarters today, that the storage dams operated in the province of Quebec have reduced very materially the cost of power and have, moreover, assured permanency of power so essential to industry.

It used to be stated as more or less of an axiom that a water power site could be economically developed to use the flow available 60 per cent of the time, or seven months in the year. This meant that for a period of five months every year, a certain number of customers could not be served with power and had to close their plant, or else operate auxiliary steam plants. This condition of affairs was not satisfactory. Modern industry requires permanency in its power supply. It can then budget its production; its business is more stable. The necessity of seasonal employment is materially decreased, if not altogether eliminated. It may be stated here that seasonal unemployment has been one of the difficult problems with which Canada has been faced for years. Permanent mill operation assured by permanent water supply has been a great benefit to the industrial centres of the province of Quebec, more particularly those located around pulp and paper mills. The old saw-mill is practically a thing of the past. It used to operate with a large force during the open season, but was closed altogether during winter. The pulp and paper mill operates twenty-four hours a day, six days per week, all the year round, provided its power supply is not failing. In certain districts, such as the Saguenay, pulp mills were closed every winter,—hundreds of hands being thrown out of work. The Lake Kenogami storage was undertaken with a view to curing the unfortunate situation, and this it has done.

Dams Built by Power Companies and Operated by the Commission

While a number of storage dams have been built by the Quebec Streams Commission, and the capital cost paid by the commission, a certain number of dams have been built at the request of power companies, under the supervision and control of the commission and at the expense of

Figure No. 7.—Mercier Dam—Gatineau River—Quebec.

these companies. In other words, the benefiting companies, instead of having to reimburse the capital cost of the storage works by yearly instalments covering the interest and sinking fund, undertook to pay at once the capital cost. Needless to say that the annual charges of the commission are then limited to the cost of operation and maintenance of the dam, and a fixed amount to cover the privilege of flooding Crown lands when such are affected. This procedure was followed in the case of the Gatineau river where the Gatineau Power Company requested the commission to build the Mercier storage dam, which was completed in the spring of 1927. The reservoir which this dam creates has a capacity of 2,132,500 acre-feet, and permits the regulation of the flow of the Gatineau river to 9,000 second-feet,—this being three times the average low water flow of the river.

In 1929, storage dams were built to control the water from Lake Cabonga, a tributary to the Baskatong reservoir. This reservoir has a capacity of 1,033,000 acre-feet, and is intended to assure adequate supply of water for a regulation of the Gatineau to 10,000 second-feet during the lowest years.

The Gatineau river was unimproved until 1925. In that year, the possibility of increasing the low water flow of the stream had been proved, and a large scheme of power development was planned.

The falls and rapids of the Gatineau have been concentrated at a few points where water is used to generate power, namely: at Farmer's rapids under a head of 67 feet; Chelsea, under a head of 96 feet and at Paugan falls, under a head of 140 feet,—the three ponds covering a distance of about sixty miles in the river.

The three power plants above-mentioned have a capacity of 120,000, 170,000 and 272,000 h.p. respectively,—a total of 562,000 h.p. This improvement would not be possible without the regulation of the flow of the stream. The cost of the dams, the unwatering of the site, etc., would be prohibitive if the amount of power were about one-third of the present installed capacity.

A similar method is followed for the regulation of the flow of the Lièvre river, where the MacLaren Company has operated for years a saw mill and a pulp mill at Buckingham. This company has under construction a paper mill at Buckingham Junction, near the mouth of the River du Lièvre. For the operation of that paper mill, power will be generated on the Lièvre, mostly at High falls. In order to increase the low water flow of the stream, a storage dam is being built at Cedar rapids, about sixty miles from the mouth of the river. This storage dam is built by the company, according to plans approved by the commission and under the direction of the commission. The dam will be operated by the commission and will be its property.

The capacity of the reservoir will be 500,000 acre-feet, and will be sufficient to regulate the flow of the Lièvre river to 3,400 second-feet.

Benefiting Third Parties to Pay Share of Cost

Any person, or company, other than the company at whose expense the dam is built, which will benefit from this dam, will be called upon to pay its proportionate share of the interest and sinking fund of the capital expenditure, as well as its share of the cost of operation of the work. All amounts collected under the interest and sinking fund charges will be refunded to the company having paid the capital expenditure, and the obligations of the latter respecting the cost of operation and maintenance will be reduced to the extent of the amount collected from the third party under this item.

General Law Governing Construction of Storage Reservoirs

Prior to 1918, there was no law governing the construction of dams in the province of Quebec. No plans of these structures had to be filed with the provincial government, and it seems that in the case of most log driving dams, no plans were made at all. While investigating the control of the flow of rivers, it soon became evident that the provincial authorities should know the type, the location, the ownership of the dams then in existence, and that all future structures be approved by Order-in-Council before the work of constructed may be proceeded with.

In 1918, an act of the legislature (R. S. Quebec 1925, Chapter 46) was passed making it obligatory for owners of all dams in the province to file a plan for the dams then existing, and stipulating that all future structures may be built only after plans of such structures have been submitted to the Department of Lands and Forests, and approved by Order-in-Council. In this way, a reliable record is kept of the structures built; the area of public lands or private lands affected; conditions upon which the public land may be used,—either for flooding or otherwise. Many structures have been built under the provision of this law,—some simply to facilitate the driving of logs, others to increase the power possibilities of the streams. In this latter category are the dams which Price Brothers and Company have built on the Shipshaw river, Saguenay district; the dam built by Donnacona Paper Company on the Jacques-Cartier river. These structures are approved upon terms determined by the Department of Lands and Forests. Provision is made for compensation for flooded Crown lands; for benefits to other parties, if any; for royalty on the amount of additional power produced, etc.

Storage reservoirs become economical only when the water may be used under a certain minimum of head. On the St. François river for example, the stored water is used under an aggregate head of 240 feet through the different power plants. Under, say 100 feet of head, the storage proposition would not be economical.

On the St. Maurice river, the stored water is used under an aggregate head of 285 feet. Though this proposition was relatively cheap, owing to no improved land having to be expropriated, the proposal would not be practical if the head used were less than 100 feet.

Many a storage proposition had been investigated by the Quebec Streams Commission and will become practicable only when the improvements of these streams for power may be undertaken on a certain scale.

When a river has its flow regulated by storage, the power possibilities of that stream soon become developed to their maximum and the cost of the power is reduced to its possible minimum.

Control of the Reservoirs

The control of the reservoirs owned by the Quebec Streams Commission forms a branch of the commission's activities which increases yearly in importance. In order to use the available amount of water to the best advantage of all power owners and prevent waste, the organization must keep in daily touch with the operators at the dams and observers at different points along the stream, so that conditions are known exactly. The opening of the gates is directed from the head office in Montreal and no initiative is left to the operators, except in case of emergency when water rises suddenly for example.

The amount of discharge is checked in two ways. A determination is made by using discharge formula applicable to the shape of openings through which water is discharged and by metering the stream.

In tunnel openings, the formula used is

$Q = AV = AC\sqrt{2gH}$.

Q = discharge in cubic feet per second.

A = area of opening in square feet.

V = velocity in feet per second.

H = is the vertical distance between the centre of the openings and water level in the reservoir.

C = a coefficient that depends on the size and shape of openings.

A series of meterings made in the river below the Gouin dam, St. Maurice river, has shown that the value of C in the above formula varies from 0.65 for small openings to 0.96,—the openings being 7½ feet wide and 12 feet high.

For spillway gates, discharging freely over an ogee sill, we use for the formula:

$Q = CLH^{3/2}$.

Q = discharge in cubic feet per second.

L = clear width of opening.

H = height of water surface of reservoir above gate sill.

C = 3.2 for low heads to 3.8 for high heads.

For discharge over stop-logs, C is taken as 3.0 for one foot head and gradually increased to 3.7 for head of ten feet.

Stop-logs are not easily operated in more than ten feet of water.

When a certain amount of water has to be discharged, it is necessary to determine by formulae the size of openings required under conditions of water levels then prevailing. After these openings have been made and the river is adjusted to the new conditions, use is made of the gauge discharge relation as indicated by the meterings, and the openings sometimes have to be corrected.

Winter Conditions

An ice cover forms on these reservoirs under average conditions in November for shallow lakes, and in December for the large and deep lakes. The temperature of the water is 32° F. near the ice cover, but its temperature rises at greater depth: 32.5 to 32.7 at a depth of the order of 50 feet.

It follows that the water discharged during winter from the bottom gates is at a temperature above freezing and no ice cover forms below the storage dam until the water has cooled to 32° F. In the case of the Gouin dam, where water is discharged at the rate of 10,000 to 13,000 second-feet during the winter months, no ice cover forms for many miles and in the next 30 miles the ice is not safe to travel upon.

Same conditions prevail on the Gatineau river, for 30 miles below the storage dam.

All dams have been built to resist ice pressure. The Gouin dam has been built to resist an ice pressure of 50,000 pounds per lineal foot of dam, taking effect under full reservoir. This condition seems to have been too severe and structures subsequently built are calculated to resist an ice pressure of 20,000 pounds per lineal foot.

As a matter of fact, the ice cover does not form opposite the gate section of the dam whenever a gate is opened.

Reservoirs Paid by Benefiting Companies

It is to be noted that the revenues derived directly from the benefiting companies are sufficient to pay the interest on the capital cost, the sinking fund in thirty years, the cost of operation and maintenance of the structures. These works are altogether self-sustaining and do not involve any cost to the tax payers.

The indirect benefits which the province receives from the increased activities brought about by more dependable and cheaper power cannot be valued in dollars and cents, but are reflected in the general prosperity which results from a better use of a most important natural resource: falling water.

Fuel Investigations and Research in Canada

B. F. Haanel, M.E.I.C.,

Chief Engineer, Division of Fuels and Fuel Testing, Mines Branch, Department of Mines, Ottawa, Ont.

Paper presented before the Second World Power Conference, Berlin, Germany, June 16-25, 1930.

Introduction

Organized effort to conduct fuel investigations and research in Canada began to assume definite form in 1908, when a comprehensive investigation of the coals of Canada was undertaken by the then newly created Department of Mines, in co-operation with Dr. Porter and others of McGill University.[1] Concurrently, the Mines Branch of that department established as a part of its organization a Fuels and Fuel Testing Division, which began to conduct special investigations such as boiler and producer gas tests, as well as chemical and physical examinations of fuels. For some years this was the only permanent organization in Canada which conducted fuel investigations and research.[2]

In 1916 a special investigation was undertaken, under the auspices of a special committee representing the joint interests of the Federal Government and the government of the province of Ontario, which had as its objective the development of an economic process for converting raw peat—of which the resources of Canada are very great—into a marketable fuel;[3] and in 1918, a board known as the Lignite Utilization Board, the membership of which was representative of the Federal Government and the governments of the provinces of Manitoba and Saskatchewan, was appointed for the purpose of developing a commercial process for converting Saskatchewan lignites, by low temperature carbonization and briquetting, into a fuel which it was hoped could compete on the open market with imported and other domestic fuels.[4] These two investigations were carried on more or less continuously for a period of about five years. In 1922 the Dominion Fuel Board [5] was created, which had as its objective the study of the fuel problems in Canada from a purely economic point of view. However, this board was responsible for various investigations, the chief one of which related to the utilization of coke as a household fuel to replace American anthracite, which was at that time the principal and practically sole fuel used for domestic purposes. While this was largely an economic problem, a considerable amount of investigational work was conducted on various Canadian coals, in order to determine their value for the manufacture of a domestic coke. When the Scientific and Industrial

(1) Results of this investigation are embodied in 7 volumes, entitled "Investigation of the Coals of Canada"—published in 1912.

(2) Results of these investigations are contained in the annual Summary Reports of the Mines Branch and in separate pamphlets.

(3) Results of the investigations conducted by this committee are contained in "The Final Report of the Peat Committee," published by the Mines Branch in 1926.

(4) The results of this investigation are embodied in the "First General Report of the Lignite Utilization Board" published in 1924.

(5) Results of the work done by this Board are contained in the "Interim Report of the Dominion Fuel Board," 1923, and the "Second Progress Report," 1923-1928.

Figure No. 1—Front and Side View of Laboratory Building.

Research Council of Alberta was created in January, 1924, a research organization was set up in the University of Alberta, to carry on fuel research and other investigations, with particular reference to the province of Alberta; and the Nova Scotia Technical College at Halifax, which is supported by the government of the province of Nova Scotia, has been engaged in later years on special fuel problems bearing on the mining and utilization of Nova Scotia coals. These constitute the principal organizations for carrying out fuel investigations and research, in Canada.

On account of the sparsity with which certain sections of the Dominion of Canada are populated, and the great distances separating the coal areas from industrial and more thickly populated centres, the various fuels required for industrial, commercial and domestic uses, are derived very largely from foreign sources—principally the United States. The imported fuels comprise: anthracite and coke for domestic purposes; bituminous coal for railway and industrial purposes; and crude oils for refining into motor spirits, lubricating oils and other products. When practically all classes of fuel could be obtained in great abundance, and at reasonably low cost, the peoples of the Dominion of Canada were not concerned with fuel problems or fuel research. It was only when a fuel shortage was threatened, and actually became a fact, that sufficient interest was aroused to create the necessary degree of enthusiasm for such investigations and research as would stimulate the use of native fuels. However, as stated above, owing to the location of the fuel resources—solid, liquid and gaseous—selection of the problems for investigation and research is influenced largely by economic considerations, such as freight rates, cost of mining, etc. Canada is not so favourably situated as some of the highly industrialized countries possessing large fuel resources, in regard to chemical and other industries which are dependent on solid fuels and their products, and on gaseous fuels, both natural and manufactured, consequently, a process or method for treating solid or other fuels, which might prove entirely commercial and profitable in European countries, for example, or in the United States, might prove to be entirely uneconomic when employed under conditions obtaining in Canada.

Outline of Investigations Conducted in Fuel Research Laboratories

The Fuel Research Laboratories of the Department of Mines are especially concerned with investigations which it appears would have an immediate commercial application, and while what is termed pure or academic research, is conducted, and on an increasing scale, an attempt is made to only carry on such research as will have a bearing on pressing economic problems. The principal investigations which have been conducted during the past few years pertain to:

(1) Chemical and physical survey of coal seams *in situ*.
(2) Investigation of problems concerning preparation of coals for markets.
(3) Testing of coals, on both small and large scales, with a view to improving the efficiency with which they can be utilized for various purposes, and to ascertain how their field of application can be extended.

The results of such investigative work afford a basis for the preparation of a 'use classification' of Canadian fuels. The large scale tests involved in these investigations include coal cleaning experiments and testing, according to various methods in use commercially, before and after cleaning, for (1) pulverized fuel burning, (2) high temperature carbonization, (3) low temperature carbonization, (4) domestic use, (5) briquetting and (6) determination of the value of gas and oils recovered in the course of carbonization, for the generation of power in internal combustion engines of different types, and for other purposes.

One of the functions of the Fuel Research Laboratories is to obtain as complete information as possible regarding commercial processes for the treatment of solid and other fuels, which are in the laboratory or semi-commercial stages of development, and also processes which are in successful commercial operation. These laboratories are also available for carrying out research on special problems with which coal operators and large consumers of coal are confronted. Such investigations and research will be conducted in co-operation with the parties specially interested.

At present the Fuel Research Laboratories are engaged in making a survey of the coking bituminous coals of Canada, and studying methods for improving the quality of coke by blending with other coals or by altering the methods employed for heat treatment, and in other ways improving the physical properties of the coke and raw coal. In this connection special mention may be made of full size by-product oven coking tests made in 1924 on coals from the Maritime provinces, and of special coking tests on bituminous coals from western Canada made in commercial by-product ovens at Winnipeg, the results of which showed that there is to be found in abundance in Canada coals quite suitable for the production of metallurgical and domestic coke.[6]

While low temperature carbonization was not looked upon by members of the staff of the Fuel Research Laboratories with much favour in past years, recent tests carried out on Nova Scotia coal, according to a well known low temperature carbonization process, have shown that a rather extensive field exists in certain portions of Canada for the introduction of some such process, inasmuch as a bituminous coal which is more or less unsuitable for the manufacture of a high temperature coke, when the objective is a domestic fuel, is an excellent fuel when submitted to the right low temperature treatment. While the laboratories are interested and are engaged on research work which has as its objective the conversion of solid fuels into liquid fuels, and the conversion of gases—both natural and manufactured—into fuels and other compounds, it must be borne in mind that the introduction of a process, even though technically feasible, would have a small chance of meeting with economic success at the present time when crude oil and its products can be obtained in great abundance, and at comparatively low cost. This state of affairs, of course, may change at any time, and in a few years a process which is now uneconomic may then be entirely economic and feasible.

[6] See Investigations of Fuels and Fuel Testing, 1924 and 1927.

Figure No. 2.—Large Scale Testing Floor showing Pulverized Fuel Boiler Installation.

Economic Utilization

So far as the Fuel Research Laboratories of the Department of Mines are concerned, its objective is not to conserve natural fuel resources—when conservation is used in the term 'to save'—but first of all to show how wastefulness in their utilization can be decreased or eliminated, and more especially to indicate means and ways for their more extensive development and use along economic lines. Conservation, of course, does not imply that a natural resource should be kept intact for some future generation, but that natural resources should be conserved for the best and most useful purpose, by utilizing them in such a manner that the products obtained from them can serve the largest number of purposes; and that only that portion of a fuel which is not suitable or cannot be used for more valuable purposes, be used for the generation of heat for steam raising, or for other purposes where heat is required. But the natural resources of any country will not be developed unless their development and utilization prove profitable, and the utilization of certain of the fuel deposits in Canada at the present time may not prove profitable if the fuel is used only for the generation of heat, consequently, fuel research must be conducted in order to ascertain whether other uses exist or can be found for such fuels: for example, oil is being used extensively on the British Columbia coast and by the railways traversing the Rocky mountains, in place of coal. The displacement of coal by oil has, therefore, placed a heavy burden on the coal operators who formerly supplied the coal for such purposes. The Fuel Research Laboratories are at present engaged in the conducting of large scale tests, accompanied by other investigations, on representative commercial samples of coal from the various collieries in British Columbia for the purpose of ascertaining their value as fuel for use in steam raising when burned in the pulverized form, and how the standard equipment available should be changed in order to adapt it to such use. The successful substitution of oil by powdered coal, both in stationary plants, where fuel oil is now burned, and perhaps on the railways and ocean-going steamships which are at present burning oil, would not only be of great assistance to colliery operators in western Canada, but would also reduce very appreciably importations of fuels in the liquid form from foreign sources—a phase, of course, which everyone must view as temporary.

Work of Other Fuel Research Organizations in Canada

As previously stated, fuel research is conducted by other organizations in Canada, e. g. the research staff of the Scientific and Industrial Research Council of Alberta.[7] This organization is conducting detailed laboratory work on the coals of Alberta, with a view to their scientific classification and suitability for various uses. During recent years the fuel investigations in Alberta have included a study of the general characteristics of the different coals as mined; special screening, weathering and storage tests; a study of the amenability to briquetting in the raw state; special laboratory carbonization and coking experiments; and tests in different types of domestic heating systems.

Valuable work has also been conducted on the tar sand deposits of Alberta with a view to developing a process for the economic separation of the bitumen content from the sand. Such a process would prove of great value and would make possible in the near future development of these immense deposits on a large scale. The raw bitumen thus separated has been and is being investigated by the Fuel Research Laboratories at Ottawa, especially in the direction of its utilization as a source of motor spirits, fuel oils, and other petroleum products, by high pressure and temperature cracking, with and without hydrogenation. In passing, it might be mentioned that the results of this work have confirmed that by the employment of high pressure and temperature cracking a large yield of motor spirits can be obtained from the bitumen content, and that the tar deposits as a whole would prove an almost inexhaustible source of motor spirits and other oil products, so far as Canada is concerned. A large amount of research has also been carried on by the Mines Branch, Department of Mines—as well as by the Industrial Research Council of Alberta—in connection with the utilization of both the raw tar sands and the bitumen content by itself, first, in the building of roads, and secondly, as a road oil. This work is still progressing.

A separate organization known as the "Turner Valley Gas Committee" was recently appointed to investigate means and ways of conserving the enormous quantity of natural gas which at present is surplus gas in the Turner Valley oil field, situated 40 miles south of Calgary, Alberta. The objective of the investigation being carried on by this committee is to determine the feasibility of piping long distances to industrial centres, and whether or not any of

(7) Investigations conducted by this organization are embodied in reports entitled "Annual Report of the Scientific and Industrial Research Council of Alberta."

Figure No. 3.—View of By-product Coke Oven Installation at Rear of Fuel Research Laboratories.

the processes for utilizing natural gas for the manufacture of motor spirits, chemicals, lampblack, or other substances, are economically feasible.

Investigative work is being carried out at the Nova Scotia Technical College on Nova Scotia coals,[8] to determine the most efficient grate setting for burning the various kinds of Nova Scotia coals under boilers for steam raising. The main objective of the tests involved is to indicate how existing small boiler installations can be easily and inexpensively altered to burn Nova Scotia coals more efficiently. Tests are also being carried out in a domestic hot water heater to ascertain how bituminous coals, coke, etc. should be burned in order to eliminate smoke, and to determine the efficiencies with which such coals can be burned. The weathering properties of slack coal when banked for winter storage and tests on commercial powdered fuel boiler plants have been and are being carried out.

Special work has been conducted at the Nova Scotia Technical College on the oil shales of Nova Scotia. This work is complementary to that conducted by the Federal Department of Mines on oil shales from other parts of the Dominion but mainly on the oil shales of the province of New Brunswick. The Federal Department developed a suitable laboratory retorting method and examined a large number of representative samples of oil shales. This work included a special study of the nature of the shale oil with a view to ascertaining its suitability for refining by high pressure cracking.

At present, the attention of the Department is directed to the examination of the oil shale resources of the Dominion with a view to their economic exploitation. In conjunction with this work research is being conducted on the conversion of solid fuels into liquid fuels and the manufacture of synthetic liquid fuels from gases—both natural and manufactured. Investigations related to the manufacture of motor spirits and other liquid fuels, according to pressure temperature cracking and other oil refining processes, will be extended. Oils resulting from the distillation of solid fuels at low temperatures, and the bitumen obtained from the tar sands of Alberta, will in the near future be subjected to detailed investigation and research.

Laboratory Facilities at Ottawa

The facilities of the Fuel Research Laboratories provide:

(a) Fully equipped chemical laboratories for routine analyses of all kinds of fuels—solid, liquid, and gaseous.
(b) Carbonization and research laboratory for research and plant control.
(c) Research laboratories for research on oils and gases—both natural and manufactured.
(d) Domestic furnace testing installation.
(e) Commercial size pulverized fuel boiler installation.
(f) Coal washing equipment, composed of wet and dry coal cleaning plants.
(g) Commercial scale by-product recovery coke oven with all accessories.
(h) Full size commercial scale briquetting installation.
(i) Gas producers.
(j) Internal combustion engines for testing the value of various oils obtained through the process of heat treating coals, oil shales, etc., for the production of power.

A large space is also provided for the erection of low temperature carbonization and other retorts for treating solid fuels and oil shales.

The Fuel Research Laboratories at Ottawa provide facilities for conducting investigations and research on, first, a small laboratory scale; second, a large laboratory scale; and third, a technical or semi-commercial scale. As an illustration, the investigational programme of the carbonization of solid fuels at high and low temperatures may be given. First, the coal in the seam is studied, and fundamental testing and research is conducted on a small scale on a large number of samples. This involves research on methods for examining the coal for its carbonization amenabilities and its classification as to coking properties, etc. For this investigation special tests on 20 (g.) samples are employed, according to high and low temperature carbonization practice. Then, on a select number of coals, tests are conducted on scales from 5 to 100 pounds, to indicate commercial yields of products, with special reference to the tar oils. This scale includes large scale laboratory tests, to secure sufficient tar oils for studying their refining properties, and also box coking tests for quality of coke to be expected in commercial practice. The results obtained in the small and large scale laboratory tests are subsequently checked, using a further selected number of coals on a technical or semi-commercial scale, either in semi-commercial high and low temperature carbonization installations at Ottawa or in commercial plants.

Supplementing the investigations on the different scales as outlined above, a limited amount of fundamental research of an academic nature is conducted on the raw fuels and the products therefrom, in co-operation with different Canadian universities. This is accomplished by certain members of a university staff interested in fuel research who spend their summer (vacation) time on special problems at the Fuel Research Laboratories, and on their return to their duties at the university, assign to undergraduates and graduate students, special small problems in fuel research, for thesis purposes.

The problems met with in Canada are in many respects dissimilar to those which are common to other countries. As stated previously, these laboratories are concerned chiefly with industrial research which has as the main objective the testing and investigation of processes developed on a technical, and those which have been successfully applied on a commercial scale in other countries, which it would appear could be applied to advantage in Canada. Pure research of an academic nature, while of immense value both to the present and future generations, requires more extensive and elaborate facilities and a much larger staff of specially trained men than contemplated by the Fuel Research Laboratories, and is not particularly the class of research which can be profitably carried out by a staff of engineers—chemical, mechanical, and mining, whose main objective is the application of science and engineering to industries in general; and while considerable pure research is being conducted in these laboratories, the staff depends very largely for its guidance on the academic research work on fuels conducted in the laboratories of other countries.

[8] The reports of the Nova Scotia Technical College are contained in the Annual Report of the Nova Scotia Department of Mines.

THE
ENGINEERING JOURNAL
THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XIII JULY 1930 No. 7

Amendments to the By-laws, 1930

At the meeting of Council held on May 30th, the scrutineers presented their report on the result of the ballot for the amendments to the By-laws, which closed on May 12th, 1930. The proposals to amend Sections 13 and 37 carried; those for Sections 34 and 75 were lost.

As a result the minimum term of office for councillors will become two years instead of one as at present, and the date after which a member whose annual fee is unpaid is considered in arrears will be June 30th instead of March 31st, also interest on overdue accounts will not be charged after June 1st, 1930.

In the case of Section 34 the necessary number of affirmative votes, namely two-thirds of all valid ballots, was not reached, four additional favourable votes being required for the amendment to carry.

The urgently needed additional revenue from members' fees will, therefore, not be available during 1931, and Council will no doubt have to consider what steps are necessary in order to make The Institute's expenditure balance its income.

The changes in Sections 13 and 37 will now be put in effect in accordance with the By-laws, and correction slips for insertion in members' copies of the By-laws will be issued as soon as possible.

Past-Presidents' Prize

Announcement is made by the Council of The Institute that the subject selected for papers to be submitted in competition for the Past-Presidents' Prize for the coming prize year (July 1st, 1930 to June 30th, 1931) will be

"ENGINEERING EDUCATION IN CANADA"

Two years ago the subject of "Engineering Education" was prescribed for the prize and seven papers were submitted. At the last Annual Meeting the Committee on the award of this prize reported that while several of the papers were of a high order, it was unable to recommend any one of them for the prize.

It is hoped that the papers in this competition will offer ideas and suggestions, both critical and constructive, which will be of value to Canadian universities and engineering schools, and which will also stimulate interest in the subject among practising engineers and employers of engineers. It is with this idea that the subject has again been chosen, and the following notes have been prepared by a committee of Council to suggest the treatment desired. It is not essential, however, that the arrangement of the papers should conform rigidly to that outlined below:—

(1) Curricula of Applied Science Faculties and Engineering Departments of Canadian Universities.

Pre-requisite admission standards; allocation of time between lecture and laboratory or workshop periods; tendency toward or away from specialization during regular four-year undergraduate course; recognition and guidance of special tendencies and abilities as revealed during the undergraduate course; place of cultural studies as distinguished from more strictly scientific and practical training; need and opportunities for intellectual and moral inspiration deriving from personal contacts with teaching staff; influence of organized recreation and participation in general college activities outside the class-room.

(2) The need and opportunity for organized collaboration by practising engineers and corporate or municipal bodies employing engineers, in the practical training of undergraduates during vacation periods and of young graduates in the early years following graduation.

The Institute and Specialized Branches of Engineering

It is a commonplace to say that the increasing complexity of modern life leads to greater specialization in the industries and professions. This in turn gives rise to many problems connected with professional education, training, and practice, for in many cases it is no longer possible for a professional man to cover the whole field of even the one division which he has chosen. For example, though all lawyers and medical men must have had the prescribed general professional training, a great number are dealing in their daily work only with some one sub-division of law or medicine.

Engineering is affected in a similar manner, and an important problem to be solved in carrying on the work of a Dominion-wide organization like The Engineering Institute of Canada, is how best to aid those of our members who have specialized in this way. They naturally desire the latest and most authoritative data in their particular branches of work, and wish to be in touch more particularly with their fellow-specialists for discussion of the problems in which they are mutually interested.

In the case of radio and aeronautical engineering, which hardly existed when The Institute took its present shape, the need is perhaps the greatest. The Council of The Institute has been considering this question for some time, and the progress made so far is summarized in an announcement published in a recent number of the E-I-C News*. Discussions are now pending, which, if brought to a successful conclusion, will mark a new feature of The Institute's work and its relations with other national engineering societies. The object desired is the further development of professional sections of our branches, and their co-operation with Canadian, British or American technical organizations dealing with specialized branches of engineering.

It is expected that the report of the committee which Council recently appointed to study this question will be presented at the Plenary Meeting of Council to be held in September next, and its proposals will be awaited with great interest.

Meeting of Council

A meeting of Council was held at eight o'clock p.m., on Friday, May 30th, 1930, with President A. J. Grant, M.E.I.C., in the chair, and five other members of Council present.

The minutes of the meeting held on May 6th, 1930, were taken as read and confirmed.

The Secretary presented a report submitted by the Executive Committee of the Ottawa Branch regarding the future policy of The Institute in connection with aeronautical and radio engineering. Group-Captain E. W. Stedman, M.E.I.C., and Major W. A. Steel, A.M.E.I.C., who were in attendance at the request of Council, gave a full explanation of the suggestions contained in the report, which involved the systematic development of professional sections of The Institute's branches, particularly in connection with aeronautical and radio engineering, and the co-ordination of their activities. It was suggested that space should be allocated regularly in the Journal to the proceedings of these specialized sections, and that negotiations should be carried on with other engineering societies specializing in these branches of engineering with a view of such co-operation as might be found possible.

Council gave this proposal sympathetic consideration, and after considerable discussion a committee was appointed under the chairmanship of Mr. J. A. McCrory, M.E.I.C., to consider the matter in detail and to bring in a report to the Plenary Meeting of Council to be held on September 22nd, 1930. The Secretary was directed to publish an announcement that this question was receiving consideration by Council.

The membership of the Gzowski Medal Committee for the year 1930 was approved as follows:

W. C. Adams, M.E.I.C., Chairman.
A. Duperron, M.E.I.C.
P. S. Gregory, M.E.I.C.
O. O. Lefebvre, M.E.I.C.
C. M. McKergow, M.E.I.C.

In order to avoid the possibility of conflict with other meetings it was decided that the Annual General Meeting of The Institute, called for January 22nd, 1931, should be adjourned to February 5th, 1931, instead of January 29th, 1931, as previously decided.

The report of the scrutineers was presented on the ballot for the amendments to the By-laws, and the amendments proposed to Sections 13 and 37 were declared to be carried, while those to Sections 34 and 75 were lost.

The membership of the Plummer Medal Committee for the year 1930 was approved as follows:

J. R. Donald, M.E.I.C., Chairman.
W. H. DeBlois, M.E.I.C.
W. G. H. Cam, M.E.I.C.
G. P. Cole, M.E.I.C.
N. P. Dalziel, M.E.I.C.

The membership of the Past-Presidents' Prize Committee for the year 1930 was approved as follows:

C. M. McKergow, M.E.I.C., Chairman.
F. A. Combe, M.E.I.C.
E. P. Fetherstonhaugh, M.E.I.C.
T. R. Loudon, M.E.I.C.
J. B. Porter, M.E.I.C.

The report of the Board of Examiners was presented regarding the examinations held in May 1930, and stated that out of ten candidates for admission as Associate Member, Junior or Student, six were successful in passing, while four failed.

A letter from the Executive Committee of the Winnipeg Branch was presented, transmitting a report of a committee of that Branch with respect to the recent Report of The Royal Commission on Technical and Professional Services. The Winnipeg Branch drew attention to the status of certain junior and assistant engineers contemplated in the grading recommended in the Commission's Report, and suggested that the Council of The Institute should take action in the matter. The Council, while in sympathy with the desire of the Branch that adequate treatment should be accorded to all the members of the Civil Service, directed the Secretary to point out that Council can see no practicable way of giving effect to the Branch recommendation.

Nine resignations were accepted, three reinstatements were effected, and a number of special cases were considered.

A number of application for admission and for transfer were considered, and the following elections and transfers were effected:

Elections		Transfers	
Associate Members	4	Assoc. Member to Member	1
Juniors	3	Junior to Member	1
Affiliate	1	Junior to Assoc. Member	12
Students admitted	9	Junior to Affiliate	1
		Student to Assoc. Member	12
		Student to Junior	3

The Council rose at twelve fifty-five a.m.

Recent Graduates in Engineering

In addition to the list of Juniors and Students of The Institute who have recently completed their course at the various universities, as published in the June issue of the Journal, congratulations are also in order to the following, results of which examinations were received too late for publishing with the list last month:—

McGill University

Honours, Medals and Prizes

Benard, Frederick, Mixcoac D.F., Mexico.—B.Sc., (El.); Honours in Electrical Engineering; Montreal Light, Heat and Power, Consolidated's First Prize.

Berenstein, Leslie, Montreal, Que.—B.Sc., (Ci.); Honours in Civil Engineering.

Cooper, Lawrence O'Toole, Schumacher, Ont.—B.Sc., (Me.); British Association Medal; Undergraduates' Society Second Prize for Summer Essay; Honours in Mechanical Engineering.

Francis, John Barten, Westmount, Que.—B.Sc., (El.); Montreal Light, Heat and Power Consolidated's Second Prize; Jenkins Bros. Limited Scholarship.

Haines, Julius Holmes, Montreal, Que.—B.Sc., (Ci.); Departmental Prize for Summer Essay.

Matheson, John Hegan Parks, New Glasgow, N.S.—B.Sc., (Chem.); Honours in Chemical Engineering.

Mellor, John Harold, Richelieu, Que.—B.Sc., (Mech.); Babcock and Wilcox Limited Scholarship.

Skelton, Cecil Hastings, Westmount, Que.—B.Sc., (Me.); Crosby Steam Gauge and Valve Company's Prize for Summer Essay.

*Vol. 3, No. 20, June 26th, 1930.

Thomas, William Frank, Montreal, Que.—B.Sc., (Mi.); Sir William Dawson Research Fellowship in Mining Engineering.
Yeomans, Richard Henry, Montreal, Que.—B.Sc., (El.); Undergraduates' Society's First Prize for Summer Essay.

Degree of B.Sc.

Berger, Bernard Avrom, B.Sc., (Me.), Outremont, Que.
Blanchet, Paul Maurice, B.Sc., (Ci.), Rothesay, N.B.
Boissonnault, Bertrand Octave, B.Sc., (Chem.), Outremont, Que.
Bowles, William Shedden, B.Sc., (Ci.), Westmount, Que.
Butler, Howard Claude, B.Sc., (Me.), Ottawa, Ont.
Calder, Frank, B.Sc., (Ci.), Montreal, Que.
Cosser, Walter Geoffrey, B.Sc., (Me.), Schumacher, Ont.
Dixon, Meredith F., B.Sc., (Me.), Montreal, Que.
Evans, Delano Ernest, B.Sc., (Ci.), Montreal, Que.
Fraser, Norman Innes, B.Sc., (Ci.), Kingston, Ont.
Hartney, James Rowan, B.Sc., (Me.), Regina, Sask.
Hutchinson, Walter John Basil, B.Sc., (El.), St. Vincent, B.W.I.
Jehu, Llewellyn, B.Sc., (Ci.), Lachine, Que.
Klein, Herman, B.Sc., (El.), Montreal, Que.
Koehler, Julius Wilbur, B.Sc., (El.), Swift Current, Sask.
Laing, Addison K., B.Sc., (Ci.), Hamilton, Ont.
Leverin, Harold Leicester, B.Sc., (Ci.), Ottawa, Ont.
McCabe, Russell Irving, B.Sc., (Me.), St. Johns, Que.
Magor, Philip Douglas, B.Sc., (El.), Westmount, Que.
Morrison, Thomas Jack, B.Sc., (Me.), Westmount, Que.
Nation, Frederick Spencer, B.Sc., (Ci.), Toronto, Ont.
Ogilvy, James Angus, B.Sc., (Mi.), Montreal, Que.
Rodger, Norman Elliott, B.Sc., (Ci.), Amherst, N.S.
Southam, William Watson, B.Sc., (El.), Hamilton, Ont.
Tait, Gordon Ewing, B.Sc., (Me.), Westmount, Que.
Timm, Charles Ritchie, B.Sc., (El.), Westmount, Que.
Wallace, Keith Bell, B.Sc., (Me.), Montreal, Que.
Wheatley, Eric Edmund, B.Sc., (Me.), Westmount, Que.

Degree of M.Sc.

Hardy, Robert McDonald, M.Sc., Winnipeg, Man.

University of Toronto

Degree of B.A.Sc. (with honours)

Fisher, Charles Boddy, B.A.Sc., (El.), Montreal, Que.
Morgan, James Clarence, B.A.Sc., (Chem.), Toronto, Ont.

University of Manitoba

Medals

Emerson, Robert Alton, Winnipeg, Man.—B.Sc., (Ci.); University Gold Medal; Joseph Doupe Gold Medal.
Woodhall, Thomas Latimer, Winnipeg, Man.—B.Sc., (El.), University Gold Medal.

Degree of B.Sc.

Bereskin, Abraham Isaac, B.Sc., (Ci.), Ottawa, Ont.
Cohen, Herman Mordecai, B.Sc., (El.), Winnipeg, Man.
Dempsey, Frank Craig, B.Sc., (Ci.), Carberry, Man.
Ferrier, Fred Clifford, B.Sc., (El.).
Ford, Albert, B.Sc., (Ci.), Winnipeg, Man.
Henderson, Robert Pritchard, B.Sc., (Ci.), Winnipeg, Man.
Hurst, William Donald, B.Sc., (Ci.), Winnipeg, Man.
Klempner, Harold, B.Sc., (Ci.), Winnipeg, Man.
Levin, Max, B.Sc., (Ci.), Winnipeg, Man.
Macdonald, Ernest Gordon, B.Sc., (Ci.), Winnipeg, Man.
McCalpin, Lloyd Alexander, B.Sc., (El.), Winnipeg, Man.
McCormick, Archibald Thomas, B.Sc., (El.), Winnipeg, Man.
McEachern, Sinclair, B.Sc., (Ci.), Winnipeg, Man.
Oddlafson, Edward William, B.Sc., (El.), Hanover, Ont.
Peters, Henry Frederick, B.Sc., (Ci.), Slave Falls, Man.
Stratton, Frederick Stephen, B.Sc., (El.), Winnipeg, Man.
Weselake, Edward Joseph, B.Sc., (El.), Winnipeg, Man.

Results of the May Examinations of The Institute

The report of the Board of Examiners, presented at the Meeting of Council held on May 30th, certified that the following candidates, having passed the examinations of The Institute, have satisfied the examiners as regards their educational qualifications for the class of membership named:

Schedule C. For admission to Associate Membership:—

R. A. Bradley, Jr.E.I.C.	St. Catharines, Ont.
W. S. Buchanan	Quebec, Que.
G. W. Holder, Jr.E.I.C.	Sturgeon Falls, Ont.
K. L. MacMillan	Mount Royal, Que.
W. N. McGuinness	Montreal, Que.
O. S. Platou	Montreal, Que.

OBITUARY

James Marmaduke McCarthy, M.E.I.C.

Members of The Institute will learn with regret of the death of James Marmaduke McCarthy, M.E.I.C., which occurred at Quebec, Que. on May 22nd, 1930.

Mr. McCarthy was born at Sorel, Que. on February 8th, 1864, and graduated from McGill University in 1887.

An engineer of great capabilities, Mr. McCarthy designed and constructed the substructures of many bridges in Canada and the United States, and was consulting engineer to the Province of Quebec in connection with the St. Lawrence river storage dam. He also designed and constructed waterworks systems, notably the system at Valcartier military camp at the outbreak of the World War. Following his retirement from civil engineering, Mr. McCarthy became associated with Price Brothers and Company, Ltd., later being named vice-president of this company, which position he held until his death.

He had many other interests, however, and in addition was vice-president of the American Light and Traction Company, president of the Quebec Elevator Company, a member of the firm of Emerson, McMillan and Company, bankers, New York, a director of the Quebec Power Company, the Royal Trust Company, the International Paper Company of Canada and of the International Hydraulic Company of New York.

Mr. McCarthy was a member of the Quebec Garrison Club, the New York Yacht Club and the Lawyers' Club of New York.

Mr. McCarthy joined The Institute as a Student on January 20th, 1887, became an Associate Member on February 27th, 1890, and transferred to full Membership on May 6th, 1897. He took an active interest in Institute affairs, and was a member of Council in 1900 and 1902.

PERSONALS

J. W. Lucas, S.E.I.C., who graduated from the University of Alberta in the spring, with the degree of B.Sc., is now with the Beauharnois Construction Company at Beauharnois, Que.

J. W. D. Farrell, A.M.E.I.C., superintendent of water works for Regina, Sask., has been appointed registrar of the recently established Professional Engineers Association of Saskatchewan.

J. I. Dore, S.E.I.C., who graduated from Queen's University this spring with the degree of B.Sc., is now connected with the Forest Products Laboratories of Canada, in Ottawa, Ont., as chemist in the wood preservation division.

C. L. Blackmore, Jr.E.I.C., a member of the staff of the Canadian International Paper Company, who was formerly stationed at Deer Lake, Newfoundland, has been transferred to Gatineau, Que. Mr. Blackmore graduated from McGill University in 1927 with the degree of B.Sc.

H. L. Swan, M.E.I.C., formerly assistant district engineer with the provincial department of Public Works at Merritt and Cranbrook, B.C., has been appointed district engineer, engineering district No. 1, with the provincial department, and is located at Victoria, B.C.

J. Inglin, A.M.E.I.C., formerly electrical engineer with the Imperial Tobacco Company of Canada, at Montreal, is now on the staff of the Fraser-Brace Engineering Company, and is located at Copper Cliff, Ont. Mr. Inglin graduated from the Swiss Federal College at Zurich, in 1921.

G. H. Wood, A.M.E.I.C., a member of the engineering staff of the Dominion Water Power and Reclamation Service, Department of the Interior, located at Niagara Falls, Ont., received the degree of C.E. at the commencement exercises at the University of Toronto held recently. Mr. Wood graduated from the same university in 1917 with the degree of B.A.Sc.

A. M. Johansen, S.E.I.C., has accepted a position as junior mechanical engineer with the Mexico Tramways Company and affiliated companies in Mexico. For an indefinite time, Mr. Johansen's address will be Bayonne, N.J. He graduated from McGill University in 1929 with the degree of B.Sc., and later was connected with Babcock-Wilcox and Goldie-McCulloch, Ltd., at Galt, Ont.

C. H. Attwood, A.M.E.I.C., has been appointed Deputy Minister of Mines and Natural Resources for Manitoba. Mr. Attwood was formerly chief engineer of the Dominion Water Power and Reclamation Service for the Manitoba district, having joined that Service in 1914, when he became engineer in charge of Alberta and Saskatchewan power and storage surveys with headquarters at Ottawa. Mr. Attwood was elected president of the Association of Professional Engineers of Manitoba for the year 1929, and at the present time is the representative of the Winnipeg Branch on the Council of The Institute.

Fred L. Macpherson, M.E.I.C., who has been on the staff of the provincial Department of Public Works since 1917, first as district engineer in the Kootenays and latterly as office engineer at headquarters, Parliament buildings, Victoria, has been assigned a new position as highway traffic and utilities engineer in that department with headquarters at the court house, Vancouver. Mr. Macpherson is in charge of the new offices opened up to take care of all work connected with the licensing and control of the operations of public passenger and freight vehicles under the Public Carrier Regulations, passed pursuant to part V of the "Highway Act 1930." All matters pertaining to traffic enumerations, the regulation of traffic on the provincial highways, and problems generally concerning the control thereof, are being administered from this office under the department of Public Works. The need for centralizing such work in the commercial capital of the province is evidenced by the rapidly increased use of the highways, particularly by commercial vehicles. Mr. Macpherson is no stranger to the Vancouver district since he was municipal engineer of the adjoining municipality of Burnaby from 1909 till 1917.

ELECTIONS AND TRANSFERS

At the meeting of Council held on May 30th, 1930, the following elections and transfers were effected:

Associate Members

KREBSER, Edward Meili, B.Sc., C.E., (Univ. of Vermont), asst. shop supt., The Canadian Bridge Company, Ltd., Walkerville, Ont.

CREIGHTON, Leslie Floyd, B.A., B.E., (Univ. of Sask.), asst. engr., Dept. of Highways, Govt. of Saskatchewan, Regina, Sask.

MOES, Geriacus, Cert. Engrg. (Liverpool Univ.), elect'l. engr., plant engr's. dept., Canadian Westinghouse Co. Ltd., Hamilton, Ont.

SCOULAR, William Buick, B.Sc., (Glasgow Univ.), designing engr., mech'l. dept., Dominion Bridge Co. Ltd., Montreal, Que.

Juniors

BREWER, Harold Byron, B.Sc., (Univ. of N.B.), Canadian Industries Limited, MacMasterville, Que.

GRAY, Reginald Arthur George, Elect'l. Engrg. Diploma, (Regent St. Polytech.), asst. engr., elect'l. engr's. office, C.N.R., Montreal, Que.

WALKER, Egbert Ernest, (Grad. I.E.E.), check inspr., automatic telephone dept., Northern Electric Company, Ltd., Montreal, Que.

Affiliate

CROSBY, Irving Ballard, S.B., (Mass. Inst. Tech.), A.M., (Harvard Univ.), consltg. geologist, 6 Beacon Street, Boston, Mass.

Transferred from the class of Associate Member to that of Member

MIFFLEN, Sydney Clarence, B.Sc., (McGill Univ.), office engr., mining engrg. dept., Dominion Coal Company, Ltd., Glace Bay, N.S.

Transferred from the class of Junior to that of Member

TIPPET, Henry Jackson, division engr., The Connecticut Company, New Haven, Conn.

Transferred from the class of Junior to that of Associate Member

BONHAM, Robert Lincoln, B.Sc., (Queen's Univ.), asst. supt. of operation and mtce., Canada Creosoting Co. Ltd., Winnipeg, Man.

BUCHMANN, Karl Emil, B.A.Sc., (Univ. of Toronto), dftsman., International Nickel Company, Copper Cliff, Ont.

CAMPBELL, George Wilfred, asst. engr., Reclam. Branch, Dept. of Public Works, Winnipeg, Man.

FARNSWORTH, Raymond Harrington, B.Sc., (Queen's Univ.), chief dftsman., Price Bros. & Co. Ltd., Quebec, Que.

GUY, Richard W., B.Sc., (McGill Univ.), senior examiner, Elect'l. Standards Lab., Dept. of Trade and Commerce, Ottawa, Ont.

HADLEY, William Fraser, Lieut. Col., (Grad. R.M.C.), manager, Scott Estate, Hull, Que.

HUMPHREY, Harold William, B.Sc., (N.S. Tech. Coll.), engr., transmission constrn. dept., Public Service Electric & Gas Co., Newark, N.J.

JOHNSTONE, Ralph George, B.Sc., (N.S. Tech. Coll.), elect'l. engr., asst. to director of sales in paper gear dept., Harland Engineering Company, Montreal, Que.

MacKENZIE, Russell George, asst. engr., in charge of sidewalk constrn., City of Vancouver, B.C.

MEDLAR, George Elmer, engr. in charge of field and office work, Essex Border Utilities Commission, Windsor, Ont.

MOLKE, Eric Charles, Grad. Engr., (Univ. of Vienna), struct'l. engr., hydro-electric system, City of Winnipeg, Man.

PYBUS, Ralph Carr, B.Sc., (Univ. of Man), engr. for British Columbia, for Carter-Halls Aldinger Co. Ltd., Vancouver, B.C.

For transfer from the class of Junior to that of Affiliate

SALE, Charles P., B.A.Sc., (Univ. of Toronto), member of firm, Sale & Sale, Barristers, Solicitors, etc., Windsor, Ont.

Transferred from the class of Student to that of Associate Member

BLACK, Hugh Murray, B.Sc., (McGill Univ.), sales engr., English Electric Company of Canada, Ltd., Toronto, Ont.

BOYD, Ivan William, B.Sc., M.Sc., (Queen's Univ.), master mechanic, Siscoe Gold Mines, Ltd., Amos, Que.

BROOKS, Charles Lennox, B.Sc., (McGill Univ.), general traffic engr., Eastern Area, Bell Telephone Company of Canada, Montreal, Que.

CHAMBERS, Harold Joseph Ashbridge, B.A.Sc., (Univ. of Toronto), asst. engr., Canadian Bridge Company, Ltd., Walkerville, Ont.

CHESHIRE, William Vernon, B.Sc., (Univ. of Man.), on equipment service engr's. staff, Northern Electric Co. Ltd., Montreal, Que.

CRAIN, George Edwin, B.Sc., (McGill Univ.), sales mgr., Genesee Bridge Co., Rochester, N.Y.

EGGERTSON, E. Grettir, B.Sc., (Univ. of Man.), designing elect'l. engr., hydraulic dept., The Aluminum Company of America, Pittsburgh, Pa.

EYFORD, Cornell Thomas, B.Sc., (Univ. of Man.), distribution engr., Winnipeg Electric Company, Winnipeg, Man.

FAGAN, James Wilfrid, B.Sc., (McGill Univ.), production supt., Northern Electric Co. Ltd., Montreal, Que.

HERSCOVITCH, Charles, B.Sc., (McGill Univ.), estimating engr., Dominion Engineering Works, Ltd., Montreal, Que.

HILL, Stanley Clayton Howard, B.Sc., (McGill Univ.), asst. protection engr., operating dept., Shawinigan Water & Power Company, Montreal, Que.

JONES, Harry Anderson, B.Sc., (Univ. of Sask.), asst. engr., city engr's. dept., Regina, Sask.

Transferred from the class of Student to that of Junior

CORNISH, Wilfred Ernest, B.Sc., (Univ. of Man.), lecturer in elect'l. engrg., University of Alberta, Edmonton, Alta.

KELLETT, James Edward, B.Sc., (Univ. of Man.), res. engr., Manitoba Good Roads Board, Dauphin, Man.

PRUDHAM, William Merrill, B.A., B.Sc., (McGill Univ.), switchboard engr., Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.

Students admitted

ALLEN, Elmer Bertrand, (Undergrad., Univ. of Sask.), Govan. Sask.

BLACK, Frank Leslie, Undergrad., (N.S. Tech. Coll.), 169 Cornhill St., Moncton, N.B.

BUTLER, Howard Claude, B.Sc., (McGill Univ.), 48 Clarendon Avenue, Ottawa, Ont.

EVANS, Delano Ernest, B.Sc., (McGill Univ.), 1464 Mansfield St., Montreal, Que.

HARTNEY, James R., B.Sc., (McGill Univ.), 3483 Peel St., Montreal, Que.

HOWORTH, John, (Undergrad. Univ. of Man.), 100 Elm Park Road, St. Vital, Man.

MORRISON, Thomas Jack, B.Sc., (McGill Univ.), 456 Claremont Ave., Westmount, Que.

PATRIQUEN, Frank Andrew, B.Sc., (Univ. of N.B.), Fairville, N.B.

WOODHALL, Thomas Latimer, B.Sc., (Univ. of Man.), 441 College Ave., Winnipeg, Man.

BOOK REVIEW

American Railway Signaling Principles and Practices

Alternating Current Track Circuits

Published by the Signal Section, American Railway Association, New York, 1930, paper cover, 6 x 8¾ in., 83 pp., figs., charts, tables, $0.35.

"Alternating Current Track Circuits" is the subject of chapter XI of a book entitled "American Railway Signaling Principles and Practices", which is being prepared by the Signal Section of the American Railway Association. Each chapter, as written, is being published in pamphlet form, so that the information contained therein may be placed in the hands of those interested in railway signal work without waiting for the entire series; and chapter XI is the eighth chapter released to date*.

The booklet containing this chapter, which has been presented to The Institute through the courtesy of the publishers, deals with all phases of alternating current track circuits as used in railway signaling and points out that the use of alternating current for the operation of track circuits was developed in the year 1898, due to the return propulsion current of electrically operated roads interfering with the direct current track circuit. Stray earth currents and return propulsion current from adjacent electric lines also interfered with direct current track circuits in use on roads which were not electrically operated.

The various types of alternating current relays, track transformers, impedance bonds, etc., as well as formulae for the calculation of the ballast and rail resistance of an alternating current track circuit, are clearly explained. Instructions for the adjustment, operation and maintenance of alternating current track circuits, including the proper phase angles to be maintained between the two currents of a two-element relay are shown, and the chapter concludes with a useful series of questions on the subject matter.

*The titles of the series so far published are as follows:—

Chapter II — Symbols, Aspects and Indications.
" V — Batteries.
" VI — Direct Current Relays.
" VII — Direct Current Track Circuits.
" VIII — Transformers.
" X — Alternating Current Relays.
" XI — Alternating Current Track Circuits.
" XXIII — Highway Crossing Protection.

E. S. Taylor,
Signal Engineer, Eastern Lines,
Canadian Pacific Railway Company,
Montreal.

The Link Belt Company has recently patented a new metal for chains called "Promal." This metal is considerably harder than malleable iron and also has a higher average yield point and ultimate strength. The Company has made numerous tests on these Promal chains and particularly recommend them for four general classes of service: (1) chain drives, elevators and conveyors operating under gritty or abrasive conditions; (2) chain drives where greater strength is required than the corresponding size of malleable iron chain provides; (3) drag, scraper and flight conveyors where the chain drags and is subject to abrasion; and (4) heavy duty drives of comparatively high speed, short centres and large sprocket ratios.

Details of the physical properties of Promal, with specifications and prices of Promal chains may be obtained from Link-Belt Company, Indianapolis, by asking for Book No. 950.

BRANCH NEWS

Border Cities Branch

R. C. Leslie, A.M.E.I.C., Secretary-Treasurer.
H. J. Chambers, S.E.I.C., Branch News Editor.

The regular monthly meeting of the Border Cities Branch was held in the Prince Edward hotel on April 11th. The speakers for the evening, Mr. Hugh McIntosh and Mr. Austin Ion, both of the Bell Telephone Co. of Canada, were introduced by Mr. Reynett, district manager of the Bell Telephone Co. of Canada.

Mr. McIntosh in his address outlined the method of operation of the step-by-step automatic telephone system. Likening the entire system to a tree, with the roots representing the parties calling, the trunk being the switching apparatus, the limbs the various lines and the leaves the parties called, Mr. McIntosh then showed the manner in which the dialling of a number by the caller manipulates, by the impulses thus set up, the various switches in the system, ultimately connecting up the caller with the party called.

The electrical devices required in the step-by-step system, the speaker stated, are the dial, the line finder, the first, second and third signal switches and the connector switch. The dial is the means of setting the switches in operation. It also gives the signal and controls the speed with which the signal is given. Its rotation sends out impulses equivalent in number to the number dialled and at the same time temporarily disconnecting the receiver to prevent the clicking caused by these impulses returning to the ear of the caller. The line finder, the first, second and third signal and connector switches actuated by these impulses, bring themselves into alignment and open up a line of communication between the caller and the party called. Should the line to the party called, however, be found busy, the line is immediately grounded and sends back the "busy call."

Mr. McIntosh then briefly outlined the immense amount of study and investigation necessary in order to obviate any annoyances which might arise in operation. He stated that whereas fourteen line finders for two hundred subscribers was the estimated probable need, seventeen were actually used to guard against any congestion. In addition to this the speaker pointed out that a loading scheme split up into twenty-two groups was found necessary. These groups were arrived at by observation and were arranged according to the frequency with which certain types of subscribers use the telephone.

The speaker then concluded by stating that the need for the automatic telephone was due chiefly to the inability of the Bell Telephone Co. of Canada to see ahead a steady supply of suitable girls, due chiefly to the small families of modern parents, and also because these small families are becoming even smaller. This in due course he stated would make it economically imperative that the automatic system be adopted.

It was then moved by J. Cummings and seconded by R. Armstrong that a hearty vote of thanks be conveyed to the speaker by the Border Cities Branch. A vote of thanks was conveyed to Mr. McIntosh by O. Rolfson, A.M.E.I.C., the Chairman of the Branch.

Mr. Austin Ion then dealt very briefly on the mechanics of the automatic telephone system. The new office he stated was located in the wire centre of the system. He stated that it was necessary to order equipment two years ahead of when it would be needed. He also stated that the modern cable contains 1,200 pairs of wires whereas formerly there were only 400 pairs to a cable. The contact points of switches he pointed out are now made of "contact metal," they formerly being platinum. This change greatly reduced the cost of switches.

With reference to the equipment in the new building Mr. Ion stated that there would be a primary service of 2,200 volts. There will also be five direct current generators with a total of 1,500 amps. at 60 volts for charging the batteries. To give an idea of the immensity of the scheme the speaker stated that 2 tons of choke coils would be used. The equipment required for the automatic system, the speaker stated, was selected with stress being laid upon maintenance. He stated that the present machines are of necessity very sturdy in order to keep maintenance costs at a minimum.

In closing the speaker stated that the switch-over for the Border Cities will entail 12,500 telephones and will be made on July 5th at midnight by a group of men specially trained in this operation in order to avoid mishaps.

It was then moved by A. E. West and seconded by Mr. Baird that a hearty vote of thanks be conveyed to Mr. Ion by the Border Cities Branch. This was conveyed by Mr. Rolfson who thanked the speaker for his very illuminating address and the trouble he had gone to in the preparation of the equipment for its illustration.

Following this, moving pictures of trans-Atlantic telephony and the development of the present telephone system were shown. These showed briefly the engineering difficulties that have been overcome and the wide use to which the telephone is now being put.

Hamilton Branch

John R. Dunbar, A.M.E.I.C., Secretary-Treasurer.
J. A. M. Galilee, Affiliate E.I.C., Branch News Editor.

The first meeting of the newly elected executive committee of the Hamilton Branch was held in the Wentworth Arms hotel at 12.30 p.m., June 11th, 1930. Mr. McLaren was in the chair, with five other members of the executive present.

After the minutes of the previous meeting had been read and approved, several letters from Mr. Durley, General Secretary, were read and acted upon.

A letter from J. Stodart, M.E.I.C., regarding the Fire Prevention Campaign of the Hamilton Chamber of Commerce was read. Mr. Stodart was appointed permanent representative of the Branch on the general committee in connection with this campaign.

The following chairmen of committees were appointed with the option of selecting their own committees:—

Papers............ E. M. Coles, A.M.E.I.C.
Entertainment...... G. A. Colhoun, A.M.E.I.C.
Publicity.......... J. A. M. Galilee, Affil. E.I.C.
Membership........ F. H. Adams, A.M.E.I.C., with the following out of town representatives:
H. G. Bertram, M.E.I.C., Dundas.
G. R. Marston, A.M.E.I.C., Simcoe.
F. H. Midgley, M.E.I.C., Galt.
S. Shupe, M.E.I.C., Kitchener.

J. A. M. Galilee, Affil.E.I.C., was appointed Branch News Editor and was authorized to attend all meetings of the Executive Committee.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

The annual meeting was held on June 10th. M. J. Murphy, A.M.E.I.C., chairman of the Branch, presided. The annual report and financial statement was presented and on motion adopted. Scrutineers R. H. Emmerson, A.M.E.I.C., and T. H. Dickson, A.M.E.I.C., reported on the balloting for election of Branch officers and stated that a tie had resulted in the voting for the office of committee-man. A second ballot was canvassed, after which, it was announced that the following will act for the year 1930-31:

Chairman.....................L. H. Robinson, M.E.I.C.
Vice-Chairman.................G. E. Smith, A.M.E.I.C.
Secretary-Treasurer............V. C. Blackett, A.M.E.I.C.
Executive Committee...........E. T. Cain, A.M.E.I.C.
T. L. Landers, M.E.I.C.
J. G. MacKinnon, A.M.E.I.C.
C. S. G. Rogers, A.M.E.I.C.
A. S. Gunn, A.M.E.I.C.
A. F. Stewart, M.E.I.C.
(Ex-officio)....................M. J. Murphy, A.M.E.I.C.

A vote of thanks was tendered the retiring officers on motion of C. S. G. Rogers, A.M.E.I.C., seconded by E. T. Cain, A.M.E.I.C.

Tenth Annual Report

The ninth annual meeting of Moncton Branch was held on May 20th, 1929.

The Executive Committee held four meetings during the year. There were seven meetings of the Branch, two of which were open to the public. At these meetings, papers were read, addresses delivered and business transacted as follows:—

1929

Nov. 5.—A supper meeting was held in the Y.M.C.A. H. J. Crudge, A.M.E.I.C., building engineer, Canadian National Railways, Moncton, read a very interesting paper on "The New Canadian National Railway Hotel and Station at Halifax."

Dec. 12.—A supper meeting was held in the Y.M.C.A. A very instructive illustrated address was delivered by T. H. Dickson, B.A., B.Sc., A.M.E.I.C., on "The Construction, Operation and Maintenance of Unit Cars."

1930

Jan. 22.—A supper meeting was held in the Y.M.C.A. An address of unusual interest was delivered by J. A. Wilson, A.M.E.I.C., Controller of Civil Aviation, Ottawa, on the subject "The Progress of Aviation in Canada." This meeting was attended by members of the Moncton City Council, the staff of the local airport, and many prominent citizens.

Feb. 20.—A public meeting was held in the City Council Chamber. A very instructive paper was read by C. H. Wright, B.Sc., M.E.I.C., district manager and engineer of the Canadian General Electric Co., Halifax, on "Canada a Land of Opportunity."

April 14.—A supper meeting was held in the Y.M.C.A. G. S. Stairs, B.Sc., A.M.E.I.C., Director of L. E. Shaw Ltd., Avonport, N.S. and Chipman, N.B., read a very interesting paper on "Some Aspects of Clay and Burned Clay Products."

April 29.—A special meeting of the Branch was held for the purpose of discussing Institute affairs with the General Secretary, R. J. Durley, on the occasion of his annual visit to the Branch.

May 22.—A meeting was held for the purpose of nominating Branch officers for the season 1930-31.

A Maritime Professional Meeting was held in Moncton, under the auspices of this Branch, on July 30th and 31st, 1930. From the many kind words of appreciation received from visitors from other Branches, we are happy to believe that the meeting was a success in every way.

The attendance at our meetings during the past year has been very good, and L. H. Robinson, M.E.I.C., Chairman of the Papers Committee, is to be congratulated on the high standard of the addresses delivered. It is particularly gratifying to note that, of the five papers read at Branch meetings during the season, two are to appear in full in the Journal.

Our total membership shows a decrease of one, as compared with last year. It is with sincere regret that we record the removal, by death, of James Black Hegan, M.E.I.C., and Charles Ludlow Wetmore, M.E.I.C., two valued members of Moncton Branch.

The following is a statement of our membership at the present time:—

Membership

	Resident	Non-Resident	Total
Members	9	2	11
Associate Members	18	12	30
Juniors	2	2	4
Students	3	4	7
Branch Affiliates	2	0	2
	34	20	54

The thanks of the Executive of Moncton Branch are due to L. H. Robinson, M.E.I.C., Chairman of the Papers Committee, E. T. Cain, A.M.E.I.C., Chairman of the Entertainment Committee, The Moncton Tramways, Electricity and Gas Co. Ltd., for the loan of a moving picture projector, and the gentlemen who kindly furnished the musical entertainment for our meetings.

Financial Statement
(For the fiscal year June 1, 1929, to May 31, 1930.)

Receipts

Cash in bank, June 1st, 1929	$114.35

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

The Aluminum Industry in Canada

At the noon luncheon held at the Chateau Laurier on May 22nd, R. E. Parks, A.M.E.I.C., general superintendent of the Aluminum Company of Canada, Limited, at Arvida, Quebec, gave an address upon the subject of "The Arvida Operations of the Aluminum Company of Canada, Limited." John McLeish, M.E.I.C., chairman of the Ottawa Branch, was chairman of the luncheon meeting.

Mr. Parks in his opening remarks sketched the history of the aluminum industry to date. In 1924 when the American aluminum interests first began to consider the Saguenay as a possible location for a plant, the power development at Isle Maligne was nearing completion. They acquired a major interest in that development and the ownership of the Chute-à-Caron development, about 18 miles farther down the river.

Isle Maligne is capable of developing 350,000 primary horse power of which the Aluminum Company of Canada at Arvida have contracted for 100,000 h. p. The Chute-à-Caron development will, when fully completed, provide some 700,000 h. p.

This latter development will be in two steps. The present dam will be capable of producing 250,000 h. p. which it is intended will be available on February 15th, 1931. When this amount is insufficient, additional development is possible to make up the 700,000 h. p.

In connection with the Chute-à-Caron dam there was one engineering feature of particular interest. The river had to be entirely diverted to build the dam. A hole is being built into the dam which will be plugged at the proper time. The "plug" will be arranged by means of an obelisk—a concrete structure reinforced with cables, the structure being about 100 feet high and 45 feet square and shaped at its base to fit the bed of the river. The obelisk during its course of construction rests upon a platform with legs supporting it on the side next to the river. It will be set into place by having the supporting legs dynamited thus allowing the obelisk to drop into place. This method has been used before on small streams but never on such a large river.

The Arvida plant actually consists of three separate and distinct units devoted respectively to, first, the purifying of the bauxite or raw product to produce almost pure alumina, second, the making of the carbon electrodes for use in the electrolytic process of reduction of the alumina, and third, the making of the aluminum itself. These operations are carried on in three separate plants.

The first plant receives the bauxite from British Guiana in South America and removes the greatest portion of the impurities. In the old method of obtaining aluminum, chemical means were used, but at the Arvida plant a new process is utilized never commercially used before.

In electric furnaces the bauxite is mixed with sufficient coke under proper conditions to reduce the impurities at a high temperature—some 2,500 degrees centigrade. The iron, silicon, titanium and other impurities in the bauxite are reduced to the metallic, or elemental condition forming a ferro-alloy which sinks to the bottom and the aluminum oxide or alumina remains floating at the top. The molten purified alumina is decanted through a trough at the top of the furnace, and as it pours from the trough it is blown into a spray by means of steam nozzles. This spray is collected in a large steel-lined room in the form of small spheres known as "pills." This operation is the only spectacular part of the aluminum business. After some slight further purification by leaching with acid, this alumina is dried and is sent to the aluminum furnaces.

With regard to the carbon electrodes, petroleum coke is ground and mixed with coal tar pitch to produce a plastic mass which is pressed into blocks by means of large hydraulic presses. These blocks are baked in large electric furnaces to drive off the volatile matter. In these operations, careful control is required if the finished product is to be uniform in quality and sufficiently pure for the production of aluminum.

In the production of the aluminum the treated ore and the electrodes are brought into the final plant, the final separation being a simple electrolytic process.

In the electrolytic process, cryolite, found only in commercial quantities in Greenland, is made use of. This cryolite is a double fluoride of sodium and aluminum and when melted in a carbon-lined furnace has the property of dissolving aluminum oxide very much as coffee will dissolve sugar.

This discovery was made in 1886 by Charles M. Hall, a then recent graduate of Oberlin College, who made use of a small battery in his mother's wood shed to carry on his experiments. Some improvements have been made since this discovery but essentially there has been very little change.

In the process a direct current is led into the molten bath by means of the carbon electrodes previously mentioned and the aluminum that is "plated out" by the current collects on the bottom.

At Arvida 1,000 employees are divided up so that some 800 work at the plant itself and 200 on the railway and at Port Alfred. Of this number about 35 per cent are graduate engineers, mostly from Canadian universities. The town of Arvida has about 2,000 inhabitants but there is provision in the layout of the site for a future growth up to some 50,000 inhabitants.

In 1928, the American aluminum interests were reorganized. The old parent company, the Aluminum Company of America, only retained those properties within the borders of the United States. A new Canadian company was organized to take over those properties outside of the United States. This new Canadian company is known as Aluminum Limited, and it has properties all over the world, including some in Norway, England, Japan, India, Germany, Switzerland, etc., some 50 subsidiary companies in all.

The Canadian company, stated the speaker, is entirely separate from the American company and between the two there is keen competition which will undoubtedly increase as time goes on. When new uses are found for aluminum, when the markets are broadened, and the present properties are unable to take care of the demand, then the facilities at Arvida will be expanded. Conditions at Arvida are very favourable toward this expansion and a city of some 35,000 to 50,000 people will undoubtedly some day result.

Among the new uses for aluminum are their uses in the manufacture of shingles, ridge roll, doors, window frames, stair treads, decorative hardware, I-beams, construction of railway cars and street cars, sleeping cars, etc.

Other uses for aluminum are side rods for locomotives, collapsible tubes for toothpaste, aluminum foil for chewing gum and chocolate, acid tanks, turpentine stills, transmission cables, aeroplane parts, seaplane sheathing, citric acid pans, extended automobile moulding, bronze powder and for furniture.

At the commencement of his address, Mr. Parks extended a most cordial invitation to the members of the Ottawa Branch to visit the plant and to become guests of the Saguenay Branch of The Engineering Institute of Canada whenever they were in the vicinity of the Lake St. John country. At the conclusion of the address the chairman expressed to Mr. Parks the great appreciation of the local Branch for the interesting address.

The Colonial African Empire

Many of the members of the local Branch availed themselves of the opportunity afforded by a kind invitation extended to them from the Ottawa Military Institute to listen to an address on the subject of "The Colonial African Empire" on Monday evening, May 26th. The address was given at the offices of the Royal Canadian Air Force Photographic section, Department of National Defence, Jackson building, Ottawa. The speaker of the evening was Brigadier H. St. J. L. Winterbotham, C.M.G., D.S.O., who until about two years ago had been in charge of the Geographical section, General Staff, War Office, England. He was also for some time chairman of the Air Surveys Committee in Great Britain.

Brigadier Winterbotham during the past eighteen months has been visiting the various Crown Colonies throughout the Empire under a commission from the Colonial office, with the object of investigating and reporting upon the survey methods employed by them. His tour will shortly be completed and it was while en route to Jamaica from Hong Kong that he made an unofficial visit to Ottawa and took the opportunity to confer with the various survey branches of the Dominion Government services.

The speaker gave a brilliant word picture on the life, temperament, characteristics and customs of the many native tribes in the various great colonies and protectorates, interspersed with humorous and witty stories relating to the conditions at the outpost and shrewd observations on the best way to handle racial problems. His address was listened to with the greatest attention by his hearers.

Lieutenant-Colonel C. Beresford Topp, D.S.O., A.D.C., who presided, introduced the speaker, and at the conclusion of the address a hearty vote of thanks was extended to him by Major-General A. G. L. McNaughton, M.E.I.C., chief of the general staff, Department of National Defence, seconded by Major-General J. H. MacBrien.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer.

May Meeting

The Saskatchewan Branch of The Institute met in the Kitchener hotel, Regina, on Friday evening, May 30th, some thirty-three members and guests being present. Vice-Chairman D. A. R. McCannel, M.E.I.C., occupied the chair.

Professional Association of Engineers

Mr. McCannel announced that the Professional Association of Engineers for Saskatchewan had appointed J. W. D. Farrell, A.M.E.I.C., superintendent of waterworks, Regina, as secretary and registrar of the association. He urged all engineers throughout the province to get in touch with Mr. Farrell with a view to registering as members of the association. The Engineers Act came into force on May 1st, 1930, and the first general meeting of the association will be held in Regina on September 5th next. Provisional officers are:—

President

Prof. C. J. MacKenzie, M.E.I.C., Dean of Engineering, University of Saskatchewan, Saskatoon, Sask.

Vice-President

D. A. R. McCannel, M.E.I.C., City Commissioner, City of Regina, Regina, Sask.

Councillors

J. R. C. Macredie, M.E.I.C., district engineer, C.P.R., Moose Jaw, Sask.

J. R. Cowley, electrical superintendent, Saskatoon, Sask.

W. H. Hastings, A.M.E.I.C., geologist and engineer, Department of Railways, Labour and Industries, Regina, Sask.

L. A. Thornton, M.E.I.C., Saskatchewan Power Commissioner, Regina, Sask.

J. E. Underwood, A.M.E.I.C., consulting engineer, Saskatoon, Sask.

R. N. Blackburn, M.E.I.C., chief mechanical superintendent, Department of Public Works, Regina, Sask.

W. R. Warren, A.M.E.I.C., Deputy Minister of Telephones, Regina, Sask.

H. S. Carpenter, M.E.I.C., Deputy Minister of Highways, Regina, Sask.

Old Friends as Visitors

The chairman welcomed R. O. Wynne-Roberts, M.E.I.C., and his son, L. W. Wynne-Roberts, A.M.E.I.C., to the meeting. Both of these gentlemen in years gone by, while residing in Regina, were active in the affairs of the engineering organizations of that time, commencing with the Regina Engineering Society and later the establishment of a Branch of the Canadian Society of Civil Engineers. Each has also served as chairman of the Toronto Branch of The Institute and Mr. L. W. Wynne-Roberts is now Councillor for that Branch.

Mr. R. O. Wynne-Roberts spoke reminiscently of his early associations in Regina. He expressed his pleasure at renewing old acquaintances and meeting old friends. He urged the members to invest their best in the society in order to get the best out of it.

Mr. L. W. Wynne-Roberts conveyed greetings from the Toronto Branch and extended an invitation to the members of the Saskatchewan Branch to visit Toronto and to participate in the annual meeting of The Institute which it is expected will shortly be held in that city.

The Rancho La Brea Tar Pits

One of the most interesting geological discoveries of the past century, the Rancho La Brea tar pits of southern California, was the subject of a non-technical address by Professor H. E. Simpson, State Geologist of the University of North Dakota.

Professor Simpson opened his address by commenting on the fact that Friday, May 30th, was Memorial Day across the line. "This has come to be a very sacred holiday or holy-day in the States" he declared. "It has taken on a new significance with the passing of the veterans of the Civil War and the coming of the Great War. May we make the day sacred to the boys of both countries who gave their lives for humanity."

He was not going to talk shop to the engineers present, he said. Rather he was going to take them to the field of scientific tragedy. He would relate to them "The Geological Story of the Rancho La Brea Tar Pits." These pits were located within the present limits of Los Angeles, California, and the thirty-two acres embracing these pits is now being converted into a park. Years ago when some Chinese workmen were digging asphalt from them for paving purposes they had discovered masses of bones embedded in the sticky mass, and had burned them on cool mornings to keep themselves warm.

One day, the speaker continued, a geologist saw a skull lying by the fire and recognized in it the skull of a sabre toothed tiger, a species long extinct in North America. Following this discovery, geologists immediately interested themselves in the animal remains embedded in the tar. Scientific exploration revealed the largest collection of pleistocene, or ice age, animals in the world to-day. The skeletons of many of these mammals are now mounted in the Los Angeles museum. It is believed that these animals existed from 200,000 to 500,000 years ago.

Professor Simpson described the formation of the tar pits along anticlinal ridges. Gas pressure had forced oil to the surface and explosions had blasted small craters along the top of the ridge. These craters had filled with a tarry deposit from the oil which had seeped up from below. Dust or water accumulating on the surface of the tar had made them into veritable death-traps for animals which ventured on the treacherous surface. Insects as small as flies and the most gigantic animals in North America, said the speaker, had been trapped in this natural tangle-foot. Some pits contained thousands of skeletons including probably every species of mammal then in existence in southern California. Seventeen elephants were caught in one pit. The carnivorous or meat eating animals outnumbered the herbivorous or vegetarian animals by ten to one.

Following the address Professor Simpson showed a series of lantern slides illustrating the pits and the animal remains found in them. He also exhibited specimens of the bones of some of the animal remains which had been perfectly preserved in the tar pits.

Sault Ste. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer.

The regular meeting of the Sault Ste. Marie Branch was held in the Y.M.C.A., on May 30th, at 8 p.m., following a dinner.

R. S. McCormick, M.E.I.C., chief engineer of the Algoma Central Railway, spoke on the subject, "The Development of the Steam Locomotive in America." His paper is summarized as follows:

Transportation is the story of the industrial development of the world and the application of steam to transportation brought about the industrial revolution. The railroad and steamboat gave a world market for expansion to every factory, farm and mercantile establishment.

The development of the steam locomotive is the development of the science of railroading. Just one hundred years ago the first locomotive was used on a railroad in America. This was the Stourbridge Lion brought from England in 1829, and made a run of three miles and return, but it was too heavy for the roadbed, weighing as it did about five tons.

Old Ironsides was built in 1832 by Matthias Baldwin for the Philadelphia, Germantown and Morristown Railroad—such was the beginning of "Baldwin's." Old Ironsides attained a speed of thirty miles handling a load of thirty tons gross. It ran on a schedule but only in fair weather, horses being used on rainy days.

All these engines employed the three basic principles of Stephenson's Rocket, namely, a horizontal multitubular boiler, pistons directly connected to the driving wheels and the use of exhaust steam to furnish a draft.

Mr. Baldwin built other engines introducing ground metallic joints in place of canvas and red lead joints and adopting the 4-2-0 type of wheel arrangements.

About this time, 1835, the Norris locomotive works were established, Mr. Norris building engines with the driving wheels in front of instead of behind the firebox, thus giving greater tractive effort due to greater weight on the drivers.

The next logical step was the use of two pairs of driving-wheels, placing one pair in front of the fire box and one behind it. The original designer of this type which was and is yet known as the American or 4-4-0 type was Henry R. Campbell who, in 1836, had it built by James Brooks of Philadelphia.

In 1837 Garratt and Eastwick built a locomotive introducing the equalizing bar between the two pairs of drivers.

Ross Winans of Baltimore in 1846 produced a locomotive with four pairs of drivers coupled but very compactly grouped and held in a rigid frame as now employed in the Consolidation and Mikado type.

The first Canadian railway was a short line of sixteen miles connecting La Prairie and St. Johns, Quebec, opened for traffic in 1836, horses furnishing the motive power until in 1837 a locomotive was imported from England. The first engine to run in Ontario was the Lady Elgin built in Portland, Maine, and making its first run in 1852.

Early locomotive development in Canada followed the design of the United States builders. At present the two companies building engines are the Montreal Locomotive Works at Montreal, and the Canadian Locomotive Works at Kingston.

Many types of engines were introduced, differing in wheel arrangement. The American or 4-4-0 type already spoken of; the Atlantic, 4-4-2; the Pacific, 4-6-2; the Mountain, 4-8-2; the Mikado, 2-8-2; the Santa Fe, 2-10-2; and others. The two new engines built last year for the Algoma Central are of the Santa Fe type. The tractive effort of No. 50 is 60,250 pounds, handles 1,300 tons on heaviest grades, cylinder h.p. 2,590, and boiler pressure 250 pounds.

Many improvements have been made in the locomotive in the last few decades. In 1889 Baldwins' produced the first compound locomotive. One of the greatest forward steps was the introduction of the superheater. Other developments followed, such as the multiple throttle, the feedwater heater, the mechanical stoker and innumerable other appliances which go to make the modern locomotive what it is. Improvements and experimentation still continue. Operating conditions on our railways today demand the pulling of heavier trains at higher speeds at lower costs.

The steam engine has two competitors—the electric locomotive and oil-electrics. Electrification, at this date, is only possible economically by reason of a uniform regular traffic density. Under no other condition can it be justified for mail line tonnage haulage.

The oil-electric is a new departure in prime movers and is being experimented with in England, on the continent of Europe and in America. One of the chief obstacles in design of the new power is the transmission, as a variable transmission between engine and driving wheels is required. The capital cost of this type of power works against its adoption and maintenance costs are bound to be high.

It seems likely that the steam locomotive will remain for a long time the everyday motive power for hauling heavy tonnage over great distances at lowest ton rate costs.

A hearty vote of thanks was tendered Mr. McCormick for his interesting paper.

Preliminary Notice

of Applications for Admission and for Transfer

June 14th, 1930

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in September 1930.

R. J. Durley, *Secretary.*

* The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ARVESEN—RAGNER WOLL, of Sault Ste. Marie, Ont., Born at Sarpshorg, Norway, April 8th, 1884; Educ., Graduate, Porsgrund Tech. College, Norway, 1903; 1903-07, ap'ticeship, Randsford Paper Mills and Borregaad Paper Mills, Norway; 1907-08, asst. to mill supt., Vethugsfoss Paper Mills, Norway; 1908-09, dftsman., Riordon Paper Co.; 1909-10, on constrn., Can. Pacific Mills, B.C.; 1910-14, on constrn., Powell River Paper Co.; 1914-15, dftsman., Standard Steel Car Co., Baker, Pa.; 1916-17, designer, Price Bros. & Co. Ltd., Quebec; 1917-20, sulphite mill supt., Belgo Paper Company; 1920-22, mill engr. and supt., Holmen Hellefos Paper Co., Norway; 1922-23, designer, Bethlehem Steel Co., Wilmington, Del.; 1923-26, Charles Walmsley Company, Quebec; 1926 to date, designer, Abitibi Power & Paper Co. Sault Ste. Marie, Ont.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Wanted

ELECTRICAL ENGINEER, M.Sc., A.M.E.I.C., graduate, seven years experience in high tension calculation design and construction, seeks connection. Location immaterial. Age 30. Married. Apply to Box No. 7-W.

CIVIL ENGINEER, A.M.E.I.C., experience: highways, railways, drainage projects, stream diversion, earth, timber and concrete dams, laying large and small pipe, timber structures, concrete walls and pavements. Location, construction or maintenance. Desires position as engineer or superintendent. Location immaterial. Apply to Box No. 34-W.

CIVIL AND MECHANICAL ENGINEER, aggressive practical engineer, with background of experience in design, construction, maintenance and operation of pulp and paper mill, desires change. Especially qualified to reduce mill costs. Apply to Box No. 53-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., (Ont., 15 years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Apply to Box No. 107-W.

CIVIL ENGINEER, B.Sc., Jr.E.I.C., with general engineering experience in construction, estimating, draughting, preliminary designing and building maintenance, desires position with opportunities. At present employed as buildings supervisor in public utility company. Available on short notice. Apply to Box No. 173-W.

ENGINEER. Sales executive, A.M.E.I.C., age 37, presently employed as district representative, desires change in wider field. Experience (Canada and abroad), covers structural steel and iron foundry work as chief draughtsman, designer, etc. Available on reasonable notice. Apply to Box No. 227-W.

CIVIL ENGINEER, A.M.E.I.C., graduate, R.P.E.P.Q. Twenty years experience surveying and construction hydro-electric, railways, and paper mills, desires position. Will go anywhere if terms satisfactory. Apply to Box No. 294-W.

Situations Wanted

CIVIL ENGINEER, B.A., B.Sc., with six years experience on surveys; layout and construction of hydro-electric works; design of highway bridges and construction of highways; desires position as assistant engineer on design and construction of reinforced concrete and steel structures. Available on short notice. Location immaterial. Apply to Box No. 301-W.

MACHINE DESIGNER. Experienced machine designer and draughtsman shortly open for position. A.M.E.I.C. Considerable experience in mining and winding machinery. Well up in steam power house equipment layouts and piping. Own design in successful operation. Accustomed to structural work. References good. Present location Montreal. Interview easily arranged. Apply to Box No. 329-W.

CIVIL ENGINEER, A.M.E.I.C., Reg. Pro. Eng. Ont. and N.B., age 47, married, twenty years experience in this country, twelve years in Scotland as construction and municipal engineer, specializing in roadway, water and sewer works, desires similar position, available forthwith. Just completed sewer and waterworks schemes for town in Maritime Provinces. Have also been engaged as engineer and superintendent with contractors on steam shovel excavation, concrete and caisson works for large buildings in Toronto, etc. Apply to Box No. 336-W.

CIVIL ENGINEER, graduate '29, desires engineering position with possibilities of forming connections. Willing to learn. Work in construction preferred, water power, or municipal suggested. Past experience consists chiefly of survey work in charge of party. Location in B.C. or western provinces preferred. Apply to Box No. 338-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., is open for engagement. Twenty-four years general experience both as engineer and as contractor. Has specialized in the construction of wharves, dams, foundations, etc. Apply to Box No. 358-W.

Situations Wanted

CIVIL ENGINEER, graduate, age 32, A.M.E.I.C. Ten years experience; seven years on design, construction, erection work and maintenance of paper mill and mine buildings and machinery. Three years on hydro-electric work in charge of surveys and field investigations. Present position, associate hydro-electric engineer, U. S. Engineers on office investigation, design and estimates; desires permanent position in Canada. Apply to Box No. 362-W.

MECHANICAL ENGINEER, B.A.Sc., Univ. of Toronto '21, A.M.E.I.C., married. Pulp and paper mill maintenance experience: draughting, layout of buildings, machinery and piping, mechanical design. Also experienced in reinforced concrete and steel building design and construction work. Apply to Box No. 370-W.

ELECTRICAL ENGINEER, B.Sc. '23, A.M.E.I.C., experience estimating pole line, cable and wire layouts, supervising, estimates, in charge of cost inventory and appraisal work, in charge of draughting, records and budget control work, instructing engineering principles. Seven years with one company. Four years instructing in electrical engineering at evening classes, desires position along the above lines with opportunities for advancement. Best of references. Apply to Box No. 376-W.

CONSTRUCTION ENGINEER, Canadian, speaking and writing French and English, A.M.E.I.C., P.E.Q. Twenty years experience in water power development, roadway, water and sewer works, as engineer in charge or superintendent, desires position. Available on short notice. Apply to Box No. 380-W.

GRADUATE ENGINEER, N. S. Tech. Coll., age 25, desires permanent position with industrial concern. Since graduation has spent two years apprenticeship with Can. Westinghouse Co. Apply to Box No. 382-W.

EXECUTIVE, B.Sc. McGill, M.E.I.C., comprehensive experience, with clean and successful record, desires permanent position, preferably in or near Montreal. Experience covers research, design, installation, operation, purchasing, organization and responsible management. Apply to Box No. 401-W.

CIVIL ENGINEER, B.Sc., '24, Jr.E.I.C., C.P.E.Q., Canadian, age 30, married. Experience: Construction power developments, railways, highways, pulp and paper mills, maintenance pulp and paper mills, railways, desires permanent position with opportunity for advancement. Apply to Box No. 402-W.

Situations Wanted

MECHANICAL ENGINEER.—Any organization which can use the services of an aggressive and practical engineer is requested to open negotiations by communicating with the advertiser. Canadian, university graduate, age under 30. Experience as mechanical superintendent, chief draughtsman, estimating, purchasing, construction, costing, stores control, etc. Qualified for engineering, production, purchasing, sales, or in a business capacity. Accustomed to responsibility, proven ability in the industrial field. Apply to Box No. 406-W.

MECHANICAL AND CIVIL ENGINEER, experienced as construction superintendent, mechanical superintendent, and chief engineer, desires position. Especially equipped to make reports on mill and town developments, personnel, etc. Bilinguist. All references furnished to interested parties. Apply to Box 411-W.

CIVIL ENGINEER, D.L.S., graduate, experience in surveying, calculating and municipal work, and in charge of office and field parties. Best of references. Apply to Box No. 413-W.

FACTORY, MILL OR PLANT MANAGER, open to consider new connection; Canadian, age 43, married, university graduate in engineering, 15 years experience concentrated on industrial engineering and plant management. Character and ability amply proven by past record. Full particulars and experience on request to Box No. 417-W.

Situations Vacant

SALES ENGINEER, with knowledge of and experience in the heating and power plant field. Salary and commission. State age, experience and qualifications to Box No. 553-V.

DRAUGHTSMEN—one or two draughtsmen experienced in general pulp and paper mill work and construction, for a company in the province of Quebec. Apply at once to Box No. 554-V.

MECHANICAL DRAUGHTSMAN AND DESIGNER wanted by large pulp and paper mill. Should have technical education and mechanical experience, but pulp and paper mill experience not essential. State in detail, age, education, experience, and salary desired, and when could report and other particulars. Apply to Box No. 560-V.

ELECTRICAL ENGINEER, preferably graduate Canadian university, with test floor experience. Opening offers permanent employment for right applicant along lines of plant maintenance and with every possibility of considerable new construction work in the near future. Please give complete information in first letter, stating age, experience, and salary expected, to Box No. 561-V.

MECHANICAL ENGINEERS. Two young graduate engineers with sales ability wanted by a well-known Canadian company. Apply, giving full particulars, to Box No. 562-V.

TOWN ENGINEER, for a town in Maritime Provinces. Electrical and civil engineer, or electrical engineer with sufficient knowledge of civil engineering to take charge of water and sewerage system, building of roads and sidewalks, etc. Must be able to speak French. Apply to Box No. 565-V.

MINING ENGINEERS.—Graduate mining engineers. Applications from young mining engineers able to do surveying surface and underground in B.C. Apply to Box No. 569-V.

TECHNICAL GRADUATE, for work in concentrating mill. Applicants will be expected to qualify for intermediate or final registration under terms of the Engineering Act of B.C. Apply to Box No. 570-V.

SALES ENGINEER. Canadian stoker manufacturers desire services of experienced mechanical engineer to take charge of distribution. Location Montreal. Apply at once to Box No. 580-V.

ENGINEER.—A large company desires to employ a young engineering graduate, preferably with some experience. This position offers an opportunity for acquiring a sound grounding in practical engineering as applied to industry and excellent prospects for the right man. In applying give in detail your personal history, education, experience, the particular branch of engineering or industry in which you are most interested, salary expected, and enclose a snap or photograph. Present employees are informed of this advertisement. Apply to Box No. 583-V.

DRAUGHTSMAN.—Young man with some experience for about fourteen months work for city engineer's office in northern Ontario. Apply at once to Box No. 584-V.

MECHANICAL DRAUGHTSMEN.—Two mechanical draughtsmen, between the age of 25 and 35, with good mechanical drawing board design experience as well as general plant layout work. Location Montreal. Apply to Box No. 588-V.

RADIO ENGINEER.—Canadian manufacturer of broadcast receivers requires development engineer. University degree or equivalent experience required. Give full details of qualifications in application. Apply to Box No. 591-V.

Water Power in Brazil

A. W. K. Billings, M.E.I.C.,
Vice-President in Charge of Construction and of the Hydraulic Developments in Brazil, Brazilian Traction, Light & Power Co. Ltd.

Paper read before the Montreal Branch of The Engineering Institute of Canada, April 3rd, 1930.

The consideration of "Water Power in Brazil" by The Engineering Institute of Canada is specially appropriate. Brazil is the richest country in the world in potential water power; its present development of this important resource is due principally to Canadian enterprise and capital.

Thirty two years ago a noted American engineer, Fred S. Pearson, one of the pioneers in public utility engineering saw the opportunities in many Central and South American countries and enlisted the aid of a group of Canadians, known to many of you. With their support in the following seventeen years until his death in the sinking of the Lusitania he transformed and developed the public utilities of São Paulo, Rio de Janeiro, Mexico City and Barcelona. It is fitting here to couple with his name those of Sir William Mackenzie, who boldly backed these enterprises, Sir Alexander Mackenzie, who guided the Brazilian Company for over twenty-five years, and of F. A. Huntress, who directed it technically for twenty years.

To-day the light, power, transportation, gas and telephone services of São Paulo, Rio de Janeiro, Santos, and of the surrounding region, representing over two thirds of the water power developed in Brazil, are directly due to the courage and enterprise of this one Canadian Company, the Brazilian Traction, known there as the "Light" or the "Canadian Company". It is one of the largest public utilities outside of Canada and the United States.

American capital only recently has started to come in and by extensive purchases within the last three years of smaller companies outside the region served by the Brazilian Traction now owns about one-sixth of Brazil's developed water power.

Extent of Brazil

Brazil is relatively undeveloped and, over a great area, even unexplored and unknown. It comprises half the area and half the population of South America. It has approximately the same size as Canada or the United States, excluding Alaska, but extends over a much greater range of climate from the great forests of the equatorial valley of the Amazon, the world's greatest river, to the plains of the temperate zone in the extreme southern portion. It has a population of 39,000,000. The language of the country is Portuguese. It is bounded by ten of the twelve countries of South America, that is, by all these except Chile and Ecuador.

Only a small part of this enormous area is of interest in connection with water power. The Amazon valley in Brazil has no appreciable water power nor need of it. The relatively unknown subtropical region further south has great potential wealth in agricultural and other directions but has little known water power and no population or market for such power. Therefore attention will be confined to the plateaus of the southern portion, temperate in climate, well populated with fine types of Brazilians and of European settlers. This region produces, among other things, seventy per cent of the world's supply of coffee and has many important cities and towns. These include Rio de Janeiro of 1,300,000 population, usually considered the most beautiful city and harbour in the world, São Paulo of 1,050,000 population, a modern city and, next to Los Angeles, the most rapidly growing city of its class, and Santos, a city of 160,000 and an important seaport. This temperate portion of Brazil extends roughly parallel to the coast from twenty degrees to thirty-two degrees south. Here only are found the population, industries, market and transportation facilities which justify and require ample power supply, and also the physical and topographical conditions which permit such supply by water power.

Physiography

This portion of Brazil is endowed naturally with marvellous riches in potential water power because of a simple and very favourable surface formation and climate.

Anyone visiting Brazil sees for several hundred miles along the coast what appears to be and is called a mountain range, the Serra do Mar. It is really the edge of a great plateau. The geological formation along the coast is one of the most ancient—the Archaic or pre-Cambrian. The ancient rocks forming the plateaus are decomposed to considerable depths but the surface is not eroded very deeply nor are there many harder ridges protruding. The

highest point in Brazil is the peak of Itatiaia, half way between Rio and São Paulo, which is merely the highest point of the edge of one of these several plateau steps, and is only 9,100 feet above sea level.

Ages ago the nearly level peneplain, consisting mainly of granite, gneiss and similar rock, rose very slowly, breaking along faults parallel to the present coast, until today we see this plateau in one or several steps with the floor tilting very gently inland, away from the ocean. This raising and tilting, which formed the Serra do Mar, geologically was rapid. Few of the rivers draining this plateau could keep pace with the rising of the land by cutting down their courses to the ocean. The result is that with few exceptions the rivers of this region flow to the interior forming the great river basin of the Parana and Paraguay rivers.

The slope of these rivers is almost imperceptible, starting at, say, one in three thousand, and erosion is consequently not marked. The valleys are shallow and broad and the country resembles rolling prairie. The result is that the heavy rains which fall on this plateau, even a few miles from the precipitous slope of the Serra do Mar, flow in sluggish rivers northwest to the Parana, then southwest to the River Plate at Buenos Aires, reaching the Atlantic ocean only after twenty-five hundred miles of travel.

A few important rivers, including the São Francisco, Doce and Parahyba, are exceptions to the usual rule and after flowing for a long distance east, parallel to the faults, turn directly to the ocean—the first named in one great fall, Paulo Affonso, and the other two in a series of cascades along their lower courses.

The great rivers flowing to the interior cross many beds of harder rock, usually basalt, appearing either as a fault or as an anticline, and the resulting cascades and rapids, including all the famous falls of Brazil, cut long canyons in these beds of hard rock.

This extensive plateau or series of steps gently sloping toward the interior receives the prevailing southeast winds from the south Atlantic which are, of course, heavily charged with moisture. Along the narrow hot coastal plain the resulting rainfall is six to seven feet per year but the expansion and cooling through a few degrees of these breezes as they are forced to ascend abruptly twenty-five hundred feet at the edge of the plateau causes very heavy rainfall along this crest, decreasing further inland to an average of from four and a half to five feet.

At the crest of the plateau at the Serra do Cubatão development of the Brazilian Traction Company the average annual rainfall is about sixteen feet. Last year it was twenty-two and one half feet and in each of two months —February and December—was fifty-two inches. The heaviest daily rainfall was eleven and one half inches. Nearby the São Paulo Railway has recorded seven and a half inches of rain in one and a half hours, and such downpours on the precipitous slopes of a mountain side, particularly of the highly decomposed nature of these, can do great damage unless proper precautions are taken in the design and construction of engineering works.

Such rainfall is exceeded in a few other places. Without discussing British Columbia, the Ghats back of Bombay and Calcutta have a rainfall of thirty feet in the seven weeks of the normal moonsoon season.

In Brazil, these heavy rainfalls occur only at the edge of each plateau. The evaporation from a free water surface at the crest of the Serra is only about two feet per year while twenty miles inland the rainfall has dropped to five feet and the evaporation from a free water surface has increased to nearly as much. These conditions then continue fairly uniform over a great part of the plateau to the north.

The runoff, expressed in percentages, must be approximated with such variable rainfall, but is approximately 33 to 83 per cent, averaging 53 per cent on the drainage areas nearest the Serra.

Hydrology

With such variations of climate in a few miles it is essential to organize proper observations and records of rainfall, evaporation, stream flow, humidity, air and water temperatures and so forth. For this work the Company employs more than one hundred observers and uses twenty-four automatic stream flow recorders for isolated locations, visited usually once per month.

Space is too limited to discuss the relation to the water supply of variations in the solar radiation as evidenced by the cycle of visible sun spots, radio interference, the variations of ocean temperatures and currents, fluctuations of inland lake levels, the varves or bands of different colours in the clays deposited below glaciers, rings of trees as measured extending even three thousand years back, and similar indications. The importance of this difficult and involved subject is just becoming evident and in Brazil this study is especially important as the relation of weather to the solar radiation cycle seems clear. In the interior of Canada and the United States conditions are different.

In a few places small rivers have broken away from the parent system and have cut their way through the edge of the plateau to reach the ocean. In other cases one river has captured the headwaters of another.

All such phenomena are obviously of the greatest interest to the engineer, even more than to the geologist, for they suggest projects of magnitude which, by taking advantage of such conditions, are cheaper than those following conventional methods.

Statistics

In these days of world power congresses it is the fashion to collect and publish statistics of the potential water power of each country. It seems to the writer that much of this effort is wasted. First, there is the difficulty of defining what really constitutes potential water power and for what portion of the year it must be available in order to be counted; second, in countries like Africa and South America which have the greatest potential resources of this kind the lack of exploration or of observations of flow and fall make such statistics the wildest of guesses; and third, the visible water powers are often secondary in economic importance and value to the invisible water powers, obtainable by diversion. This is particularly true in Brazil. Only those water powers which can be developed commercially within a reasonable period and which will command a market are, in the writer's opinion, worth consideration and study.

The statistics usually given for Brazil, which are far more incomplete than they appear, show about 43,000,000 h.p. in the visible falls above 10,000 h.p. Estimates of these vary from 20,000,000 h.p. to 60,000,000 h.p.

Waterfalls

No attempt will be made to catalogue the many great waterfalls of Brazil which are seldom seen even by the Brazilians themselves. Nearly all of them are relatively inaccessible and in the author's opinion they will play a small part in the economic future of Brazil. In fact, by obstructing navigation on these great rivers they will retard rather than advance the development of the country. Only a few which are closer to the centres of population will be developed and thus become an asset.

The number of large falls on many of these rivers is astonishing. That Rio Grande which in part of its course forms the northern boundary of the State of São Paulo, has in seven of the better known falls at least 1,800,000 h.p. and much more exists in unnamed falls. Yet even this power will hardly be developed to an appreciable extent.

Argentina has studied two of these great waterfalls, Iguassu and Guayra, because of its lack of water power, but the development of petroleum deposits, the increasing economy of thermal stations located at the point of consumption, the administrative difficulties due to lack of international treaties, and the physical difficulties of distance, isolation and backwater conditions all count heavily against the possible development of such powers even for Argentina. The "Chade" Company in Buenos Aires put in last year the first sixth (two units of 75,000-h.p. each) and is now putting in the second sixth of what will ultimately be a 900,000-h.p. steam station.

In the portion of Brazil where power is of importance the local conditions favour cheap water power development close at hand so that these more remote falls are of little interest. Steam plants cost in Brazil as much or more than hydro-electric plants even for the initial installation, besides which there is the considerable expenditure for imported fuel. Oil fuel costs about $16.00 per ton at present and coal in proportion. It is therefore rare to find any steam power or thermal plants in this part of Brazil except those required as a reserve under public service contracts.

There are no coal mines of value in Brazil but it is probable that petroleum will be found in the southwestern portion, particularly in the state of Paraná and the adjacent portion of the state of São Paulo. This however will not affect appreciably the water power situation except to postpone still further the development of the remote waterfalls.

All of these natural falls suffer the serious disadvantage of very high backwater in the long narrow canyons down-

Figure No. 1.—Map of Southeastern Part of Brazil.

Figure No. 2.—Rio de Janeiro (view from Corcovado).

stream which result from the erosion by the fall itself. Thus the Paulo Affonso fall is reduced in flood season by over ninety feet, that is from 262 feet in the dry season to 170 feet in the wet season,—similarly the Iguassu fall is diminished 105 feet from 230 feet to 125 feet, the Guayra fall by 117 feet from 380 feet to 263 feet and so on.

Some of the largest falls, for example Urubú-Pungá on the Paraná and Itapura on the lower Tieté, become mere rapids in the flood season while others, such as Pirapora on the São Francisco, disappear altogether at such seasons.

It will be of interest to describe in a few words several of the larger falls. The greatest of all and probably the largest in the world is the Guayra fall on the Paraná at the place where this river becomes the boundary between Brazil and Paraguay. Estimates of this power vary from twelve million to twenty million horse power. Some are even higher and go as high as forty million horse power.

The Guayra fall, better known in Brazil as Sete Quedas, is typical of many others. The Paraná river at this point is conservatively estimated to have a minimum flow of 408,000 second-feet or double the average flow of the Niagara river at Niagara, while in flood season it has a flow several times as great, probably exceeding 2,660,000 second-feet.

The total drop of 385 feet applies to nearly twenty-five miles of river. Between the main falls and Porto Mendes, the head of navigation from Argentina, the river is a raging torrent between 500 and 600 feet deep. In the flood season the water level above the falls rises only about eight feet whereas below the falls it rises 125 feet.

There is a considerable transport of produce, especially maté, the tea of the Argentine, around the falls by rail. Large steamers can come up to Porto Mendes but above the falls for the maté transportation and other traffic smaller steamers of not over 300 tons are used.

Another similar fall, smaller than Guayra but still estimated to have from 3,000,000 to 14,000,000 h.p., is the Santa Maria fall on the Iguassu river, more usually referred to as the Iguassu fall. This is often illustrated and described in books of travel because it is easily reached by river navigation up the Paraná from Buenos Aires. The backwater is excessive, approximately 125 feet, while the dry season flow is only 12,400 second feet. It is on the boundary between Argentina and Brazil. The many studies made by the Argentine government and private interests indicate that it cannot be developed economically. In addition to this Brazil and Argentina have not agreed on any method of developing the falls, which would normally be done in Brazilian territory.

Another noted waterfall is that of Paulo Affonso on the São Francisco river between the states of Alagoas and Sergipe. There is a possibility that this fall may be developed as it is the principal obstacle to navigation on this river, which, if eliminated, would facilitate the development of an important region. Mineral wealth in this section may require a considerable amount of power. A project has been advanced for pumping water from this river by the power thus produced through a divide into an extensive and well populated section which for centuries has been scourged by frequent droughts and famines.

This fall of Paulo Affonso has approximately 262 feet head and 35,000 second feet in the dry season but only 164 feet head with about 354,000 second feet in the flood season. There are therefore 800,000 h.p. available but on account of physical conditions the economic development of any considerable amount of power is not easy.

Another river which is known by the government explorations to have considerable water power is that Rio Grande river, already mentioned. On account of the location of this river with relation to the important States of Minas and São Paulo it is possible that some of these falls may be developed—in fact, 10,000 h.p. has already been developed on a branch of the main river at the fall called Marimbondo. The cost of diversion dams across such large rivers is great and the initial step is therefore heavily penalized. Such plants, even if constructed later, will probably operate in parallel with high head storage plants as such interconnection appears economically desirable.

The flow of the Parahyba river, already mentioned, reaches 283,000 second feet in the lower portion and the amount of power along its course is large. It is probable that plants on this river will be developed to operate in parallel with high head storage plants elsewhere. The Brazilian Traction Company possesses the principal rights on this river and has already built one plant at Ilha dos Pombos with 120,000 h.p. installed and an ultimate capacity of slightly over 200,000 h.p.

Another river of less importance from the standpoint of water power but likely to be developed because of its proximity to the largest deposit of high grade iron ore in the world, is the Rio Doce, 220 miles north of Rio. This iron ore deposit has been known and its development has been advocated for very many years but the work has not yet been commenced. When started the ore will be shipped to Germany and England and perhaps the United States, and not less than five per cent, of the ore thus exported will be refined locally into steel products.

Glancing briefly at some of the typical power plants in Brazil, it may be noted that when the earlier ones were built the largest water wheel units were only 5,000 kw. and the largest steam turbines were even smaller. Today the largest hydraulic turbines are in the reaction type about 80,000 h.p. and in the impulse type about 70,000 h.p. whilst steam turbines reach 260,000 h.p. in a single unit.

It should also be noted that whereas thermal plants, either steam or internal combustion, are relatively uniform in design, hydraulic plants differ greatly because each must be adapted to the particular local conditions. Hardly any two hydraulic plants are alike and each has to be built where the head and flow are obtainable most economically. The difficulties encountered call for an entirely different order of engineering than steam plants, which are usually constructed in large cities and amply provided with all facilities.

Marmelos

The first hydro-electric plant in Brazil was built in 1889 at Marmelos on the Parahybuna river near Juiz de Fora. This had initially one 60-h.p. unit, later two more, and three 400-h.p. units were added.

Parnahyba

The first plant of importance, a remarkable plant for its day, was that of Parnahyba, on the Tieté river near São Paulo. The original installation consisted of three horizontal wheels of 2,000 h.p. each under seventy-five feet head direct connected to generators with transmission at 20,000 volts a distance of 17 miles. Both in size of direct connected hydraulic unit and transmission voltage and distance this plant was quite exceptional and went into operation in 1901. It was later increased to about 28,000 h.p. and is still operating as one of the four plants of the Brazilian Traction supplying São Paulo, but will eventually be replaced by a station forming part of the Serra development later described.

Bananeiras

Another of the older installations is that of Bananeiras supplying Bahia, a city of 300,000 people, 850 miles northeast of Rio. Due to construction difficulties this plant was not completed when first built. The American interests are now building a large reinforced concrete multiple arch dam, the largest in South America, which will increase the storage by 74,000,000 tons and the capacity to 12,000 h.p. with provision for 12,000 additional later when required.

Itatinga Plant

The power for the supply of the Santos Docks is produced by the Itatinga plant built in 1912 on the slope of the Serra do Mar. It consists of a diversion dam, a covered canal running at the base of precipitous cliffs, connecting by individual penstocks to five 4,000-h.p. units operating under a static head of 2,070 feet. The transmission to Santos is over 20 miles of 40,000-volt line; this plant has for many years supplied in part also the city of Santos, the balance of the power required coming from the Serra plant.

Usina Isabel

A small plant of special interest is the Usina Isabel now owned by the Brazilian Traction and located on the

Figure No. 3.—Harbour of Rio de Janeiro.

Figure No. 4.—Ilha dos Pombos Development supplying Rio. North Channel Dam looking North—South Sector No. 3 discharging Two Thousand Cubic Feet per Second

Mantiqueira range about midway between Rio and São Paulo. It has only 4,000 h.p. but operates under the unusual head of 3,080 feet.

This plant was built during the war, and by a curious error in marking the profile the pipeline arrived from Germany with the bottom portion light and the top portion designed for full head. The Brazilian engineers were not daunted by this but revised the location, substituting canal for part of it, juggled the new line to suit the bends and pipe as actually furnished, and had left over about one third of the total tonnage which they sold at a profit. So they deserve credit not only for building what is still a high head plant but for overcoming under necessity a serious difficulty.

Chaminé

The American interests are also building a 10,000-h.p. plant called Chaminé about 30 miles southeast of Curityba, capital of the State of Paraná. The power will be transmitted 34 miles at 66,000 volts. A reinforced concrete diversion dam turns the water into a pressure tunnel 6½ feet in diameter and 6,880 feet long and penstocks 1,120 feet long, giving 788 feet head. Provision is made for two more units or a total of 20,000 h.p. when needed.

Rasgão Plant

About a century and a half ago, the search for gold along the Tieté river northeast of São Paulo caused an attempt to divert the river across a narrow neck and thus lay bare the bed in a loop of several miles in length. Many slaves must have been employed, for a deep cut, later called the Rasgão, was made but the work was abandoned when hard rock was encountered.

Later the Brazilian Traction Company projected a small plant here, but there was little expectation of building it until a prospective drought prompted a rapid decision in 1924 to build a 32,000-h.p. plant. This commenced operation 11½ months after the first cabled proposal to undertake this construction. This rush job was executed under difficulties particularly in the shipment and receipt of the equipment.

This plant operates in parallel with the Serra, Sorocaba and Parnahyba plants in serving the São Paulo district. The head is 80 feet; the units have a maximum capacity of 16,000 h.p. each; the transmission distance is 27 miles at 88 kv.

Sorocaba

The Sorocaba installation was the second plant, built in 1912, to augment the supply of the city of São Paulo and the surrounding region. It has today 78,000 h.p. with reaction turbines under 680 feet static head. The transmission is over 48 miles at 88,000 volts, while one pair of circuits supplying the Paulista Railway reaches to a distance of 197 miles. The reservoir has an available storage of 234,000,000 tons.

Ribeirão das Lages

Another important installation is that of Ribeirão das Lages owned by the Brazilian Traction Company. It has a capacity of 85,000 h.p. and is the first plant built in 1906 for supplying the city of Rio de Janeiro and vicinity. This includes a reservoir of 192,000,000 tons available storage, now supplemented by the diversion of a tributary of the Parahyba river called the Pirahy. The regulated flow is brought through two 8-foot feeders 5,400 feet long to a valve house from which descend eight penstocks connected to multiple jet vertical impulse wheels operating under 1,020 feet static head. This power is transmitted 53 miles at 88,000 volts and the plant operates in parallel with a larger plant at Ilha dos Pombos on the Parahyba river.

Ilha dos Pombos

The second largest plant in Brazil has been built on the lower portion of the Parahyba river by the Brazilian Traction Company. Eight Stoney gates and three large automatic sector gates of reinforced concrete form a diversion dam and turn the flow from the two existing channels on either side of the island called Ilha dos Pombos, into an ancient channel.

By dredging the pasture land off the rock bed of this ancient channel a canal one and a half miles long was formed, which gives a head of 112 feet, diminishing in the

flood season to slightly less than one hundred feet. The extreme minimum flow of the river is 7,000 second-feet, the maximum 283,000 second-feet or about one third more than the flow of the Niagara river at Niagara.

A power house of simple design utilizes this head with three reaction units already installed totalling 116,000 h.p. and provision for two more, or 204,000 h.p. altogether. There is only one floor to the main building, the entire

control being on a gallery level with the exciter platform. The plant is arranged electrically on the unit system, the switches and high tension structure are on the roof, and the transmission is by four circuits on two tower-lines 94 miles at 132,000 volts to Rio de Janeiro.

The automatic reinforced concrete sector gates mentioned are the largest yet built. Each gate is 148 feet long, 35 feet in radius, 24 feet in clear depth of water over the sill, and weighs over 2,100 tons. It floats rising and falling into the sector chamber below according to the water pressure in the chamber. This pressure is controlled by a large ring gate, controlled in turn by a small funnel in water at the upstream pool level so that the vertical movement of this funnel moves the gate correspondingly, and for any given position of the funnel a variation of river flow and level causes the main sector gate to rise or fall until the level is restored. Each of these gates can pass at normal water level 1,800 tons of water per second.

These sector gates are very sensitive, regulating the pool level to a fraction of an inch. They are ideal for large reservoirs discharging clear water but are almost too sensitive, as the resulting variation of flow is somewhat dangerous to people who happen to go down to the riverbed below. The standard Stoney gate seems preferable, and for streams carrying much sand, boulders, and debris, we prefer roller gates or similar types in which the gate proper and all its mechanism except the sill itself, lifts out of the flow.

Serra Development

The largest development in South America is the Serra do Cubatão plant of the Brazilian Traction Company near São Paulo, which has at present installed two units producing 96,000 h.p. maximum and on order a third unit of 70,000 h.p. maximum. The ultimate capacity of this one project is approximately 750,000 h.p. The present transmission is 21 miles at 88 kv. later 132 kv. or 154 kv.

This development takes advantage, in a logical way, of the topographic and climatic advantages already discussed. Nevertheless it has attracted a great deal of attention and favourable comment, in fact is treated in the Brazilian press very much as if it were a new kind of Columbus' egg. Usually an hydro-electric development is so isolated that no one sees it or cares to see it. This one however is on the principal highway connecting São Paulo and its seaport Santos, travelled daily by thousands. It is plain that the plan is merely the common-sense working out of obvious facts, yet the public interest aroused in Brazil is gratifying, even if at times somewhat embarrassing.

At any time during twenty years this plan could have been easily determined from the topographic maps of this region of which thousands of copies were sold to the public. Anyone capable of tracing the contours on these maps can imagine the whole plan. Yet no one did this and three independent investigations passed by the region as devoid of interest, even though it was on the principal highway and included the only cascade on the Serra which is visible from the seaport. This seems a somewhat remarkable fact.

Examining the contour map it is evident that if a dam were built across the Tieté river below the city of São Paulo and the crest gradually raised, the resulting lake would inundate the lower portion of the city until a level between the 725 and 750 meter contours above sea level were reached, when the water would flow over several low depressions in the very flat divide or watershed between the Tieté and the coastal plain and bay of Santos, and for this diversion direct to the ocean a head of 725 meters thus becomes available.

In order to avoid flooding the city and the more important valleys it is obviously possible to build a number of low dams in the affluents, where the land is unpopulated and worth little, and to connect the resulting reservoirs by canals and tunnels across the low divides. This is the original Serra project of about 320,000 h.p.

It was later seen that further improvement could be obtained by omitting the interconnecting canals and tunnels, letting the ordinary excess flow and the stored waters pass down the Tieté and then be pumped into the main reservoir. This makes tributary a much larger drainage area.

The enlarged project includes a storage reservoir of available capacity 1,040,000,000 tons, a connection by pumping to an existing one of 194,000,000 tons, eight others to be constructed as needed, all totalling 2,500,000,000 tons or 3,500,000,000 kw.h. reserve storage; the corresponding regulated flow, ultimately about 3,500 second-feet, passes as needed through a variable head auxiliary power plant of 20,000 h.p. into a small reservoir of 25,000,000 tons, which serves as a natural channel to reach the crest of the Serra. Here the flow down the existing gorge is closed by a concrete dam and turned aside through a short tunnel and siphon to the top of a steep spur, down which the penstocks lead to the power house. Each penstock is slightly over five feet in diameter at the top reducing progressively to 43 inches at the bottom in the present lines and 49 inches in the third and future lines, and a little over 5,000 feet long on the slope. The net static head is 2,360 feet plus from 10 to 60 feet at the auxiliary power station.

Pumping for Storage and Flood Control

The conditions described of heavy rainfall and very slight grade to the rivers result each year in prolonged flooding of all the valleys in this region. While the velocity is low this flooding effectually prevents normal development and the elimination of such flooding by rectification of the river channels has long been discussed but not yet started nor would it alone be effective at reasonable cost.

Storage of these flood waters, such as projected in the original Serra plan, is advantageous but insufficient; diversion of these flood flows or the regulated flow to the ocean direct helps greatly. The combination of all three elements, storage, diversion, and rectification on a sufficiently large scale, is effective and the next few years will see a considerable part of the flooding immediately adjacent to São Paulo and downstream eliminated by such works.

After the 750,000,000 kw.h. available without pumping is utilized the pumping lifts are from 40 to 88 feet for the next step, providing 500,000,000 kw.h. primary power per year, and 16 feet additional for the third step providing over 1,100,000,000 kw.h. primary and 650,000,000 kw.h. secondary power per year, and so on when economically justified by future demand.

Obviously these pumped storage supplies use principally power otherwise wasted, rarely requiring primary power or on-peak power, and give in primary power when needed, at moderate additional investment and expense, from 13 to 24 times as much as the secondary power used in pumping.

Pumping will be done also, if possible, during floods even when the reservoirs are full, in order to spill direct to the ocean as much of the excess flow up to 5,000 second feet as is practicable. This will aid materially in solving the remainder of the flood prevention problem.

The rectification of the Rio Grande and Pinheiros rivers, requiring several million yards of dredging, that of the Tieté itself (now projected by the City of São Paulo and requiring a similar amount of dredging), and the flood prevention will benefit greatly the valuable valley lands, and these will bear a considerable part of the cost of this work.

Dredging Procedure

In the dredging marked success has been obtained with electrically driven suction dredges. At present there are

Figure No. 7.—Serra Development supplying São Paulo.

Figure No. 8.—Serra Development—View of 12-inch Suction Dredge.

five of these, each 12-inch discharge with 250 to 350 h.p. in motors, the power being delivered by a submarine cable running along the pontoon line.

The necessary material is hauled to the places where the nearest highway crosses these meandering streams, full of logs and obstructions. A suitable spot in the cleared swamp is chosen, the hull and machinery erected, the swamp drainage is obstructed temporarily to form a pool and the dredge then starts digging its channel.

Meanwhile the dense undergrowth and forest are cut down and burned or removed to the side, the stumps are grubbed to the slight extent possible and the power and telephone lines erected along the future channel. These swamps have usually a layer of one to three yards of vegetable matter and peat in a tangle of tree trunks and roots. This gives considerable trouble and requires raising and cleaning of the cutter and repriming of the dredge every few minutes. This material caves and slides toward the cutter sometimes 200 feet in advance.

The material underlying the swamp is decomposed granite or gneiss. Where this material has become kaolin mixed with sand it is very easy digging; where less completely decomposed a monitor or powerful water jet is often used to facilitate the cutting. Wash-borings are made in advance always to determine the conditions. The dredge material is pumped to dumps or if near enough to dikes, dams and roadfills, and held by brush to the desired slopes, leaving finally the clay and sand several hundred yards from its original location.

For some of the larger dams the hills are taken down by dredge and monitor as borrowpits. At other times the dredged channels rectifying the tortuous meanderings of the river furnish such fill for these dams. Elsewhere powerful pumps, 450 h.p. each, and monitors with booster pumps of 200 h.p. serve to build roadfills and dikes.

Sanitation

In general the districts served by the Brazilian Traction are healthful and therefore prosperous and important industrially. It must not be thought that malaria is unimportant; malignant tertiary malaria is more to be feared than yellow fever for several reasons, yet in Brazil as elsewhere the public in general is very careless.

The coastal plain almost everywhere in Brazil is infected with malaria; the higher plateau and much of the lower areas further inland are not. It is essential in all work that great care in sanitation be exercised from the very beginning, the Company has had complete success in its recent work when even governmental work nearby has been infected and seriously delayed. Extreme vigilance is necessary, especially where police powers are not held and military discipline in the enforcement of sanitary measures is lacking.

Every labourer is examined when first recruited before transportation is furnished, and again at the job before commencing work. Men who show enlarged spleen or other evidence of malarial infection are rejected. In doubtful cases (and lately in all cases for work in the coastal plain where recent work by others in the vicinity has been badly infected) a drop of blood is tested microscopically. This test is repeated frequently in watching the sanitary conditions in the camps, and in curing any imported cases.

In transmission line construction through the swamps, for example back of Rio, where malaria is endemic and in

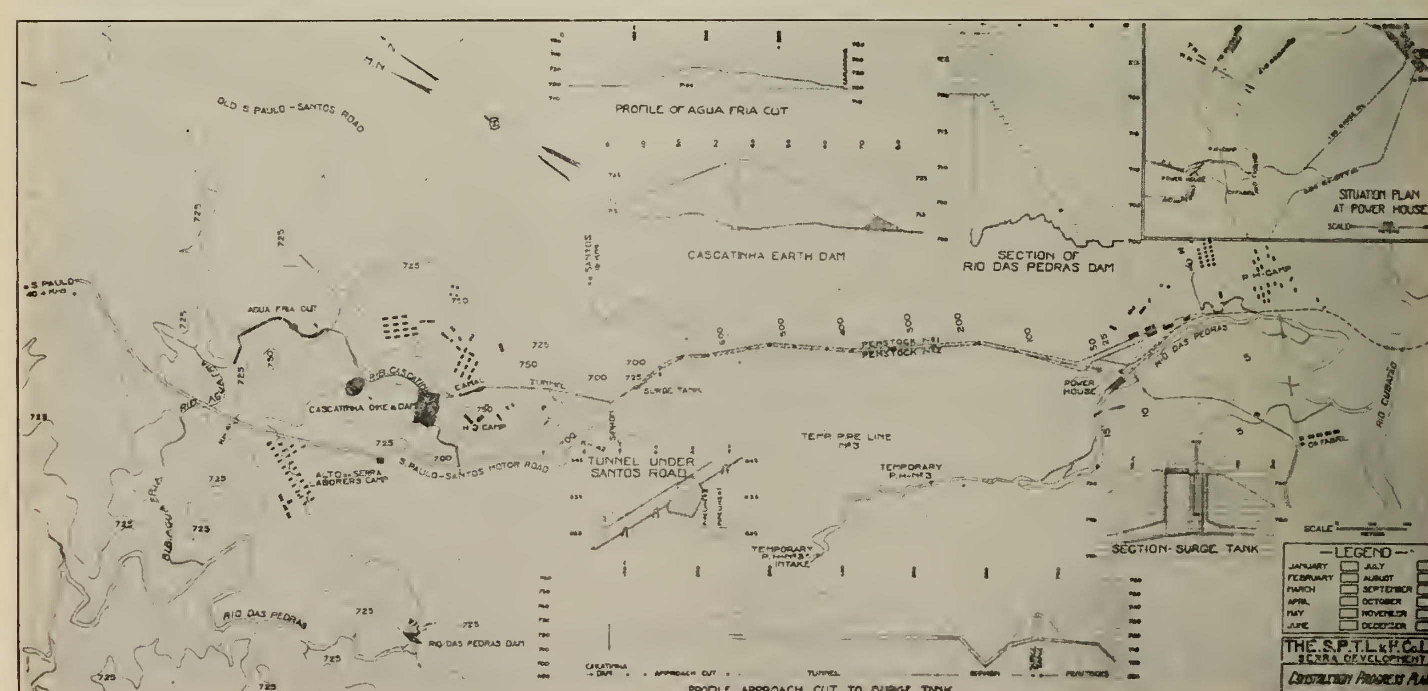

Figure No. 9.—Serra Development—Construction Progress Plan.

the past nearly depopulated these swampy districts, all men are sent in by trucks on the highways after daylight and brought out before dusk.

This policy has succeeded perfectly. Occasional cases are found during the season, but all have been proven to be imported, and so far in several years work with several thousand men, no cases have been contracted or transmitted in the Company's camps, nor has any woman or child come down with malaria.

Labour

On any such work one finds a conglomeration of labourers of every nationality. The country is drawn on entirely although newly arrived immigrants are attracted because of steady work, proper medical attention, regular pay, food at wholesale cost, and fair treatment, while they are learning the language and becoming accustomed to the country. Unfortunately elsewhere in Brazil there is often exploitation of the labourer. The Company have always tried to give the men a square deal and for these reasons labourers anywhere in Brazil come willingly when they hear that the "Light" needs men.

At the Serra the climate is hard on the Brazilians who are unaccustomed to the continual rains and cold. In the first year and a half of the Serra construction, to build up a force of 3,800 men over 26,000 men were brought in from all parts of Brazil.

Water Transportation

The reservoirs and dredged channels on the plateau and the Cubatão river and tidal channels on the coastal plain lend themselves also to the solution of a very pressing transportation problem, the remedying of the congestion of the port of Santos and of the means of transportation between this and São Paulo.

Seventy years ago the São Paulo Railway was granted the exclusive right to operate a railway between these points in a zone forty miles wide; the resulting railway, with its inclined planes and extensive protection against rains and slides, has the reputation of being the most costly railway in the world; consequently its charges average nearly half of the trans-Atlantic freight rate. Its equipment is insufficient and negotiations to modify the old concession and modernize the transport by the construction of an adhesion line, electrically operated, have not yet succeeded.

The plan, which would be carried out if the new electric line is not built, would be the discharge of part of the freight into lighters of two hundred tons capacity of a uniform special design, the towing of these to the base of the Serra adjacent to the power house, the lifting of these to the lake at the crest by inclined planes and the further towing of these lighters to any point on the rectified channels of the rivers at São Paulo. Two of the three dams would be passed by mechanical boat lifts, smaller and simpler than those on the Trent canal at Kirkfield and Peterborough; the third would be passed by an ordinary lock.

This water transport can compete with the railways both now and later, and the remedying of this congestion which occurs every few years and each year works serious injury to the commerce of the port and state is essential.

Market

One naturally asks, where can this power be sold? This portion of Brazil is largely, for its rapid development and prosperity, dependent, up to the present time, on coffee production and textile manufacturing. Little is known of the mineral wealth but the indications are that this is by no means small. Years of investigation and the commencing of development will be necessary before one can speak confidently of these possibilities but it is believed that extensive mineral exploitation and metallurgical development will be seen in Brazil in the near future.

Bauxite, which today is so essential as the raw material for the production of aluminum, and which occurs principally in semi-tropical countries like Brazil, is known to exist over wide areas but has not been prospected or developed. Manganese, lead and silver, some gold, diamonds in quantity, phosphate rock, nickel, and other minerals of importance are known to exist, even comparatively close to the thickly settled portions, but so far have received too little attention to be able to speak with confidence of the practical possibilities.

The fact remains that the load grows, in spite of the temporary reverses and setbacks to which any new, rapidly developing country is subject. Many years work in public utility work in foreign countries where one's expectations are usually exceeded by the actual results, makes the writer an optimist, and even though a pessimist is sometimes defined as "a man who has done business with an optimist," he is very confident of the future in a new country like Brazil. What they need most is systematic investigation of their great but unknown natural resources. The rest will follow.

In résumé, Brazil is half of South America but the southern part only is of interest from the standpoint of water power. Natural conditions, simple but unusual, favour greatly not only the existence of enormous water power in isolated though spectacular waterfalls but also the practical utilization of invisible waterpowers of much greater value in the populated and highly developed districts around Rio and São Paulo. The development of water power in Brazil is a great factor in its progress. It justifies fully the pride which Brazilians feel in their country and the pride which Canadians should take in the fact that such development has been led and is still being led by Canadian interests.

The Toronto Sewerage System

Geo. Phelps, A.M.E.I.C.,
First Assistant Engineer of Sewers, City of Toronto, Ont.

Paper read before the Montreal Branch of The Engineering Institute of Canada, March 27th, 1930.

The city of Toronto is situated on the north shore of Lake Ontario, occupying a waterfront of about 10 miles in length. It has an area of 35 square miles, a population of 606,370, and is served by 719 miles of sewers. From the point of view of drainage, it is well situated, the north city limit being 350 feet above lake level, with a fairly even fall to the lake, and, generally speaking, a fall eastward and westward to the Don and Humber rivers, respectively.

With the exception of certain low-lying areas near the lake front, Toronto is sewered on the combined system; that is to say, both sewage and storm water are carried in the same sewers to the lower part of the city. There the sewage is taken into the high and low level intercepting sewers, by means of which it is conveyed to the sewage disposal plant, and storm water in excess of three times the dry weather flow is discharged into the lake and Toronto bay from a number of storm overflow sewers.

For the districts known as North Toronto, a complete sewerage system has recently been installed, together with a separate sewage treatment plant, and none of the sewage from this district is taken into the before mentioned interceptors.

The low-lying areas along the lake front and Toronto bay are sewered on the separate system, the sanitary sewers conveying the sewage to four different points, where it is raised by means of pumps into the interceptors, and the storm sewers discharging directly into the lake. All buildings in these districts are provided with separate drains for sewage and storm water.

The sewage from the high level interceptor is discharged by gravity, and that from the low level interceptor is raised by means of pumps to the sewage disposal plant, which is situated on the lake front, near the east end of the city. The effluent from this plant is discharged into the lake in deep water, 2,300 feet from the shore.

As a typical example of the sewer work carried out in Toronto, a brief description will be given of the design and construction of the North Toronto sewerage system, which includes 13 miles of trunk sewers, 65 miles of lateral sewers, and a very up-to-date activated sludge treatment plant. The total cost of this work was nearly $10,000,000.

Prior to annexation by the city in 1912, North Toronto was a separate municipality, with a population of about 5,000. It was partially served by a sewerage system only capable of taking the sanitary flow, which was treated at three small disposal plants. Directly following annexation, the city, anticipating the growth and improvements which would take place, commenced the preparation of a comprehensive sewerage scheme, the construction of which, due to the Great War and other delays, was not proceeded with until 1926.

North Toronto covers an area of 2,800 acres, and has a population of 50,000 at the present time. The accompanying map (figure No. 1) gives a diagram of the recently constructed trunk sewers, which follow more or less the general slope of the ground from northwest to southeast.

As a preliminary to the design of the system, surveys were made of the various creeks and watersheds, and the

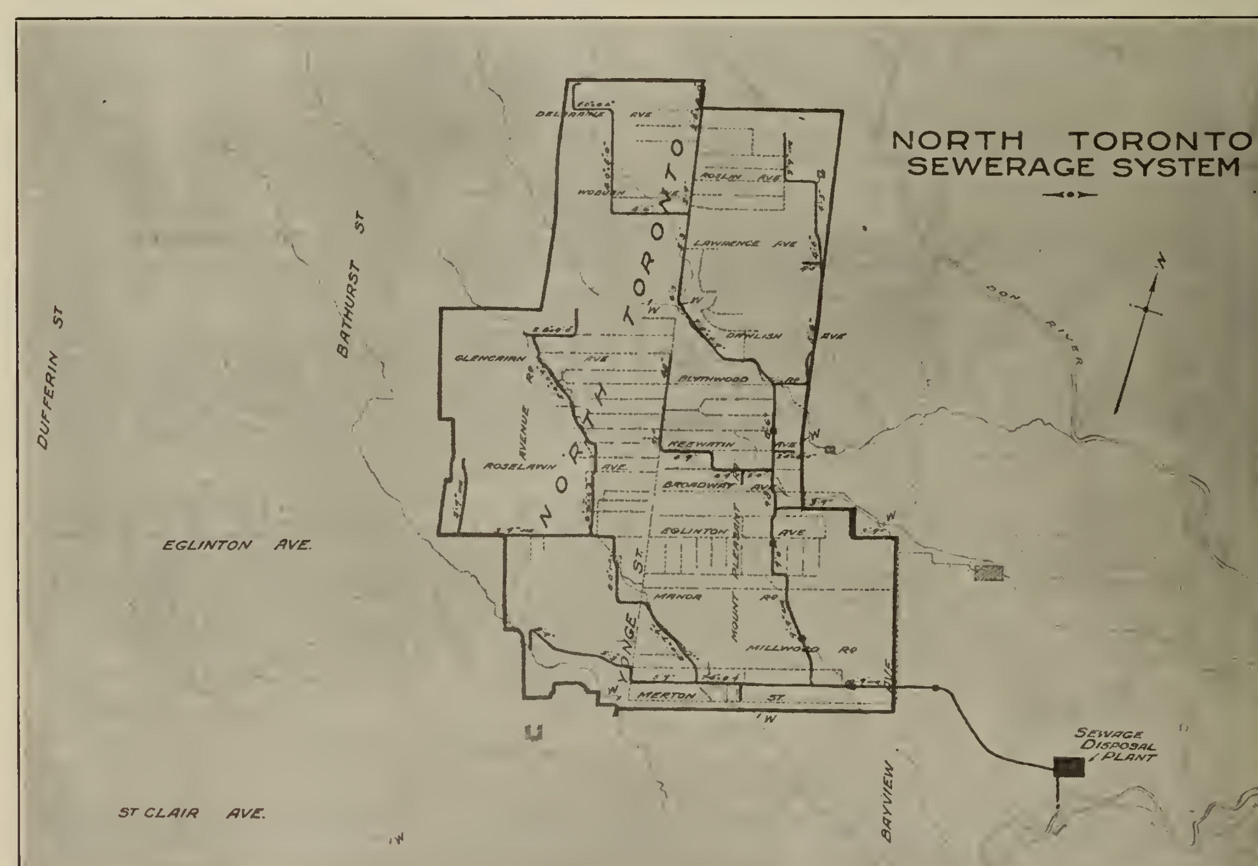

Figure No. 1.—Plan of North Toronto Sewerage System.

extent of the drainage areas was computed. Gauging weirs were built in the creek beds, and records kept of the flow for over ten years. The method of gauging was to place a box about 50 feet back from the weir in which small hooks were set. Corks were hung on the hooks, and as the water entered through holes in the bottom of the box these floated off and indicated the maximum depth of water flowing over the weir. The information thus obtained led to the conclusion that the heaviest flow from unimproved land occurs during the spring run-off, and is caused by melting snow. For areas of about 1,000 acres, the greatest run-off recorded was two-tenths of a cubic foot per second per acre.

These gaugings, considered along with the rainfall records, indicate that the run-off of melting snow is never coincident with a thunderstorm of extreme intensity. The latter is the more important factor, and causes a much greater run-off from an improved area. The North Toronto sewers, therefore, were made large enough at the upper end to take the run-off of melting snow from the unimproved portion of the drainage area lying to the northwest of the city limits, but only a very small allowance was made for the drainage of this area in the larger sewers towards the lower end, as the creek flow becomes an almost negligible quantity at the time when maximum run-off is to be expected from the improved city area. When the lands lying outside the city are built up and served with improvements, it is expected that their drainage will be taken care of by means other than as provided by the city sewers.

The Department of Works, Toronto, maintains three tipping-bucket rain-gauges, with automatic recorders, in the east, west, and north sections of the city. From these, together with the records received regularly from the meteorological office, which is centrally located, the rate of rainfall to be allowed for in sewer design is determined.

In figure No. 2 is shown a characteristic rainfall curve compiled from the heaviest storms of each month over a period of 24 years. This curve is merely typical of the variation in intensity throughout the duration of a heavy storm. The dotted curves show the rate of rainfall for storms of extreme intensity which occurred between 1918 and 1930. Storms of like intensity may be expected about once a year, but are usually of short duration. A rainfall at the rate of six inches per hour over a period of five minutes is an extremely heavy storm for this district. The heavy line shows the rainfall rates allowed for in the design of sewers in Toronto. At a first glance it would seem that a greater rate than two inches per hour should be allowed for the first ten minutes, but a storm of extreme intensity is always of short duration, and, owing to unevenness of ground surface and various other causes, the run-off in the earlier part of the storm is much retarded. It is, therefore, safe to assume that from five to ten minutes elapse before the rain-water is fully concentrated in the sewers, and during this time the intensity of the storm is considerably reduced. Experience in Toronto shows that sewers designed on the stepped curve shown in figure No. 2 are of sufficient capacity to deal with the heaviest storms, and where such sewers have been surcharged the trouble has been caused by some peculiar local condition not allowed for in the design. One other very important factor enters into the calculation of storm water run-off, and that is the permeability of the surfaces to be drained. The tendency of recent years has been towards wider pavements, the paving of lanes, and smaller lots with houses built closer together and usually with garages and paved side drives and yards, resulting in a considerable increase of impervious surface. Measurements taken recently in fully built-up residential districts where streets are paved show that the impervious surface averages about 56 per cent of the total area. The whole of the rainfall on any area does not reach the sewers,

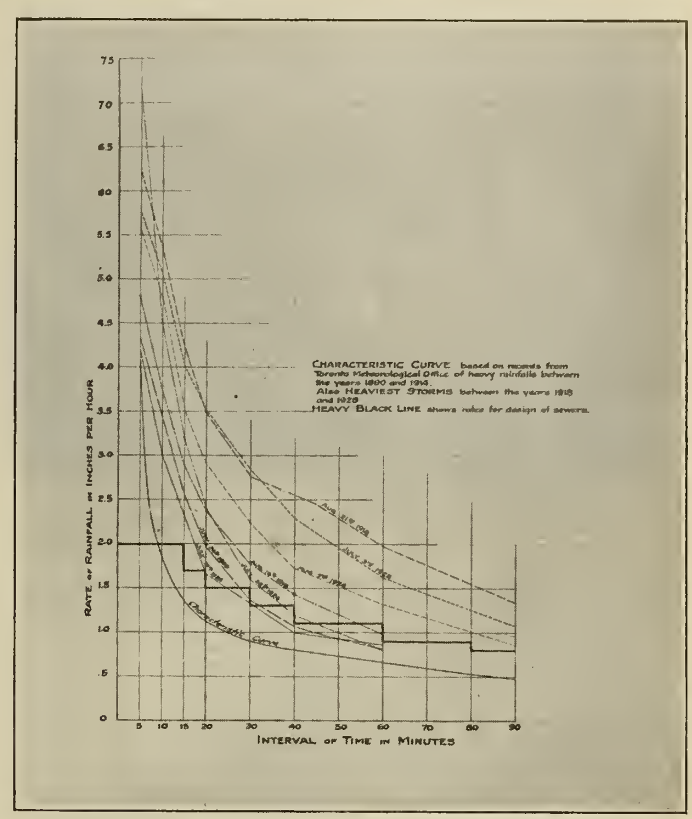

Figure No. 2.

and the amount to be allowed for becomes a matter of experience rather than measurement. The practice in this city is to allow a coefficient of impermeability varying from .45 for residential areas to .8 for fully built-up areas in the centre of the city. An allowance of .2 is considered sufficient for park lands.

Preliminary to the design of the North Toronto system, the approximate lines of the main trunks were decided on. Borings were taken along these lines to determine the strata through which the sewers would pass, and tentative profiles were plotted. To reach the site selected for the sewage treatment works, the trunk from the most northerly section necessarily crossed a deep ravine which intersects the area, and in this ravine there are certain lands which have to be served. As the land southward immediately rises 70 feet, the trunk sewers from this point on were very deep, reaching about 95 feet below the surface as a maximum. Tunneling was obviously the only method to be adopted for construction under these conditions, and, as the strata through which the sewers would pass consisted largely of wet sand and clay, a considerable pressure on the sewers had to be allowed for. No reliable information could be found as to pressures which might be expected in undisturbed ground at such a depth, and, therefore, it was decided to build circular sewers and allow for the full pressure of wet sand from the surface down. The main sewer, 10 feet 9 inches in diameter, has a five-ring brick wall, or an equivalent thickness, of first-class concrete, viz., about 22½ inches.

In order to obtain information for future guidance, Goldbeck pressure cells were built in outside the sewer wall in various locations, and tests of the earth pressures are being made from time to time. This experimental work is being carried out by the University of Toronto, in conjunction with the Department of Works of the city. As might be expected, earth pressures have been increasing on the cells at very different rates under various conditions of depth and strata, and as much as 30 pounds per square

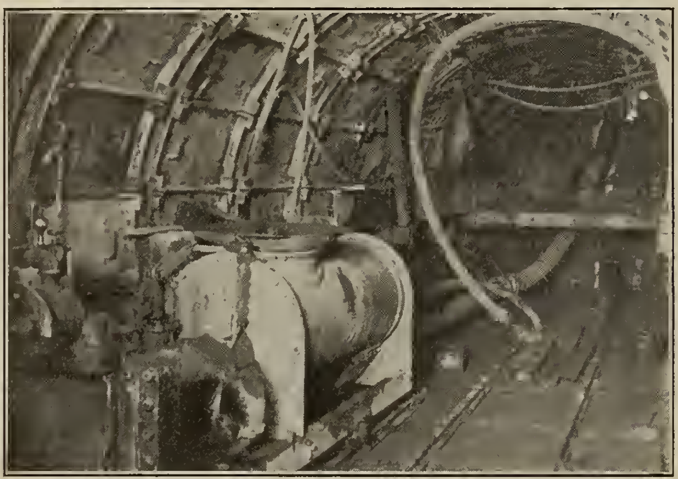

Figure No. 3.—Placing Concrete in Leaside Sewer.

inch have been recorded. It is hoped that the figures obtained will be published when the tests are complete.

The construction of sewers by the tunneling method is fairly simple in good ground at moderate depths, but considerable difficulty is encountered where the work has to be carried out in water-bearing strata, the difficulty increasing with the depth. In the North Toronto system it was necessary to carry out the construction of the main sewers very largely under compressed air to keep the tunnels free from water. Working shafts were placed about 2,000 feet apart, and were usually constructed by sinking concrete caissons from the ground surface to the sewer level. The caissons, with an air lock built in each, were sunk by mining below the bottom and allowing the constructed portion to sink a few feet. Another length was then built on at the top, and the process of mining and sinking was repeated until a point below the invert level of the sewer was reached. After constructing about 50 feet of sewer in each direction from this shaft, air locks were built in both sections of the sewer, and, when these were in commission, the vertical air lock was taken out, leaving the shaft clear to facilitate operations. Ground conditions made it necessary to carry out a large part of the work under air pressures of between 20 and 30 pounds per square inch in order to keep the headings fairly dry. At such pressures the working conditions are somewhat dangerous, and shortly after construction commenced a considerable amount of compressed air sickness occurred amongst the workmen. The seriousness of the situation was quickly recognized, and regulations governing the use of compressed air on such work were drawn up by the Provincial Board of Health, in conjunction with the Department of Works and the Department of Public Health of the city, and after consultation with the contractors who were carrying out the work. The regulations, which were put into force immediately, called for a limitation of the hours of work in accordance with increasing pressures; regular medical examination of workers; proper wash and rest rooms; a supply of hot coffee and sugar; identification badges for workmen, and, in addition to other requirements, the maintenance of a medical compressed air lock. For pressures up to 22 pounds per square inch. working hours are limited to two shifts per day of four hours each; from 22 to 29 pounds, two shifts of three hours each; and from 29 to 34 pounds, two shifts of two hours each. A further reduction in working hours is made for higher pressures. The period of decompression on coming out of compressed air is very important, and varies from 15 minutes for 22 pounds per square inch to 40 minutes for 40 pounds per square inch. An inspector was specially appointed by the provincial authorities to see that the regulations were properly carried out. All air locks were fitted with recording pressure gauges as a check on the method of air lock operation. The effect of the enforcement of the regulations was very marked, and sickness was much reduced.

The most common form of compressed air sickness affects the limbs, and is generally known as the "bends." Whilst under pressure, the blood is called upon to absorb an excess amount of oxygen and nitrogen. The former is more readily absorbed than the latter, and small bubbles of nitrogen are formed in the blood stream. Some of these bubbles settle in the joints, and expand when the worker passes to atmospheric pressure, causing violent pains in, and incapacity to use, the limbs. An attack is sometimes delayed as much as an hour after leaving the air lock. The most effective remedy is for the worker to return under pressure, and whilst this is being slowly reduced, to move and gently exercise the limbs. Another frequent form of compressed air sickness, commonly known as the "staggers," affects the balancing nerves, so that the worker is sometimes unable to stand. A prolonged period in hospital is often required before a cure can be effected.

The medical lock is usually in the form of a steel boiler, with a diaphragm across the middle, and air-tight doors in one end and in the diaphragm. One compartment is fitted with an electric heater and a bed for the use of the patient. The doctor or attendant can remain in the outer compartment at any desired pressure, observe the patient through a glass bull's-eye in the middle door, and regulate the pressure in either compartment by means of suitable valves and gauges.

The pressure and volume of compressed air necessary for the construction of any particular piece of tunnel work depends upon several factors, and cannot be determined by any rule. The nature of the sub-strata, the ground-water level, the size of the sewer, and the depth below the surface of the ground all have to be taken into consideration, and the engineer has to be guided simply by experience in determining what plant he will provide. In the North Toronto work, air pressures varied between ten and thirty pounds per square inch, and at one shaft the volume of free air used ran as high as 7,000 cubic feet per minute.

A general plan of the North Toronto trunk system is shown in figure No. 1. The work was divided into 25 contracts, and 292 contracts were let for the lateral sewers. Alternative bids were received for trunk sewer construction in brick or concrete, and where the price was the same, or the difference in price very small, brick construction was favoured. Generally speaking, all trunks constructed in

Figure No. 4.—Balliol Street Sewer showing "Flying Arch" Method of Construction.

open cut were of concrete, whilst brickwork was more usual in tunnel construction. As a result, about 80 per cent of the whole trunk system was of brickwork. The lateral sewers were almost entirely of vitrified tile pipe, but a comparatively small quantity of reinforced concrete pipe was used for sizes between 30 and 42 inches in diameter.

The brick sewers in tunnel were constructed by the usual method, which is well known and does not vary greatly. Concrete construction allows rather more variation in method, particularly in the manner of mixing and placing the concrete. Steel inner forms were used in all cases, and the placing of concrete was usually done by hand, with very good results. In one of the larger sewers, the contractors installed a mixing plant on the surface, and constructed a pipe chute to the tunnel behind the air lock, through which all concrete was conveyed. The chute discharged directly into hoppers on wheels, which were run along the tunnel and dumped into a concrete placer. The placer shown in figure No. 3 was operated by compressed air, and discharged the concrete through a flexible hose into place behind the forms. This method was found to be very satisfactory, and the results were excellent. No reinforcing material was used in the concrete sewers in tunnel construction. In practically all cases the tunnels were sheeted with timber before the sewer wall was built, and all sheeting was left in place.

In ground where it was difficult to hold the air pressure and keep the tunnel dry, the contractor was allowed to excavate for, and construct the top half of the sewer first, carrying this forward for a few shifts before constructing the invert. This is known as the "flying arch" method of construction, and is illustrated by figure No. 4. It should be used only as an emergency method, as the construction of short lengths of complete cross-section is more satisfactory. In such cases it was found necessary to take particular care with the joint at the springing line, in order to get a bond between the top and bottom sections of the sewer. As construction progressed, cement grout was forced under heavy pressure through pipes placed in the wall of the sewer to fill up all open joints in the work and cavities that might be left between the completed sewer and the surface of the excavation. Finally, any small leaks were caulked and filled, and rough spots in the sewer were finished off. Grouting after completion of the sewer wall was found to be necessary in both brick and concrete sewers where these passed through water-bearing strata.

It will readily be seen that very careful engineering work was necessary in transferring the line for the sewer from the surface down a shaft, producing this through the air locks, and sometimes around two or three curves to meet a similar line coming from a shaft two thousand feet away. Careful checking was always carried out by an engineer independently of the resident engineer on the job, and on joining up, the headings were never found to be more than an inch or two off line.

An activated sludge treatment plant has been built in the valley of the Don river to treat the sewage conveyed by this system, and the effluent is discharged into the river. The plant consists of grit chambers, preliminary and final sedimentation tanks, aeration tanks, sludge digestion tanks, glass-covered sludge drying beds, and storm water tanks. It is a very complete plant of the most modern type, designed by Dr. George G. Nasmith and Mr. Harrison P. Eddy, consulting engineers.

The whole of the work in connection with the above system was carried out under the direction of Mr. R. C. Harris, Commissioner of Works for the City of Toronto.

A Short Monograph on Nomography (Part II)*

F. M. Wood, A.M.E.I.C.,
Assistant Professor, McGill University, Montreal.

We have now discussed the elementary types of alignment charts which are composed of straight line scales. The simpler formulae involving three variables may be adapted to one or other of these types by suitable transformation.

Equations in three variables of a slightly more complicated nature may require treatment which will give charts containing one or more curved lines in place of the straight lines. The most general case, that having three curved lines, is given by the determinant form

$$\begin{vmatrix} f_1\alpha & f_2\alpha & 1 \\ \phi_1\beta & \phi_2\beta & 1 \\ \psi_1\gamma & \psi_2\gamma & 1 \end{vmatrix} = 0.$$

Here the α scale is given by the relations

$$x = f_1\alpha\,; \quad y = f_2\alpha\,;$$

which result in a curved locus unless these functions of α are linear. Similarly for the β and γ scales.

Two Parallel and One Curved Scale

We will consider first the case with one curved line. The determinant for this chart may be expressed

$$\begin{vmatrix} f_1\alpha & f_2\alpha & 1 \\ 0 & \beta & 1 \\ 1 & \gamma & 1 \end{vmatrix} = 0.$$

*Part I of this paper was published in the June 1930 issue of The Journal.

It is evident that this determinant is more difficult to transform, as one of the constants in the first column has been replaced by a function. If it is found that this form gives an α scale which lies outside the β and γ scales, and if it is considered desirable to bring the α scale between the other two scales (as for instance when the α scale is found to extend to a great distance from the others), the determinant may be expressed in the alternative form

$$\begin{vmatrix} \dfrac{-f_1\alpha}{1-2f_1\alpha} & \dfrac{f_2\alpha}{1-2f_1\alpha} & 1 \\ 0 & \beta & 1 \\ 1 & -\gamma & 1 \end{vmatrix} = 0.$$

Here we have simply reversed the γ scale with respect to the β scale.

The key determinants for the two kinds of transformation (enlargement of one of the scales and translation vertically) follow. The steps traversed in arriving at these transformations are not given but are left as an exercise for the reader.

Equation:— $f_1\alpha\,(\beta - \gamma) + f_2\alpha - \beta = 0$

or $$\frac{f_1\alpha - 1}{f_1\alpha}\,\beta - \gamma + \frac{f_2\alpha}{f_1\alpha} = 0$$

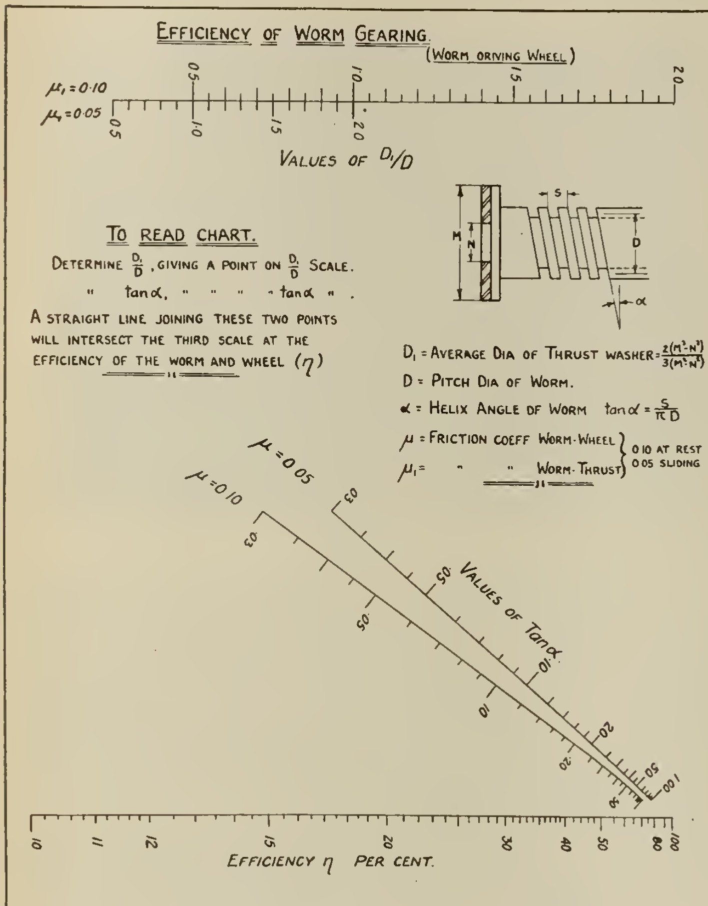

Figure No. 15.

(*a*) Case when $f_1\alpha$ has values lying between 0 and 1.

$$\begin{vmatrix} f_1 & f_2 & 1 \\ 0 & \beta & 1 \\ 1 & \gamma & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} \dfrac{f_1}{(1-m)f_1+m} & \dfrac{mf_2}{(1-m)f_1+m} & 1 \\ 0 & \beta & 1 \\ 1 & m\gamma & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} \dfrac{f_1}{(1-m)f_1+m} & \dfrac{mf_2+nf_1}{(1-m)f_1+m} & 1 \\ 0 & \beta & 1 \\ 1 & m\gamma+n & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} \dfrac{mf_1}{(m-1)f_1+1} & \dfrac{mf_2}{(m-1)f_1+1} & 1 \\ 0 & m\beta & 1 \\ 1 & \gamma & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} \dfrac{mf_1}{(m-1)f_1+1} & \dfrac{m(f_2+nf_1)}{(m-1)f_1+1} & 1 \\ 0 & m\beta & 1 \\ 1 & \gamma+n & 1 \end{vmatrix} = 0$$

(*b*) Case when $f_1\alpha$ has values either greater than 1 or negative.

$$\begin{vmatrix} \dfrac{f_1}{(1+m)f_1-m} & \dfrac{-mf_2}{(1+m)f_1-m} & 1 \\ 0 & \beta & 1 \\ 1 & -m\gamma & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} \dfrac{f_1}{(1+m)f_1-m} & \dfrac{-mf_2+nf_1}{(1+m)f_1-m} & 1 \\ 0 & \beta & 1 \\ 1 & -m\gamma+n & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} \dfrac{mf_1}{(1+m)f_1-1} & \dfrac{mf_2}{(1+m)f_1-1} & 1 \\ 0 & -m\beta & 1 \\ 1 & \gamma & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} \dfrac{mf_1}{(1+m)f_1-1} & \dfrac{m(f_2+nf_1)}{(1+m)f_1-1} & 1 \\ 0 & -m\beta & 1 \\ 1 & \gamma+n & 1 \end{vmatrix} = 0$$

Note that m is assumed as positive, n may be either positive or negative.

Illustration. The equation for the efficiency of worm gearing with the worm driving the wheel is

$$\eta = \frac{\tan\alpha}{\left\{\tan(\alpha+\phi) + \dfrac{D_1}{D}\tan\phi_1\right\}}$$

(See figure No. 15)

Here ϕ and ϕ_1 are constants, denoting angles of friction. η, α, D_1 and D are the variables, the last two being suitably combined in the form D_1/D, thus reducing the number of variables to three. We see that it is necessary to form a determinant with $\tan\alpha$ and $\tan(\alpha+\phi)$ in the same row. If we denote

$$\tan\alpha \text{ by } A_1;\ \tan(\alpha+\phi) \text{ by } A_2;\ \frac{D_1}{D}\tan\phi_1 \text{ by } B;$$

and η by C, the equation takes the form $C(A_2+B) = A_1$. The first trial determinant is, say,

$$\begin{vmatrix} C & 0 & 1 \\ 0 & A_2 & 1 \\ \dfrac{A_1}{A_2} & -B & 1 \end{vmatrix} = 0$$

This was obtained by filling in the C, A_2 and $-B$, to represent $C(A_2+B)$; then it was found that $\dfrac{A_1}{A_2}$ was necessary in the lower left hand corner, with the two zeros as shown.

If we divide the second column by $-A_2B$ this becomes

$$\begin{vmatrix} C & 0 & 1 \\ 0 & -\dfrac{1}{B} & 1 \\ \dfrac{A_1}{A_2} & \dfrac{1}{A_2} & 1 \end{vmatrix} = 0.$$

In this form the C and B scales are perpendicular to each other; therefore we transform as follows:—

$$\rightarrow \begin{vmatrix} C & 0 & 1 \\ 0 & -1 & B \\ A_1 & 1 & A_2 \end{vmatrix} \rightarrow \begin{vmatrix} 1 & 0 & \dfrac{1}{C} \\ 0 & -1 & B \\ A_1 & 1 & A_2 \end{vmatrix}$$

$$\rightarrow \begin{vmatrix} 1 & 0+1 & \dfrac{1}{C} \\ 0 & -1+0 & B \\ A_1 & 1+A_1 & A_2 \end{vmatrix} \text{ or } \begin{vmatrix} 1 & 1 & \dfrac{1}{C} \\ 0 & -1 & B \\ A_1 & 1+A_1 & A_2 \end{vmatrix}$$

$$\rightarrow \begin{vmatrix} 1 & 1 & \dfrac{1}{C} \\ 0 & -1 & B \\ \dfrac{A_1}{1+A_1} & 1 & \dfrac{A_2}{1+A_1} \end{vmatrix} \rightarrow \begin{vmatrix} 1 & \dfrac{1}{C} & 1 \\ 0 & -B & 1 \\ \dfrac{A_1}{1+A_1} & \dfrac{A_2}{1+A_1} & 1 \end{vmatrix} = 0$$

We could have found this determinant form by a purely analytical transformation of the equation $C\,(A_2 + B) = A_1$ to the form

$$\frac{f_1\alpha - 1}{f_1\alpha}\,\beta - \gamma + \frac{f_2\alpha}{f_1\alpha} = 0$$

Thus our equation gives

$$A_2 + B = \frac{A_1}{C} \quad \text{or} \quad \frac{A_2}{A_1} + \frac{1}{A_1}\,B = \frac{1}{C}$$

or

$$\frac{1}{A_1}\,B - \frac{1}{C} + \frac{A_2}{A_1} = 0$$

Here B corresponds to β; $\frac{1}{C}$ corresponds to γ;

$$\frac{1}{A_1} = \frac{f_1\alpha - 1}{f_1\alpha}; \quad \frac{A_2}{A_1} = \frac{f_2\alpha}{f_1\alpha};$$

Hence the determinant form

$$\begin{vmatrix} f_1\alpha & f_2\alpha & 1 \\ 0 & \beta & 1 \\ 1 & \gamma & 1 \end{vmatrix} = 0$$

corresponds to

$$\begin{vmatrix} \frac{A_1}{A_1 - 1} & \frac{A_2}{A_1 - 1} & 1 \\ 0 & B & 1 \\ 1 & \frac{1}{C} & 1 \end{vmatrix} = 0.$$

Transforming this to give a $(-B)$ scale by using $m = -1$ we obtain

$$\begin{vmatrix} \frac{A_1}{1 + A_1} & \frac{A_2}{1 + A_1} & 1 \\ 0 & -B & 1 \\ 1 & \frac{1}{C} & 1 \end{vmatrix} = 0.$$

Returning to the equation for the efficiency of worm gearing, it is assumed that the efficiency range is from 10 to 100%. Therefore $\frac{1}{C}$ varies between 10 and 1, or over 9 units. The $\frac{D_1}{D}$ range is assumed as 0.5 to 2, and using a value of $\tan\phi_1 = 0.10$ this gives a range for the B scale of $-B = -0.05$ to -0.2, approximately 0.2 units. It is seen that the A scale lies between the other two scales since A_1 is always positive.

Our first transformation will therefore be the magnifying of the B scale 45 times (i.e. $9 \div 0.2$). Substituting $m = 45$ in the key determinant concerning $m\beta$, we get

$$\frac{mf_1}{f_1\,(m-1) + 1} = \frac{45\,A_1}{44\,A_1 + (1 + A_1)} = \frac{45\,A_1}{1 + 45\,A_1}$$

since

$$f_1 = \frac{A_1}{1 + A_1}$$

similarly

$$\frac{mf_2}{f_1\,(m-1) + 1} = \frac{45\,A_2}{1 + 45\,A_1}$$

and our determinant becomes

$$\begin{vmatrix} \frac{45\,A_1}{1 + 45\,A_1} & \frac{45\,A_2}{1 + 45\,A_1} & 1 \\ 0 & -45\,B & 1 \\ 1 & \frac{1}{C} & 1 \end{vmatrix} = 0.$$

Here it is seen that the C scale is 10 units higher than the B scale, because $\frac{1}{C}$ has a range from 1 to 10, and $-45\,B$ has a range from 0 to -9. Therefore use the value $n = -10$ and obtain the final form

$$\begin{vmatrix} \frac{45\,A_1}{1 + 45\,A_1} & \frac{45\,(A_2 - 10\,A_1)}{1 + 45\,A_1} & 1 \\ 0 & -45\,B & 1 \\ 1 & \frac{1}{C} - 10 & 1 \end{vmatrix}$$

$$\rightarrow \begin{vmatrix} \frac{45\tan\alpha}{1 + 45\tan\alpha} & \frac{5\,(10\tan\alpha - \tan\overline{\alpha + \phi})}{1 + 45\tan\alpha} & 1 \\ 0 & 5\frac{D_1}{D}\tan\phi_1 & 1 \\ 1 & \frac{1}{9}\left(10 - \frac{1}{\eta}\right) & 1 \end{vmatrix} = 0$$

The chart has been constructed for two values of $\tan\phi_1$ (0.05 and 0.10) and also for two values of $\tan\phi$ (0.05 and 0.10). This is done to make the nomogram more comprehensive. In any particular problem interpolation can be made quite easily in case some intermediate value of $\tan\phi$ or of $\tan\phi_1$ is to be used.

For purposes of comparison a second chart has been made in which the α scale lies outside the other two scales. Here we use the key determinant containing the term $-m\beta$, where m is chosen equal to 50. This choice is made instead of 45 in order to reduce the length of the α scale. The resulting form is

$$\begin{vmatrix} \frac{50\tan\alpha}{50\tan\alpha - 1} & \frac{50\tan(\alpha + \phi)}{50\tan\alpha - 1} & 1 \\ 0 & 50\,\frac{D_1}{D_1}\tan\phi_1 & 1 \\ 1 & \frac{1}{\eta} & 1 \end{vmatrix} = 0$$

(See figure No. 16)

No further transformation is necessary since the two parallel scales are found to lie opposite each other in this form.

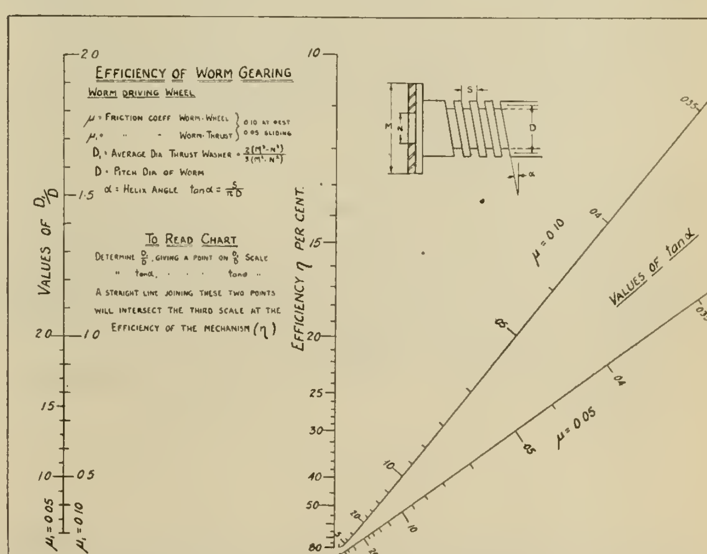

Figure No. 16.

In some cases the determinant form

$$\begin{vmatrix} f_1\alpha & f_2\alpha & 1 \\ 0 & \beta & 1 \\ 1 & \gamma & 1 \end{vmatrix} = 0$$

is not suitable because better results might be obtained by using the reciprocal scales $\frac{1}{\beta}$ and $\frac{1}{\gamma}$. The new form is found to be

$$\begin{vmatrix} \frac{f_1\alpha}{f_2\alpha} & \frac{1 - f_1\alpha}{f_2\alpha} & 1 \\ 0 & \frac{1}{\beta} & 1 \\ \frac{1}{\gamma} & 0 & 1 \end{vmatrix} = 0$$

This gives two perpendicular scales in place of the parallel scales, a result which seems to follow in general whenever two scales are changed to their reciprocals.

If the above form is found to give an α scale unsuitable for plotting (for instance one lying beyond the quadrant of the $\beta\gamma$ scales) the modified form

$$\begin{vmatrix} \frac{f_1\alpha}{f_2\alpha-(m-n)f_1\alpha+m} & \frac{1-f_1\alpha}{f_2\alpha-(m-n)f_1\alpha+m} & 1 \\ 0 & \frac{1}{\beta+m} & 1 \\ \frac{1}{\gamma+n} & 0 & 1 \end{vmatrix} = 0$$

may be used.

By a suitable choice of m and n the β and γ scales may be translated laterally. If either one is translated across to the other side of the origin, it will be found that the α scale has been brought within the $\beta\gamma$ quadrant. Suppose, for instance β has a range of values from 1 to 20. then $\frac{1}{\beta}$ will be graduated from 1 unit to $\frac{1}{20}$ unit above the origin. By choosing $m = -21$, the $\frac{1}{\beta + m}$ scale will be graduated from $\frac{1}{20}$ to 1 unit below the origin, and still in the same direction.

Of course we may in any case use different sizes for our scales along the X and the Y directions. This use of different scale sizes is equivalent to multiplying either the first column, or the second column by some constant.

In case one of the variables β or γ has a range of values passing through zero, thus making the expression $\frac{1}{\beta}$ or $\frac{1}{\gamma}$ indeterminate for the zero value of the variable, the form just given in which m and n are to be given suitable values will overcome the difficulty.

No illustration has been chosen for this case since it is not used to any great extent. Parallel scale charts are preferable where possible because of the greater accuracy obtainable. In charts with perpendicular scales only half the area of the paper is utilized.

The more general case with three curved scales, given by the form

$$\begin{vmatrix} \alpha_1 & \alpha_2 & 1 \\ \beta_1 & \beta_2 & 1 \\ \gamma_1 & \gamma_2 & 1 \end{vmatrix} = 0$$

cannot be treated in any routine manner. Sometimes, however, depending on the form of the equation in the particular case, suitable multiples of columns one and two may be taken and manipulated in such a manner as to eliminate one of the variable elements of the determinant, giving the new form

$$\rightarrow \begin{vmatrix} n\alpha_1 + m\alpha_2 + l & \alpha_2 & 1 \\ n\beta_1 + m\beta_2 + l & \beta_2 & 1 \\ n\gamma_1 + m\gamma_2 + l & \gamma_2 & 1 \end{vmatrix} = \begin{vmatrix} \alpha_3 & \alpha_2 & 1 \\ \beta_3 & \beta_2 & 1 \\ 0 & \gamma_2 & 1 \end{vmatrix} = 0$$

which gives two curved scales and one straight scale.

There is not much transformation possible here, except to the forms

$$\begin{vmatrix} \frac{\alpha_3}{\alpha_2} & \frac{1}{\alpha_2} & 1 \\ \frac{\beta_3}{\beta_2} & \frac{1}{\beta_2} & 1 \\ 0 & \frac{1}{\gamma_2} & 1 \end{vmatrix} = 0 \qquad \begin{vmatrix} \alpha_3 & a\alpha_2 + b\alpha_3 + c & 1 \\ \beta_3 & a\beta_2 + b\beta_3 + c & 1 \\ 0 & a\gamma_2 + c & 1 \end{vmatrix} = 0$$

Equations Containing Four Variables

There are two main methods of making nomograms for these equations. (a) The first may be called the "successive partial solution" method. To illustrate this method, let us consider the example $\alpha + \beta + \gamma + \delta = 0$. A nomogram is first made for the equation $\alpha + \beta = P$ which may take the form of three parallel scales for α, β, and P. Given values of α and β will thus secure corresponding values of P. The next step is to construct a nomogram for the relation $P + \gamma + \delta = 0$, which also may take the form of three parallel scales for P, γ, and δ. If care is taken to have the P scale the same in both of these nomograms, they may be superimposed on each other and the same P scale may be used in connection with γ and δ as is used with α and β. The P scale is generally called the support scale. Our chart will then be made up of five scales for α, β, P, γ, and δ.

The advantage of these charts is that they are easy to construct. They are used almost exclusively in cases in which the scales may be constructed along sets of parallel lines. For this reason they have a limited application. They have also the disadvantage that errors in reading are accumulative particularly in cases involving five or six variables. (b) The second method employs a combination of the alignment chart and the intersection chart. An example is given in the chart for yield of bonds to maturity (figure No. 17). Here the two variables n = time and Y = yield, are represented by sets of lines, the Y lines being straight and the n lines slightly curved. The intersection of an n and a Y line gives a point which is collinear with a point on the I scale on one side and a point on the Present Value scale on the other.

The simplest case for such a chart is given by the form

$$\begin{vmatrix} \alpha & \beta & 1 \\ 0 & \gamma & 1 \\ 1 & \delta & 1 \end{vmatrix} = 0$$

Here the two sets of lines $x = \alpha$ and $y = \beta$ will determine (by their intersection) points (α, β) which must be collinear with points on the γ and δ scales.

A slightly more complicated case is given by the equation

$$\begin{vmatrix} f_1(\alpha, \beta) & f_2(\alpha, \beta) & 1 \\ 0 & \gamma & 1 \\ 1 & \delta & 1 \end{vmatrix} = 0$$

Here the sets of lines for α and β need not be straight, and they are in general inclined to the principal axes. In order to plot these sets of lines it is necessary to take the equations $x = f_1(\alpha, \beta)$; $y = f_2(\alpha, \beta)$ and eliminate one or other of the variables from them, obtaining two new equations

$$F_1(x, y) = \phi\alpha \text{ and } F_2(x, y) = \psi\beta.$$

By substituting particular values for α and β these equations will give us curves which may be plotted as ordinary graphs in x and y. If this elimination cannot be effected without excessive labour, it will be necessary to substitute in the equations $x = f_1(\alpha, \beta)$ and $y = f_2(\alpha, \beta)$ simultaneous values of α and β and evaluate corresponding values of x and y. These points may then be plotted, and all points having the same value of α (or the same value of β) joined up.

It may be a difficult matter to express the given equation in one of the determinant forms given above. There are two ways of proceeding. (*a*) The first is by transforming the given equation analytically until it has the appearance of the expanded form of the determinant, e.g., $\alpha(\gamma - \delta) + \beta - \gamma = 0$

or $$f_1(\alpha, \beta)(\gamma - \delta) + f_2(\alpha, \beta) - \gamma = 0.$$

(*b*) The second is by putting the given equation immediately into some determinant form which may suggest itself in a haphazard way, and then transforming this determinant by use of the set of rules.

A systematic method of attack during this stage of the work seems impossible to formulate. A given equation may or may not be expressible in this type of chart. The nature of the results of the investigation depends on the form of the equation and on the ingenuity and experience of the student.

Let us assume that we have obtained the form

$$\begin{vmatrix} \alpha & \beta & 1 \\ 0 & \gamma & 1 \\ 1 & \delta & 1 \end{vmatrix} = 0$$

The transformations of this determinant are similar to those in the case of the nomogram with two straight and one curved scale.

They are:

$$\begin{vmatrix} \dfrac{\alpha}{(1-m)\alpha + m} & \dfrac{m\beta}{(1-m)\alpha + m} & 1 \\ 0 & \gamma & 1 \\ 1 & m\delta & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} \dfrac{\alpha}{(1-m)\alpha + m} & \dfrac{m\beta + n\alpha}{(1-m)\alpha + m} & 1 \\ 0 & \gamma & 1 \\ 1 & m\delta + n & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} \dfrac{m\alpha}{(m-1)\alpha + 1} & \dfrac{m\beta}{(m-1)\alpha + 1} & 1 \\ 0 & m\gamma & 1 \\ 1 & \delta & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} \dfrac{m\alpha}{(m-1)\alpha + 1} & \dfrac{m(\beta + n\alpha)}{(m-1)\alpha + 1} & 1 \\ 0 & m\gamma & 1 \\ 1 & \delta + n & 1 \end{vmatrix} = 0$$

(Suitable for cases in which α lies between 0 and 1, or does not extend far beyond the γ and δ scales.)

$$\begin{vmatrix} \dfrac{\alpha}{(1+m)\alpha - m} & \dfrac{-m\beta}{(1+m)\alpha - m} & 1 \\ 0 & \gamma & 1 \\ 1 & -m\delta & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} \dfrac{\alpha}{(1+m)\alpha - m} & \dfrac{-m\beta + n\alpha}{(1+m)\alpha - m} & 1 \\ 0 & \gamma & 1 \\ 1 & -m\delta + n & 1 \end{vmatrix} = 0$$

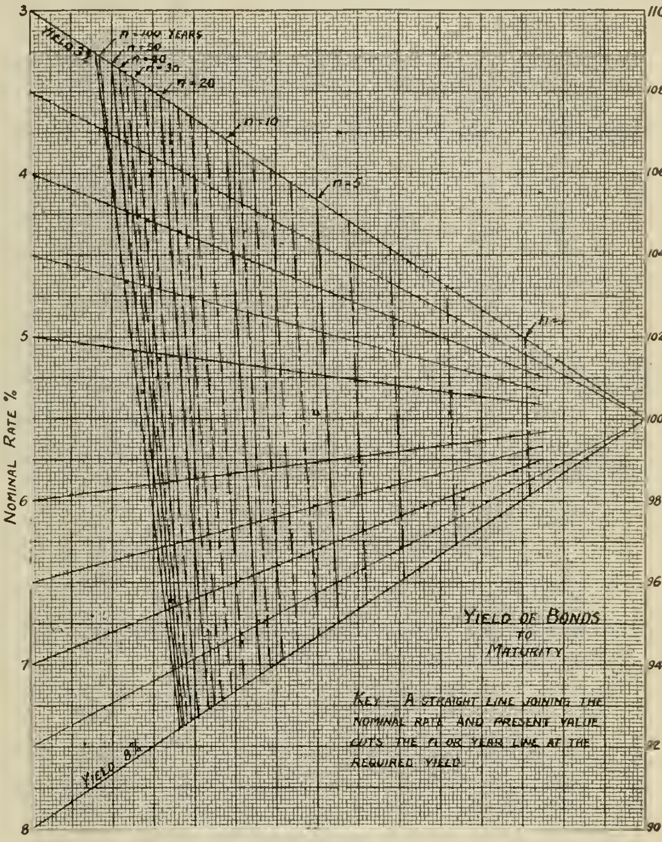

Figure No. 17.

or

$$\begin{vmatrix} \dfrac{-m\alpha}{1-(m+1)\alpha} & \dfrac{-m\beta}{1-(m+1)\alpha} & 1 \\ 0 & -m\gamma & 1 \\ 1 & \delta & 1 \end{vmatrix} = 0$$

$$\begin{vmatrix} \dfrac{-m\alpha}{1-(m+1)\alpha} & \dfrac{-m(\beta + n\alpha)}{1-(m+1)\alpha} & 1 \\ 0 & -m\gamma & 1 \\ 1 & \delta + n & 1 \end{vmatrix} = 0$$

(Suitable for other cases of α.) See also appendix B.

Example. Yield to maturity of bonds given by the equation

$$R\frac{I^n - 1}{I - 1} - PI^n + 100 = 0,$$

where P = present value of \$100 bond.
R = Nominal rate of interest per cent, or yearly dividend on the bond.
n = Number of years to maturity.
I = $1 + \text{yield} = 1 + Y$.

(See figure No. 17)

The yield Y is the interest bearing value of the bond as an investment.

If for instance the returns from the initial investment of P dollars are equivalent to a yield of 6% on this investment, then $I = 1.06$.

Let us first use the analytical method of transforming the given equation to the form

$$f_1(\alpha, \beta)(\gamma - \delta) + f_2(\alpha, \beta) - \gamma = 0.$$

We first obtain:

$$\frac{I^n - 1}{I - 1}(R + P) - P\left(\frac{I^n - 1}{I - 1} + I^n\right) + 100 = 0$$

or

$$\frac{I^n - 1}{I - 1}(R + P) - P\frac{I^{n+1} - 1}{I - 1} + 100 = 0.$$

This gives directly

$$\frac{I^n - 1}{I^{n+1} - 1}(R + P) - P + \frac{100\,(I - 1)}{I^{n+1} - 1} = 0,$$

so that we have the substitutions

$$f_1(\alpha, \beta) = \frac{I^n - 1}{I^{n+1} - 1};\quad f_2(\alpha, \beta) = \frac{100\,(I - 1)}{I^{n+1} - 1};$$

$$\gamma = P\,;\quad \delta = -R;$$

giving the determinant

$$\begin{vmatrix} \dfrac{I^{n-1}}{I^{n+1} + 1} & \dfrac{100\,(I - 1)}{I^{n+1} - 1} & 1 \\ 0 & P & 1 \\ 1 & -R & 1 \end{vmatrix} = 0.$$

Using the second method we may take as our first trial determinant

$$\begin{vmatrix} R & 1 & 0 \\ -100 & \dfrac{I^n - 1}{I - 1} & I^n \\ -P & 0 & 1 \end{vmatrix} = 0$$

We can divide the three rows by R, -100, and $-P$ respectively, and obtain the new form

$$\begin{vmatrix} \dfrac{I^n - 1}{100\,(I - 1)} & \dfrac{I^n}{100} & 1 \\ -\dfrac{1}{R} & 0 & 1 \\ 0 & \dfrac{1}{P} & 1 \end{vmatrix} = 0$$

This would give us the two scales $-\frac{1}{R}$ and $\frac{1}{P}$ perpendicular to each other. It is evident from previous discussion that this may be transformed to give two parallel scales of $-R$ and P. There are two ways of doing this. (1) The first is by comparing the two forms

$$\begin{vmatrix} f_1 & f_2 & 1 \\ 0 & \beta & 1 \\ 1 & \gamma & 1 \end{vmatrix} \quad \text{and} \quad \begin{vmatrix} \dfrac{f_1}{f_2} & \dfrac{1 - f_1}{f_2} & 1 \\ 0 & \dfrac{1}{\beta} & 1 \\ \dfrac{1}{\gamma} & 0 & 1 \end{vmatrix}$$

Here we must solve for

$$\frac{f_1}{f_2} = \frac{I^n - 1}{100\,(I - 1)};\quad \frac{1 - f_1}{f_2} = \frac{I^n}{100},$$

giving

$$f_1 = \frac{I^n - 1}{I^{n+1} - 1};\quad f_2 = \frac{100\,(I - 1)}{I^{n+1} - 1},$$

so that the required form is

$$\begin{vmatrix} \dfrac{I^n - 1}{I^{n+1} - 1} & \dfrac{100\,(I - 1)}{I^{n+1} - 1} & 1 \\ 0 & P & 1 \\ 1 & -R & 1 \end{vmatrix} = 0$$

as already obtained by the analytical method.

(ii) The second way is by determinant transformation which will not be carried out here.

It is found by inspection that the (I, n) network of lines lies between the scales of P and $-R$, i.e. that $(I^n - 1) \div (I^{n+1} - 1)$ is a positive proper fraction. It is therefore unnecessary to reverse the R scale in sign.

For the chart it is desired to show the following ranges of value:—

R from 3 to 8, P from 90 to 110, n and I to suit.

In its present form, the determinant gives the R scale 5 units in length and the P scale 20 units long. Therefore, we must multiply the R scale by the multiple $m = 4$ and the resulting $-4\,R$ scale has a range of values from -12 to -32. We must therefore raise the R scale a distance $n = 90 + 32 = 122$ in order to place the P and R scales on the same level.

The final determinant form becomes

$$\begin{vmatrix} \dfrac{f_1}{(1 - m)\,f_1 + m} & \dfrac{mf_2 + nf_1}{(1 - m)\,f_1 + m} & 1 \\ 0 & \gamma & 1 \\ 1 & m\delta + n & 1 \end{vmatrix} = 0$$

where

$$f_1 = \frac{I^n - 1}{I^{n+1} - 1};\quad f_2 = \frac{100\,(I - 1)}{I^{n+1} - 1};$$

$$\gamma = P\,;\quad \delta = -R\,;\quad m = 4\,;\quad n = 122.$$

After substituting and simplifying, this reduces to

$$\begin{vmatrix} \dfrac{I^n - 1}{4\,I^{n+1} - 3\,I^n - 1} & \dfrac{122\,I^n + 400\,I - 522}{4\,I^{n+1} - 3\,I^n - 1} & 1 \\ 0 & P & 1 \\ 1 & 122 - 4\,R & 1 \end{vmatrix} = 0$$

It is a good policy to expand this final form and check it with the original equation before proceeding with the actual plotting.

To obtain the I or yield lines we must eliminate n from the equations

$$x = \frac{I^n - 1}{4\,I^{n+1} - 3\,I^n - 1};\quad y = \frac{122\,I^n + 400\,I - 522}{4\,I^{n+1} - 3\,I^n - 1};$$

Denoting $(I^n - 1)$ by N, these relations become

$$x = \frac{N}{4\,IN - 3\,N + 4\,I - 4};\quad y = \frac{122\,N + 400\,(I - 1)}{4\,IN - 3\,N + 4\,I - 4};$$

Eliminating N from these equations, we obtain

$$\frac{y}{x} = \frac{122\,N + 400\,I - 400}{N} \quad \therefore \text{ giving } \quad N = \frac{400\,x\,(I - 1)}{y - 122\,x};$$

Substituting this for N in the equation in x above, we get

$$4\,x\,(I - 1) = N\,(1 + 3\,x - 4\,Ix);$$

i.e.,

$$\frac{4\,x\,(I - 1)}{1 + 3\,x - 4\,Ix} = \frac{400\,x\,(I - 1)}{y - 122\,x}$$

which reduces to

$$y = (422 - 400\,I)\,x + 100.$$

We have taken some trouble to effect this elimination of n but have been more than repaid in finding that I lines are straight. We could have plotted the I and n lines by substituting simultaneous values of I and n in the equations in x and y, and evaluating x and y for each case.

On inspecting the chart we see that there are eleven I lines and twenty-two n lines. This would require 242 separate determinations of x and y. However, we may with our present knowledge plot the I lines quite easily. All that remains is to determine a sufficient number of points on the n lines to obtain smooth curves. If we determine the value of x where each n line cuts the integral yield lines (i.e. at yields of 3, 4, 5, 6, 7, 8) we should have no difficulty in plotting. This means 6 × 22 or 132 separate determinations of x only, evidently a great saving in labour.

On inspection of the equation for the I lines.

$$y = (422 - 400\,I)\,x + 100,$$

it is seen that for $x = 0$, $y = 100$ irrespective of the value of I. Therefore all I lines meet on the P scale at $P = 100$.

Again putting $x = 1$, we find that

$$y = 522 - 400\, I = 522 - 400\,(1 + Y)$$
$$= 122 - 400\, Y = 122 - 4 \text{ times yield in percent.}$$

But the R scale is plotted according to this formula ($y = 122 - 4\,R$). Therefore our I linescut the R scale at the corresponding values of R and each I line passing through an R point may be arked as a yield line, with yield the same as the value of R.

For plotting the n lines, we must use the relation

$$x = \frac{I^n - 1}{4\,I^{n+1} - 3\,I^n - 1} = \frac{I^n - 1}{I^n(4\,I - 3) - 1}.$$

The work may be conveniently tabulated with columns for $I = 1.03$, 1.04 etc. and rows for values of n. Values of I^n may be determined and entered in this table, and coupled with each value, and directly underneath it. the corresponding value of $I^n\,(4\,I - 3)$. The value of x may then be read off a slide rule, or, if thought necessary, a table of logaritthms may be resorted to. If any value of x appears to be incorrect on plotting, the table affords a convenient method of checking.

There are some equations in four variables which permit a choice of the network variables α and β. In the example just illustrated this is not the case, as the I and n variables are practically inseparable, unless we are willing to deal with three-variable functions e.g.

$$n \log I = \log\,(R - 100\,I + 100) - \log\,(R - PI + P)$$

If we take the example

$$K^3 - 3\left(\frac{1}{2} - \frac{x_o}{t}\right)K^2 + 6\,np_o\frac{x_o}{t}K - 3\,np_o\left\{\frac{x_o}{t} + 2\left(\frac{1}{2} - \frac{d'}{t}\right)^2\right\} = 0$$

(From Hool and Johnson's Concrete Engineers' Handbook) where the variables are, $K\frac{x_o}{t}$, p_o, $\frac{d'}{t}$. This may be written

$$K^3 - \tfrac{3}{2}\,(1 - 2\,A)\,K^2 + 6\,nABK - 3\,nB\left\{A + \tfrac{1}{2}\left((1 - 2\,C)^2\right)\right\} = 0$$

where

$$A = \frac{x_o}{t};\; B = p_o\;;\; C = \frac{d'}{t}\;;$$

to give the determinant form

$$\begin{vmatrix} f_1\,(\alpha, \beta) & f_2\,(\alpha, \beta) & 1 \\ 0 & \gamma & 1 \\ 1 & \delta & 1 \end{vmatrix} = 0,$$

this equation must be expressed as

$$f_1\,(\alpha, \beta)\,(\gamma - \delta) + f_2\,(\alpha, \beta) - \gamma = 0.$$

We see that there is no term containing both γ and δ here, so that if we wish to have a network of $\alpha\;\beta$ lines, there must be no term containing both γ and δ.

(*a*) Suppose we wish to have a chart with a network for the variables K and B. Our given equation is in a suitable elementary form since it contains no term including both A and C. We therefore rearrange it

$$(K^3 - \tfrac{3}{2}\,K^2) + 3\,A\,(K^2 + 2\,nBK) - 3nAB - \tfrac{3}{2}\,nB\,(1 - 2\,C)^2 = 0$$

The desired form is

$$f_1\,(K, B)\,(A_1 - C_1) + f_2\,(K, B) - A_1 = 0.$$

Therefore we divide through by $\frac{3}{2}\,(K^2 + 2\,nBK)$ and obtain

$$\frac{nB}{K^2 + 2n\,BK}\left\{-\,2A - (1 - 2C)^2\right\} + \frac{2\,K^3 - 3\,K^2}{3\,(K^2 + 2\,nBK)} + 2\,A = 0$$

The determinant form of this is

$$\begin{vmatrix} \dfrac{nB}{K\,(K + 2\,nB)} & \dfrac{K\,(2\,K - 3)}{3\,(K + 2\,nB)} & 1 \\ 0 & -\,2\,A & 1 \\ 1 & (1 - 2\,C)^2 & 1 \end{vmatrix} = 0$$

(*b*) If we wish to have a chart with a network for K and A, we must eliminate the term containing B and C. Dividing through by $3\,nB$ we have

$$K^3 - \tfrac{3}{2}\,K^2 + 3\,AK^2)\,\frac{1}{3\,nB} + (2\,AK - A) - \tfrac{1}{2}\,(1 - 2\,C)^2 = 0$$

This must be of the form

$$f_1\,(K, A)\,(C_1 - B_1) + f_2\,(K, A) - C_1 = 0$$

Therefore we transform thus:—

$$K^2\,(K - \tfrac{3}{2} + 3\,A)\left\{\frac{1}{3\,nB} - \tfrac{1}{2}\,(1 - 2\,C)^2\right\}$$
$$+ \tfrac{1}{2}\,(1 - 2\,C)^2\left\{K^2\,(K - \tfrac{3}{2} + 3\,A) - 1\right\} + (2\,AK - A) = 0$$

or

$$\frac{K^2\,(K - \frac{3}{2} + 3\,A)}{K^2\,(K - \frac{3}{2} + 3\,A) - 1}\left\{-\,\tfrac{1}{2}\,(1 - 2\,C)^2 + \frac{1}{3\,nB}\right\} + \frac{2\,AK - A}{K^2\,(K - \frac{3}{2} + 3\,A) - 1} + \tfrac{1}{2}\,(1 - 2\,C)^2 = 0$$

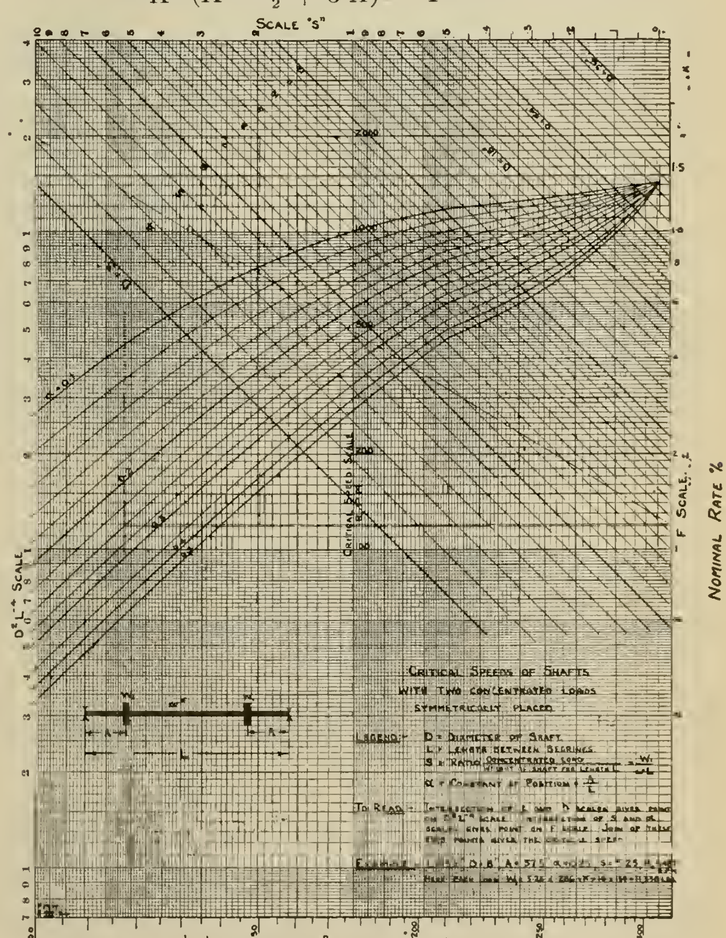

Figure No. 18.

This gives the determinant form

$$\begin{vmatrix} \dfrac{K^2(K-\frac{3}{2}+3A)}{K^2(K-\frac{3}{2}+3A)-1} & \dfrac{A(2K-1)}{K^2(K-\frac{3}{2}+3A)-1} & 1 \\ 0 & -\frac{1}{2}(1-2C)^2 & 1 \\ 1 & -\dfrac{1}{3nB} & 1 \end{vmatrix} = 0$$

which simplifies to

$$\begin{vmatrix} \dfrac{2}{K^2(2K-3+6A)+2} & \dfrac{-2A(2K-1)}{K^2(2K-3+6A)+2} & 1 \\ 0 & \dfrac{1}{3nB} & 1 \\ 1 & -\frac{1}{2}(1-2C)^2 & 1 \end{vmatrix} = 0$$

(c) If we try to use a network for the variables K and C we find it impossible to obtain a suitable form for charting after the terms containing A and B have been eliminated. The chart with the network of K and B lines does not appear as suitable as that with the network for K and A, because the (KB) network extends far beyond the space between the straight line scales for A and C. However, it is a good policy in any example to study with care each alternative in its elementary form before making a choice. No further discussion will be made of this example, since the actual chart does not differ essentially from that for the yield to maturity.

Binary Scales

In certain cases the equation may give a determinant form like

$$\begin{vmatrix} 0 & f(\alpha,\beta) & 1 \\ 1 & \gamma & 1 \\ 2 & \delta & 1 \end{vmatrix} = 0$$

Here the point given by the simultaneous values of α and β is on the line $x = 0$ and is not obtained by the intersection of an α and a β line. This scale along the $x = 0$ line is called a binary scale, and it is evident that every point on this scale will represent an infinite number of simultaneous values of α and β.

In order to facilitate the solution of these nomograms an auxiliary network of lines, made up of a set of α and a set of β lines, is chosen and drawn on the chart in a more or less arbitrary manner. This network must be arranged in such a way that the ordinate of the point of intersection of an α and a β line shall satisfy the relation $y = f(\alpha, \beta)$. Simultaneous values of α and β will thus give us the correct position on the $x = 0$ scale by simply projecting horizontally from this point of intersection of the α and β lines.

Speaking generally, what we have done is chosen arbitrarily two sets of lines

$$F_1(x, y) = \phi_1\alpha \quad \text{and} \quad F_2(x, y) = \phi_2\beta$$

which, on elimination of x, give us the relation $y = f(\alpha, \beta)$. An example should aid in the understanding of the above theoretical discussion. Let us take the formula which the writer has used in connection with some charts for critical speeds of shafts.

$$N_c^2 = K\frac{d^2}{l^4}\left(\frac{A+A_1+P.\,S+P_1S^2}{M+2N+P^2.\,S+M_1+2PP_1.\,S^2+P_1{}^2S^3}\right)$$

$$= K\frac{d^2}{l^4}F.$$

(See figure No. 18)

The expression F is a function of two variables, S and α, the symbols A, A_1, P, P_1, M, M_1, N, denoting various functions of α. Many of these α functions could not be determined easily except by graphical means, so that their functional relationship with α was not obtained algebraically.

The determinant for the equation was obtained by using its logarithmic form

$$2\log N_c = \log(Kd^2 \div l^4) + \log F,$$

which gives

$$\begin{vmatrix} 2 & \log F & 1 \\ 1 & \log N_c - 3 & 1 \\ 0 & \log\dfrac{Kd^2}{l^4 \times 10^6} & 1 \end{vmatrix} = 0$$

in the final form for plotting.

This is a parallel line nomogram with a ($\log N_c - 3$) scale in the centre, and two binary scales (one on each side) for $\log F$ and $\log\left(\dfrac{Kd^2}{10^6 l^4}\right)$.

Since the $\left(\dfrac{K\,d^2}{l^4}\right)$ scale is the simpler of the two, we will examine it first. The binary scale gives

$$y = \log\left(\frac{K}{10^6}\right) + \log(d^2) - \log(l^4)$$

In choosing the auxiliary network of d and l lines, the relation $x + y = \log(d^2)$ was chosen arbitrarily. In this way the d lines were a set of parallel lines inclined at 45° to the horizontal. It follows from this choice that the l lines must satisfy the relationship

$$x + \log\left(\frac{K}{10^6}\right) + \log(d^2) - \log(l^4) = \log(d^2),$$

or

$$x = \log(l^4) - \log\left(\frac{K}{10^6}\right).$$

The auxiliary network is thus made up of sets of d lines and l lines satisfying the equations

$$x + y = \log(d)^2 \quad \text{and} \quad x = \log(l^4) - \log\left(\frac{K}{10^6}\right).$$

The latter set of lines need not be drawn but may be represented by a scale along the bottom of the chart, marked off in accordance with the relation in x. To obtain a point on the binary $\left(\dfrac{d^2}{l^4}\right)$ scale, the point of intersection is obtained between the "d" line and the vertical "l" line. The ordinate of this point of intersection is projected horizontally across to the binary scale along $x = 0$.

Of course the binary scale is not marked in any way. It is simply a line on which points are obtained by the help of the network of "d" and "l" lines.

In order to have the "$l - d$" network within the boundaries of the chart, it may be necessary to modify slightly the arbitrary equations. The general form for these is

$$x = \log(l^4) - \log\frac{K}{10^6} + \text{constant } C$$

$$x + y = \log(d^2) \qquad + \text{constant } C$$

The scale along the X axis may be chosen arbitrarily, both as to its size and the position of the origin. The important point to bear in mind is that the Y scale must conform to the Y scales of the main determinant, and that the binary scale must be placed in conformity with the main determinant also; that is, along the line $x = 0$ in the main determinant.

Turning now to the binary scale for the function F, placed along the line $x = 2$ at the right border of the chart, the network of lines for the variables α and S was chosen as follows:—

An arbitrary scale for S was chosen and drawn along the top of the chart, so that the S lines are perpendicular to this scale, in the same way that the "l" lines are perpendicular to the "l" scale. In other words we have arbitrarily made S equal to some function of x.

To aid in plotting the (αS) network, the binary F scale has been marked off along the right side of the chart, and since our determinant tells us that $y = \log F$, the marking on the scale is logarithmic and similar to the marking of the N_c scale in the centre, with corresponding values reduced in the ratio $\frac{1}{1000}$, because the N_c scale has been plotted from the equation

$$y = \log N_c - 3.$$

The next step is to make a table of values for F for a set of fairly equally spaced values of S, and over a range of values of α required by the problem. The table may be arranged similarly to the table for the yield to maturity chart, with values of α marked along the top for the columns, and values of S marked down the side for the rows. The expression

$$F = \frac{A + (A_1 + P)\,S + P_1S^2}{M + (2\,N + P^2)\,S + (M_1 + 2\,PP_1)\,S^2 + P_1{}^2S^3}$$

is evaluated for each combination of S and α and entered in the table.

These values of F are now plotted as ordinates along the S lines and the points corresponding to each value of α joined by a curved line. We thus obtain a set of α lines and the intersection of any S and any α line will determine a point of intersection which must be projected horizontally across to the binary F scale.

To solve the original equation for N_c a straight line is drawn between the point on the binary $\left(\frac{d^2}{l^4}\right)$ scale and the point obtained on the binary F scale. This line will cut the N_c scale at the satisfying value of N_c.

It may be noted that the simple form of the given equation

$$\begin{vmatrix} 2 & \log F & 1 \\ 1 & \log N_c & 1 \\ 0 & \log\left(K\frac{d^2}{l^4}\right) & 1 \end{vmatrix} = 0$$

was modified slightly. The scale for N_c was dropped three units with respect to the scale for F because the range of values of N_c is between 100 and 4,000 and the range for F is in the neighbourhood of 0.05 to 1.5.

It is readily seen that there are an innumerable number of ways in which the auxiliary networks for the binary scales may be chosen. If possible, a mathematical choice is most suitable as in the case of the $\frac{d^2}{l^4}$ scale.

A choice giving straight lines for at least one of the variables should also be made. Sometimes, however, some arbitrary choice is necessary as in the case of the F scale above. In these cases it is generally possible to make one of the sets a set of parallel straight lines. Curved loci should be avoided because of the labour involved in their construction.

Cases With More Than Four Variables

The general type of determinant for the case of five variables is

$$\begin{vmatrix} f_1\,(\alpha\beta) & f_2\,(\alpha\beta) & 1 \\ \phi_1\,(\gamma\delta) & \phi_2\,(\gamma\delta) & 1 \\ \psi_1\rho & \psi_2\rho & 1 \end{vmatrix} = 0$$

in which the variables α and β form one network, γ and δ form a second network, and ρ is represented by a curved line. The line of collinearity in this case is between a point of intersection in the $(\alpha\beta)$ network, another point on intersection in the $(\gamma\delta)$ network, and a third point on the ρ scale.

The general type of determinant for the case of six variables may be written

$$\begin{vmatrix} f_1\,(\alpha\beta) & f_2\,(\alpha\beta) & 1 \\ \phi_1\,(\gamma\delta) & \phi_2\,(\gamma\delta) & 1 \\ \psi_1\,(\rho\mu) & \psi_2\,(\rho\mu) & 1 \end{vmatrix} = 0.$$

It is difficult to lay down a set of rules for the suitable treatment of these more complicated types of equations, or to codify and tabulate methods of procedure in the work of transformation for charting purposes. A good policy is to pair off the variables whenever possible and in this way make use of binary scales. It is evident, however, that these cases call for a certain amount of ingenuity in their successful treatment. Each new equation which the writer has investigated has opened up new vistas of thought and research, and he does not feel that he has as yet arrived at that happy condition of experience which would justify him in an attempt to assemble these different views into a complete and harmonious picture. He hopes that the picture which has been presented to cover the case of three variables will fulfil the hopes expressed at the outset, and not appear to the reader as too futuristic in design.

Appendix A.

Rule 6—for determinants was the basis of our discussion of alignment charts. This rule states that the area of the triangle between the three points (a_1b_1) (a_2b_2) and (a_3b_3) is

$$\frac{1}{2}\begin{vmatrix} a_1 & b_1 & 1 \\ a_2 & b_2 & 1 \\ a_3 & b_3 & 1 \end{vmatrix}$$

and that if these three points are collinear the relation

$$\begin{vmatrix} a_1 & b_1 & 1 \\ a_2 & b_2 & 1 \\ a_3 & b_3 & 1 \end{vmatrix} = 0$$

will be true.

In a similar manner Rule 5 may be studied and used as a basis for the discussion of "charts of concurrence." This rule states that when three lines

$$\left.\begin{array}{l} a_1x + b_1y + c_1 = 0 \\ a_2x + b_2y + c_2 = 0 \\ a_3x + b_3y + c_3 = 0 \end{array}\right\}$$

are concurrent, then the relation

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = 0$$

will be true.

If therefore we can express a given equation or formula in three variables in this latter determinant form, and arrange the members in such a way that the top row are functions of one variable, the middle row functions of a second variable, and the bottom row functions of the third variable, it will be possible to construct a chart in which there will be a set of straight lines $a_1x + b_1y + c_1 = 0$ for the different values of the first variable, and similar sets of lines for the other two variables. These lines are easily plotted by evaluating a_1, b_1, c_1, for each of the values of the first variable; similarly for the others.

The condition of solution of the given equation is obtained when the lines corresponding to the particular values of the three variables are found to be concurrent. This, it is seen, is the procedure in the case of charts of intersection or concurrence.

It is an interesting fact that the alignment chart corresponding to the determinant form

$$\begin{vmatrix} a_1 & b_1 & 1 \\ a_2 & b_2 & 1 \\ a_3 & b_3 & 1 \end{vmatrix} = 0$$

and the chart of concurrence corresponding to the same determinant form, bear a definite geometric relation to each other.

It may be shown that the polar of the point (a_1b_1) with respect to the circle with unit radius and centre at the origin, is the straight line $a_1x + b_1y - 1 = 0$.

Thus the unit circle has the equation $x^2 + y^2 = 1$ and the polar of any point (x_1y_1) is $xx_1 + yy_1 = 1$; therefore the point (a_1b_1) will have as its polar the line $a_1x + b_1y = 1$.

It is seen then, that the point (a_1b_1) on the scale representing the variable α in the alignment chart, will have as its polar the line $a_1x + b_1y - 1 = 0$. If we write the determinant for the intersection chart in the form

$$\begin{vmatrix} a_1 & b_1 & -1 \\ a_2 & b_2 & -1 \\ a_3 & b_3 & -1 \end{vmatrix} = 0.$$

we see that this polar is identical with the line on the intersection chart representing the first variable. A particular value of the first variable α will determine a point (a_1b_1) on the alignment chart scale, since a_1 and b_1 are functions of α.

The same value of α will determine the line

$$a_1x + b_1y - 1 = 0$$

in the set of α lines in the intersection chart, and the point in the alignment chart is the pole of the line in the intersection chart. It follows also from the theory of poles and polars that when the three points in the alignment chart are collinear the three lines in the intersection chart are concurrent. It is also true that the line of collinearity in the alignment chart is the polar of the point of concurrence in the intersection chart.

We will close with a simple illustration. Take the determinant form

$$\begin{vmatrix} 0 & \alpha & 1 \\ \beta & 0 & 1 \\ \gamma & \gamma & 1 \end{vmatrix} = 0$$

The alignment chart corresponding to this equation is composed of the α scale along the line $x = 0$, the β scale along the line $y = 0$, and the γ scale along the line $x = y$. The "concurrence" chart for this determinant form is made up of the set of α lines $\alpha y - 1 = 0$ or $y = \frac{1}{\alpha}$, the β lines $\beta x - 1 = 0$ or $x = \frac{1}{\beta}$, and the γ lines $\gamma x + \gamma y - 1 = 0$ or $x + y = \frac{1}{\gamma}$. Although this intersection chart is a common type, the corresponding alignment chart in this case is not very popular, because of the position of the scales.

Appendix B

Classification of formulae for the various types of alignment chart, and corresponding determinant forms with adjustments.

I. *Three Parallel Scales.*

General equation $\alpha + \beta + \gamma = 0$. α and γ scales on outside give the determinant form

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & -\frac{1}{2}\beta & 1 \\ 2 & \gamma & 1 \end{vmatrix} = 0.$$

Transformations of this are

$$\begin{vmatrix} 0 & \alpha & 1 \\ \frac{2}{m+1} & \frac{-m\beta}{m+1} & 1 \\ 2 & m\gamma & 1 \end{vmatrix} \qquad \begin{vmatrix} 0 & \alpha & 1 \\ \frac{2}{m+1} & \frac{-m\beta+n}{m+1} & 1 \\ 2 & m\gamma+n & 1 \end{vmatrix}$$

(impossible when $m = -1$)

also

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & m(-\frac{1}{2}\beta) & 1 \\ \frac{2}{2-m} & \frac{m\gamma}{2-m} & 1 \end{vmatrix} \qquad \begin{vmatrix} 0 & \alpha & 1 \\ 1 & m(-\frac{1}{2}\beta)+n & 1 \\ \frac{2}{2-m} & \frac{m\gamma+2n}{2-m} & 1 \end{vmatrix}$$

(impossible when $m = 2$).

If α and β are required on the outside scales, the determinant form used is

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & -\frac{1}{2}\gamma & 1 \\ 2 & \beta & 1 \end{vmatrix} = 0$$

with its transformations. If β and γ are required on the outside scales, use

$$\begin{vmatrix} 0 & \beta & 1 \\ 1 & -\frac{1}{2}\alpha & 1 \\ 2 & \gamma & 1 \end{vmatrix} = 0$$

etc.

II. *Two Parallel Lines and a Diagonal Straight Line.*

General equation $\alpha + \beta\gamma = 0$.

The corresponding elementary determinant forms are

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & \beta & 1 \\ \frac{\gamma}{1+\gamma} & 0 & 1 \end{vmatrix} = 0$$

and

$$\begin{vmatrix} 0 & \alpha & 1 \\ 1 & \gamma & 1 \\ \frac{\beta}{1+\beta} & 0 & 1 \end{vmatrix} = 0.$$

By using different forms of the given equation $\alpha + \beta\gamma = 0$ a set of six determinant forms may be obtained. The forms of the equation used are

$$\alpha + (-\beta)(-\gamma) = 0$$

$$\beta + \alpha\left(\frac{1}{\gamma}\right) = 0 \qquad \beta + (-\alpha)\left(-\frac{1}{\gamma}\right) = 0$$

$$\gamma + \alpha\left(\frac{1}{\beta}\right) = 0 \qquad \gamma + (-\alpha)\left(-\frac{1}{\beta}\right) = 0$$

$$\frac{1}{\beta} + \gamma\left(\frac{1}{\alpha}\right) = 0 \qquad \frac{1}{\beta} + (-\gamma)\left(-\frac{1}{\alpha}\right) = 0$$

$$\frac{1}{\gamma} + \beta\left(\frac{1}{\alpha}\right) = 0 \qquad \frac{1}{\gamma} + (-\beta)\left(-\frac{1}{\alpha}\right) = 0$$

$$\frac{1}{\alpha} + \left(\frac{1}{\beta}\right)\left(\frac{1}{\gamma}\right) = 0 \qquad \frac{1}{\alpha} + \left(-\frac{1}{\beta}\right)\left(-\frac{1}{\gamma}\right) = 0$$

The corresponding elementary determinant forms, with their transformations, may be arranged thus:

$$\begin{vmatrix} 0 & \beta & 1 \\ 1 & \alpha & 1 \\ \frac{1}{1+\gamma} & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} 0 & m\beta & 1 \\ 1 & \alpha & 1 \\ \frac{m}{m+\gamma} & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} 0 & m\beta+n & 1 \\ 1 & \alpha & 1 \\ \frac{m}{m+\gamma} & \frac{n\gamma}{m+\gamma} & 1 \end{vmatrix}$$

$$\begin{vmatrix} 0 & \beta & 1 \\ 1 & -\alpha & 1 \\ \frac{1}{1-\gamma} & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} 0 & m\beta & 1 \\ 1 & -\alpha & 1 \\ \frac{m}{m-\gamma} & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} 0 & m\beta+n & 1 \\ 1 & -\alpha & 1 \\ \frac{m}{m-\gamma} & -\frac{n\gamma}{m-\gamma} & 1 \end{vmatrix}$$

$$\begin{vmatrix} 0 & \frac{1}{\alpha} & 1 \\ 1 & \frac{1}{\beta} & 1 \\ \frac{1}{1+\gamma} & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} 0 & \frac{m}{\alpha} & 1 \\ 1 & \frac{1}{\beta} & 1 \\ \frac{m}{m+\gamma} & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} 0 & \frac{m}{\alpha}+n & 1 \\ 1 & \frac{1}{\beta} & 1 \\ \frac{m}{m+\gamma} & \frac{n\gamma}{m+\gamma} & 1 \end{vmatrix}$$

$$\begin{vmatrix} 0 & \frac{1}{\alpha} & 1 \\ 1 & -\frac{1}{\beta} & 1 \\ \frac{1}{1-\gamma} & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} 0 & \frac{m}{\alpha} & 1 \\ 1 & -\frac{1}{\beta} & 1 \\ \frac{m}{m-\gamma} & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} 0 & \frac{m}{\alpha}+n & 1 \\ 1 & -\frac{1}{\beta} & 1 \\ \frac{m}{m-\gamma} & -\frac{n\gamma}{m-\gamma} & 1 \end{vmatrix}$$

$$\begin{vmatrix} 0 & \frac{1}{\gamma} & 1 \\ 1 & \beta & 1 \\ \frac{1}{1+\alpha} & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} 0 & \frac{m}{\gamma} & 1 \\ 1 & \beta & 1 \\ \frac{m}{m+\alpha} & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} 0 & \frac{m}{\gamma}+n & 1 \\ 1 & \beta & 1 \\ \frac{m}{m+\alpha} & \frac{n\alpha}{m+\alpha} & 1 \end{vmatrix}$$

$$\begin{vmatrix} 0 & \frac{1}{\gamma} & 1 \\ 1 & -\beta & 1 \\ \frac{1}{1-\alpha} & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} 0 & \frac{m}{\gamma} & 1 \\ 1 & -\beta & 1 \\ \frac{m}{m-\alpha} & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} 0 & \frac{m}{\gamma}+n & 1 \\ 1 & -\beta & 1 \\ \frac{m}{m-\alpha} & -\frac{n\alpha}{m-\alpha} & 1 \end{vmatrix}$$

NOTE: If the variable α or β, or both, have values extending through zero, the determinants containing reciprocal fuctions $\frac{1}{\alpha}$ and $\frac{1}{\beta}$ may be used after a slight modification.

Thus

$$\begin{vmatrix} 0 & \frac{1}{\alpha} & 1 \\ 1 & \frac{1}{\beta} & 1 \\ \frac{1}{1+\gamma} & 0 & 1 \end{vmatrix} \rightarrow \begin{vmatrix} 0 & 1 & \alpha \\ \beta & 1 & \beta \\ \frac{1}{1+\gamma} & 0 & 1 \end{vmatrix}$$

$$\rightarrow \begin{vmatrix} 0 & 1 & (\alpha+n) \\ \beta & 1 & (\beta+n) \\ \frac{1}{1+\gamma} & 0 & 1 \end{vmatrix} \rightarrow \begin{vmatrix} 0 & \frac{1}{\alpha+n} & 1 \\ \frac{\beta}{\beta+n} & \frac{1}{\beta+n} & 1 \\ \frac{1}{1+\gamma} & 0 & 1 \end{vmatrix} = 0$$

If the α and γ scales are required on the parallel lines, this may be accomplished by writing the equation $\alpha + \gamma\beta = 0$, and interchanging the β and γ in the first four forms. In a similar manner may the β and γ variables be interchanged in the last two forms. If the parallel scales are running in the wrong direction the signs of both may be changed.

Thus

$$\begin{vmatrix} 0 & \beta & 1 \\ 1 & -\alpha & 1 \\ \frac{1}{1-\gamma} & 0 & 1 \end{vmatrix} \rightarrow \begin{vmatrix} 0 & -\beta & 0 \\ 1 & \alpha & 1 \\ \frac{1}{1-\gamma} & 0 & 1 \end{vmatrix}$$

It is evident that any pair of the variables may be chosen for the parallel scales. If it is found that a given choice places the diagonal scale outside the parallel scales, this condition may be remedied by using the determinant form having the sign of one of these variables changed.

III. Collinearity of the origin, a point on a straight line scale for one variable, and a point given by the intersection of two sets of lines for the other two variables.

General equation $\alpha + \beta\gamma = 0$; more general equation is

$$f_1(\alpha\beta) + \gamma f_2(\alpha\beta) = 0.$$

Determinant forms are given for $\alpha + \beta\gamma = 0$ only. Some of these (in which γ appears in the top row) are unsuitable for the more general form

$$f_1(\alpha\beta) + \gamma f_2(\alpha\beta) = 0.$$

$$\begin{vmatrix} \alpha & \beta & 1 \\ -\gamma & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} \alpha & -\beta & 1 \\ \gamma & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} \beta & \alpha & 1 \\ -\frac{1}{\gamma} & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} \beta & -\alpha & 1 \\ \frac{1}{\gamma} & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix}$$

$$\begin{vmatrix} \frac{1}{\alpha} & \frac{1}{\beta} & 1 \\ -\frac{1}{\gamma} & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} \frac{1}{\alpha} & -\frac{1}{\beta} & 1 \\ \frac{1}{\gamma} & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} \frac{1}{\beta} & \frac{1}{\alpha} & 1 \\ -\gamma & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} \frac{1}{\beta} & -\frac{1}{\alpha} & 1 \\ \gamma & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix}$$

These all have the straight scale for the γ variable. The β variable may be placed on this scale by interchanging the two variables, or by using the original equation $\alpha + \gamma\beta = 0$.

$$\begin{vmatrix} \beta & \frac{1}{\gamma} & 1 \\ -\alpha & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} \beta & -\frac{1}{\gamma} & 1 \\ \alpha & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} \frac{1}{\beta} & \gamma & 1 \\ -\frac{1}{\alpha} & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} \frac{1}{\beta} & -\gamma & 1 \\ \frac{1}{\alpha} & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix}$$

In these forms the straight line represents the α variable. In making a choice of one of the above forms it is advisable to decide first which two of the three variables will be given, and which one solved for. One of the given variables should then be assigned to the straight line scale along $y = 1$, and the other given variable assigned to the ordinate (for the point of intersection). Thus if the given variables are β and γ, we may choose one of the forms

$$\begin{vmatrix} \alpha & \beta & 1 \\ -\gamma & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} \alpha & -\beta & 1 \\ \gamma & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} \frac{1}{\alpha} & \frac{1}{\beta} & 1 \\ -\frac{1}{\gamma} & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} \frac{1}{\alpha} & -\frac{1}{\beta} & 1 \\ \frac{1}{\gamma} & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix}$$

In this way the third variable is made to fit within the bounds of the chart.

The vertical and horizontal scales may be chosen independently as regards their size. In addition to this adjustment, the variable along the ordinate may be expanded or contracted (to fit in between the origin and the line $y = 1$) and the straight line scale may also be moved laterally any desired amount. These transformations are given for one determinant form only. The other forms may be developed as desired, by symmetry.

$$\begin{vmatrix} \alpha & \beta & 1 \\ -\gamma & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} m\alpha & m\beta & 1 \\ -\gamma & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} \quad \begin{vmatrix} m(\alpha+n\beta) & m\beta & 1 \\ -\gamma+n & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix}$$

IV. *Two Perpendicular scales and an Inclined Straight Scale.*
General equation $\alpha + \beta + \gamma = 0$. The variables may be interchanged as in the case of type I (three parallel scales). Elementary form of determinant

$$\begin{vmatrix} -\frac{1}{\alpha} & -\frac{1}{\alpha} & 1 \\ 0 & \frac{1}{\beta} & 1 \\ \frac{1}{\gamma} & 0 & 1 \end{vmatrix} = 0.$$

Transformations to alter the position and size of the scales are:

$$\begin{vmatrix} \frac{-1}{\alpha-m-n} & \frac{-1}{\alpha-m-n} & 1 \\ 0 & \frac{1}{\beta+m} & 1 \\ \frac{1}{\gamma+n} & 0 & 1 \end{vmatrix} \qquad \begin{vmatrix} \frac{-k}{\alpha-m-n} & \frac{-l}{\alpha-m-n} & 1 \\ 0 & \frac{l}{\beta+m} & 1 \\ \frac{k}{\gamma+n} & 0 & 1 \end{vmatrix}$$

$$\begin{vmatrix} \frac{1}{\alpha+m+n} & \frac{1}{\alpha+m+n} & 1 \\ 0 & \frac{1}{m-\beta} & 1 \\ \frac{1}{n-\gamma} & 0 & 1 \end{vmatrix} \qquad \begin{vmatrix} \frac{k}{\alpha+m+n} & \frac{l}{\alpha+m+n} & 1 \\ 0 & \frac{l}{m-\beta} & 1 \\ \frac{k}{n-\gamma} & 0 & 1 \end{vmatrix}$$

The perpendicular scales may be altered in inclination to each other thus:

$$\begin{vmatrix} \frac{1+k}{\alpha-m-n} & \frac{-1}{\alpha-m-n} & 1 \\ \frac{k}{\beta+m} & \frac{1}{\beta+m} & 1 \\ \frac{1}{\gamma+n} & 0 & 1 \end{vmatrix} \qquad \begin{vmatrix} \frac{1+k}{\alpha+m+n} & \frac{1}{\alpha+m+n} & 1 \\ \frac{k}{m-\beta} & \frac{1}{m-\beta} & 1 \\ \frac{1}{n-\gamma} & 0 & 1 \end{vmatrix}$$

The horizontal and vertical scales may be adjusted as before.

V. *Two Parallel Scales and One Curved Scale.*
General equation $\alpha_1 + \beta + \alpha_2\gamma = 0$.
The corresponding determinants for this are

$$\begin{vmatrix} \frac{1}{1+\alpha_2} & \frac{-\alpha_1}{1+\alpha_2} & 1 \\ 0 & \gamma & 1 \\ 1 & \beta & 1 \end{vmatrix} \qquad \begin{vmatrix} \frac{1}{1-\alpha_2} & \frac{\alpha_1}{1-\alpha_2} & 1 \\ 0 & \gamma & 1 \\ 1 & -\beta & 1 \end{vmatrix}$$

The transformation for these are

$$\begin{vmatrix} \frac{1}{1+m\alpha_2} & \frac{-m\alpha_1}{1+m\alpha_2} & 1 \\ 0 & \gamma & 1 \\ 1 & m\beta & 1 \end{vmatrix} \qquad \begin{vmatrix} \frac{1}{1+m\alpha_2} & \frac{n-m\alpha_1}{1+m\alpha_2} & 1 \\ 0 & \gamma & 1 \\ 1 & m\beta+n & 1 \end{vmatrix}$$

$$\begin{vmatrix} \frac{1}{1-m\alpha_2} & \frac{m\alpha_1}{1-m\alpha_2} & 1 \\ 0 & \gamma & 1 \\ 1 & -m\beta & 1 \end{vmatrix} \qquad \begin{vmatrix} \frac{1}{1-m\alpha_2} & \frac{m\alpha_1+n}{1-m\alpha_2} & 1 \\ 0 & \gamma & 1 \\ 1 & -m\beta+n & 1 \end{vmatrix}$$

VI. *Two Perpendicular Scales and One Curved Scale.*
General equation $\alpha_1 + \beta + \alpha_2\gamma = 0$.
The corresponding elementary forms are

$$\begin{vmatrix} -\frac{\alpha_2}{\alpha_1} & -\frac{1}{\alpha_1} & 1 \\ 0 & \frac{1}{\beta} & 1 \\ \frac{1}{\gamma} & 0 & 1 \end{vmatrix} \qquad \begin{vmatrix} \frac{\alpha_2}{\alpha_1} & -\frac{1}{\alpha_1} & 1 \\ 0 & \frac{1}{\beta} & 1 \\ -\frac{1}{\gamma} & 0 & 1 \end{vmatrix}$$

These are really identical when plotted except that they are in different quadrants of the co-ordinate plane.
Transformations are

$$\begin{vmatrix} \frac{-\alpha_2}{\alpha_1-n\alpha_2-m} & \frac{-1}{\alpha_1-n\alpha_2-m} & 1 \\ 0 & \frac{1}{\beta+m} & 1 \\ \frac{1}{\gamma+n} & 0 & 1 \end{vmatrix}$$

Here n or m may be chosen to translate the γ or β scale across the origin in cases where the α scale lies outside the quadrant for β and γ. m and n may also be chosen to eliminate zero values in the denominators.

$$\begin{vmatrix} \frac{-(\alpha_2+k)}{\alpha_1-n\alpha_2-m} & \frac{-1}{\alpha_1-n\alpha_2-m} & 1 \\ \frac{k}{\beta+m} & \frac{1}{\beta+m} & 1 \\ \frac{1}{\gamma+n} & 0 & 1 \end{vmatrix}$$

This form may be used when it is desired to incline the β and γ scales at any required angle with each other. If the angle is made quite acute the scales may be translated some distance from the origin (the origin not necessarily shown on the paper). In this way the chart may be made to resemble the charts of type V.

VII. *Two Parallel Scales and a Network for Two More Variables.*
General equation $f_1(\alpha\beta) + \gamma + f_2(\alpha\beta) \cdot \delta = 0$.
Corresponding determinant is

$$\begin{vmatrix} \frac{1}{1+f_2(\alpha\beta)} & \frac{-f_1(\alpha\beta)}{1+f_2(\alpha\beta)} & 1 \\ 0 & \delta & 1 \\ 1 & \gamma & 1 \end{vmatrix}$$

Treatment for this type is the same as for type V, by substituting

$f_1(\alpha\beta)$ for α_1; $f_2(\alpha\beta)$ for α_2; γ for β; and δ for γ;

VIII. *Two Perpendicular Scales and a Network for Two More Variables.*
Similar treatment to that of type VI.

IX. *Two Parallel Scales and a Third Parallel (Binary) Scale.*
General equation $f(\alpha\beta) + \gamma + \delta = 0$.
Corresponding determinant form

$$\begin{vmatrix} 0 & f(\alpha\beta) & 1 \\ 1 & -\frac{1}{2}\gamma & 1 \\ 2 & \delta & 1 \end{vmatrix}$$

The treatment of this type is similar to that of type I.
All cases containing binary scales may be treated similarly to the corresponding types with single scales.

Cross Index for Classifying Equations

Equation Form	*Type of Chart*
$\alpha + \beta + \gamma = 0$	I, IV.
$\alpha + \beta\gamma = 0$	II, III, I after taking logarithms.
$\alpha_1 + \beta + \alpha_2\gamma = 0$	V, VI.
$f_1(\alpha\beta) + \gamma + f_2(\alpha\beta) \cdot \delta = 0$	VII, VIII.
$f(\alpha\beta) + \gamma + \delta = 0$	IX (similar to type I).
$f(\alpha\beta) + \phi(\gamma\delta) + \psi(\mu\nu) = 0$	Similar to type I.

Exponential equations reduced to logarithmic form.
Equations containing products also reduced to logarithmic form whenever possible.

Determination of the Constituents of Concrete

A. K. Light, B.Sc.,
Chemist, Testing Laboratories, Department of Public Works, Ottawa.

Paper read before the Ottawa Branch of the Society of Chemical Industry, November 21st, 1929.

The importance underlying the following method is that it places in the hands of the engineer a means whereby he can have a check made on any concrete mix in order to ascertain whether it was made according to specifications. Likewise, it may be used for the purpose of investigating causes of failure in concrete.

It is frequently of great interest, especially in the case of failures, to know the type and proportions of the various constituents, viz. cement, sand, gravel or broken stone, entering into the composition of the concrete. At present in our department records are kept of all this data, but unfortunately in past years, and even at present in works not under our jurisdiction, no records are kept. Thus when it is desirable to know the mixture in any given specimen of concrete, mechanical and chemical examinations are resorted to in an endeavour to arrive at the necessary data.

The examination and separation of a piece of concrete into its various constituents, at first thought, seems comparatively simple, but upon consideration proves to be extremely difficult. In the first place, the sample may not truly represent the mass of the concrete, for due to segregation of aggregates, non-uniformity of batches or variations in placing, the homogeneity of the mass may vary greatly. However, examination, as far as practicable, of the mass, and a careful selection of a large composite sample taken from the various parts of the concrete, may obviate this variation to a great extent. The next problem is in the actual chemical composition of the constituents themselves, for they all contain silica, ferric oxide, alumina, lime, magnesia, the alkalies and small amounts of other substances, in varying proportions, and though it is easy to determine the amount of these compounds "in toto" in the concrete, it is very difficult to apportion them to the cement and aggregates constituting the concrete.

The method given in Bulletin 61 of the Iowa State College, "Estimation of the Constituents of Portland Cement Concrete," by Geo. W. Burke, goes a long way towards solving the problem, but offers many pit-falls, and is only accurate under certain well-defined conditions. It is however, well worthy of consideration and gives results which are at least approximate.

An outline of the method is as follows:—

The original large representative sample is carefully broken into 2 inch or smaller pieces and reduced to one of about 1,000 to 1,500 grams, which is heated in a muffle furnace for about 3 hours at a temperature of about 600 to 700°C. Dehydration of the cement takes place at this temperature allowing the coarse aggregate to be separated by hand from the sand and cement, and cleaned by brushing and scraping. Separation is then made on the ¼-inch sieve, the portion passing being classified as the "sand-cement mixture." Part of this mixture is analysed for silica and lime, while the balance is used to obtain, as nearly as possible, a representative sample of the original sand. This is obtained by rubbing the mixture in a mortar with a rubber-faced pestle and sieving until the sand portion is free of cement. This sand is then analysed for silica, and lime, and by making calculations with the percentages of either of these constituents in the sand-cement mixture, and also the assumed percentages in the cement, the proportions of sand and cement in the mixture may be arrived at.

The pitfalls and possible sources of error in the method as found by ourselves, and borne out by H. F. Kreige of the State Highway Commission, Jefferson City, Mo., and L. G. Carmick of the Division of Tests, U. S. Bureau of Public Roads, may now be discussed.

In breaking down the original sample to 2-inch size it is difficult to prevent the breaking of the aggregate also, especially if it is soft. At a temperature of 600 to 700°C. limestone and dolomite are liable to be partially calcined, become friable, and thus break down readily with the rubbing, going into the sand-cement mixture or even into the discarded cement portion, and thus impairing the results. Similarly, gravels of other origins may disintegrate somewhat at this temperature due to expansion stresses, expulsion of water or unsoundness due to weathering. If a lower temperature is used the cement is not completely dehydrated and is difficult to separate from the aggregate. The complete separation of the sand, especially in the fine particles, is difficult to achieve and is another source of error. The presence of rotten or weathered aggregate is a very common occurrence and the percentage often runs high. This material is very friable, as a rule, especially after heating at the temperature used here.

Where the sand is non-calcareous and little affected by dilute hydrochloric acid, great improvement in the results is obtained by washing the separated sand with dilute acid in order to remove any adhering cement.

To sum up: In order to obtain accurate results by this method the aggregates, both coarse and fine, must be resistant to the temperature used, must be sound and not easily crumbled, and not appreciably affected by hydrochloric acid, otherwise the results will be vitiated in proportion to the extent that these requirements are not fulfilled. In any case it is most necessary to use every care and precaution in carrying out the method in order to obtain the best results.

A method which gives the ratio of cement to aggregates, but does not give a separation of the aggregates has been proposed by H. F. Kriege, already mentioned. We have checked this method in many ways by the use of known mixtures of cement and aggregates of different types and have found it to give very good results. We have also used it in checking the cement content of some concretes which showed signs of disintegration in a very short time after being placed, in order to ascertain whether the contractor made the mix as rich in cement as specified.

This method is based on the difference in the state of combination of the silica in the cement and in the aggregate. In the former it is present as mono-, di-, and tri-calcium silicates, while in the latter it is present either free or combined as some impure aluminium silicate. The silica may therefore be separated from the calcium silicates by chemical treatment which will have little or no effect on it either in the free state or combined in the aluminium silicates. The only types of Portland cement concrete we found that failed to give us dependable results under this method where those which contained either diatomite or basic slag or similar materials. The bulk of the silica in diatomite is readily soluble in alkali, while the basic slags liberate silicic acid upon treatment with dilute hydrochloric acid.

Strict precautions must be taken in the procuring and preparation of the sample as with the method already described. The ultimate sample taken for analysis should be ground to pass at least a 100 mesh sieve, and care should be taken that none is lost during the grinding.

The method of analysis is as follows:—

Weigh triplicate samples of 10 grams into 250 c.c. beakers, moisten with hot water and stir to prevent the formation of lumps. Add slowly, with thorough stirring, 100 c.c. of 1:3 hydrochloric acid, and after all effervescence has ceased, allow the mixture to settle until the supernatent liquid is clear. Decant through a prepared Gooch crucible, retaining as much of the residue as possible in the beaker, and wash the residue with hot water, twice by decantation. Add 75 c.c. of a 4 per cent solution of sodium hydroxide to the residue and heat to about 75 or 80°C., stirring constantly. Hold the mixture at this temperature for 10 to 15 minutes and then allow to settle. Filter and wash by decantation through the same Gooch crucible into the acid solution previously filtered. Finally transfer all the residue to the crucible and wash thoroughly with hot water. The suction on the Gooch crucible should be regulated so that filtration is not more rapid than a dropping rate. Quantitatively transfer the solution from the filter flask to a suitably sized beaker and evaporate the solution to dryness. After baking on the hot-plate, moisten the residue with concentrated hydrochloric acid, evaporate and bake again. Take up the residue with about 75 c.c. of 1:4 hydrochloric acid and boil until all soluble material is in solution. Filter, wash well with both hot dilute hydrochloric acid and hot water and finally ignite the residue in a platinum crucible and weigh. Moisten the residue with a few drops of concentrated sulphuric acid, and add 10 to 15 c.c. hydrofluoric acid. Evaporate to dryness, ignite and weigh again, the loss in weight representing the silica liberated from the cement in the original concrete mixture. This weight divided by the average silica content of Portland cement—about 21.5 per cent—gives the percentage of cement in the original concrete.

The first method described has the advantage of allowing an examination of the aggregate being made; its petrographic nature, granulometric analysis and other physical properties may be determined. The second method offers a means of determining the proportion of cement to aggregate. By combining these two methods it is possible to arrive at a fairly accurate means of making a thorough examination of a specimen of concrete and of determining fairly closely the proportions of the mix used in its making, subject, of course, to such vitiating circumstances as have already been described. One of the chief controlling factors in determining the strength of concrete, is the amount of water used in proportion to the quantity of cement, and it is unfortunate that there is no method of determining how much of this all important constituent was used in making the concrete. However, such data as the strength and density of the concrete, nature and grading of the aggregate, and quantity of cement should go a long way towards solving the problem of why the concrete failed.

Too much importance cannot be placed on the value of such information as may be acquired from these methods, not only from the point of view of checking up on the contractor, but from the fact that the knowledge of the causes of a failure may obviate a recurrence of the same conditions in future structures.

VOLUME XIII AUGUST 1930 No. 8

The Fourth Plenary Meeting of Council

The fourth Plenary Meeting of Council will be held at Headquarters on Monday, Tuesday and Wednesday, September 22nd, 23rd and 24th, 1930. Facilities will be provided, as on previous occasions, for the attendance of Councillors from all parts of the Dominion, and it is expected that as heretofore the gathering will be attended by a large majority of the members of Council.

The Plenary meetings of Council have, in the past, proved to be a most powerful influence in welding together The Institute's Branches and the membership at large, since they afford a most favourable opportunity for the expression of different points of view and result in the working out of Institute policies on the basis of the greatest possible benefit to the membership at large. They are of particular advantage in promoting the formation and renewal of personal acquaintanceships between members of Council. They permit of personal discussion, and in many cases enable Councillors who cannot attend other Council meetings to familiarize themselves with the work of the Headquarters' staff, and with the activities of Council, in a way which would otherwise be impossible. While all members of Council receive the minutes of Council meetings, there are always a considerable number for whom the Plenary meeting is the only occasion on which they can get first-hand acquaintance with the Council's business, so as to realize the extent and complexity of the many questions on which Council has to render decisions.

Among the topics to be dealt with at the forthcoming meeting may be named the financial problems before The Institute; the policy to be adopted regarding specialized branches of engineering and the formation of professional sections of branches; the relations between The Institute and the Provincial Professional Associations; the publications of The Institute, and the work of the various special committees which are studying questions of importance. A period will naturally be allotted for general business, at which time Councillors will be at liberty to bring up matters which they consider should be dealt with by Council, but which have not already been included in the agenda. It is thought that individual members of The Institute can render a service by suggesting to the Councillors of their respective Branches questions of importance which they think should receive consideration at the Plenary meeting.

There is every reason to believe that the Plenary meeting of 1930 will be as well attended and as fruitful of results as those held in 1927, 1928, and 1929.

Notes on Education, Employment and Remuneration

Discussions regarding engineering education, professional employment and the resulting remuneration are always of interest to an engineer, whatever the branch of the profession in which he may be engaged. Such matters form an important part of The Institute's activities, as is evidenced by the work of our Employment Service Bureau, and the enquiries which are being conducted by The Institute's committees on Engineering Education and on Classification and Remuneration.

The recent successful meeting held in Montreal by the Society for the Promotion of Engineering Education, a body with which The Institute has always had cordial relations, is a reminder of the admirable work done by that Society in collecting and discussing information on its special subject and in the preparation of the reports contained in its proceedings. The findings of the Society's committees during the past six years have just been published in the form of a comprehensive report* collecting the bulletins issued during the progress of its investigations. These deal primarily with engineering education, but include incidentally a mass of interesting particulars regarding the career of the young engineer after graduation.

The reports are of course based on conditions existing in the United States, although many comparative data are given in respect to European and Canadian conditions. The attitude of practising engineers and industrial managers towards the younger members of the profession and the opinions of engineering graduates and non-graduates on the present situation have been carefully studied.

The results of the present system of engineering education and training have been examined in detail as regards the careers and earnings of certain typical groups of engineering graduates. The resulting information has increasing value, for as time goes on the proportion of non-graduate to graduate engineers tends steadily to diminish.

It will be interesting to see how far the results of the enquiry now being made by The Institute's Committee on Remuneration will bear out the figures shown by the Society for the Promotion of Engineering Education

*Report of the Investigation of Engineering Education 1923-29. Vol. I. Pittsburgh. Office of the Secretary S.P.E.E., University of Pittsburgh, 1930.

reports. These were based on about five thousand replies, and indicate that the median rate for engineering graduates one year out of college was about $1,800 per annum, rising in five years to about $2,800 and at ten years to some $4,000 per annum. Individual replies naturally showed a wide range above and below these figures.

The Institute's questionnaire, if replies are received from a sufficient proportion of the members, will afford material for another valuable report, outlining Canadian conditions, and will contribute considerably to our knowledge of the reasons for the alleged migration of young engineers to other countries.

It is noteworthy that many members of The Institute now resident in the United States are desirous of returning to Canada. Recent investigations have shown that the percentage of technical graduates of Canadian universities now living in the United States is by no means so large as had been supposed, and the number is gradually being reduced, largely through the activities of such bodies as The Engineering Institute and the Technical Service Council.

It must be remembered, however, that the compensation of engineers is mainly controlled by supply and demand. Favourable conditions as regards engineering employment existed during 1928 and 1929, as is shown by the reports of our Employment Service Bureau. While this satisfactory activity has not been continued during 1930, and opportunities are less numerous now than then, it does not appear from the information on hand that any considerable number of our members are at present looking for positions. It is somewhat remarkable that the number of non-members who desire to apply for employment through The Institute's Service Bureau is just now larger than the number of Institute members who are enquiring. It would thus seem that unemployment in Canada as regards our members is not at this time a really serious factor.

It is, however, well to realize that under present conditions there is but little work available for engineers arriving in Canada from outside of the country. During the past few years the publicity given to engineering and industrial achievements in Canada has resulted in a considerable influx of young engineers from Britain and the continent of Europe, and this still continues. It has been found desirable, therefore, to take steps to bring this situation to the attention of the European representatives of the Dominion and Provincial governments, the colonization departments of the Canadian railways and other authorities from whom information is asked by intending immigrants. These officers have been requested to state that at present the prospects in Canada for the employment of engineers from other countries are not favourable, since the supply of our own men is, just now, more than adequate to meet the demand.

The cutting down of industrial activities in Canada, while quite marked, has been less serious than in Britain or the United States, and has led to the present situation as regards employment, of which engineers in Canada are fully aware. Employers naturally take the very reasonable view that in such opportunities as do occur, preference should be given to our own men.

The work of The Institute's Service Bureau and the publication of the E–I–C News has been of great value in establishing and maintaining cordial relations with the managers of industrial concerns and others interested in the employment of engineers.

The task of our Employment Bureau would be greatly facilitated if members, whether looking for employment or not, would comply with the request made in the E–I–C News for July 24th, 1930, by obtaining, filling in and returning to Headquarters, the Institute's registration forms, thus placing Headquarters in possession of a definite record of their professional careers and experience. It is only in this way that the office can be enabled to reply adequately to enquiries received for men capable of undertaking special work or qualified for particularly responsible positions.

Publications of Other Engineering Societies

From time to time announcements have appeared in The Engineering Journal regarding the exchange arrangements which exist between The Engineering Institute of Canada and the founder engineering societies of the United States, whereby members of The Institute may secure the publications of the American societies at the same rate as charged to members of those societies. A list of these publications, with the amounts charged, is given below and subscriptions may either be sent direct to New York or through headquarters of The Institute.

OBITUARIES

Henry Alexander Bowman, M.E.I.C.

It is with deep regret that the death of Henry Alexander Bowman, M.E.I.C., which occurred on June 8th, 1930, at Winnipeg, Man., is reported.

Mr. Bowman was born in London, England, on August 13th, 1855, and received his education by private tuition, subsequently joining the Royal Artillery, London, in which he held the rank of captain.

Coming to Canada in 1895, Mr. Bowman settled on a farm in Petersfield, Man., but in 1902 he became a member of the engineering staff of the Manitoba Department of Public Works, and has been connected with the department since that time. In 1912 he was acting Deputy Minister of Public Works, and in 1918 he was made acting chief engineer. During the year 1918 Mr. Bowman was

H. A. BOWMAN, M.E.I.C.

made chief engineer of the Reclamation Branch of the department, which office he filled until his death.

Mr. Bowman was intensely interested in the education of young engineers, and particularly in the development of young men engaged in engineering work, who had not had the advantage of university training. To the end that such young men might be encouraged to study, he instituted a series of examinations for juniors in his department, and contributed substantial cash prizes to be awarded to those who took high standings in the examinations.

Mr. Bowman was for two years chairman of the Board of Examiners of the Association of Professional Engineers of Manitoba.

He joined The Engineering Institute as an Associate Member on May 2nd, 1907, becoming a full Member on May 6th, 1930. Mr. Bowman was a charter member of the Winnipeg Branch of The Institute, and from its inception until extreme pressure of public duties and failing health prohibited, was an active member and regular attendant at Branch meetings.

William Newton Ryerson, M.E.I.C.

Deep regret is expressed in recording the death of William Newton Ryerson, M.E.I.C., which occurred at New York on July 7th, 1930.

Mr. Ryerson was born in New York, N.Y. on December 7th, 1874, and attended the New York public schools and the Columbia Grammar school, where he was graduated in 1892. He entered the school of mines at Columbia University the following year, and graduated in 1896 with the degree of electrical engineer.

Following his graduation, Mr. Ryerson was employed by the Sprague Electric Elevator Company, Bloomfield, N.J., and later was with the Western Electric Company, New York. In October 1898, he became associated with the Metropolitan Street Railway Company of New York, on construction and power work and substation operation, remaining with that company until June 1901, when he left to form a connection with the Manhattan Company as chief operator of their steam electric generating station. Mr. Ryerson's chief interest at that time seemed to be on electric railways and subways, and in October 1901, he became superintendent of the substations for the Interborough Rapid Transit, with which concern he remained until April 1905. About that time, some of the big hydro developments on the Canadian side of Niagara Falls were started, and Mr. Ryerson became assistant superintendent of construction for the Niagara Construction Company, and later in the same year, superintendent of construction for the Ontario Power Company, Niagara Falls, Ont., which position he held until January 1909.

At that time Mr. Ryerson became general manager and chief engineer, and also a director of the Great Northern Power Company, Duluth, Minn., which position he held for over thirteen years, and it was here that he became well known among the light and power companies of the country, serving on several committees of the National Electric Light Association. In 1922 Mr. Ryerson joined the management department of Day and Zimmermann, Inc., engineers, of Philadelphia, Pa., and in January 1925 he became assistant to the vice-president in charge of operations and engineering of the United Gas Improvement Company of Philadelphia. When the Trojan Engineering Corporation was organized in September 1928 Mr. Ryerson became its president, which position he held at the time of his death.

Mr. Ryerson was a Fellow of the American Institute of Electrical Engineers, and a member of the American Society of Mechanical Engineers, the National Electric Light Association, the International World Power Conference, and the American Gas Association.

He joined The Engineering Institute of Canada as a Member on December 12th, 1907.

Edward Herbert Pense, A.M.E.I.C.

Members will learn with regret of the death at Welland, Ont., on June 6th, 1930, of Edward Herbert Pense, A.M.E.I.C.

Mr. Pense was born at Kingston, Ont., on June 16th, 1880. He graduated from the Royal Military College in 1900, and received the degree of B.Sc. in mining from Queen's University in 1903.

After some months spent on railway location and construction work, he entered the service of the Department of Public Works in 1904, as an assistant engineer, remaining with the Department until 1916, when he went overseas with the rank of company commander in the Canadian Engineers, and served in France until the end of the War. On his return to Canada, Mr. Pense was employed on the St. Lawrence Ship Canal survey from 1920 to 1923, when he was transferred to the staff of the Welland Ship Canal. Here he was employed as assistant engineer on sections 7 and 8 until his death.

Mr. Pense was a well-read scholarly man of varied attainments, and was also interested in athletics.

He joined the Canadian Society of Civil Engineers as a Student on October 11th, 1900, and became an Associate Member on December 10th, 1910.

PERSONALS

J. P. A. Laforest, A.M.E.I.C., has been appointed city engineer of Granby, Que. Mr. Laforest was formerly city engineer of Longueuil, Que.

C. G. Clark, S.E.I.C., is assistant to the chief engineer, Atlantic Sugar Refineries, Saint John, N.B. Mr. Clark graduated from the Nova Scotia Technical College in 1930 with the degree of B.Sc.

W. C. McLeod, S.E.I.C., is at present with the Canadian Westinghouse Company, Ltd. at Hamilton, Ont. Mr. McLeod graduated from the Nova Scotia Technical College in 1930 with the degree of B.Sc.

J. H. Parks Matheson, S.E.I.C., who graduated from McGill University this spring with the degree of B.Sc., is now in the employ of Shawinigan Chemicals, Ltd., at Shawinigan Falls, Que.

Geo. G. Reid, S.E.I.C., has joined the staff of the Canadian Consolidated Felt Company Ltd., at Kitchener, Ont. Mr. Reid graduated from the Nova Scotia Technical College in 1929 with the degree of B.Sc.

A. Holland, A.M.E.I.C., executive engineer, Public Works Department, Accra, Gold Coast Colony, West Africa, is at present in England on leave and is located at 10 St. John's Road, Queen's Park, Chester.

O. B. Bourne, A.M.E.I.C., formerly designer with the Department of Works, City Hall, Toronto, Ont., is now with the Beauharnois Construction Company, at Beauharnois, Que.

O. J. Frisken, S.E.I.C., has joined the staff of Babcock-Wilcox and Goldie-McCulloch, Ltd. at Galt, Ont. Mr. Frisken, who graduated from Queen's University in 1929 with the degree of B.Sc., was formerly heating engineer with the Trane Company of Canada, Toronto, Ont.

R. L. Weldon, A.M.E.I.C., who has for some time been manager of manufacturing and director of Newfoundland activities of the International Power and Paper Company, at Montreal and Corner Brook, Nfld., has been transferred by the company to New York, N.Y.

T. Linsey Crossley, A.M.E.I.C., is now making his headquarters in the laboratory of the Don Valley Paper Company, Toronto. While retaining his interest in the Industrial Laboratories, Ltd., Mr. Crossley will devote his time entirely to consultation and testing in the technology of pulp and paper.

E. V. Ahara, Jr.E.I.C., who was formerly with Ruths Steam Storage (Canada) in Toronto, is now connected with the Abitibi Power and Paper Company, Ltd., at Toronto. Mr. Ahara is a graduate of the University of Toronto of the year 1922, and was at one time mechanical engineer with the Combustion Engineering Corporation.

Ed. Prevost, Jr.E.I.C., has resigned as construction engineer for the Atlas Construction Company to accept a similar position with Ulric Boileau Ltd. and Damien Boileau Ltd. on their joint contract for the construction of the new University of Montreal. Mr. Prevost graduated from the Ecole Polytechnique, Montreal, with the degree of B.Sc., in 1921.

C. E. Potter, Jr.E.I.C., who was formerly with Roy H. Bishop, architect, at Oshawa and Toronto, Ont., is now on the staff of Robertson and Janin of Ontario, Ltd., Toronto. Mr. Potter, who graduated from the University of Toronto in 1925, was for a time with the engineering department of the Wayagamack Pulp and Paper Company, at Flamand, Que. and was later on the staff of the Toronto Transportation Commission.

T. R. Cooil, Jr.E.I.C., who for the past few years has been field engineer in charge of sewer and water maintenance and construction in the city engineer's department, Saskatoon, Sask., has been appointed city engineer for the city of North Battleford, Sask. Mr. Cooil graduated from the University of Saskatchewan in 1926, with the degree of B.Sc.

A. C. Brown, M.E.I.C., is now connected with Sir John Jackson (Singapore) Ltd., Singapore Naval Base, Singapore. Since 1926 Mr. Brown has been on the staff of Baldry, Yerburgh and Hutchinson (Roads) Ltd., At one time Mr. Brown was engineer and manager for the Hollinger Power Development at Cochrane, Ont., and in 1922 was engaged on the construction of the Welland Ship Canal at St. Catharines, Ont.

C. R. Townsend, Affil. E.I.C., who was formerly woods superintendent of the Laurentide Ottawa Company, Ottawa, and was later located at Grand'Mere, Que., is now connected with the forestry department of the Canada Power and Paper Corporation at Wayagamack Island, Three Rivers, Que. Mr. Townsend graduated from the University of New Brunswick, having secured the degree of B.Sc. in 1920 and that of M.Sc. in 1923.

Professor W. G. Worcester, M.E.I.C., professor of ceramic engineering at the University of Saskatchewan, and chairman of the Saskatchewan Branch of The Institute has been given an honorary degree by the University of Ohio, Columbus, O. from which college he graduated, in appreciation of his work in ceramics. Professor Worcester is on the staff of the Department of Labour and Industries and has been very active in the development of the clay industries of Saskatchewan.

J. K. Davidson, Jr.E.I.C., has resigned his position as assistant engineer with the Dominion Bridge Company, Ltd., Montreal, to take up duties as resident engineer on the construction of a filtration and pumping station for the Water Commissioners of Brantford, Ont. Mr. Davidson is a graduate of the University of St. Andrews, Dundee, Scotland, of the year 1926, and had been connected with the Dominion Bridge Company since his arrival in this country.

James Forgie, M.E.I.C., has been appointed by the Commissioners for the Port of New York Authority as consulting engineer for all future construction work, associated with Messrs. Robert Ridgway, chief engineer of the New York Board of Transportation and also Professor W. H. Burr and Mr. Daniel Moran, who served as consultants in the building of the Hudson river bridge. Mr. Forgie is an engineer of international repute, who has been identified with the construction of tunnels, particularly of the Pennsylvania tunnels between Manhattan and New Jersey.

Major G. W. F. Ridout-Evans, A.M.E.I.C., has joined the staff of Morrow and Beatty Limited, at Fitzroy Harbour, Ont. Prior to accepting his present position Major Ridout-Evans was with the Dominion Bridge Company, Ltd. He was at one time assistant engineer with Morrow and Beatty at Kapuskasing, Que. Major Ridout-Evans served overseas during the war from 1915 to 1919, and on his return to Canada he was with the Great Eastern Paper Company Ltd. at River Madeleine, Que. In 1922 he was in the employ of the Robert Reford Company, Ltd. at Quebec, Que.

W. H. Jones, M.E.I.C., presented a paper on the "Cracking of Petroleum Oils and Low Temperature Coal Tars" in April last before the Institute of Fuel, London, England.

W. H. JONES, M.E.I.C.

Mr. Jones is assistant chief engineer, London office of the Universal Oil Products Company of Chicago. He graduated from the University of Manitoba in 1914 with the degree of B.Sc., and served in the Canadian Engineers and the Royal Air Force from 1914 to 1919. On returning to Canada, Mr. Jones was variously engaged until the beginning of 1922, when he received an appointment with the Roxana Petroleum Corporation (Shell) at Wood River, Ill., as chief surveyor in charge of extensive oil refinery construction work and later as superintendent of "cracking" (method of oil refining). Towards the end of 1924 he was engaged by the M. W. Kellogg Company of New York to undertake the supervision of their cross cracking plant contracts in Europe with headquarters in London. On completion of these contracts he joined the Anglo-Persian Oil Company, Ltd. as senior assistant engineer and consultant, London office, in connection with their cracking plant developments and remained with them until 1927. Mr. Jones was subsequently engaged for a short time by the Medway Oil and Storage Company as assistant manager in charge of production and in 1928 received his present appointment with the Universal Oil Products Company. Mr. Jones was not only closely associated with cracking in its early commercial development in the United States, but has taken a prominent part in introducing and developing this method of gasoline production in Great Britain and other European countries. He represented the London office of his company at the World Power Conference, which was held in Berlin in June.

BOOK REVIEWS

Modern Bridge Construction

By F. Johnstone Taylor. Crosby Lockwood & Son, London, 1930, buckram, 5½ x 8¾ in., 235 pp., front., figs., $4.50.

The aim of the author as set forth in the preface is to deal with his subject in such a way that the work will serve the needs of the average civil engineer who requires some knowledge of bridge construction, and of those engineering students who, without intending to specialize in bridge work, also require a good grounding in the subject to add to their general knowledge and to meet the requirements of general examinations. The use of higher mathematics is avoided as much as possible.

In a very general way the elements of design and modern methods of construction are set forth. Masonry bridges, small steel bridges, trussed girders, steel arch bridges, swing bridges, bascules, drawbridges and vertical lift bridges, suspension bridges and concrete bridges are treated in twelve chapters comprising 231 pages of reading matter. To attempt to explain methods of design, construction and erection, even in a general way, covering such a wide field as outlined above, in such a small volume is a very difficult task indeed. The brevity with which the several types are treated is such, that unless one has a fair knowledge of the subject, he will have difficulty in following the discussion. The explanation of design methods is in general so concise that one wonders whether an engineer, with little knowledge of the subject, would be able to add any material knowledge to his store.

The book is written for English engineers. Although many of the typical examples illustrated are to be found in the British Isles, there are several noteworthy examples of United States and Canadian bridge construction. In some instances one notices symbols, used without explanation of their meaning, which are not familiar to Canadians accustomed to a somewhat different nomenclature.

The book is well printed on excellent paper with an attractive binding. It is remarkably free from typographical errors. The diagrams and cuts are, in general, not so well drawn as are those found in technical books published on this side of the Atlantic, nor do they show the same finish.

While the reviewer doubts whether the author has attained fully his purpose in writing the volume, he is of the opinion that it has value to the Canadian engineer interested in bridges, because it gives him a bird's eye view of practically all types, and, from experience, the reviewer knows that, over a period of years, many bridge engineers have actual experience with perhaps but two or three of these. To such therefore this volume will repay careful perusal.

W. P. Copp, M.E.I.C.,
Professor of Civil Engineering,
Dalhousie University,
Halifax, N.S.

Les sources de l'énergie calorifique et le chauffage industriel

Volume 1, by Emilio Damour. Librairie Polytechnique Ch. Béranger, Paris, 1930, buckram, 9¾ x 6 in., 477 pp., illus., figs., tables, 110 fr.

This is the third edition of a text-book prepared for the engineers following the post-graduate courses given at the Conservatoire National des Arts et Métiers, Paris, an institution which aims to give sound theoretical and specialized training to those already engaged with the different industries.

The complete text will be contained in two volumes and will be exhaustive, treating of all the different sources of heat and of its industrial utilization, including electrical heating. This first volume is devoted to the following subjects: the scientific basis of technical heating; the theory of industrial heating furnaces; the control of combustion.

The book is up to date, giving a special consideration to all the recent developments. It contains numerous figures, graphs, tables of technical data and several examples of numerical calculations.

The author, besides being a professor, is an engineer connected with one of the largest industrial concerns in France and his treatment of the subject is advantageously influenced. His book can be recommended to all those interested in heat engineering, whether they are students or engineers.

L. Brunotto,
Librarian,
Ecole Polytechnique,
Montreal.

Gauges and Fine Measurements

By F. H. Rolt. Macmillan and Company, London, 1929, buckram, 5¾ x 8¾ in., v. 1, 366 pp., v. 2, 357 pp., figs., tables, 2 vols., $13.00.

The development of mass production methods in mechanical engineering has been going on for more than twenty years, but its most rapid advance occurred during the War, when quantities of mechanical products had to be manufactured on an interchangeable basis by firms having no previous experience in this class of work. The production of the parts themselves, and that of the jigs and fixtures required for their manufacture, is entirely dependent on the provision of adequate gauges and methods of precision measurement. Means are, in fact, necessary by which the variations in the dimensions of parts due to wear of the cutting tools, drills, or dies, can be adequately controlled, and by which the variation in size of successive pieces can be held within any desired limits. During the War, the production of munitions was in many cases found to be dependent not on the capacity of the machine tool equipment of the manufacturing firms, but on the supply of the gauges required to measure and inspect the product during and after manufacture.

Engineers who are not familiar with this subject do not always realize the precision of measurement required in modern manufacturing processes. It is obvious that gauges must be made more closely to their nominal dimensions than the parts which they measure. Measurements made for the purpose of checking gauges, therefore require extreme accuracy, and for this purpose measurements have frequently to be made to within one-millionth of an inch. For example, in some instances it has been necessary to take account of the difference in length between the British inch, based on the Imperial standard yard, and the inch recognized in the United States by the Bureau of Standards, which is based on 39.37 inches, being equivalent to one meter. In fact, the length of a standard one-inch block made to United States requirements and measured at 62 degrees F. is thirty-three-millionths of an inch shorter than an inch based on the Imperial standard yard. It is interesting to note that gauge blocks wrung together are not actually in contact, but are separated by a grease or liquid film whose thickness has been determined as from two to three one-millionths of an inch, a thickness which seems to be independent of the nature of the liquid constituting the film. Blocks which are chemically clean can only be wrung together imperfectly or with difficulty.

The first steps in gauging and precision measurement as applied to engineering work were due to Sir Joseph Whitworth, who commenced his work about 1840 and subsequently developed a remarkable measuring machine and a system of gauging to promote interchangeability. The most striking advances in recent years were made possible by the introduction of the block and slip gauge system in 1908 by the Swedish firm of Johansson. Since that time, to name only a few of the leading features of the art, measurement with an accuracy of one one-millionth has become a practical necessity to meet the requirements of industry, the measurement and accurate manufacture of screw threads has been put upon an entirely new footing, optical projection has been applied to precision measurement, and methods and apparatus have been developed for the complete measurement of gear wheels, hobs and other similar objects.

Mr. Rolt was associated with Sir Richard T. Glazebrook and J. E. Sears, Jr., at the National Physical Laboratory at Teddington during the War and his experience gave him an intimate acquaintance with the needs of industry as regards the art of measuring both in the laboratory and in the field.

The first volume of his book deals with general machine gauging, standards of length, including measurement in terms of the wave lengths of light, methods of comparing line standards, the history of standards of length, both primary and secondary; the author then proceeds to the discussion of standard gauge blocks, end gauges, the stability of gauges, the preparation of flat surfaces, and measurement by optical interference methods.

The first volume closes with a chapter on end-measuring machines, comparators, and indicators as used in the laboratory and in the work shop.

The second volume discusses many types of limit gauges, micrometers and other types of workshop measuring instruments; deals with the manufacture of jigs and position gauges, and with the methods and difficulty of setting out angles. Internal measurements are considered, then tests for flatness and straightness, and there is an interesting chapter on the design of measuring instruments. The volume concludes with two chapters on the measurement of gears.

The knowledge of the principles and methods employed described in this book is of the first importance in every modern tool-room, and the author is to be congratulated upon the admirable way in which he has dealt with his subject. It is hoped that he will be able to complete this excellent treatise by the issue of a third volume on screw-thread measurement.

The work can be recommended as an authoritative text-book; its utility is increased by a copious list of references appended to each chapter, and an adequate index for each volume.

Cracking of Petroleum Oils and Low Temperature Coal Tars

Of interest to fuel technologists is a paper on the above subject by W. H. Jones, b.sc., m.e.i.c., which was presented by the author and discussed at meetings of The Institute of Fuel, held at The Chemical Societies' Rooms, Burlington House, Piccadilly, London, on April 9th and 30th of 1930.

The author reviews in his paper the application of "cracking" in the petroleum industry, for the production of gasoline and its remarkable development since the World War, when practically no gasoline was produced by this method. The gasoline production by cracking to-day is approximately one-third of the total world gasoline production.

With the increasing development of low temperature carbonization or distillation of coal for the production of coal tar oils, the necessity of devising some means of dealing with these oils to derive the greatest economic advantage is of increasing importance. The paper deals with the cracking of the tar oils into gasoline of exceptionally high "anti-knock" quality. In the addendum to the paper results are given of the successful cracking of coal tar oils in a commercial size Dubbs cracking plant built in Belgium especially for this purpose under the author's supervision. The plant is the first of its particular kind in the world.

The paper and full discussion was published in the journal of The Institute of Fuel in July.

BRANCH NEWS

Calgary Branch

A. W. P. Lowrie, A.M.E.I.C., Secretary-Treasurer.
W. H. Broughton, A.M.E.I.C., Branch News Editor.

The Calgary Power Company extended an invitation to members of the Calgary Branch of The Institute and their friends to visit the Ghost river development situated at the confluence of the Bow and Ghost rivers on Saturday, June 21st. The weather conditions were threatening but about 30 members and friends attended and, as the rain kept off, thoroughly enjoyed the 35-mile trip and hospitality of the Company.

Members of the staff of the Calgary Power Company conducted the visitors through the plant and explained the mode of operation which is fully modern and practically fully automatic.

After dinner, H. J. McLean, A.M.E.I.C., production manager of the Company, gave a talk on the construction and operation of the plant, pointing out the very efficient way in which it can be co-ordinated with the Kananaskis and Horseshoe plants further up the river so as to make maximum use of the flow and the storage still further upstream. The dam proper is of concrete in the bed of the Bow river, 928 feet long, flanked on the north by a blanket fill 740 feet long along the face of the Ghost Hill, and by an hydraulic fill 2,020 feet long on the south. At the extreme south is the spillway which also is of concrete construction.

In addition to the average daily flow down the two rivers there is a storage lake immediately above the dam of 74,000 acre-feet at an available head of 108 feet. The plant was designed and all the concrete work is constructed for three turbines of 18,000 h.p. each, of which two are installed and are delivering power to practically all the towns of southern Alberta and as far north as Edmonton. There is also a house turbine of 1,450 h.p. installed and in operation. The third main turbine will be installed when load conditions warrant.

The power house is incorporated in the dam and the penstocks, immediately on the face of the dam, lead directly from the reservoir to the turbines which obviates much trouble due to objectionable ice conditions during our crisp and bracing winter months.

That those present had thoroughly enjoyed their trip and the hospitality of the Calgary Power Company was evidenced by the enthusiasm with which they responded to a vote of thanks to the Company and to Mr. McLean, proposed by F. K. Beach, A.M.E.I.C., and seconded by Mr. B. S. Smith.

Quebec Branch

Philippe Méthé, A.M.E.I.C., Secretary-Treasurer.

The annual meeting of the Quebec Branch was held on May 26th, under the presidency of A. B. Normandin, A.M.E.I.C., president of the Branch.

The Council members were elected as follows:—

President (Honorary for life)	A. R. Décary, D.A.Sc., M.E.I.C.
President	S. L. de Carteret, M.E.I.C.
Vice-President	Hector Cimon, A.M.E.I.C.
Secretary-Treasurer	Philippe Méthé, A.M.E.I.C.
Councillors	F. T. J. King, M.E.I.C.
	Alex. Larivière, A.M.E.I.C.
	L. C. Dupuis, A.M.E.I.C.
	J. A. Lefebvre, M.E.I.C.
	Louis Beaudry, A.M.E.I.C.
	J. G. O'Donnell, A.M.E.I.C.
Ex-officio (Vice-Pres. E.I.C.)	W. G. Mitchell, M.E.I.C.
" *(Past-President)*	A. B. Normandin, A.M.E.I.C.
" " "	A. E. Doucet, M.E.I.C.

BRANCH ACTIVITIES

Four meetings were held during the year:—

1929

Oct. 28.—The Quebec Branch had the privilege to welcome as guest of honour, at a luncheon at the Chateau Frontenac, Brigadier-General C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., president of The Institute.

1930

Jan. 27.—Noulan Cauchon, A.M.E.I.C., president of the Ottawa Town Planning Commission, on "Hexagonal Planning."

Mar. 24.—H. R. Wake, A.M.E.I.C., property engineer for the Aluminum Company of Canada, at Arvida; the buildings of the company at Arvida.

May 7.—A. A. MacDiarmid, M.E.I.C., and J. S. Bates, A.M.E.I.C., of Price Bros Co. Ltd.; the properties and process of manufacturing of the Donnacona Insulating Board, and the mill required to produce it.

FINANCIAL STATEMENT

Revenues

Cash in Bank, June 30th, 1929	$203.28	
Interest on bank deposit	5.53	
Rebates from Headquarters	232.20	
		$441.01

Expenditures

Stamps, telephones, telegrams, convocation cards	$ 36.17	
Luncheons and meetings	109.24	
Gratuity to the secretary	100.00	
		$245.41
Cash in bank June 1st, 1930		$195.60

PHILIPPE MÉTHÉ, A.M.E.I.C.,
Sec.-Treasurer.

RAPPORT DES ACTIVITÉS DE LA SECTION (1929-30)

La saison s'ouvre le 28 octobre par la visite du président de l'Institut, le Brigadier-Général C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C. A cette occasion, les membres se réunissent à un déjeuner intime au Château Frontenac.

Le 27 janvier, causerie sur l'urbanisme et le lotissement hexagonal par monsieur N. Cauchon, A.M.E.I.C., président de la Commission d'Urbanisme d'Ottawa.

Le 24 mars, causerie par monsieur H. R. Wake, A.M.E.I.C., ingénieur de la Aluminum Co. of Canada, Arvida; la construction des usines de la Compagnie, à Arvida.

Le 7 mai, Messieurs J. S. Bates, A.M.E.I.C., et A. A. MacDiarmid, M.E.I.C., tous deux de la Cie Price exposent aux membres de la section de Québec, les procédés de fabrication de leur nouveau produit isolant, le Donnacona Insulating Board, ainsi que les différentes caractéristiques de ce produit.

RAPPORT FINANCIER (1929-30)

Recettes

En caisse au 30 juin 1929	$203.28	
Intérêts sur dépôt	5.53	
Remises du Bureau-Chef	232.20	
		$441.01

Déboursés

Timbres, téléphones, invitations	$ 36.17	
Dépenses pour déjeuners-causeries, réunions	109.24	
Allocation au secrétaire	100.00	
		$245.41
En caisse, le 1er juin 1930		$195.60

PHILIPPE MÉTHÉ, A.M.E.I.C.,
Secrétaire-trésorier.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

On April 17th a paper was given before the Montreal Branch by Mr. F. W. Skinner, consulting engineer of New York City, describing the new Hudson River Bridge. This bridge when completed will be the longest span in the world.

Mr. Skinner introduced his paper by describing the three different types of bridges, namely, arch, cantilever and suspension. Two examples of the first were the Hellgate and the Staten Island bridges, having spans of 1,016 and 1,050 feet respectively. In the second class were the Quebec and Forth bridges with spans of about 1,800 feet each, while the third class was exemplified by the Brooklyn and Detroit-Windsor Ambassador bridges.

The economic length of span for cantilever bridges was stated by the speaker to be 2,500 feet, but suspension bridges were in his opinion competitive for all spans over 1,000 feet and moreover these could be built in places where it would be impossible to erect any other type of bridge.

Tribute was paid by Mr. Skinner to Messrs. John A. Roebling and Successors of Trenton, N.J., to whose skill in the perfection of wire and cable manufacture, the suspension bridge largely owed its development. It was for this reason that they were awarded the contract for the four 36-inch cables for the Hudson River Bridge, at a cost of approximately $13,000,000.

The bridge will have a span of 3,600 feet and will cost a total of $75,000,000. There will be eight traffic lanes capable of handling 30,000,000 vehicles annually, on the main roadway, and later on a second lower roadway can be added which will practically double the original capacity. The cables are supported at either bank by two steel towers 650 feet high and containing 20,000 tons of steel each. These supporting towers are very carefully anchored; that on the New Jersey side being in solid rock while that on the New York side is in concrete, weighing in all some 260,000 tons. Each cable is a mile long between anchorages and is made up of 62 strands of 432 wires each. The wires are 0.196 inch in diameter and are cold drawn from acid open hearth carbon steel having an ultimate strength of 288,000 pounds per square inch.

Temporary working platforms are carried just below the cables and the wires are drawn over the anchorages at the rate of nearly 123 tons a day, so that it is expected the bridge will be opened to traffic on scheduled time in 1932.

D. C. Tennant, M.E.I.C., occupied the chair.

GHOST RIVER POWER DEVELOPMENT

W. H. Abbott, A.M.E.I.C., addressed the Montreal Branch on April 24th on the problems encountered in connection with two large hydraulic earth-fills on the Ghost River Power Development.

As Mr. Abbott's paper was printed in full in the June issue of the Journal, no further account of it will be given here.

H. Massue, A.M.E.I.C., occupied the chair.

ELECTRICITY IN THE EIGHTEENTH CENTURY

On May 1st Dr. L. E. Pariseau gave another of his most interesting addresses to a crowded hall, his subject on this occasion being "Electricity in the Eighteenth Century."

The Doctor traced the development of the early investigations in the science of electricity and described at some length the work of some of the outstanding investigators of this early period. The lecture was illustrated by a number of slides which were reproductions of the illustrations and text of some of the earliest books on the subject, selected from Dr. Pariseau's own collection.

On a motion by J. L. Busfield, M.E.I.C., the thanks of the meeting were conveyed to the speaker by the chairman, D. C. Tennant, M.E.I.C.

COTTRELL PROCESS

A paper was presented by Mr. P. E. Landolt, of New York city, on May 8th describing the electric precipitation of finely divided particles by means of the "Cottrell Process."

Mr. Landolt explained that this process resulted from experiments conducted by Sir Oliver Lodge and Dr. Frederick Cottrell. More than a century ago attempts were made to precipitate particles after the same manner as is found in nature but without any marked success. Finally, however, Sir Oliver Lodge applied the present process to the manufacture of sulphuric acid and Dr. Cottrell followed by applying the method to a number of other uses such as the cleaning of gases, recovery of by-products, etc.

Mechanical means had been tried without success for the removal of finely divided foreign bodies from gases. Up to a certain point it was found economical to allow dust to settle but after that it was found that the falling speed of very fine particles was disappearingly small. The other mechanical process was by the use of the inertia of the suspended matter by such means as centrifugal force. When, however, this was applied to gases containing very finely divided matter the process either failed or became prohibitively costly due to the size and power of the required apparatus.

Sir Oliver Lodge's experiments on flue dust and sulphuric acid, from 1904-05, laid down the principles of electric precipitation. By this process electrodes are introduced into the gas and the particles charged by the discharge electrode are collected by the other.

Mr. Landolt told of the many practical applications which had been made in various industries and mentioned a number in Quebec, such as Brown Corporation, La Tuque, Noranda Mines Ltd., Noranda, and Aluminum Company, Arvida, etc.

THE QUEST OF THE UNKNOWN

Professor Harold B. Smith, President of the American Institute of Electrical Engineers, addressed the Montreal Branch and local members of the A.I.E.E. at a special meeting held on May 21st.

Professor Smith took as his title "The Quest of the Unknown" and in this connection outlined his experiences in a lifelong study of dielectrics. A number of slides were shown illustrating various transformers and other experimental equipment developed or built by the speaker in the course of his researches and culminating in a unit of 1,000,000-volt capacity recently completed.

In the course of his talk Professor Smith drew a parallel between his expeditions to southern Thibet and other little known parts of the world, and his experiments in the field of scientific research, conveying to his audience something of the thrill of "high adventure" to be derived from the latter. Finally, in closing the speaker advised every engineer to "find some problem and then stick to it."

The chairman of the meeting was D. C. Tennant, M.E.I.C., and a vote of thanks to the speaker was proposed by Julian C. Smith, M.E.I.C., after a most interesting discussion.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

The elections were quiet this year. Three new members won their seats by acclamation and the Executive Committee stands as follows for the coming year:—

Walter Jackson, M.E.I.C., Chairman
E. P. Murphy, A.M.E.I.C., Vice-Chairman
R. W. Downie, A.M.E.I.C., Secretary-Treasurer

C. W. West, A.M.E.I.C.	F. L. Haviland, M.E.I.C.
J. K. Wyman, A.M.E.I.C.	*J. C. Moyer,
W. R. Manock, A.M.E.I.C.	*C. G. Cline, A.M.E.I.C.
N. Bates, A.M.E.I.C.	*H. D. Davison, A.M.E.I.C.

Ex-officio
A. J. Grant, M.E.I.C.
E. G. Cameron, A.M.E.I.C.
C. H. Scheman, M.E.I.C.
M. B. Atkinson, M.E.I.C.

*New members.

Following a very pleasant custom, which was instigated by our late Chairman, E. G. Cameron, A.M.E.I.C., the members of the "old" and "new" executive met at the Lookout Golf course on May 22nd to discuss and elect the officers for the coming year. Truth to tell there was little discussion as the majority was more than eager for a game and matters pertaining to chairman and vice-chairman seemed to be of secondary importance. Both Walter Jackson and Harbour Master Murphy are prime workers besides being acknowledged good fellows so that there was very little question as to the shoulders upon which the mantle of authority and responsibility would fall. As for our secretary-treasurer, fortunately for us, he is a perennial.

It may be of interest to the Branch members to note that this year we have four members on the executive who ten years ago were signatories to the Charter, namely Messrs. Jackson, Grant, Moyer, and Davison.

The chief excitement of the golf game centred around two sets, a foursome composed of Messrs. Grant, Redfern, Atkinson and Beattie who were settling an old grudge, and a twosome containing the famous "Pro" Johnny Sears and an hitherto unknown player from the west.

Nobody knows yet who won the foursome but, to everyone's surprise, the twosome went to the dark horse. Having played at St. Andrews and at many of the other famous clubs Johnny was loud in his praises of "Lookout," frankly admitting that the hazards were too much for him and he was not up to his usual form when he turned in a score of 141. At St. Andrews he had made an 83 but being two up on his opponent he rested on his laurels and retired at the fourth hole.

ANNUAL MEETING

The annual meeting was held on June 4th at the Welland house, St. Catharines. Owing to the sultry weather the attendance was not large but the 150 guests who did brave the heat enjoyed themselves immensely. From Bridgeburg, nearly forty miles away, came a contingent of twenty-eight members, probably the best percentage from any section of this district. Following the dinner a brief interval was allowed for speakers and the introduction of new officers.

Then Dr. A. P. Coleman, Professor Emeritus of the University of Toronto, explained some very beautiful lantern views taken during one of his trips when he "forded" the continent. After which the younger members had their innings and danced until the early hours of the morning.

E. G. Cameron, A.M.E.I.C., was in charge of proceedings and the Branch is rather proud of the manner in which he handled a difficult situation when, for a short period, the lantern behaved as though it were endowed with long ears. Now that Walter Jackson has taken over the reins, other Branches will be asked to submit bids for a fully developed chairman (the highest or any tender not necessarily accepted).

Before commencing the programme the ladies were ably represented by a speaker in the person of Mrs. A. J. Grant who desired to express her opinion that making the annual meeting into a mixed gathering was a happy thought and one that should appeal to the wife of every engineer. She had been wrestling with Mr. Grant for a good many years to find out just what he did at these meetings and now she was satisfied that they were innocuous.

First of all Mayor McCordick welcomed the gathering to St. Catharines and spoke warmly of the friendships he had made with many of the engineers in the surrounding district. The Welland ship canal was responsible for the presence of many and, now that the great work of construction was practically complete, he felt keen sorrow that some of them would be forced to leave for other parts and other activities.

President A. J. Grant spoke of Institute affairs and deplored the fact that the recent ballot for increased dues was lost by a narrow margin. Many proposed activities will be impaired by the result and he trusted that members will realize that the situation is serious and will derive fresh impetus to canvass all possible prospects for new members. A determined effort in this direction would go far in offsetting the ill effect. In closing he desired to pay tribute to Mr. Cameron for the untiring energy which had been given to Branch and Institute affairs and wished every success to the new Chairman, Mr. Walter Jackson.

Mr. Cameron immediately took up the gauntlet and with a burst of unexpected eloquence paid Mr. Grant back right handsomely, ending with the quotation "We the Branch bask in the reflected glory of your position."

A somewhat pleasant feature of the gathering was the re-union between Mr. and Mrs. Brodie Atkinson who had not seen each other for several months. Of course there is an explanation for this state of affairs, namely that Mrs. Atkinson had been visiting her parents in California and had just returned a few hours previously whereas

Brodie had been over to England giving expert testimony before a Parliamentary Commission concerning a proposed vertical lift bridge across the River Tees near Stockton.

Most of the Branch Members had met Mr. Durley at previous annual meetings but never before had an assistant secretary been permitted to travel thus far from home. Mr. J. F. Plow has just entered upon the duties of this office and, much to the credit of Headquarters, was allowed to visit us and introduce himself.

Introducing Dr. Coleman, Mr. Cameron explained that he was a "realistic" speaker. On a similarly hot night in 1914, at the Engineering Club at Thorold, Dr. Coleman had chosen for his subject the "glacial age" and before very long most of the guests were calling for their wraps. Tonight, advised Mr. Cameron, if the subject was mentioned it might be as well to limit the thickness of ice to about a quarter of a mile instead of the previously mentioned two miles.

Dr. Coleman then took the floor and, after the lantern had been sufficiently humoured, entertained the gathering with his very acute and pertinent observations while travelling through seventeen states and five provinces. Most of the views were coloured by his own brush and some were original sketches, for he is not only an eminent geologist and naturalist but also an artist in water colour and word painting.

He took us through the south and showed us how the darkies lived, to the prairies where Indians roamed around in Packards purchased with profits from oil lands, and to the Yellowstone where the tints in the rocks vied with the beautiful colouring in the waterfalls and streams. Then with never a stop at cities which hold little interest for the naturalist he led us to the beauties of the coast, the sunken gardens and the gorge near Victoria, the Seven Sisters at Vancouver and back by way of the Okanagan and Kootenay Lake to Lake Louise and Banff. There he showed us tame "wild" animals, mule deer that came right up to the car and bears which grew so friendly that they had to be enticed in the opposite direction before the party could move ahead.

Again Mr. Cameron rose to the occasion and referred to the applause as a "conservative measure of our appreciation." Then thanking Dr. Coleman for himself and on behalf of the Branch he declared an adjournment before going ahead with the dance.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

DRAUGHTSMEN—One or two draughtsmen experienced in general pulp and paper mill work and construction, for a company in the province of Quebec. Apply at once to Box No. 554-V.

MECHANICAL ENGINEERS. Two young graduate engineers with sales ability wanted by a well-known Canadian company. Apply, giving full particulars, to Box No. 562-V.

TOWN ENGINEER, for a town in Maritime Provinces. Electrical and civil engineer, or electrical engineer with sufficient knowledge of civil engineering to take charge of water and sewerage system, building of roads and sidewalks, etc. Must be able to speak French. Apply to Box No. 565-V.

SALES ENGINEER. Canadian stoker manufacturers desire services of experienced mechanical engineer to take charge of distribution. Location Montreal. Apply at once to Box No. 580-V.

DRAUGHTSMAN—Young man with some experience for about fourteen months work for city engineer's office in northern Ontario. Apply at once to Box No. 584-V.

RADIO ENGINEER—Canadian manufacturer of broadcast receivers requires development engineer. University degree or equivalent experience required. Give full details of qualifications in application. Apply to Box No. 591-V.

ENGINEERS—A large electrical manufacturing concern requires several young engineering graduates, Mechanical, Electrical or Chemical, for work on factory and inspection methods, manufacturing problems and cost reduction. Men who have graduated within the last two or three years preferred. Please state in first instance, education, full qualifications, experience, references, salary required, kind of engineering work particularly desired, age and when available. A snapshot or photograph is desirable. Apply to Box No. 594-V.

DRAUGHTSMEN.—Preferably familiar with cruising, flotation and cyanide mill work. Men experienced in concrete, structural steel and plant layouts considered. Only Canadian citizens need apply. Work will be about eight months. Apply by letter. Location, Canada. Apply to Box No. 595-V.

ELECTRICAL ENGINEER, preferably with sales experience, to handle engineering equipment in Montreal and vicinity. Apply to Box No. 596-V.

ESTIMATOR OR QUANTITY SURVEYOR, required for a large building construction company. Must be experienced in this particular work and acquainted with Canadian methods of taking off and extending building quantities in detail. Apply giving age, experience and references to Box No. 597-V.

DRAUGHTSMAN wanted, experienced in industrial plant layout and equipment and in details of modern factory construction. Location Montreal in office of architectural engineer. State in detail age, education, experience, salary, etc. Apply to Box No. 598-V.

Situations Wanted

ELECTRICAL ENGINEER, M.Sc., A.M.E.I.C., graduate, seven years' experience in high tension calculation design and construction, seeks connection. Location immaterial. Age 30. Married. Apply to Box No. 7-W.

CIVIL ENGINEER, A.M.E.I.C., experience: highways, railways, drainage projects, stream diversion, earth, timber and concrete dams, laying large and small pipe, timber structures, concrete walls and pavements. Location, construction or maintenance. Desires position as engineer or superintendent. Location immaterial. Apply to Box No. 34-W.

CIVIL AND MECHANICAL ENGINEER, aggressive practical engineer, with background of experience in design, construction, maintenance and operation of pulp and paper mill, desires change. Especially qualified to reduce mill costs. Apply to Box No. 53-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years' experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Apply to Box No. 107-W.

COLLEGE GRADUATE, age 34, with over ten years' experience in power developments and pulp and paper mill construction and maintenance, largely in direct charge of design or construction; desires new connection as chief or assistant engineer or construction superintendent. Apply to Box No. 167-W.

ENGINEER—Sales executive, A.M.E.I.C., age 37, presently employed as district representative, desires change in wider field. Experience (Canada and abroad), covers structural steel and iron foundry work as chief draughtsman, designer, etc. Available on reasonable notice. Apply to Box No. 227-W.

MACHINE DESIGNER. Experienced machine designer and draughtsman, shortly open for position. A.M.E.I.C. Considerable experience in mining and winding machinery. Well up in steam power house equipment layouts and piping. Own design in successful operation. Accustomed to structural work. References good. Present location Montreal. Interview easily arranged. Apply to Box No. 329-W.

CIVIL ENGINEER, A.M.E.I.C., Reg. Pro. Eng. Ont. and N.B., age 47, married, twenty years' experience in this country, twelve years in Scotland as construction and municipal engineer, specializing in roadway, water and sewer works, desires similar position, available forthwith. Just completed sewer and waterworks schemes for town in Maritime Provinces. Have also been engaged as engineer and superintendent with contractors on steam shovel excavation, concrete and caisson works for large buildings in Toronto, etc. Apply to Box No. 336-W.

CIVIL ENGINEER, graduate '29, desires engineering position with possibilities of forming connections. Willing to learn. Work in construction preferred, water power, or municipal suggested. Past experience consists chiefly of survey work in charge of party. Location in B.C. or western provinces preferred. Apply to Box No. 338-W.

CONSTRUCTION ENGINEER, Canadian, speaking and writing French and English, A.M.E.I.C., P.E.Q. Twenty years' experience in water power development, roadway, water and sewer works, as engineer in charge or superintendent, desires position. Available on short notice. Apply to Box No. 380-W.

GRADUATE ENGINEER, N.S. Tech. Coll., age 25, desires permanent position with industrial concern. Since graduation has spent two years' apprenticeship with Can. Westinghouse Co. Apply to Box No. 382-W.

CIVIL ENGINEER, B.Sc., '24, Jr.E.I.C., C.P.E.Q., Canadian, age 30, married. Experience: Construction power developments, railways, highways, pulp and paper mills, maintenance pulp and paper mills, railways, desires permanent position with opportunity for advancement. Apply to Box No. 402-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), graduate. Eighteen years' experience in survey and construction, railway, hydro-electric and buildings. Experience comprises both office and outside work. Desires responsible position. Would consider position with commercial or manufacturing firm. Available about August 15th. Apply to Box No. 425-W.

ELECTRICAL ENGINEER, B.A.Sc., age 25 years, single; two five-month summer vacation periods on electrical construction and maintenance; three years and three months with large electrical manufacturing company, including twelve months' standard test course, twenty-one months' machine design, six months' commercial experience. Apply to Box No. 426-W.

CIVIL ENGINEER, S.E.I.C., 1930 graduate of Nova Scotia Tech. with experience as plane table topographer, instrumentman and draughtsman and particularly interested in hydro-electric power development and reinforced concrete design, desires position. Willing to go to foreign fields. Available at a few weeks' notice. Apply to Box No. 431-W.

Radio Inductive Interference

Methods Employed to Locate and Suppress the Interference at its Source

H. O. Merriman, A.M.E.I.C.,

Engineer in Charge, Interference Section of Radio Branch, Department of Marine, Ottawa.

Paper read before the Montreal Branch of The Engineering Institute of Canada, November 21st, 1929.

Co-operation of Public Utilities

The Dominion government is the only government, as far as the author knows, which provides a regular service to broadcast listeners for the suppression of inductive interference. The situation in other countries varies considerably. In Europe the noise level from interference in the cities tends to be lower than in this country on account of the extensive use of the underground wiring system. Radio engineers who have recently returned from Europe tell, however, that the inductive interference is considerable when listening on the receiver to distant or weak stations.

There is a tendency in Europe and in the United States to increase the power of the broadcasting stations and, thereby, increase the signal strength, so that the receivers do not require to be set for extreme sensitivity and, in this way, the inductive interference is not so noticeable.

Many of the public utilities in the United States have a well organized inductive interference investigation section and spend a considerable amount of money along this line, for the purpose of increasing the good will of their consumers.

An increase in the electric load, of some 10 or 20 per cent, is attributed, by some public utilities in the United States, to be a direct result of the introduction of radio receivers into the homes. The increased load due to radio includes, besides the actual power consumed by the radio receivers and battery chargers, an extra light and heating load, which meter readings have proved to follow the installation of a radio receiver in the home.

In Canada the public utilities are, generally, co-operating in a very satisfactory manner with the Radio Branch in the suppression of interference. The Bell Telephone Company and the telegraph companies besides assisting the Radio Branch, have developed their own methods of suppressing interference from the normal operation of their equipment and are installing the necessary devices wherever the apparatus is found to be causing interference.

The British Columbia Electric Railway Company has, for some time, been employing an electrician for the investigation and suppression of interference from their lines, and this electrician has been working in conjunction with the radio inspector in Vancouver and accompanying the radio investigators on tours in the surrounding district.

The Toronto Hydro-Electric Commission, besides assisting the radio inspectors, maintains a number of inspection gangs, independent of the emergency, construction, or repair gangs, who devote their entire time to periodic inspections of their overhead system. In this way, the distribution system is maintained in such a condition as to give very little interference to radio reception.

Interference Carried on Power Lines

All electrical conductors carrying current are surrounded by three types of fields, which may influence radio receivers having aerials within these fields of influence.

These fields are:—

(1) *Electromagnetic*—which varies according to the current in the conductor.

(2) *Electrostatic*—which varies according to the voltage.

Under normal conditions on electric power lines, these electromagnetic and electrostatic fields, surrounding the conductor, do not extend for more than a few yards from the power line. In some cases, however, the third type of field, called the

(3) *Field of electric radiation*, which is produced by a very sudden change in voltage, called an electrical surge, may radiate and cause interference to radio receivers whose aerials are a considerable distance from the power lines. An electric surge may travel many miles along a power line and produce a radiation which may be picked up on radio receivers. A surge, due to a spark on the power line, may be induced from one line to another and be carried a greater distance on the secondary system than on the one on which the spark occurred.

The amount of interference caused by an electrical surge to a radio receiver depends not only on the characteristic of the surge, but on the characteristic of the wires carrying the surge. Sometimes, telegraph interference, produced by the breaking of a 100-volt battery, will cause greater radio interference than the switching of high voltage power lines. It is often found that radio interference caused by a fault on the distribution system may be carried a greater distance on the electric railway feeders, which run parallel to the distribution system near the fault, than on the

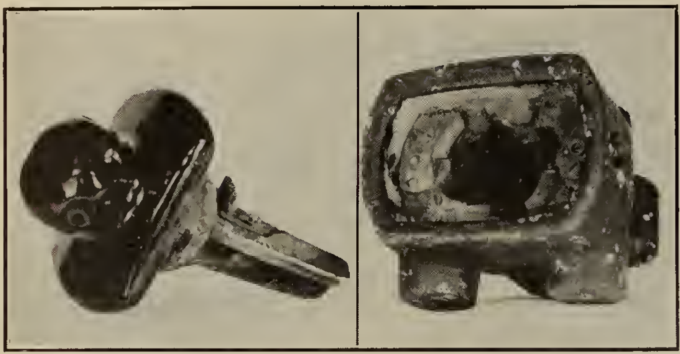

Figure No. 1—Defective Cutout Plug—2,200-Volt Circuit.

wires connected directly to the fault. This is probably due to the fact that the capacity from the distribution primary to ground is considerable, as the transformers act as condensers to drain off the interference from the distribution system, while the capacity of electric railroad feeders to ground is very much less.

Summary of Sources of Inductive Interference Investigated During Fiscal Year 1928-1929 by the Radio Branch

Domestic and commercial apparatus	1,650
Distribution systems and power lines	4,271
Total Sources (other than radio)	5,921

Summary of Sources Found on Distribution Systems and Power Lines, Listed Above

Cutouts (transformer fuses)	3,186
Lightning arresters	194
Loose series connections ((other than cutouts)	182
Contacts with ungrounded metal (such as guy-wires, brackets, transformer cases, etc.)	441
Contacts with grounded material (other than lightning arresters)—(such as trees, poles, grounded metal, etc.)	126
Defective insulators or bushings	24
Sources unknown	8
Faults on lines over 8,000 volts	110
Total	4,271

In dealing with radio inductive interference, the sources are divided into two general classes, that is those originating on power lines and distribution systems, and those caused by electrical machinery and apparatus.

As so many sources handled by the Radio Branch are caused by power lines and distribution systems, this class of interference will be dealt with first.

It will be seen from the summary, that, of a total of 5,921 cases of inductive interference investigated during the year, 4,271, or about 72 per cent of the total, were found on the power lines and distribution systems. These 4,271 cases are referred to again in the latter part of the summary, and it is worthy of note that 2,186 sources were caused by defective cutouts or transformer fuses.

Although defective transformer cutouts cause very considerable radio interference (in some cases, a single defective cutout may practically destroy all radio reception throughout an entire city), as a general rule the interference is intermittent and does not seriously interfere with radio reception for a greater distance than from one-quarter to one mile from the source.

While other sources of interference are not so numerous, they very often cause more serious interference. A fault on a high voltage power line in Quebec caused radio interference to all receivers along this line for a distance of thirty miles. This was actually caused by an unused power line picking up potential by induction and radio investigators found that a spark occurred from the grounding chain to a steel tower.

Transformer Fuses

The majority of the cases of interference are caused by the old type of porcelain fuse plugs having open fuses. Both the type which plugs straight in and that which closes with a quarter turn are equally bad from the interference point of view. Very few cases of interference have been found to be caused by oil immersed fuses, or the cartridge type, including the expulsion fuses.

On examination of the interfering fuse plugs, it is usually found that the copper jaws have lost their temper due to heat and the blades are corroded. It is very often found that the copper fuses, from the blade to the jaw, making a perfect metallic contact of very small area (not much more than a pin point). A defective transformer fuse is shown in figure No. 1. This probably accounts for the intermittent nature of the interference, as there will be no interference as long as this fuse contact holds, but the slightest vibration caused by wind or passing traffic will break this pin point of copper and the arcing from blade to jaw will recommence, causing interference. The test used, therefore, to locate defective cutouts, is what is known as the mallet test and consists of tapping the pole with a wooden mallet while an observer listens to the interference on a radio receiver. This test will, usually, show up the defect, whether the interference could be heard, or not, before the test, as the vibration will either start or stop the interference, or change its characteristic.

A great improvement in reception conditions has been noticed in some of the cities which are gradually discarding the old type of cutout and installing on all the larger types of transformers either the oil cutout or the expulsion fuse.

Another cause of interference has been noticed occasionally, particularly on high voltage, small current fuses, such as those used to protect potential transformers. In these cases interference was traced to an open wire fuse. which had burnt away for a short distance from the fuse terminal, and was arcing from the end of the fuse wire to the fuse terminal. The fuse wire had probably been damaged when being connected under the head of the terminal screw and had burnt off for a short distance but due to the limited current, there was not enough heat to

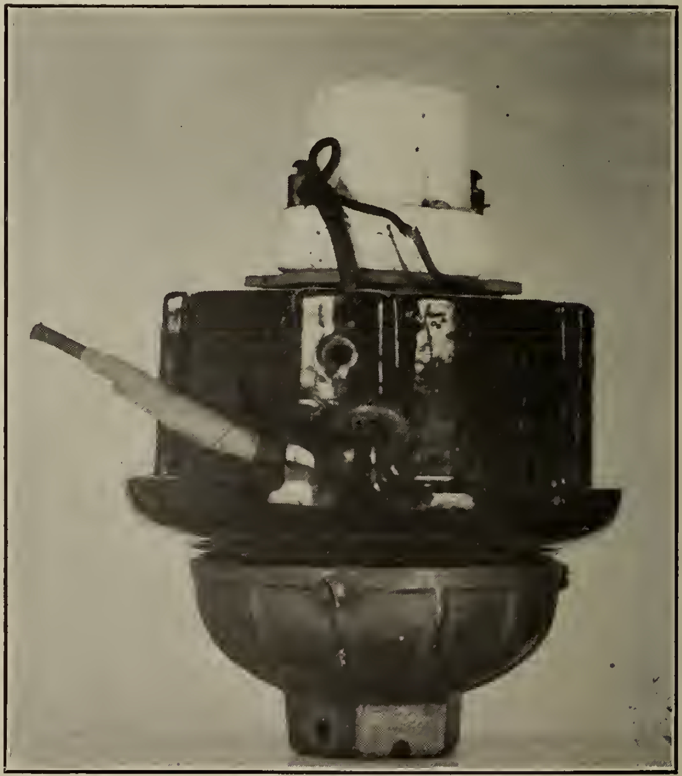

Figure No. 2—Street Light Fixture Causing Interference.

Figure No. 3—Super Heterodyne Receiver installed in Car.

blow the fuse completely, and the transformer continued to operate as the primary current arced steadily across the gap.

Lightning Arresters

It will be seen by the summary that 194 lightning arresters were found to cause radio interference. Most of these cases were caused by the old type of lightning arrester, consisting of a resistance and series gaps from line to ground. In most cases, the electrodes of the gaps were corroded, or some of them short-circuited, causing an unbalance of the electrostatic field and sparking across some or all of the series gaps. The newer type of arresters enclosed in porcelain gives very little radio interference.

Loose Series Connections

Loose series connections on circuits of 220 volts, or less, usually do not cause very widespread interference.

Loose connections to 500-volt motors, where they are kept in continual vibration, have caused very considerable interference. Greater interference, however, is caused by the loose connections on higher voltage, particularly where the current flowing through the loose connection is small.

Some of the most far reaching cases of interference have been traced to loose series connections, including poor contacts at disconnecting switches on overhead lines carrying little or no power current. A case of this kind was traced along an 11,000-volt line, about fifteen miles from the broadcast listener's receiver, and was found to be caused by a poor contact in an open air disconnecting switch connected to about a mile of line, which was under potential but carrying no load.

Contacts With Ungrounded Metal

Four hundred and forty-one sources of interference were dealt with under the heading: "Contacts with Ungrounded Metal," including power wires in contact with insulated guy-wires, loose tie-wires on insulators, power wires in contact with pole line hardware, transformer cases, etc., and, also, parts of series street lighting fixtures within sparking distance of the conductor.

Many of these sources of radio interference have been found, also, to create hazardous conditions for the linemen or the general public. A case of interference was recently traced, along the 2,200-volt primary, a distance of three-quarters of a mile from the receiver affected, and it was found that an unused radio aerial was in contact with the 2,200-volt primary. The owner of the aerial informed the investigator that a radio dealer had arranged to connect a set to this aerial the following day.

A common fault found on series street lighting fixtures was caused by the leads from the auto-transformer to the lamp sparking to some insulated metal in the lamp fixture. These leads were insulated to withstand only the low voltage of the lamp and the fault did not cause any trouble with the lighting systems on account of the fact that the metal in contact with the leads was insulated from line and ground. Although these leads were only required to withstand 50 volts, or less, which is the voltage across the lamp, from the point of view of lighting and power, they were subject to the full voltage of the line as far as radio interference was concerned, as the iron of the fixture formed an intermediate plate of series condensers from line to ground and a spark occurred, through the poor insulation of the lead, to the iron. Figure No. 2 shows a street light fixture with iron ring removed to show defective wiring. This matter was brought to the attention of the manufacturers, who were pleased to alter the design of their fixtures, insulating all conductors connected to the lines to withstand the high voltage test.

Tie-Wires

Loose tie-wires on power wires are believed to be the cause of much interference from high voltage power lines. Practically all high voltage power lines cause a certain amount of interference which is usually referred to as normal high tension fry, but the amount of this interference varies very greatly. The interference from lines

Figure No. 4—Radio Investigator and Lineman locating Fault.

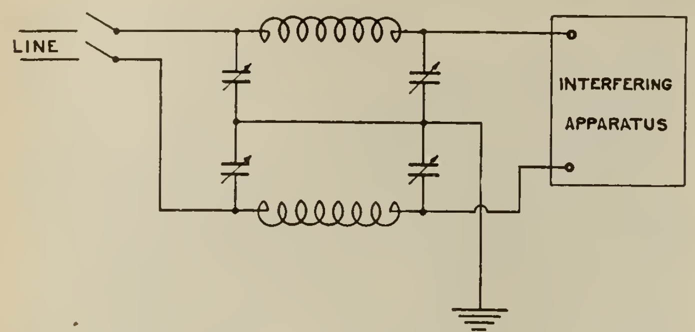

Figure No. 5.—Diagram of Tuned Radio Frequency Rejector Circuit.

using the suspension type of insulator is practically always less than that caused by lines of similar voltage using the pin type of insulator.

Some new 13,000-volt insulated lines, using insulated tie-wires, have been found to be very quiet, while, as a general rule, the bare lines of this voltage give less radio interference than insulated lines after the insulation becomes old.

A number of cases have actually been found, where the tie-wire was loose on the insulator, and a great deal of the interference was eliminated when this fault was repaired. Usually, however, the interference from an individual tie-wire is so small, compared with the total interference from the line, that such definite results cannot be obtained.

Interference Less in Wet Weather

It is often found that interference from high voltage power wires, having pin type insulators, is less in wet weather. An experiment was carried out on a tie-wire, which was found to be loose and causing radio interference; it was found that the spitting sound ceased as well as the radio interference, when a few drops of water were placed on the tie-wire.

It has, also, been found that considerable radio interference may be caused by a power wire in loose contact with an insulator (the tie-wire having been completely removed), and the interference ceased when the power wire was pressed hard against the top of the insulator.

The Ohio Brass Company have developed an insulator having a metal top and, also, one having a metallized surface on the top, in order to eliminate interference of this kind, but the Radio Branch has had no experience in connection with this new type of insulator in actual practice.

Effect of Reduced Voltage

Experiments were conducted with the co-operation of the Hydro-Electric Power Commission of Ontario on a 90,000-volt pin type line between Niagara Falls and Toronto. The voltage of this line was gradually reduced from 90,000 volts to zero, and it was found that the radio interference gradually reduced from the maximum at 90,000 volts to about one-half the intensity at 20,000 volts. The investigators expected to find that there would be a critical value of the voltage below which the interference would materially reduce, but such was not the case.

Methods of Locating Interference

The investigation usually starts from a report of interference made by a broadcast listener.

Numerous methods have been tried to obtain useful information from the broadcast listener, which might assist the investigator. Questionnaire forms have been used for the purpose of ascertaining from the broadcast listener the characteristics of the interference, but it has been found that the broadcast listener usually finds difficulty in describing the interference in a way that would prove helpful to the investigator, so that this form is seldom used. It has been found that more useful information can be obtained by a few minutes talk on the telephone, and using a simple card.

Investigators in different cities use different methods of handling and filing these cards, as conditions in the large cities call for a different system from that used in smaller towns.

General Patrol

In order to locate the interference it is first necessary to determine the area affected and the points at which the interference is greatest. A general patrol of the district is, therefore, made, using a superheterodyne radio receiver with a loop antenna, in an automobile. The loop antenna is turned parallel to the various wires and an endeavour is made to determine which system of wires radiates interference with greatest intensity. The directional effect of the loop is used solely for this purpose, as it is found that, in less than 1 per cent of the cases will the loop point directly to the source of interference, but gives greatest intensity when the loop parallels the wires carrying the interfering surge.

The volume control of the receiver is, also, used to determine the location where the interference is greatest. Although the greatest interference is not always heard near the source, in many cases the source is found somewhere in that vicinity.

Mallet Test

A more detailed investigation is then made in the location where the source of interference is suspected. If it is suspected that the interference is caused by some wires or apparatus on the poles of the distribution system, these poles are struck a moderate blow with a five-pound wooden mallet, while the interference is noted on the radio receiver. The blow of the mallet will cause a vibration corresponding to that produced by passing traffic and, if a loose connection or faulty contact exists on the pole, it will cause the radio interference to start, stop or change its character. In the case of loose transformer cutouts and other similar faults, a very slight vibration will sometimes affect the interference, such as tapping the pole with the hand, or tapping a pole several spans away with a mallet.

Shaking Guy-Wires

Some types of interference, such as caused by a power wire lying on a guy-wire, may be located by shaking the guy-wires, thus causing all the wires in the vicinity to swing as they would in windy weather. Very often, shaking the guy-wire will start or stop radio interference from a fault, up to a distance of half a mile from the guy-wire being shaken. If the interference starts and stops instantaneously with the shaking of the wire, the immediate vicinity is investigated for the fault. If, however, a second or two elapses after the guy-wire is shaken, a search is made a considerable distance from this point for the fault.

Bamboo Pole

A jointed pole, consisting of three five-foot sections of bamboo about one inch in diameter, has been found very useful for shaking individual wires while listening to the interference from the radio receiver. This bamboo pole may, sometimes, be used to temporarily remove wires which are in contact with other wires or pole line hardware, without the necessity of a lineman climbing the pole.

Portable Receiver

A portable receiver has been found very useful in addition to the receiver carried in the automobile. Frequently, it is desired to patrol a power line away from the highway, or carry the receiver into buildings. This portable receiver should be as light as possible and does not require to be as sensitive as the receiver in the car. To atone for the lack of sensitivity, the portable receiver may be placed with the loop near some wire connected to the power systems under investigation. The ground wire on the pole will conduct the interfering surge from the power wire to the radio receiver. This portable receiver may be used with a probe antenna or a radio frequency exploring coil, for pick-up, in place of the loop, where it is desired to determine which of a number of wires carries the interfering surge with the greatest intensity. The receiver with the loop is intended to determine the field of radiation within several yards, while the exploring coil and probe antenna are intended to determine this field within a few inches.

Radio Frequency Exploring Coil

The radio frequency exploring coil consists of a honeycomb coil of approximately 75 turns. This must be thoroughly insulated, so that it can be used with safety near high voltage bus-bars in a power house. It is used in the same way as the loop antenna, but, being small, has the advantage of determining which bus-bar carries the interference, when these bus-bars are in close proximity. It possesses the same directional characteristics as the loop.

The use of the radio frequency exploring coil, is, however, limited to places where the receiver can be carried within a few feet of the power wires or bus-bars, as the radio frequency exploring coil cannot be used with a long lead. The capacity between the wires of a long lead would by-pass the pick-up from the coil.

The Probe Antenna

The probe antenna is used in place of the radio frequency exploring coil where it is not convenient to place the radio receiver within a few feet of the power wires. The probe antenna consists of an insulated conductor enclosed in a tubular metallic shield extending to within 6 inches of the upper end. The centre conductor is connected to the aerial binding post of the receiver, while the shielding is connected to the ground terminal of the receiver. This probe antenna will only pick up radio signals by the 6 inches which are unshielded and is, therefore, very useful for probing between wires. The shielding should be insulated, as contact from the shield to any metal or ground will cause noise in the radio receiver. An additional insulation, such as a fibre tube, may be placed over the upper end of the probe antenna for protection when working among high voltage wires.

It is useful to have the portable receiver thoroughly shielded when it is desired to work in a power house or other place where the intensity of the radiating field is so great than an unshielded receiver would pick up stray fields.

Switching Test

The switching test is only resorted to in the investigation of interference when it is convenient to switch the suspected circuits on and off without inconveniencing the power consumers, or where other methods of investigation fail.

Many sources of interference do not start immediately the circuit is closed. It is, therefore, more reliable to consider the results when opening a circuit during the time that the interference is continuous. Usually, the switching test should be repeated several times, to avoid misleading results from a coincidence in which the interference starts and stops, at the instant of switching, from some independent cause.

Surge Traps

Surge traps are usually installed in the power lines which supply the apparatus, in order to stop the flow of the surge which causes the radio interference. In exceptional cases, however, when it is not practical to do this, a surge trap can sometimes be effectively installed in the electric service wiring in the vicinity of the receiver.

Surge traps may be divided into two classes:—

(1) The tuned radio frequency rejector circuit,
(2) The untuned surge trap.

Tuned Radio Frequency Rejector Circuit

The tuned radio frequency rejector circuit, shown in figure No. 5, consists of an inductance in the power line, with a condenser connected in parallel with the inductance, the value of the inductance and the condenser being such that the impedance of the line is extremely high at the particular radio frequency which the rejector is designed to stop. This type of surge trap is seldom used as it only stops the interference to a receiver which is tuned to one particular wave length.

Surge Trap Untuned

The untuned surge trap is the type most frequently used as it is designed to stop the interfering surge, no matter what form this surge may take. The surge may consist of radio frequency oscillations either continuous or damped, or may consist of series of extremely sudden changes in voltage. These surge traps are made up of condensers, or choke coils, or both. The purpose of the condenser is to by-pass the surge, by providing a path of low impedance, but which will not conduct the power current. The choke coil is placed in the line so that it will carry the power current without any material loss and introduce a high impedance to the interfering surge. By a suitable combination of condensers and choke coils it is usually possible to prevent the surge from passing the surge

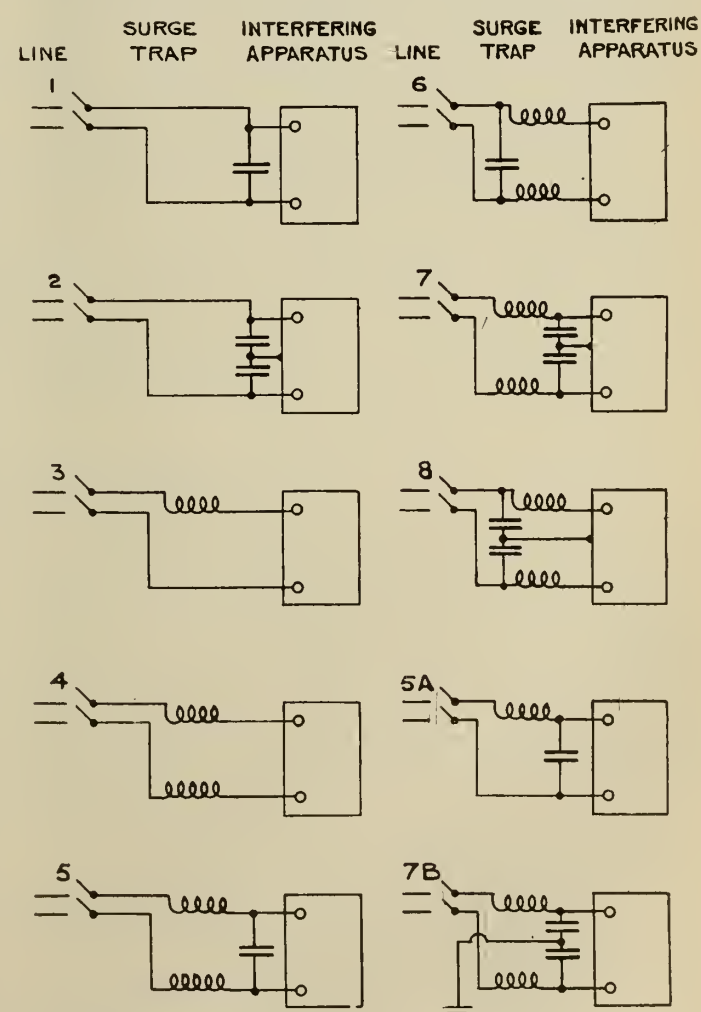

Figure No. 6.—Diagram of Surge Traps, Standard Types.

trap with sufficient intensity to cause material interference to radio reception.

As the requirements of a surge trap are dependent not only on the type of apparatus causing the interference, but also on the characteristics of the wiring supplying the apparatus, and other nearby wiring, it is not possible to recommend a definite surge trap for any given class of electrical apparatus. In order to find the most economical surge trap to eliminate the interference, it is usually necessary to conduct a few simple experiments. When conducting these experiments particular attention must be given to all details, as a slight change in the arrange-

ments, which would seem insignificant to those without experience in the matter, might make all the difference between success and failure.

Figure No. 6 shows the types of surge traps most frequently used for the prevention of interference.

All surge traps should be installed according to the regulations of the Canadian Electrical Code, as most of the provinces have accepted this code as their standard.

Condensers

Condensers used for surge traps are supplied in capacities of 1/10, ½, 1 and 2 mf., according to requirements. The value of the capacity is not critical and, if it is found that 1 mf. condenser does not reduce the interference whatever, it is seldom possible to entirely eliminate the interference by using condensers of other capacities. As a general rule, the smaller capacity is suitable for the elimination of interference in which there is a very small current surge, such as in the case of telegraph interference. Condensers of larger capacity are required, however, for such cases as battery chargers and moderately-sized motors and generators, in which there is a considerable current surge which causes the interference.

The condensers should be made to withstand a test voltage of several times the voltage of the line, as the surge which causes the radio interference very often has instantaneous values of voltage very much in excess of the line; for example, the surge on a telegraph line supplied from a fifty-volt battery will, in some cases, exceed two hundred volts.

Choke Coils

The inductance of choke coils for use in surge traps varies from ¼ to 15 millihenries, according to the special requirements. Choke coils for this purpose are designed so as to have very low distributed capacity. The distributed capacity of a choke coil is the property of a choke coil which is equivalent to a condenser connected in parallel with an ideal choke coil having no distributed capacity. This distributed capacity forms a by-pass which will conduct the surge, causing interference, to the line. It is, therefore, necessary to keep the distributed capacity as low as possible and in no case should it exceed 75 micro-microfarads (0.000075 mf.). The ideal choke coil is made by winding insulated wire in a single layer, on an insulated cylinder. As this type of construction, however, takes up considerable space, the coils may be wound according to the method known as bank winding, shown in figure No. 7.

Ordinary multiple layer winding is practically useless for construction of choke coils, as the distributed capacity between adjacent layers is excessive. Another type of choke coil, frequently used, may be described as the pancake type, in which there are a few turns per layer and many layers. In this way, the distributed capacity is kept low, as in bank winding, on account of the fact that the many layers are equivalent to condensers in series.

Choke coils should not be impregnated with wax or other dielectric, as the dielectric constant of those substances is greater than air, and, thus, increases the distributed capacity. As a general rule, no iron is required for choke coils, as the inductance of the choke coil does not require to be great and the permeability of most iron at radio frequency being very low would, thus, not materially increase the inductance of the choke coil with regard to the interfering surge but it would tend to increase the distributed capacity, and, in this way, reduce the effectiveness of the coil.

In exceptional cases, however, iron is used in the construction of "absorption type choke coils," in order to absorb the energy of the interfering surge.

Size of Choke Coil

The size of wire used in choke coils must be sufficient to carry the maximum load of the apparatus without overheating, which would cause a fire risk; or without causing excessive voltage drop, which would interfere with the operation of the apparatus. The maximum voltage drop in most of the choke coils is usually from one to three volts. This voltage drop, is, therefore, usually negligible on circuits of 110 volts or more, but must be considered when dealing with low voltage apparatus such as that supplied from 6-volt batteries.

The insulation of the choke coil to ground or between lines must withstand the voltage of the line with the necessary factor of safety. The insulation of the wire between turns is practically independent of the voltage of the line and ordinary cotton covered wire is usually sufficient for the winding, provided the choke coil as a whole is well insulated from ground and wires of different voltage. Care must be taken, however, in constructing bank wound choke coils, not to damage the insulation of the wire when the wires of the choke coil are required to cross, and double cotton covered wire is recommended in this case.

Engineering Education

Abstracts of the Seven Papers Submitted for the Past-Presidents' Prize, 1929.

The following are abstracts of the seven papers submitted for the Past-Presidents' Prize during the prize year 1928-1929.

Paper No. 1.

The first problem of the educator is to select the fundamentals from the vast store of human knowledge, that shall best fit the student for further progress.

The greatest difficulty in organizing engineering education is in providing teachers who will command respect, enforce discipline, inspire a love of study and train their students to be seekers after knowledge.

It is essential to teach only that number of subjects that can be given with thoroughness and to point out in all courses that successful application rests on good business methods, good ethics and sound economics.

It is thought that the technical student should be drilled in the use of clear forcible English, when speaking as well as when writing.

The mind trained to the proper use and definition of words and further trained to memorize and classify data and principles is fitted to show power and originality in dealing with the problems set before it.

It is desirable to weed out of the technical school and university the unfitted, the uninterested and the indifferent students.

It is desirable to encourage by scholarships and loan funds those who are anxious to learn but who have no one to pay their way. It is most unwise to allow students to spend more money than is actually required by the necessities of their college life.

The head of a school has a preponderating influence on its standards and success and great executive ability brings a school forward just as a great business concern is built by the energy and ability of its head.

If the teachers in our technical schools spend part of their lives in outside work it will enable them to be more independent to command higher salaries and be worth more in particular as educators.

Paper No. 2.

No event in recent years has signalized more clearly the growth of public esteem for the ability of engineers than the election of Herbert Hoover as President of the United States.

Engineering training is likely to develop qualities of exceptional social value in the business man or statesman of the present day.

"On what are we prospering in Canada at present? We are mining our prairie land for export wheat, and we are mining our forests for export pulpwood. We are mining our nickel, our gold and our copper for a foreign market."

A system of regular apprenticeship for the training of skilled workers is needed in every province in Canada. (Ontario passed an Apprenticeship Act in 1928.)

Canada also needs technical schools sufficient to produce 5,000 trained workers of the foreman grade annually.

For young men of exceptional ability the avenue should be direct from the shop and the technical school through the university to the job requiring executive capacity.

Paper No. 3.

The considerations covered by the title are so wide that only broad principles can be discussed.

The influence of the teacher on the student is a very important factor in education, and for this reason it is desirable that young engineers, after preliminary learning in school or college, should continue their studies in positions in actual engineering work under a practising engineer; this practise of master and pupil to be encouraged by employing corporations.

The education of an engineer is incomplete when he leaves college, and he is only commencing its more practical phase.

The Engineering Institute of Canada has shown a regrettable tendency to pay more attention to ethical professional standards and to rates of pay for members, than to the more important duty to enlarge the technical knowledge of its members.

Engineering societies could have a deciding influence on the progress of the engineering student after completion of college work and entrance into his life's work.

Engineering students for continuance of their education should attend engineering society meetings, where papers on engineering subjects are read and discussed.

There should be the closest possible co-operation between the engineering society and engineering schools.

The future of education for engineering lies with engineers, whose judgment in any educational matters should prevail over that of professional educationalists.

There is a lack of connection between prescribed courses of study and practical engineering work, only partly made up by employment of students on engineering work during summer vacations.

A more definite and systematic co-operation of large employment corporations in affording employment for engineering students during summer vacation periods is desirable. The present system is too haphazard. The Engineering Institute of Canada is the logical body in Canada to grapple with this situation.

The apprentice system combining, for students between sixteen and eighteen, field and shop work with applied study (such as engaged in by General Electric Company and Westinghouse Lamp Company) is commended.

A study of the Latin and Greek languages, as languages, is not necessary for an engineer and cannot the cultural tradition desired be obtained from translation? The ability to write and speak both English and French is necessary in Canada.

It is not possible for the engineer to know too much mathematics (including accounting), and of natural science.

The dead languages, psychology, political economy, English literature should not be included in an engineering curriculum.

The chief weakness of engineering education is the lack of relation in the student's mind of things read or heard, or supposedly learned, to practical work.

There is a lack of connection between school studies and the daily life and work of the engineer. Some engineering executives, who have achieved great material success, have become almost obsessed with the unpracticality of college education.

The greatest engineer will always be the man whose brain power would have made him great in any walk of life.

Training for executive positions is outside the scope of educational institutions.

Education for engineering research may be properly left with the colleges, with some intelligent assistance from the operating companies who benefit from the results of research.

Paper No. 4.

There are three stages in engineering education; selecting the raw material, teaching the student, and placing the graduate so that he shall be of maximum use to the world and shall make the most of his own life. A possible fourth function is to co-operate with employers in the process of absorption.

Preparatory schools are too closely supervised, with studies to be done in a set way, do too much "spoon feeding," and tend to kill the imagination and initiative of the student.

Engineering graduates in non-engineering work should have been advised by some method of selection not to enter on an engineering course.

Learning alone does not make an engineer, nor an educated man of any sort; just as necessary are those peculiarities of mind and temperament lumped under the term "personality."

A suggestion is made that a psychological or intelligence test and a personal interview might be useful in determining whether or not a prospective student should take an engineering course, the membership of The Engineering Institute of Canada to assist in this movement by acting on boards of inquiry.

The engineering professors must maintain professional contacts outside of teaching, necessary both to supplement their incomes and to keep in touch with the ever-progressing world of engineering.

Too many teachers are graduates of the institutions they serve, with limited knowledge and experience. No one should be permitted to teach in a school from which he has graduated, until he has spent an apprenticeship in teaching elsewhere. No one should be allowed to serve as an engineering teacher who has not had some years of practical experience. The Scottish practise, whereby assistant professors have greater chances of advancement by transferring to other colleges is recommended.

The main job of a college is to teach, and research should take a secondary place. Research should be in the hands of a special staff with only limited assistance from the teaching staff.

Small classes where something approaching individual teaching is given are preferred to large classes.

The abolition of "cramming" for examinations is desirable, as cramming does not give time to think quietly and "digest" one's information. The passing of examinations should be given minor importance rather than the prominence it now has. Examinations give some indication of how much knowledge a student possesses but little as to his ability to use it.

Examinations might perhaps follow more closely the system of English universities and be held say twice during the entire course and on general questions rather than detailed for each specific subject. Some combination of written and oral examinations is desirable, showing both a student's knowledge and his ability to think.

Engineering courses generally appear to deal mostly with fundamentals with only enough specialization to give the student an idea of their extent. English and economics are generally included in an engineering course.

Roughly it costs about $4,000.00 to give a student four years' engineering training, of which he pays perhaps $1,000.00, leaving a deficit of about $3,000.00 to be met out of endowments, etc. The cost of tuition should be raised to the actual cost of education, neglecting the benefits of endowments and other assistance, the fees charged to students to be graded according to their scholarship with proportionately greater discounts given the best scholars. There would then be more incentive to the student to work and the school's income would be increased. (One of the oldest technical schools in U.S.A. is adopting above plan in 1929-30.)

The engineering graduate is only the raw material from which successful engineers are made, with a substantial plus handicap on account of the training received.

A placement or employment service conducted by the school for the purpose of securing employment for its graduates is a useful link between industry and the young graduate. This necessary work is now neglected by some schools. Industrial firms should also have their own placement bureaus and should pass on to the engineering schools their suggestions for engineering courses as evident from the work of the engineering graduates.

The scheme of giving students vocational or co-operative employment early in their college courses, to be continued throughout them, appears the best method for giving the student practical experience.

The "settling-down" period of a graduate, extending over from perhaps one to five years, should be carefully checked up by the engineering school and any necessary assistance given, the graduate meanwhile to keep the school informed of his whereabouts and circumstances.

The absorption of graduates is of great importance and has been neglected by the schools; improvements have been forced by industry rather than the schools, but the present indication is that the schools are assuming their responsibilities.

The quality of those entering our schools is probably better than formerly; our teaching is improving; industry and the schools are co-operating more closely than formerly; the engineering profession is taking more interest than formerly in educational matter.

Paper No. 5.

The graduate who is trained how to think, rather than what to think, normally is the more useful in his profession, and the more capable of expansion and personal success.

The successful engineer must express and convey his thoughts to others. During his school course much opportunity should be given for debate and discussion before class or larger groups.

More attention to be given to the student during school and high school days with departments or agencies to advise with parents and children regarding suitable careers for the young student.

If a youth has little or no facility in mathematics, poor reasoning power, and lacks initiative, he would not succeed as an engineer.

More attention to be given to the school covering the period of the student from eight to sixteen years. The following are suggested:—

(1) Each school to have a person as a co-ordinating element or visitor between home and school;
(2) More care taken in electing school trustees;
(3) Assistance to teachers by an increased number of teachers who shall be receiving greater remuneration, and also be encouraged to show more initiative and individuality in teaching;
(4) Competent teachers who can arouse interest especially in mathematics, physics and chemistry; and teachers of these subjects to visit rural schools. Ability to arouse and stimulate interest to be rated as high as mastery of the subject.
(5) Facilities to be provided for more individual and less mass school work.

The conference method in class is advisable rather than the set lecture method.

After high school graduation, a year in some industrial plant as a labourer or mechanic is suggested, with one or two evenings per week at pre-university studies.

It is desirable to present to the university men with better preparation than is now the case.

Mathematics, physics and mechanics should have first consideration in an engineering course.

During college course, basic or elementary principles to be given throughout the course; from two-thirds to three-quarters of the entire time of college work is suggested in studying basic principles.

During the fourth year at college, visits to chemical, industrial and engineering works are suggested.

The National Industrial Conference Board of the United States investigating training in industry in questionnaires sent to men in pulp and paper industry received replies that subjects requiring more attention in college courses were economics, business administration, accounting, public speaking and psychology.

Attention to be given to debate and to English composition so that a student may state a case clearly before a public meeting, or state matters concisely in writing.

Close co-operation to exist between universities and industry in providing occupation for the student during vacations.

The young graduate to take an active interest in an engineering society, and such societies to make co-operation with him a definite part of their activities.

Requirements for matriculation should be more scientific and less academic.

Post graduate occupation should be regarded for at least five years as a part of training and education.

Paper No. 6.

The paper starts with a description of the Junior Technical School in Great Britain.

British engineering authorities agree that a practical training in an engineering works or industrial plant must be taken along with an engineering course.

The same year, 1824, that saw the opening of the Birkbeck Institution in London, England, produced the Rensselaer Polytechnic Institute at Troy, New York.

The American General Electric Company maintains a "testing course" absorbing about 400 engineering graduates per year on pay for a training in practical work on graduation, this "testing course" extending over from one to three years, depending on the ability and preference of the student.

In recent years modern society has come to realize that men with a solid foundation in science and engineering must be capable of taking a leading part in matters of policy and government.

The value of an arts course before the engineering course may be over-rated, unless there is a definite programme of study and objective throughout the courses.

The fundamentals that an engineer requires are founded on a knowledge of chemistry, physics, mathematics and mechanics.

Prof. George Swaine's advice in "The Young Man and Civil Engineering" is that he should enter an engineering school as soon as he can, that he should select courses that call for his most serious effort, and that he should not aim for culture, as that will come.

The ability to write and speak English well is essential.

Findings at convention of American Institute of Electrical Engineers at Niagara Falls in 1922, on engineering education as follows:—

(1) A more careful sifting of those not suited to the work;
(2) The selected group to be thoroughly drilled in mathematics;
(3) Specialization to be secondary to fundamentals;
(4) Specialization to be left until after graduation or at least until late in the course.

Adaptability to engineering is an inherent trait, and the college cannot create it, but only develop it.

The intelligence or psychology or other tests to be applied to students wishing to enter college.

There should be a point in the intelligence scale (obtained by comparison of school achievement and intelligence tests) below which students should be discouraged from entering a university.

Special provision to be made for brilliant pupils in selected classes, rather than mass instruction for students of different abilities.

The necessity of training for technical education in the trades being available to all workers.

The Engineering Institute of Canada, comprising all branches of professional engineering, to take an aggressive stand in educational matters in Canada. Suggestions made include:—Institute members to be on advisory boards of universities and have more to say regarding courses and subjects; students to be encouraged by scholarships to obtain training in industries with the co-operation of the industries; more interest in technical education for the masses; The Institute should go on record as to its educational requirements.

Paper No. 7.

The remarks affecting engineering education mentioned in this article, as well as other general statements, may well be summarized in the form of a number of suggestions or conclusions. In order that these may have definite application to specific cases they are assumed to apply in Canada and as sponsored by an engineering society such as The Engineering Institute of Canada. Statements are made at random and not necessarily in order of importance.

(1) The present facilities for engineering education in Canada insofar as number of universities are concerned are centrally located throughout the different provinces in Canada and are sufficient for present population, and equipment may be enlarged on demand rather than new universities adopting engineering courses.
(2) The general standard of engineering education in Canada is of a high grade and sufficient for the development of the country.
(3) With a higher standard of engineering education in Canada as and when insisted on by The Engineering Institute of Canada and the Provincial licensing bodies of the Professional Associations of Engineers the standards of personnel must improve.
(4) With improved personnel in the engineering profession a higher standard of appreciation from the public would be created and more remuneration obtained.
(5) The professors in engineering subjects to be granted adequate compensation on a par with practising engineers.
(6) Insistence of a more intensive infiltration of engineers into all positions,—in parliament, on commissions, in executive positions generally, in industry, in city manager and town planning positions, etc.
(7) Recognition of the fact that engineering education is bound up in an economic cycle with employment and remuneration. For fullest efficiency of engineering education public regard must be such that engineers are employed at adequate compensation in all possible variety of engineering positions and that engineering graduates are generally employed in industry. If the engineering profession is in the doldrums, engineering education must also suffer.
(8) Employing engineers and senior engineers to see that adequate salaries and chances for promotion are given where possible to junior engineers. The result of this may provide an opening for a man leaving college.
(9) An engineering society such as The Engineering Institute of Canada to assume the proper responsibility of an engineering society in educational matters and to keep all matters affecting engineering education in Canada constantly under review. This is to be in the nature of suggestions or criticisms from the entire membership of The Institute.
(10) The Engineering Institute of Canada to also have a live Educational Committee to make a study of specific cases and make recommendations. More is required than a more or less honorary list of members who bring in a more or less stereotyped report once a year but without producing results.
(11) The investigations and findings of such bodies as the Carnegie Foundation and Society for the Promotion of Engineering Education to be studied as these may have a bearing on problems of engineering education in Canada.
(12) A more active interest in research work by Canadian universities and by industry with close co-operation between the two.
(13) The employment of both professors and students in engineering during the summer vacations. The possibility of some of these being engaged on research work to be considered.
(14) An insistence on the part of employers of labour and practising engineers that all work of an engineering nature be given only to engineers or those in training for engineering courses. This is a very important requirement as many engineering students may be deprived of necessary experience in shop or on survey, particularly during the summer vacations, if this is not insisted on.
(15) Continuous training for practising engineers to be considered. These to include engineering society membership, engineer's clubs, periodicals, trade magazines.
(16) Engineering professors to attend engineering society annual meetings as the representative of their university, the expenses to be provided for annually in the budget of the university.
(17) The subject of vocational education as a preparation course for future engineering students to be studied.
(18) Attention to be given to some training for all persons in engineering works, in engineering construction, and in industry generally, so that the finished product may be as perfect as possible. Universities, schools and engineering societies to lend any possible assistance in this training.

An Economic Study of Motor Roads for Pulpwood Operations

A. A. Wickenden, A.M.E.I.C.

Chief Engineer, Lands and Woods Engineering, Canada Power and Paper Corporation, Three Rivers, Que.

Paper read before the St. Maurice Valley Branch of The Engineering Institute of Canada, June 21st, 1930.

Introduction

To obtain wood supplies for manufacturing pulp and paper many agencies exist which, while simple in themselves, are extremely sensitive to management owing to the quantities involved. As a result of the management of these agencies large sums may be saved or spent to secure identical results for it is easy to realize, when dealing in units of one hundred thousand cords that a difference of one dollar per cord represents large sums, yet the variations of unit costs are often far greater than this.

The writer has in mind several such features of management in which losses or gains can be effected by comparatively slight changes in planning and of these the subject of transport offers aspects most interesting to engineers. In this field alone we may observe factors among which roads are of great importance whether in their classification or routing.

In the following paper it has been endeavoured to show the economic principles influencing or which might influence the decision of engineers in their final choice of roads and methods for the transport of supplies and personnel in pulpwood operations. The conclusions obtained may of course apply to other forms of forest exploitation by the use of proper conversion factors.

The Necessity of Roads for Pulpwood Operations

In planning the yearly cut of pulpwood or any lumber, we have to deal with hundreds of square miles of comparatively unknown territory. These large areas known as "limits" or "freehold" lands, are generally based on some stream or streams which furnish routes of penetration and extraction. They consist of a vast tangle of thick forest, swamps, streams and lakes penetrable only by rough tote roads or to light parties along stream routes in summer and by snowshoe trails in winter.

To introduce into these forest lands the necessary personnel and horses to cut and take out the wood, to carry in the food and supplies for these, to protect the forest, to build structures whether buildings or river improvements, to supervise and keep in touch with the manifold phases of the work, are some of the problems to be solved before a supply of logs reach the block-pile. It is, therefore, obvious that some form of roads must always be organized before cutting can begin.

Whether much or little study and expenditure be given to the matter, at all times the transport of supplies and personnel has been the foremost reason for the construction of roads in woods operations and has been the main factor in the determination of routes. In this paper we will show how vitally the cost of the transport of these supplies and men is affected by the principal methods followed on land routes.

By the term "supplies" we mean all classes of food for man or beast, clothing, construction material, medical supplies, tools of every description, in short all that will be needed to shelter, feed and permit the work of the small population necessary to cut and bring to the mill its raw material, pulpwood.

The weight of these supplies varies directly with the number of cords cut and may be assumed to be forty pounds per cord as stated by Mr. G. E. Lamothe, A.M.E.I.C., in his paper read to the Annual General Meeting in 1927.

The total yearly cut of pulpwood in Canada is about 6,000,000 cords. To cut this, therefore, requires the movement of about 240 million pounds of supplies yearly or 120,000 tons. If we consider the total cut including saw lumber, firewood, poles, ties, etc., we would greatly increase this tonnage. If we think in terms of organized communications, the movement of these supplies would not appear so great but when we take into account that this amount is finally distributed by horses to the cut areas, we can easily understand that this is indeed a problem of some magnitude.

If we consider further that a good part of this horse transport moves over roads roughly hewn into the bush, we realize that the expenditure of effort and money to carry supplies merits much attention, lacking which it is easy to lose or make large sums without being aware of it.

Closer utilization and competition with foreign wood make it necessary to obtain pulpwood at a reasonable figure. Of the several factors known to the writer which would improve present methods of exploitation, selection has been made of those which show how profits may be derived from good roads and motor transport as against the old tote roads and horse transport, when long hauls and large quantities of supplies are concerned.

General Process of Transportation of Supplies

As stated before most limits are based on streams. These streams flow along irregularly curved lines, but for the purpose of this discussion we will assume figuratively that a stream has been straightened out, giving a limit of an undetermined number of miles in length by ten miles in width. In the centre of this limit flows the stream in question, as in figure No. 1, line A-Ax. Along this stream we may assume a road to be built, while point A represents a railhead or port to which all supplies for one season's cut are first freighted by land or water.

Let us now assume that an area is selected in this limit to furnish some required amount of wood. To cut this area, camps will be distributed to house a varying number of men and horses.

To these camps, (indicated by letters $b1$, $b2$, $b3$, etc., or by letters $c1$, $c2$, $c3$, etc.), supplies are transported from the railhead A or cache $A3$ as follows:—

(1) Either they are distributed directly from A to camps $b1$, $b2$, $b3$, $b4$, etc.

(2) Or they are transported to a secondary point of distribution generally called cache or depot, such as $A3$, whence distribution takes place to camps $c1$, $c2$, $c3$, etc.

In other words we have (a) primary transport to port or railhead, which is effected by ships or trains; (b) intermediate transport from port or railhead A to a cache $A3$ by ship, motor or horses; (c) secondary transport from this cache which is effected in small quantities by horsehaul.

For areas like that in figure No. 1, intermediate transport takes place as soon as secondary or retail distribution becomes uneconomical from A. The distance at which this occurs varies. Five miles seems a good figure to adopt for the distance at which retail hauling may stop, and this explains the width of ten miles for our theoretical limit, five miles on each side of the main stream route.

Based on this principle the last cache should be at Ax, five miles from the farthest extremity of the limit.

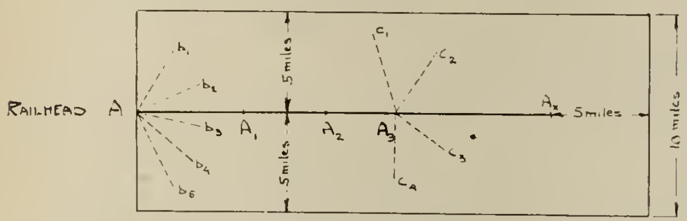

Figure No. 1.

In other words, in the limit of figure No. 1, intermediate transport will take place along line *A-Ax* of which the length equals the length of the limit less five miles.

The distance of intermediate hauling will vary from year to year. If we consider a progressive cut along divisions rectangularly placed along the route *A-Ax* as in figure No. 2, we will see that the minimum intermediate hauling is zero miles at *A* and the maximum distance is the scaled length of the line from *A* to *Ax*.

Average Haul

In planning the construction of roads in large forest areas it has been too often the practice of considering intermediate haul from railhead to cache as it occurs from year to year. Naturally, when we are close to the railhead the effect of the good or bad qualities of a road are less strongly felt. It is where exploitation goes beyond the half way point of a region that expenses multiply. For this reason, an engineer should not plan out his roads for one small section alone but for the whole region to be exploited over a number of years. This general plan, however, may be carried out in small sections over several seasons. As the cut advances and his road becomes built he may modify his views but he should not allow the permanent interests of the whole to be sacrificed for the temporary interests of a part. Hence, the first consideration in making his plans is not the distance of haul of the first year, but the average haul for the whole region. To permit such planning, however, he should be informed fully of the localities where the cuts are to take place and of the quantities to be cut, as well as any other facts applying to a cut programme. Moreover, to permit cheap transport it is obvious that regions should be progressively and fully exploited to permit the full use of all improvements put in.

With an evenly distributed timber supply, the average haul in figure No. 2 will be one half of the scaled distance from point *A* to point *Ax*. Should the distance from *A* to *Ax* be forty miles for example, the average haul would be twenty miles.

Variations from figures Nos. 1 and 2 are naturally the rule but the basic principles are always the same in solving transport problems connected with supply distribution in the forest. The deductions obtained in the above abstract figure will apply to any variations in the shape of limits since one of the principal factors is the area of the territory in question as we shall see later.

Methods of Transportation Utilized

Primary transport by water or rail. To points along the north shore of the St. Lawrence for instance, or in large streams, supplies will be carried by ships, while along the St. Maurice valley as another instance, the railroad will bring supplies to various stations on the Canadian National system. This transport is carried out mostly by various public carriers and follows the most economical routes.

Intermediate Transport

Intermediate transport is generally effected by means of:—

(a) Waterways,
(b) Horses with rough winter tote roads,
(c) Motor transport (including tractors and motor trucks).

Water Transport

From the port or railhead it may be possible to carry supplies to the "cache" by water. As mentioned by Mr. Lamothe, water transport is most desirable but, we will add, if it does not involve too much handling and if distances are sufficiently long. When it is combined with land transport, however, it has not always been found practical for short distances as the handling and re-handling of goods becomes a very costly item, as the usual way is to unload the freight car into wagons which take their load a short distance to the landing whence the boat is loaded. The reverse process is gone through at the cache where goods may be stored temporarily to permit immediately unloading the boat. If the waterway is only a portion of the route to be followed the combination of the water and land transport may become as, if not more, expensive than if a good road were used throughout. Moreover, when waterways are utilized a period occurs in the fall and spring when all communications are blocked owing to the freeze-up and the break-up. Under such conditions serious risks are taken by personnel and horses, who are reluctantly compelled to travel at such times.

Horses with Winter Tote Roads

When horses are used to transport provisions, tote roads are prepared roughly in the fall. When snow comes, the unevenness due to stumps, rocks and soft places disappears, and the road becomes passable. Sleighs are then used to carry provisions to central points of distribution. The large rough buildings called "caches" in this province, are built to shelter these provisions until the time when they are needed. It is obvious that with such an arrangement, the larger proportion of supplies needed in early fall must be put in place the previous winter to provision personnel and horses until snow roads are again in order. The roads are roughly reconnoitred and, as they are used, locations whether improved or not, are changed from a few feet to several miles from year to year. To avoid road making, frozen streams, lakes, and swamps are utilized. Side hills, which mean manual labour, are studiously avoided so that, in the effort to keep the sleighs on an even keel, it is preferred to climb steep hills, to building even such rough sidehill arrangements of sticks and logs as are constructed where unavoidable. Needless to say, spring, summer or fall travel on such roads is difficult when not impossible or ended by large sheets of water which were the best sections of the route in winter.

This method involves the necessity of halting places about every ten miles, as a total day's march is reckoned to be about twenty miles. Stables, a cook-house and rough bunkhouse are, therefore, placed at these approximate

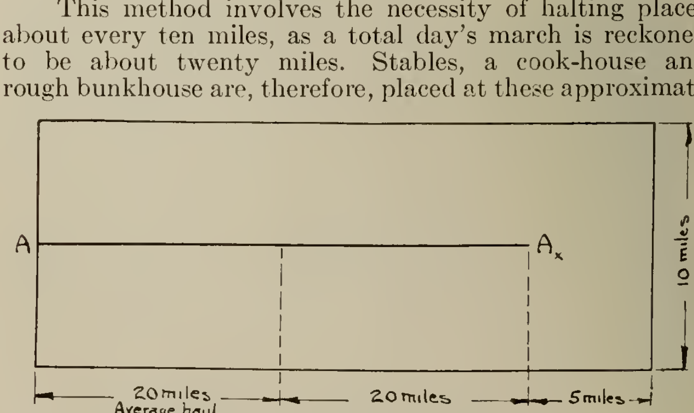

Figure No. 2.

intervals. These buildings are scarcely ever put up specially for the purpose, but are generally some old cache or contractor's building left from former years.

The principal advantage of this system is cheapness of initial road construction, but it must be fully remembered that it costs a sum which, added to yearly repair, is fully equal to the cost of maintanance of gravel roads. If these roads were used in winter only, things would be fairly tolerable, but jobbers or operating crews must be moved in during late summer and early fall before the snow comes which involves much trouble and suffering to the men and personnel involved. One particular stretch we have in mind was called by the Lake St. John men who travelled on it "Le Chemin des Larmes," the "Road of Tears." It was responsible for the loss of some fifty wagons and sleighs, the death of twenty horses and untold hardships to the men, all in one season.

Such roads do not make the forest areas accessible at all times of the year, and add considerably to the prices bid in tenders for the cut.

should be made and kept for the easier sliding of sleighs. A cost of $1,000.00 per mile may be assumed to be sufficient to build such roads in hilly country. The hauling season to be depended on is only sixty days per season.

For tractor hauling in summer the same type of gravel roads as for trucks are necessary with the only difference that the grades must be kept lower and bridges made stronger.

As in the case of hauling by horses, tractor haul in winter means filling a cache almost a year ahead of requirements, which again means disbursements of interest and insurance.

(*b*) *Trucks on Gravel Roads.*—In this instance no cache is filled the winter before. The provisions are motored into the area to be cut practically as cutting begins. The caches are filled while cutting proceeds and motor hauling can be carried on up to December if the season is good. The roads should be gravelled for a width of eight to ten feet. An extra width giving up to sixteen feet between ditches may be more roughly finished to

Figure No. 3.—Railhead Depot on Canadian National Railway.

When the cache is filled it is left, generally under guard of a watchman, until the next fall when cutting begins. It must, therefore, be insured against fire loss and involves also a capital sum, the use of which entails the loss or the payment of interest.

Motor Transport

(a) *Tractors.*—Motor transport may be effected by means of tractors or trucks. For distances of haul such as are commonly met with in the hauling of supplies from railhead to cache, tractors may be utilized on the snow in winter with trains of sleighs or on gravel or dirt in summer with trains of trailers. Needless to say the sleighs afford less resistance and permit cheaper hauling, thus making winter hauling less expensive than summer hauling.

Winter hauling also permits a much cheaper grade of tractor road to be built than for summer haul. The winter tractor road, however, is much more carefully made than the tote roads used for horse transport.

They require very careful location as grades must be kept much lower than for motor trucks. However, since frost is largely depended on to give a good bearing, the bottom is not so important as for gravel roads. The maintenance is an important item and some iced tracks

permit turnouts. The test of the quality of these roads is that they should be serviceable from spring to freeze-up in all weathers. Bridges and culverts should be substantially constructed with logs. We will not undertake here to give details of construction, but will limit ourselves to a statement of the actual cost of these roads as we have found it. In the St. Maurice region an average sum of thirty-five hundred dollars per mile should cover the first cost of stretches to be built in sections of say twenty miles more or less. The first cost above mentioned can be materially reduced in certain sections where topography permits or where stage construction is possible. This subject of stage construction was most thoroughly discussed by Mr. Alex Fraser, A.M.E.I.C., chief engineer of the Department of Roads, Province of Quebec, in his paper "A Few Economical and Technical Aspects of the Road Problem of the Province of Quebec" which appeared in the October 1929 number of The Engineering Journal. Other sections, however, demand a practically full expenditure at once, such as where rock or swamp are encountered.

It is necessary to state, however, that nothing but thoroughly supervised work will do as we have found that many disappointments are liable to be encountered through careless work.

Figure No. 4—Tote Road before the Snow.

It is also obvious that if the initial work is light, maintenance will be heavy at first, while if the initial work is heavy maintenance costs will be less. We have found grades of ten percent quite easily travelled over by motor trucks with full loads, although such grades are high for the use of tractors, the drawing power of which is much influenced by grades. The general location of these roads should be carefully made with reference to general route, cost and grades. As a rule stream valleys are followed and heights of land crossed only to reach other valleys. It is also to be carefully noted that choice of soil has a most important bearing on cost of roads, and this feature alone means close supervision and reconnoitering as building progresses since, owing to the tangled state of the forest, it is difficult to judge the ground properly until the brush and trees are cut. Needless to state, roads under heavy traffic need attention, and again it is well to emphasize the necessity of intelligent supervision, inspection and maintenance of roads during the open season.

Whether trucks or tractors are used in summer, a good gravel road must be built. It remains to prove if the extra expenditure involved justifies itself as against the method of stocking a cache a year ahead by horse transport or tractors in which initial road costs were small.

Distribution of Supplies from Caches, Secondary Transport

The distribution of supplies from the cache to the various camps scattered in an area to be operated is made by horse transport. In the early fall wagons or jumpers may be used; jumpers being rough sleds with wooden runners. The roads are merely trails with the bushes cut off. Their distance may vary owing to local conditions, but in general the hauling distance from cache to camps does not exceed five miles. The supplies are eked out as necessity arises and while the toting is bad until the freeze-up, the quantities involved do not cause too much hardship as the distances are short, the loads fairly light and the trips not too frequent.

A Comparison of Methods Outlined

It is obvious from the above enumerated facts that in comparing methods of transport we are practically fixed by geographical position in the matter of primary transport to port or railhead.

As to secondary transport, piecemeal quantities eked out through the winter for short hauls practically force us to adopt horses to accomplish this.

There now remains intermediate transport for which we may have water or land routes. We will confine the discussion to the case of land transport only and in this we have three alternatives.

Horses with cheap winter tote roads hauling provisions nearly one year before they are needed.

Tractors with more expensive winter roads to haul supplies also nearly one year ahead of requirements.

Tractors or motors with gravel roads hauling the provisions from the start of cutting operations.

In the first case we have expensive haul and cheap roads, in the second and third case cheap haul and more expensive roads. The total in each case will be analyzed to show which is the more advantageous.

Economic Factors forming a Basis for Planning Land Transport from Railhead to Cache

(1) Unit cost of horse transport for supplies (winter season).
(2) Expenses contingent to storing supplies in caches: Interest, insurance, wage of cache keeper.
(3) Unit cost of tractor transport of supplies (winter season).
(4) Unit cost of truck transport of supplies (summer season).
(5) Savings on labour costs by motor truck transport.
(6) Unit cost of roads.
(7) Area or areas to be cut and length of road from railhead to farthest cache.
(8) Density of wood.
(9) Yearly cut and weight of supplies necessary for this cut.

Unit Cost of Horse Transport

For the purpose of this discussion the unit weight will be one hundred pounds.

Our experience of the cost of horses has shown that the principal item in their cost is feeding, which varies according to the distance of haul. On the average, horses will feed every ten miles, which means that the railhead cost of their feed must be increased by the cost of road transport. We have found that the daily cost of feeding horses in the bush will run around $1.50 per day at present rates. With the horse's own daily rent this would make about $2.25 per day. For a team of two horses and teamster the cost may safely be taken to be $7.00 to $8.00 per day.

On any road the maximum return trip is twice the length of the road. Thus, for a twenty mile road the return trip is forty miles, taking two days and costing $16.00 to cover.

We have tabulated below the cost per 100 lbs. of transporting supplies by horses for distances to eighty

Figure No. 5—The Driller.

miles, the loads varying from 2,000 lbs. to 5,000 lbs. based on mileage only.

Table No. 1—Cost per 100 Lbs. for Hauling of Supplies by Horses, Winter Season

Load	Cost per 100 lbs.			
	20 Miles	40 Miles	60 Miles	80 Miles
2,000	$0.80	$1.60	$2.40	$3.20
3,000	0.53	1.07	1.60	2.14
4,000	0.40	0.80	1.20	1.60
5,000	0.32	0.64	0.96	1.28

In the following tables we have not shown the cost of horse haul on an increased scale due to greater cost of feed. In an average journey of fifty miles or one hundred miles return, five days rations are consumed, or 400 lbs. per team, some of which is used at the railhead and some along the route. When distances make necessary the hauling of horse feed to carry on the hauling itself, this factor is one which merits close attention and adds to the numerous troubles entailed by the use of animals.

We have not taken into consideration the item of loading and unloading which is fixed for all mileages.

Table No. 2—Diminution of Effective Load Due to Horse Feed, Based on Ration of 40 Lbs. per Day per Horse or 80 Lbs. per Day per Team.

Total Haul, Miles	Days for return trip	Average haul of horse rations, miles	Weight consumed for average haul of horse rations	Weight for total distance hauled lbs.	Percent of total load of 3,000 lbs.	Cents increase in haul per hundred owing to feed (from Table No. 1)
10	1	5	80 lbs.	40	1.3	0.3c
20	2	10	160 "	80	2.7	1.4c
30	3	15	240 "	120	4.0	3.2c
40	4	20	320 "	160	5.3	6.7c
50	5	25	400 "	200	6.6	8.8c
60	6	30	480 "	240	8.0	12.8c

The last two columns, in this instance, show the percentage of each load used in feeding and cost of hauling this percentage; it may also be taken as an indication of the increase in the rate per hundred pounds for an increase in distance.

This feature of a gradual increase in the cost of hauling by horses has been disregarded in our further development of this subject.

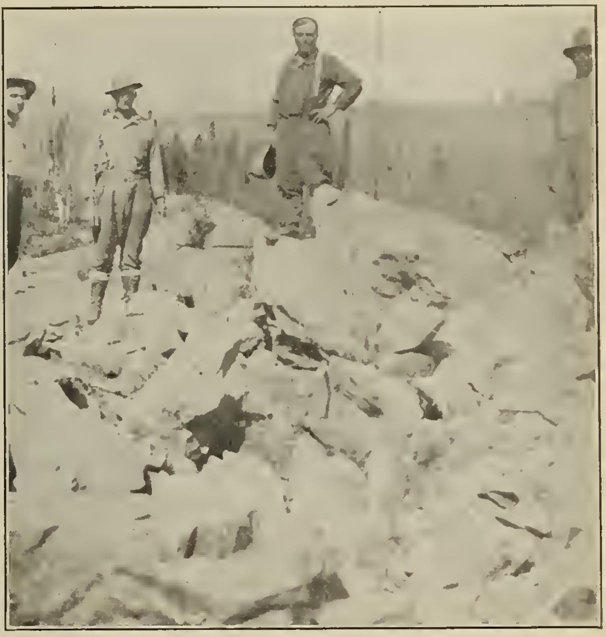

Figure No. 6—Rock Section after Blast.

It is well to state, however, that in our experience tender prices of 75 cents per hundred for a twenty mile haul seem to be a fairly representative bid by haul contractors, which it is difficult to better.

Expenses Contingent to Storing Supplies in Caches

A cache being filled almost one year ahead ties up capital for which interest must be paid. It must also be insured against the ever present danger of fire. For the latter reason mostly, it is usual to hire a cache keeper to watch the valuable supplies under his care, the more valuable because the whole next season's cut depends on the cache being carried intact through a dangerous fire season.

The value of the interest, insurance and wages to cover these expenses may be taken at 10 per cent of the total value of a cache.

The basis for this figure is the sum of interest, insurance rate, and wages expressed in percentage of the value of the cache as follows:—

Interest	7	per cent
Insurance	2½-5	" "
Wages and food	½	" "
say	10	" "

The actual value of a cache consists in the cost of goods plus transport, interest and insurance charges.

Figure No. 7—Cache and Outlying Buildings.

Figure No. 8—Gravel Road Newly Completed.

Interest and insurance form the extra expenses due to storing goods in a region one year ahead of the time needed.

The cost per hundred pounds of these expenses when the hauling is done by horses and tractors is indicated in table No. 3 below.

Table No. 3—Cache Expenses per 100 Lbs. at Varying Mileages

Average Mileage	Expense per 100 lbs.		Per 100,000 cords	
	Horsehaul	Tractors	Horsehaul	Tractors
10	$0.25	$0.23	$ 10,000	$ 9,380
20	0.27	0.24	11,000	9,590
30	0.30	0.24	12,000	9,810
40	0.32	0.25	13,000	10,030
50	0.35	0.25	14,000	10,240
60	0.37	0.26	15,000	10,460

Unit Costs of Motor Transport

For costs of motor truck transport it is well to quote the article on this subject in the Engineering News Record of August 2nd, 1928, by N. D. Douglas. In this article average costs of trucks were 7.74 cents per mile based on 1,000 trucks observed to run at speeds of 30-40 miles per hour on roads in California. Owing to the difference in roads in speed, climate and the fact that the dead season imposes a larger depreciation charge we can safely double the figures in this article. The tabulated values per 100 lbs. are as below.

Table No. 4—Motor Haul Cost per 100 Lbs. for Varying Distances Based on Varying Costs per Mile of Motor Transport of a Load of 4,000 Lbs.

Cost per Mile	Cost per Hundred in cents for haul of				
	20 Miles	30 Miles	40 Miles	50 Miles	60 Miles
15	0.15	0.22½	0.30	0.37½	0.45
16	0.16	0.24	0.32	0.40	0.48
17	0.17	0.25½	0.34	0.42½	0.51
18	0.18	0.27	0.36	0.45	0.54
19	0.19	0.28½	0.38	0.47½	0.57
20	0.20	0.30	0.40	0.50	0.60

Horse and Motor Truck Unit Costs Compared

In table No. 1, if we consider that the average load or two horses ranges around 3,000 lbs., the cost per 100 lbs. carried twenty miles is 53 cents. Comparing this with an average cost of motor transport of 17 to 18 cents per mile we find that the former costs about three times the cost of motor truck transport.

This figure is borne out by actual contract figures for filling caches, which vary from $1.50 to $2.00 per 100 pounds for horse transport and 50-60 cents for motor transport over distances of about forty miles. In other words we may safely assume that motor truck transport is ⅓ cost of horse transport (not including cache expenses).

The author's observations have led him to believe,when all is considered, that the contract figures are more reliable for practical purposes than those in the table, as they apply to actual regions similar to or actually those we exploit and take into full consideration all factors which might lead to losses, such as breakage, weather, repairs, temporary unemployment of plant, etc.

Again, if we compare winter tractor figures with summer motor truck hauling, we find from table No. 3 that the actual cost of hauling is about the same for both tractor and motor, but that other factors such as cache expenses and personnel hauling must be added to tractor costs.

Transport of Personnel

To calculate the value of the time saved in transporting personnel by motor trucks, we must remember that it is effected only in the fall when men are going in. If we calculate on a twenty-mile journey being accomplished in one day on foot and one hour by motor, the effective time saved is nine tenths of a day based on a ten-hour day.

In a labour season of 180 days this represents one half of one per cent of the total cost of labour.

Assuming a contract figure of $8.00 per cord, 100,000 cords would cost $800,000. Since 70 per cent of this amount, $560,000, goes in expenses due to labour, one half of one per cent of this sum is $2,800.00, the sum saved by motor transport, from which must be deducted the cost of transport. This difference is proportionate to mileage and may be tabulated as follows:—

Table No. 5—Savings Due to Motor Transport of Personnel on 100,000 Cords for Varying Mileage

Miles	Savings in Wages	Cost of Transport	Net Savings
10	$ 1,400.00	$ 250.00	$ 1,150.00
20	2,800.00	500.00	2,300.00
30	4,200.00	750.00	3,450.00
40	5,600.00	1,000.00	4,600.00
50	7,000.00	1,250.00	5,750.00
60	8,400.00	1,500.00	6,900.00

Unit Cost of Roads

The unit cost of a tote road may be disregarded. Its maintenance may be assumed the same as for motor roads, although Mr. Lamothe states in his article that it is higher.

The cost of a winter tractor road, as stated already, will be taken at $1,000.00 per mile, which should be deducted from savings effected over horses.

The unit cost of a road to permit motor haul may be taken to average $3,500.00 per mile in rough country as we now construct them. Some years ago we found this figure too low but by improved methods of construction we are satisfied that $3,500.00 per mile is sufficient for an average twenty miles in the Laurentian hills of the St. Maurice region, which is by no means the easiest country in which to build roads.

This $3,500.00 should also be deducted from the savings effected by motor transport, thus giving a profit or loss over horse transport.

Area or Areas to be Cut and Length of Road

This factor influences the length of road and, therefore, influences the total expenditure to be effected before the

Table No. 6—Savings Effected by Tractor Transport Over Horse Transport on Areas of Ten Square Miles Served by One Mile of Road — Average Haul 20 Miles

Cords per Acre	Total Cords per ten Square Miles	Weight of supplies for ten sq. miles in hundreds	Cost horse haul per ten sq. miles	Cost tractor haul per ten sq. miles	Difference	Cost per mile of road	Amount left over after road costs	Difference in carrying expenses of cache in favour of tractor	Net amount left over after building 1 mile of road at $1,000.00
1	6,400	2,560	$ 1,920	$ 560	$ 1,360	$1,000	$ 360	$ 75	$ 435
2	12,800	5,120	3,840	1,120	2,720	1,000	1,720	150	1,870
3	19,200	7,680	5,760	1,680	4,080	1,000	3,080	225	3,305
4	25,600	10,240	7,680	2,240	5,440	1,000	4,440	300	4,740
5	32,000	12,800	9,600	2,800	6,800	1,000	5,800	375	6,175
6	38,400	15,360	11,520	3,360	8,160	1,000	7,160	450	7,610
7	44,800	17,920	13,440	3,920	9,520	1,000	8,520	600	9,120
8	51,200	20,480	15,360	4,480	10,880	1,000	9,880	750	10,630
9	57,600	23,040	17,280	5,040	12,240	1,000	11,240	900	12,140
10	64,000	25,600	19,200	5,600	13,600	1,000	12,600	1,050	13,650

area can be completely organized for motor or horse transport. In our calculations we have assumed that a mile of road extends its influence five miles on either side which would give us a mile of road per ten square miles of area. In this connection it is well to remember that the average haul per mile of road is one half mile, as stated before. We may take, therefore, in the present discussion, that the average haul of a territory varies as one half its area. Furthermore, it is necessary to state here that in planning the cut of a yearly supply of wood several areas will be decided on. It is obvious that the engineer should be fully informed of what is to be done in this respect, not merely for one year but also as to the possibilities for future cuts so that he may plan intelligently his roads.

Density of Wood

Density of wood is generally expressed in cords per acre. The density of wood is an extremely important factor as it determines with what intensity supplies must be distributed on the area. For a fixed yearly cut, the heavier the wood crop the smaller the yearly cut area. This means a lesser mileage of road necessary to feed this cut area.

The density of wood is determined for various sections of a territory by cruises in which different methods may be used. The total number of cords for these sections is obtained, which divided by the number of acres, will give the density per acre.

Yearly Cut and Yearly Weight of Supplies Needed

The yearly cut is determined principally by mill requirements and the total growth on the forest properties of the mill.

It naturally influences the yearly weight of supplies by the ratio of forty pounds per cord already mentioned.

To obtain a comprehensive basis of comparison, all the factors above stated must be worked up together, and here it is again well to state the absolute necessity of the engineer being fully acquainted with all the features of a cut programme so that he may plan intelligently his construction programme. To permit this comparison and basing ourselves on the practically fixed ratios as between area, mileage of road, and weight of supplies, we will work out the net profit per mile for motor transport for various densities of wood on an area of 45 x 10 miles as in figure No. 10 which we can then apply to larger or smaller areas and to varying yearly cuts.

Such a regularly shaped area with an evenly distributed density of wood will not be met with in actual problems of course.

Actual timber areas will present irregularities of shape varying with the heights of land, and of density varying with the stands. The above problem will then become more complex and the determination of the distance of average haul could be solved by methods similar to those employed in finding the centre of gravity of an irregularly shaped figure.

This is especially the case when the railhead or port is not at the edge of or within the area under consideration, but outside of it by some miles.

In this case the distance of the railhead to the beginning of the limit should be added to the average haul within the limit.

It is obvious that the greater costs due to such a situation apply to horse haul as well as to motor haul. This is also the case when non productive areas must be crossed to reach productive areas.

Another caution to observe is that in filling the yearly mill requirements the cut is not concentrated in one place but is made up of quotas from various sections, giving us the required total. Such quotas are selected for various

Table No. 7—Savings Effected by Motor Truck Transport Over Horse Transport on Areas of Ten Square Miles, Based on One Mile of Road to Ten Square Miles of Forest and Average Haul of 20 Miles

Cords per Acre	Total cords per ten Sq. Miles	Weight of supplies needed for area expressed in hundreds	Cost by horse haul per ten square miles	Cost of motor haul for ten square miles	Difference	Interest and insurance of cache	Labour savings	Total amount available per mile of road	Amount left over after building one mile of road at $3,500.00
1	6,400	2,560	$ 1,920	$ 640	$ 1,280	$ 690	$ 150	$ 2,120	......
2	12,800	5,120	3,840	1,280	2,560	1,380	300	4,240	$ 740
3	19,200	7,680	5,760	1,920	3,840	2,110	440	6,390	2,890
4	25,600	10,240	7,680	2,560	5,120	2,820	590	8,530	5,030
5	32,000	12,800	9,600	3,200	6,400	3,520	740	10,660	7,160
6	38,400	15,360	11,520	3,840	7,680	4,220	880	12,780	9,280
7	44,800	17,920	13,440	4,480	8,960	4,930	1,030	14,920	11,420
8	51,200	20,480	15,360	5,120	10,240	5,630	1,180	17,050	13,550
9	57,600	23,040	17,280	5,760	11,520	6,340	1,320	19,180	15,680
10	64,000	25,600	19,200	6,400	12,800	7,040	1,470	21,310	17,810

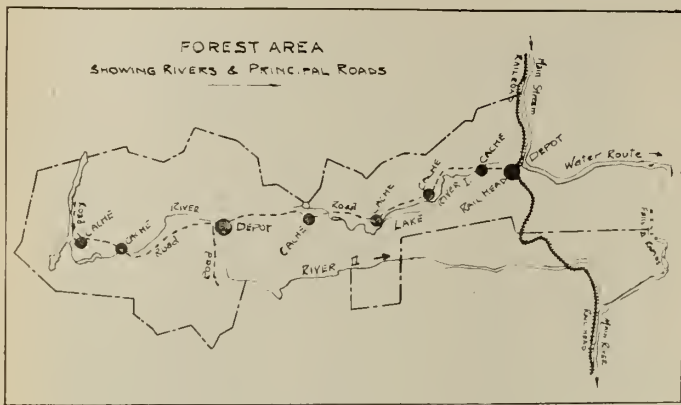

Figure No. 9.

reasons which we cannot discuss presently. Thus in the case under discussion, a mill requirement of 100,000 cords will be made up in lots ranging from 5,000 to say 30,000 cords. The supplies for each lot, however, are governed by all the principles to be developed further.

Comparison of Haul Costs as Applied to Timber Areas and Yearly Cuts

Having studied the basic costs it now remains to apply these costs to timber areas and yearly cuts.

To do this we will develop a problem on an ideal area of varying density on which we wish to cut:—

(a) a definite parcel of forest, in square miles;
(b) a definite cut, in cords.

In each case we wish to ascertain which is the most profitable: horse haul, tractor haul, or motor truck haul. This we will do in a tabulated form in each case.

Basic Data of Costs

From the preceding discussion we have secured the following facts:—

Cost horse transport . .	\$1.50 per 40 miles, \$0.75 per 20 miles.
Cost tote roads . . .	disregarded.
Cost tractor transport .	\$0.22 per 20 miles per 100 lbs.
Cost tractor roads . .	\$1,000.00 per mile.
Cost motor truck transport	\$0.25 per 20 miles per 100 lbs.
Cost motor truck road .	\$3,500.00 per mile.

We will now assume a timber area as in figure No. 3, which measures 45 by 10 miles or 450 square miles.

The full haul A to Ax is then $45-5=40$ miles.

The average haul is one half of 40 miles, that is 20 miles.

Carrying costs of caches are given in table No. 3 for tractors and for horses.

Density of wood: 1 to 10 cords per acre, each value being calculated for separately. It is well to note here that densities of less than two cords per acre can hardly be called commercial under present conditions.

Yearly cut: 100,000 cords.

Yearly weight of supplies: 4,000,000 lbs., or 40,000 hundreds.

Solution of Problem

We will first of all find the effect of density of wood on an area of ten square miles centred about the extremity of average haul $A1$. This small strip will extend one mile along the road and five miles on either side of it, giving us a section of average haul ten square miles in area.

In the case of a density of three cords per acre, the total cords per ten square miles will be 19,200 cords, as in column 2 of table No. 6.

At forty pounds per cord this means that 768,000 pounds or 7,680 hundreds will have to be hauled in to cut the ten square miles.

At 75 cents per 100 lbs. the cost to horsehaul this quantity of supplies will be \$5,760.00 as in column 4.

At 22 cents per 100 lbs. the cost to haul this quantity by tractors will be \$1,680.00 as in column 5.

The difference of \$4,080 in column 6 is, therefore, in favour of tractor haul.

This amount, however, must be lessened by the extra expenditure incurred in making a tractor road, \$1,000.00 given in column 7, which is subtracted from the value in column 6, giving us in column 8 the net sum gained for the average ten square miles, \$3,080. To this we add, (from table No. 3), the lessened carrying charges through tractor haul for caches in column 9, giving us the total advantage of tractors over horses in column 10, \$3,105.

It is true that the savings are less for areas near the railhead, but they are greater by the same amount for areas more distant than the average from the railhead.

Since the first fifty square miles can be supplied directly from the railhead, no road is necessary for their operation which explains why four hundred square miles only are controlled by the main haul road.

The same comparison has been worked out as between motor trucks and horses in table No. 7.

Effect of Wood Density on Possible Economies

If column 10 of table No. 6 be compared with column 10 of table No. 7, we note that for densities of three cords per acre and over, the motor truck is cheaper than the tractor in spite of the higher initial cost of road. This only takes the factor of supply and personnel transport and disregards those of fire protection, permanent availability, capital value, etc. For this reason and other advantages we have continued our comparisons of costs only as between horses and motor trucks.

It is to be noted that areas of one and two cords per acre are hardly commercial. More often than not they are old "cut over" stands leading to denser stands, which bring up the average density when a whole limit is considered.

Using table No. 7 which gives the difference in favour of motor transport per mile of road, we have applied this difference to a yearly cut of 100,000 cords in table No. 8.

Table No. 8—Profit Accruing from Good Roads for Total Cut of 100,000 Cords, Based on Varying Densities of Wood per Acre, and Average Haul of Twenty Miles

Cords of Wood per Acre	Square miles necessary to cut 100,000 cords	Average lineal miles of road necessary for cut of 100,000 cords	Total time to cut 400 square miles served by road	Profit or loss per mile of road from table No. 7	Profit per 100,000 cords after building road
1	156.0 sq.mls.	15.60	3 yrs.	\$ ..	\$ ..
2	78.0 "	7.80	5 "	740	5,770
3	52.0 "	5.20	8 "	2,890	15,030
4	39.0 "	3.90	11 "	5,030	19,620
5	31.2 "	3.12	13 "	7,160	22,340
6	26.0 "	2.60	16 "	9,280	24,130
7	22.3 "	2.23	18 "	11,420	25,470
8	19.5 "	1.95	20 "	13,550	26,420
9	17.3 "	1.73	24 "	15,680	27,130
10	15.6 "	1.56	26 "	17,810	27,780

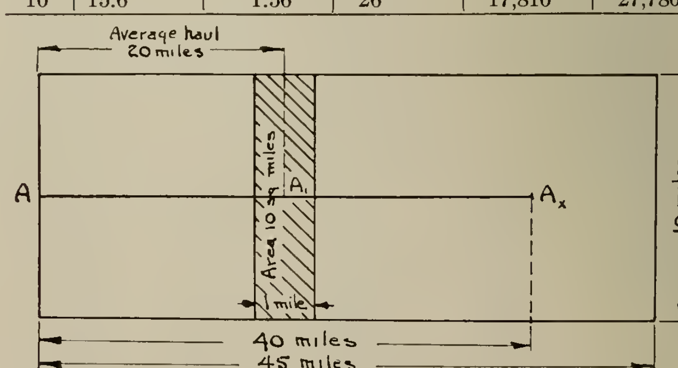

Figure No. 10.

These results are worth noting.

They show that after the road is built and the wood cut there is a surplus each year over the sums which would have been expended for transport by horses, this surplus being the greater as the density per acre increases.

Furthermore, this is done in one year's operation alone. This is not a far sighted policy which may or may not bring results in ten, twenty years or more, but immediately.

In other words, road building is not an uncertain factor. It pays now and yet this happens just in the one matter of hauling supplies and personnel for the cutting of each year's supply of wood. But it does other things. It is available and safe the year round. It brings supplies for the river drives, for building river improvements. It protects the forest, it has a capital value and it permits greater supervision and elasticity of operations, which matters have been totally ignored in computing results, having no sufficiently definite values as a base.

In the face of such facts, it is not surprising that up to date companies have departed from antiquated methods of transport, which are not only a spendthrift policy but leave no permanent benefit behind them.

Effect of Average Mileage on Possible Economies

As stated earlier, since costs vary practically directly with mileage, the figures obtained in table No. 8 may again be applied to average hauls of ten miles and above. It will be seen that the economy per mile increases as the average haul increases, as shown in table No. 9.

Table No. 9—Economy per Lineal Mile of Road Due to Motor Roads and Transport for Average Mileages Ten to Sixty Miles, Based on Cords per Acre Evenly Distributed

Cords Per Acre	Average Mileage					
	10 Miles	20 Miles	30 Miles	40 Miles	50 Miles	60 Miles
1	$ ..	$ ..	$ ..	$ ..	$ ..	$ ..
2	370	740	1,110	1,480	1,850	2,220
3	1,440	2,890	4,330	5,780	7,220	8,670
4	2,520	5,030	7,550	10,060	12,580	15,090
5	3,580	7,160	10,740	14,320	17,900	21,480
6	4,640	9,280	13,920	18,560	23,200	27,840
7	5,710	11,420	17,130	22,840	28,550	34,260
8	6,780	13,550	20,330	27,100	33,880	40,650
9	7,840	15,680	23,520	31,360	39,200	47,040
10	8,900	17,810	26,710	35,620	44,520	53,430

Finally, in table No. 10 these factors are applied to a yearly cut of 100,000 cords.

Table No. 10—Economy per 100,000 Cords Due to Motor Roads and Transport for Average Haul of Ten to Sixty Miles, Based on Cords per Acre Evenly Distributed (after deducting cost of road.)

Cords Per Acre	Average Haul					
	10 Miles	20 Miles	30 Miles	40 Miles	50 Miles	60 Miles
1	$ ..	$ ..	$ ..	$ ..	$ ..	$ ..
2	2,880	5,770	8,650	11,540	14,420	17,310
3	7,520	15,030	22,550	30,060	37,580	45,100
4	9,810	19,620	29,430	39,240	49,050	58,860
5	11,170	22,340	33,510	44,680	55,850	67,020
6	12,060	24,130	36,190	48,260	60,320	72,390
7	12,740	25,470	38,210	50,940	63,680	76,410
8	13,210	26,420	39,630	52,840	66,050	79,260
9	13,560	27,130	40,690	54,260	67,820	81,390
10	13,890	27,780	41,670	55,560	69,450	83,340

We see from the above tabulation that the further the distance, the greater the difference in favour of motor haul, to such an extent in fact, that the original cost of building a good road becomes insignificant.

From tables Nos. 7, 8, 9 and 10, we can, therefore, enunciate the principle with reference to motor transport on gravel roads that "the longer the mileage, the greater the effective economy per mile of road and per cord of wood cut" and "the greater the density, the greater the economy per mile of road and per cord of wood cut."

Mileage of Road Permissible for Varying Average Hauls and Mileage Cost of Construction

The total mileage of road possible per year is proportionate to the sums available by economies on horse transport.

For, if we consider a yearly cut of 100,000 cords, we will note that, regardless of density or distance, we need 4,000,000 pounds of supplies. For an average haul of twenty miles the expenditure to haul this by horses will be $30,000, by motor $10,000. This gives us a fixed difference of $20,000 per year in favour of motor haul.

To this we must add interest and insurance on caches, $11,000 from table No. 3, and savings on labour $2,300 from table No 5, giving us a total of $33,300, total available sum for roads.

In table No. 11 we have calculated these total available sums for roads for 100,000 cords and for average mileages ten to sixty.

Table No. 11—Sums Available for Road Building for Mileages Ten to Sixty for Each Cut of 100,000 Cords

Average haul Miles	Savings by motor transport of supplies	Interest and Insurance of Caches	Saving in time of labour	Total sum available for roads
10	$10,000	$10,000	$ 1,150	$21,150
20	20,000	11,000	2,300	33,300
30	30,000	12,000	3,450	45,450
40	40,000	13,000	4,600	57,600
50	50,000	14,000	5,750	69,750
60	60,000	15,000	6,900	81,900

If, for instance, we expend the sum of $21,150 for road building we will see that at $3,500 per mile we can build 7.05 miles of road per year and thereby complete our programme of road building quicker.

As this difference between costs of horse haul and motor haul increases with distance, however, the permissible expense per mile of road may be higher, thus reducing the mileage of road permissible but giving us a better road as shown in table No. 12.

Table No. 12—Mileage per Year Possible for Cut of 100,000 Cords for Varying Hauls and Varying Unit Costs per Mile of Road

Average Haul	Sum Available	Miles of road which can be built per year at unit prices listed						
		$3,000	$3,500	$4,000	$4,500	$5,000	$5,500	$6,000
10	$21,150	7.05	6.05	5.30	4.70	4.25	3.85	3.50
20	33,300	11.10	9.50	8.35	7.40	6.65	6.00	5.50
30	45,450	15.15	12.90	11.35	10.10	9.05	8.25	7.55
40	57,600	19.20	16.50	14.40	12.80	11.50	10.50	9.60
50	69,750	23.25	19.90	17.50	15.50	13.95	12.70	11.60
60	81,900	27.30	23.40	20.50	18.20	16.40	14.90	13.65

This enables us to state the economic principle that "The longer the average haul, the heavier may be the expenditure per mile of road," and also that based on one mile of road per ten square miles of forest, a programme of road building can be carried out ahead of actual requirements without extra expense until the whole area is covered. This means that within a limited number of years the full profit of motors can be finally secured without further expenses of construction.

Influence of Density of Wood on Number of Square Miles of Area to Permit Construction of One Mile of Road

In table No. 12 we have the maximum mileage of road permissible per 100,000 cords per year for varying average hauls and varying unit costs of road. It is now interesting to note how the total sum permissible for expenditure will affect the number of square miles to be served by one lineal mile of road. In other words we can determine the permissible density of road building.

In table No. 13, we have assumed a unit cost of $3,500.00 per mile.

The figures given are obtained as follows:—

Square miles per mile of road = square miles of stated density necessary for a cut of 100,000 cords, divided by the permissible mileage of road for 100,000 cords.

Thus, for a density of three cords per acre, an area of 52 miles is to be cut to obtain 100,000 cords and the permissible lineal mileage of road is 6.05.

The square miles of cut area per lineal mile of road for a density of three cords per acre is then $52 \div 6.05 = 8.6$ square miles per mile of road.

Table No. 13—Number of Square Miles Available to Permit Building One Mile of Road, Determined by Various Densities and Average Hauls. Road at $3,500.00 per Mile. Cut 100,000 Cords.

Density Cords	Area cut per year	Number of square miles per lineal mile of road Average Hauls					
		10	20	30	40	50	60
1	156.0	..	..	..	..	..	..
2	78.0	12.9	8.2	6.0	4.7	4.0	3.3
3	52.0	8.6	5.5	4.0	3.1	2.7	2.2
4	39.0	6.5	4.1	3.0	2.4	2.0	1.7
5	31.2	5.2	3.3	2.4	1.9	1.6	1.3
6	26.0	4.3	2.7	2.0	1.6	1.3	1.1
7	22.3	3.7	2.3	1.7	1.4	1.2	1.0
8	19.5	3.2	2.0	1.5	1.2	1.0	0.8
9	17.3	2.8	1.8	1.3	1.0	0.9	0.7
10	15.6	2.6	1.6	1.2	0.9	0.8	0.7

Table No. 13 shows us, therefore, that "As haul and density of wood increase, the number of square miles per allowable lineal mile of road diminishes."

That is, for a thick density and a long average haul we can make our routes economically closer to such an extent that, according to table No. 13, we reach such a closeness of road as one mile of road for less than a mile of limit which is almost absurd. This shows, however, that our figure of one mile of road per ten square miles of forest is well within the expendable sums.

These figures also convince us amply that executives need have no hesitancy at all to expend money in order to introduce good motor roadways into their limits where hauls of twenty and more miles are the common thing and where hauls are in fact increasing as close wood gets scarcer. This policy is a paying one, and in the end they must spend more money should they not follow it.

A road programme should be methodical and its expenditure based on the yearly mill requirements to come out of a region. As indicated previously the allowable expenditure will permit the immediate cut areas to be covered more rapidly than actual requirements. It is then that the programme should be pushed ahead with the sums available yearly for road construction. The territory to be exploited should be considered as a whole so that in cutting the cheap wood close to the railhead methods should not be such as to make the wood cut at the far extremities of a forest area more costly.

Summary and Conclusion

For a yearly mill requirement of wood a certain sum of money must be spent.

In the forest areas out of which this wood supply is to come, we have the option of making good roads for motor transport or not.

If we make good roads we will find our total expenditures for a yearly or total cut less than if we make no good roads.

If we do not make good roads we will fritter away greater sums of money on our wood and have nothing to show at the end of it.

In the latter case the area after the cut is left unorganized and unequipped to carry on cuts at greater distances, to which haul by motor eventually becomes not a matter of choice but of imperative necessity.

The fear of spending the necessary money for roads has already cost and is costing millions, for it is doubtful whether full advantage is now being taken of the possibilities of motor roads and motors for pulpwood or other forest operations.

It is not too much to say that through the neglect of the principles above enumerated, great sums of money have been and are probably being spent uselessly in using wrong methods of transport.

It is well to add, however, that the variety of problems in planning the haul of supplies and men is almost infinite and requires very careful study.

Moreover, in spending money to build gravel roads *results must be secured.* Disappointments are sure to occur unless competent location, building and maintenance are carried out. The mere installation of a good gravel road will not counteract carelessness in other directions: constant vigilance and care must be exercised to see that full use is made of the road while maintaining it in a high state of efficiency.

To the profits coming from hauling supplies and personnel on gravel roads, we may add the value of the improvement of the following features for which no determinate figures are available:—

(1) Communications available the whole year and not for part of year as for tote roads or tractor roads.
(2) Availability for all methods of transport.
(3) Transport of personnel and supplies for river drives.
(4) Facility of installing and maintaining telephones.
(5) Fire protection of forests made more efficient.
(6) More intensive utilization of wood on each area.
(7) Capital value added to forest.
(8) Greater liberty in increasing or reducing year's cut.
(9) Closer supervision of all operations.

All these advantages are secured through a lesser expenditure on the two items of haul of supplies and men alone, which shows the definite advantage of a little planning. In the same way a close study of other agencies should decrease still more the cost of every cord of pulpwood.

Therefore, on every forest area over which transport must be effected, every year should see a section of good road completed proportionate to the cut. By following this policy a network of good motor highways will be finally developed from which not only cutting operations will be cheaper from the start, but also the whole forest will benefit materially.

The Process of Zinc Coating Steel Wires

A. D. Turnbull, S.E.I.C.,
Service Supervisor, Eastern Division, Research Products Engineering Department, Northern Electric Company, Limited, Montreal.

Paper read before the Montreal Branch of The Engineering Institute of Canada, January 16th, 1930.

Wires are the webs of industry, and without their steadying force towering structures in many instances would topple to the ground. This statement, which is accredited to a structural engineer of note, is in itself significant. Among the various types of wires that lend their support to towers, bridges, masts and stagings we find those classed as guy, stay and rigging wires. These, which are stranded in the conventional manner, are invariably of steel manufacture, and thus are susceptible to atmospheric corrosion unless means are taken to protect them.

Guy D. Bengough gives the following factors which influence the rate at which corrosion takes place:

(1) The chemical composition of the iron or steel under consideration.
(2) Contact with other more or less electro-negative substances which are metallic conductors.
(3) The presence of stray electric currents passing to or from the iron or steel.
(4) The quantity of dissolved oxygen present in the water or moisture in contact with the metal.
(5) The rate of motion of water in contact with the steel or iron.
(6) The presence in the water of acids, salts or alkalis.
(7) The presence of previous rust.
(8) The temperature.
(9) The physical condition of the metal.
(10) The quantity of light falling upon the metallic surface.

It will now be understood that the phenomenon of corrosion is most complicated and some factors so influence its rate that no means as yet devised are capable of stemming its attack. Replacement of the faulty part is the only solution for the engineer.

The most practical method of protecting steel against the deteriorating effect of the weather is by zinc coating. Wire coated in such manner is classed as galvanized wire, although there is some contention that the term is a misnomer. Far rather had the word zincing be used in its stead.

Zinc gives efficient protection to steel and iron as long as the coating remains intact. If the wire be so bent as to crack the coating, corrosion of the exposed metal will begin. Zinc, however, is electro-positive to iron, thus when a portion of the iron is exposed, even though the zinc coating may deteriorate rapidly, the negative metal will be protected. The area over which the zinc can exert its protective influence is restricted and very apt to vary with conditions of exposure.

Galvanized steel wire is adapted to the following uses:

Telegraph and telephone wire.
All grades of woven and barbed fencing wire.
Netting wire.
Rigging and guy wire.
Hawser and plough wire.
Cable wire.
Grappling wire.

Zinc coated wire is further sub-divided according to the condition of the metallic coating:

(1) Wiped wire.
(2) Unwiped wire.
(3) Annealed galvanized wire.

In differentiating between the first two classes, the method of removing the wire from the zincing pan is taken into account. The latter classification is dependent upon a heat treatment that is subsequent to the process of galvanizing.

Before describing the process of galvanizing steel wires, it will perhaps be best to briefly outline the actual wire-drawing operation, since it has a distinct bearing upon the quality of product. It is imperative that a high grade of steel be chosen for the wires which are to be coated. Some steels are utterly unfit for wire-drawing, not to mention galvanizing. Defects which originate at the open hearth and are further exaggerated during the rigorous rolling from an ingot 2½ feet thick down to a rod perhaps ¼ of an inch in thickness, cause no end of trouble in the wire mills.

Thick skinned ingots resulting from improper pouring into cold moulds give rise to slivery steel. Surface seams and laps develop, which make the finished product valueless for wire-drawing. Segregation of the constitutent elements in the heat, causes blow holes and pipes in the ingot. These defects result in planes of weakness, which obviously render the wire unfit for heavy strain duty.

From the open hearth the ingots pass to the roughing rolls of the blooming mills where they are transformed into blooms. These in turn are carried along to the reheating furnaces where they are heated to a red hot temperature so that they can be further rolled in the billet mills. The billets pass to the rod-mill reheating furnace after which they are rolled into bars and rods of varying thickness. Rods are usually coiled on water-cooled reelers while they are in a red hot condition, thence they are hung in 300 or 150 pound bundles, upon the hooks of a conveyor, which transfers them to the wire-mills. This hook-conveyor is of such a length that the metal gets ample time to cool during the transfer.

The rod bundles are next removed from the conveyor and are acid immersed in lots of one ton each. The immersion takes place in pickling vats, where the ferrous oxide or fire scale, formed during the rolling, is entirely removed. This so called rod pickling is one of the most important steps in wire manufacture, for an improperly cleaned rod, viz., one that has the least trace of oxide upon the surface, means trouble; serious trouble at that.

Ordinarily the amount of ferrous oxide on the surface of the rod can be kept fairly low by using plenty of water at the rod mills. In the case of high carbon rods, however, inasmuch as the quantity of water employed in cooling will probably affect the hardness of the metal, a proper balance must obtain between the scale percentage and toughness of the steel. Good practice never exceeds 1.25 per cent scale on the rod, for obviously the more oxide present the greater the loss in metal and acid necessary to remove the oxide.

That portion of the mill devoted to cleaning the rods is called the pickling house. It is the link between the rod and wire mills. Pickling vats or tubs are usually arranged in a circle, having a crane at the centre. This crane is so proportioned, that its extreme radius makes it possible to lower and raise the batches of rods into and from the vats. Twelve pickling vats will handle an average of 240 tons in a period of 10 hours. Each vat is made to hold 1,000 Imperial gallons of solution and is constructed from wood. The solution itself is in the most cases made up of a dilute solution of sulphuric acid, ranging from 3.0 per cent to 4.5 per cent by weight. The bath is kept hot either by steam pipe coils or direct steam blowdowns, in order to accelerate the pickling action. Of the two systems the former is more efficient because it makes possible the reclamation of the latent heat in the steam besides doing away with over-dilution of the solution. Again it does not have the effect of the live steam in sweeping away the bubbles of gas that form on the steel, protecting it from acid attack.

The baths need not always be at a high temperature, for acid brittleness of the steel sometimes results from a hot pickling solution. The speed of cleaning is the real criterion of temperature. Steel that is intended for galvanizing purposes should have a low silicon content, since the presence of that element in the heat tends to form silicon carbide. Rusty rods should never be cleaned with the intention of galvanizing them later; since the surface of such rods is invariably rough and pitted.

For long pickling periods, cold hydrochloric acid is sometimes employed, since there is less danger of the iron carbides dissolving out of the steel than if sulphuric acid were used. Dissolution of the iron carbides impairs the surface of the steel and consequently the zinc would not adhere properly.

Both hydrochloric and sulphuric acid, used hot or cold, must be inhibited. Inhibitors, which are composed of organic carbohydrates, prevent the acid attack upon the steel base of the rod after the oxide scale has been removed. In many instances, batches of rods must of necessity remain in the pickling solution for some time after the scale has been removed. The acid of the pickling solution readily attacks the steel which has been laid bare and as a consequence there is a loss of both acid and metal. The author described in a paper written for September 4th, 1929, issue of the "Iron Age," a cheap efficient compound that was developed from experiments extending over an eight month period.

Chemists lately have been devoting some time to the study of inhibition. The so called 'black acid' obtained from a process in the refining of crude oils offers considerable inhibiting features. During the distillation of the crude the various hydrocarbons distill over in the general order of their boiling points. The distillate, which collects between certain limits, is further purified by scrubbing with sulphuric acid. The result is a substance that is not a definite chemical compound, but consisting of a mixture of hydrocarbons, the boiling points of which lie within certain limits. The 'black acid' commonly gives 69 per cent of 66° Baumé sulphuric acid, 9.0 per cent free hydrocarbons, 10 per cent sodium sulphate and 12 per cent oil sludge, on analysis. The free hydrocarbon content undoubtedly accounts for the passiveness of this acid when coming in contact with iron or iron carbon alloys.

Subsequent to the pickling, the rods are rinsed in a tub of cold water in order to wash off any traces of acid that may yet remain upon the steel. They are then placed upon what is termed a 'ruster,' which may assume the shape of a circular revolving platform, having annular rings that support each batch of rods. Water sprays constantly keep the steel wet and aid the formation of a greenish-brown rust coating or sull. This sulling coat, when dry, enables the rod to be drawn down to small diameters, since it acts in the capacity of a lubricant.

When the cleaner has decided that the rods are sufficiently rusted they are dipped in a vat of hot lime solution. This serves a double purpose, viz., to neutralize any acid that may be present on the steel and to lubricate the metal during the coarser drawing stages. The lime employed for this operation must be of a good grade and free from abrasive substances such as magnesium oxide.

The rods are then transferred by means of steel trucks to the baking ovens, where they undergo a mild heat treatment. The temperature of these bakers should not be less than 400° Fahrenheit, since the prime object of baking is to drive out any traces of occluded hydrogen from the surface pores of the metal. This element if present during the wire-drawing will tend to destroy the character of the lubricant and possibly spoil the product. Twenty minutes to half an hour is required for thoroughly drying out the steel, after which the rods are ready to be drawn into wire.

The trucks of rods are next removed from the bakers and taken to the wire-mill, where they are placed at the disposition of the wire-drawer. Wire mills are ordinarily arranged in benches having the machines or blocks running side by side. The block is a tapered steel cylinder upon which the wire is wound after passing through the die-hole. The taper is provided so that the wraps or turns of wire can slip upwards during the operation and thus leave room for the remainder which are constantly being wound about the block. Blocks are of variable speeds according to diameter, which varies from 16 to 28 inches in practice. For instance the 16-inch block has a constant speed of 60 r.p.m. while the 28-inch block revolves at a lower speed of 45 r.p.m. Each block is supported by a vertical drive spindle, which in turn is geared to the motor drive shaft.

There are two types of wire-drawing blocks in use to-day, viz., the multiple drive and the individual power block. The multiple drive block is driven along with nine to eleven others from one motor and is constant in speed, while the power block is equipped with a single adjustable speed motor. The former is started and stopped by means of clutches while the latter is set in motion by means of the rheostat in the motor field circuit and is stopped by the dynamic braking effect of the motor.

The chief advantages of the power block are as follows:

(1) Adjustable working speeds over a wide range, secured through an adjustable speed direct current motor and simple rugged control. This assures high quality product since the speed can be varied to suit various sizes of wires. The multiple block is lacking in this feature.

(2) Very slow starting or pulling-in speed, regardless of final working velocity. This eliminates the danger of the wire breaking in the die hole due to excessive initial velocity and heavy wear on the die is done away with entirely.

(3) Positive, easily operated, fool proof electrical safety devices. The danger to the workman is practically nil due to this feature.

(4) Increased production per operator, less floor space per unit of production and better grade finished wire.

Die holes are set in steel plates, which vary in size according to the gauge of the wire. There are from 10 to 16 holes set in a plate to facilitate operation. The die plate is firmly clamped to the bench in a position at right angles to a tangent drawn to the projection of the block circle. The tapered portion is termed the bearing or backing surface while the small end of the hole is called the size. As can be seen the wire goes through a gradual reduction in area according to the gauge of the sizing portion.

The wire-drawer is now ready to perform his duty. A bundle of rods is first placed on a stationary reel which has its base inclined at an angle of 65° to the floor. One end of the rod is pointed by a suitable device which forms part

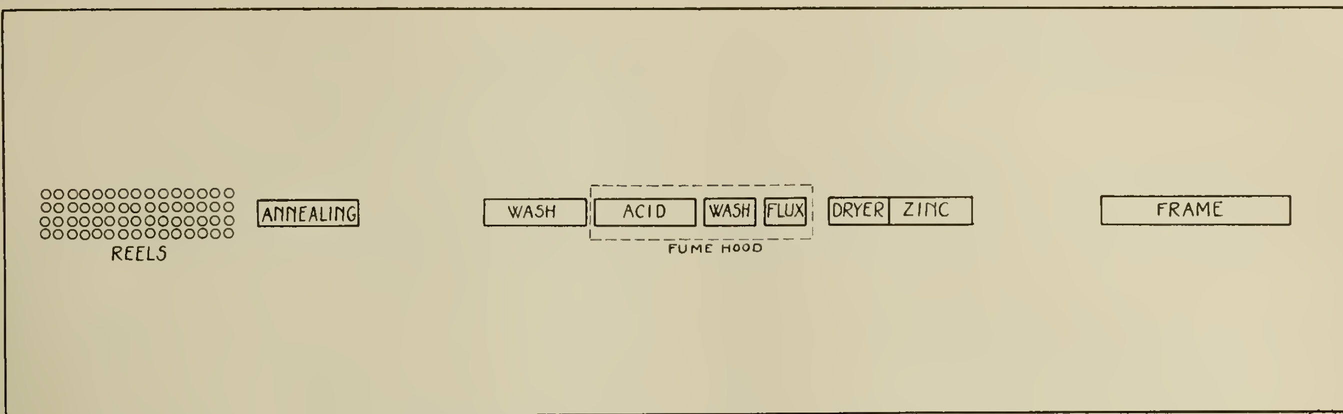

Figure No. 1.—Diagram of Layout for Galvanizer.

of the bench equipment. This enables the operator to pass about two or three inches of the stock through the die hole and thus offer a grip for the pulling attachment on the drawing block. The machine is given two or three revolutions, which causes the same number of snubbing turns to be taken about the block. The free end of the wire is then fastened to one of four guide pins at the upper portion of the machine and the clutch is thrown in again or the motor started. The rod is allowed to run through the die until the whole has been drawn, after which the wire is removed from the block and placed upon a horizontal reel. The operation progresses using another block and smaller size die until the wire has received a further draft. This continues until the desired size is reached.

After a die hole is worn out another one is used, and so on until a new plate is necessary. A properly reamed die hole will last for two or three operations, depending upon the steel being drawn and the quality of the die material. Used die plates are sent to a shop where they are reamed to a larger diameter. Frequently the holes enlarge during the actual operation, which results in a wire finishing at the same diameter as it started. Such wires are termed run-outs and are unsuitable for galvanizing.

Scratched and slivered wire is also unfit for galvanizing. Slivers are as the name implies: small flakes of steel which break off and leave pits on the wire surface. Often these flakes of steel tear off in the die hole, wedging against the bearing and scratching the wire as it passes through. This instance is analogous to emery in the bearing of a wheel and axle. Improperly reamed dies also result in scratched wire, so precautions must be taken to observe the effect of each hole during the first stages of the process.

Particular attention must be paid to the choice of lubricant in dry-drawing operation. Soft and hard greases are the most common. An experienced operator can tell by the feel of his wire whether it requires soft or hard grease in the die hole. Wires such as welding steel, which are specified to be grease free, are drawn through soap or common flour. A good rule to follow in the selection of greases is to use a soft grade when the rod is heavily limed and a hard quality when there is little or no lime on the steel. Often scratches can be eliminated at the offset by tightly wrapping the wire, just behind the die plate, with a piece of smaller diameter. This wrap pulls into the bearing when the block is started and helps to feed the wire correctly. Wrapping the wire with cotton waste dipped in graphite or lard makes an excellent lubricant when fine wires are being drawn. There is no set rule to follow in the selection of lubricants, since their choice depends upon so many factors.

After the wire is drawn to the required size, the coils are placed upon steel trucks and transferred to the galvanizing mill. This unit is laid out in straight line design, the overall length being from 230 to 275 feet. The wire enters one end as it is received from the drawing blocks and leaves the other properly galvanized. Reels such as are used in wire mills are used to support the wire at the ingoing end.

Galvanizers are generally of two sizes; the thirty and thirty-six wire units. The former has sixty reels of which thirty are in continuous use, while the latter has seventy-two reels of which thirty-six are standbys. (Figure No. 1 shows the location of these reels in respect to the other parts of the unit.) The operation of either type of mill is exactly the same, so the following will apply in each case.

Three reelmen look after the ingoing end of the installation, their duty being to remove the bright wire coils from the trucks, place them upon reels so that the wire will pass over guide rollers into the annealing furnace. Since the process is a continuous operation the wire must be fed in one long length, so the reelmen must splice the end of the coils to achieve this condition. The splice is made in the form of a hook and eye, which is strong enough to withstand any extraordinary tension which may come upon the wire during the operation.

When steel is drawn into wire it goes through a process which is known as cold-working. This radically increases its hardness and tensile strength, while at the same time its ductility is decreased. Extreme stiffness in galvanized wire is undesirable, so steps must be taken to restore its properties. The changes which are encountered in cold-working are due to the permanent crystalline deformation which ensues during the treatment. This effect is removed by annealing the steel at a temperature slightly above the critical point and slowly cooling. The operation essentially consists of uniformly heating the steel to a temperature between 770° and 850° Centigrade and then cooling slowly in air. The correct annealing temperature depends upon the composition of the steel and the diameter of the wire being galvanized. It is absolutely necessary that the steel be heated uniformly throughout, so that the whole of the ferrite and cementite be transformed into a perfectly uniform solid solution,—austenite.

This gives rise to a small grain size, which is desirable. Rapid cooling and extremely high temperatures will result in large grain sizes with consequently inferior mechanical properties. The curve in figure No. 2 shows the large grain size which is evidenced when too high a temperature is employed in annealing the steel. That portion of the line AB subtended by the angles A and A' gives the relative grain sizes for moderate and high temperatures respectively. The grain size a_1 which corresponds to the correct annealing temperature is considerably smaller than a_2 which is prevalent with the higher temperatures.

Annealing furnaces such as are employed in galvanizer mills, consist of chrome steel pans, filled to within

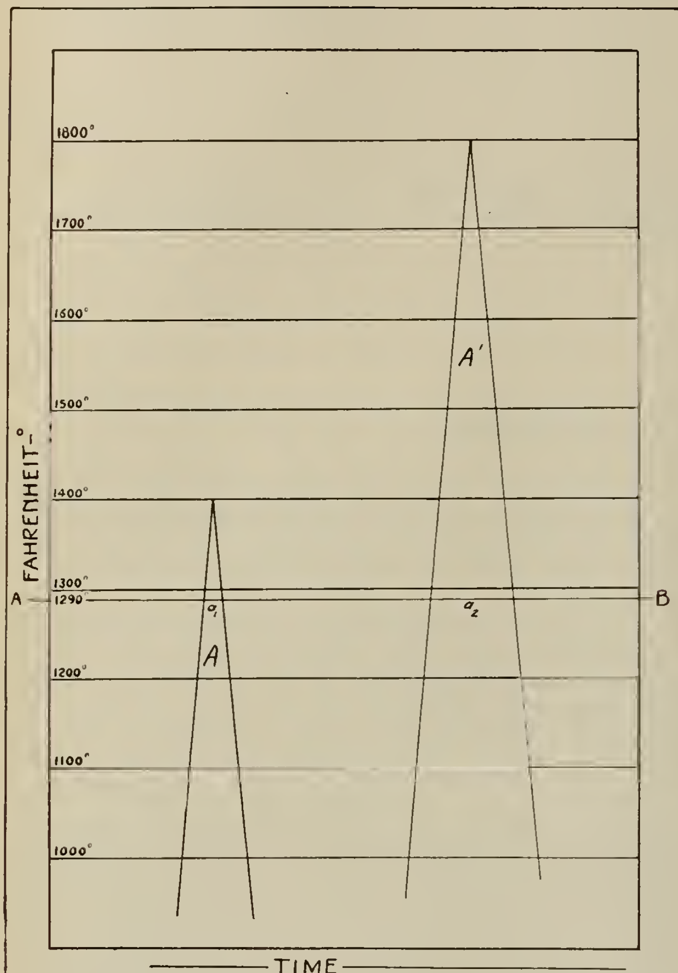

Figure No. 2.—Effect of Temperature and Rate of Cooling on Grain Size.

three inches of the top with molten lead. The metal is kept in a molten state by gas or coal fires beneath the refractory brick support, upon which the shallow pan rests. These so-called lead pans are from 22 to 28 feet in length, 54 inches wide and about 16 inches deep. The wires after passing over the guide roller are led into the metal through inverted steel combs and pass under depressing rollers which keep them submerged in the hot lead. By the time that the wires have emerged from the pan they have become annealed to the desired softness.

Lead pans frequently burn out, because of the high temperatures to which they are subjected. Their average life is from 180 to 200 days, during which period from 5,000 to 6,000 tons of wire can be annealed. Thermo-electric pyrometers keep accurate check upon the furnace temperatures so that the fireman can regulate the heat to suit the class of material being galvanized. This assures a correct balance between elongation and tensile strength.

A thin layer of coke braize sometimes is spread over the surface of the metal in order to check oxidation. The oxides of lead are called 'skimmings' and can be reclaimed by treating in a smelter. Over 50 per cent pure lead is recovered in this manner. A quantity of ferric oxide should be placed at the exit end of the pan, in such a position that the red hot wires pass through the substance. The author has found that this prevents free sulphur being carried over on the wires and also that the lead out-take is cut down considerably. Subsequent to this treatment, the wires pass through a bank of fine wood ashes, which will tend to wipe extraneous lead from the wire surfaces.

One of the qualifications of galvanized wire is that it possesses a fairly large percentage of elongation. Ordinarily the wire is bound to lose some of this property in the annealing furnace, because of the friction on being drawn through the lead. From 4.0 per cent to 8.0 per cent of the elongation is lost in this manner and unfortunately there is no means of escaping the loss. There is one other condition, however, which results in loss of tensile strength, and can be easily remedied. This is the friction encountered by the wires on passing over guides in, and adjacent to, the annealing furnace. Here the metal is in a very plastic state and deforms easily, so care must be taken to see that all guides revolve freely on their supports. Usually sheaves, running on ball or roller bearings, are provided at entrance and exit of the pan. The system is comprised of individual sheaves so that each wire fills a groove which turns only when the wire is moving. The submerged depression rollers revolve in heavy porcelain bearings, the molten lead acting in the capacity of a lubricant between roller shaft journal and bearing surface. Guide pins located in staggered formation on a horizontal pin-board are placed at entrance and exit, serving to keep the wires laterally aligned.

The air cooling system comprises two horizontal grooved rollers, placed about thirty feet apart and elevated to such a height that the operators can pass underneath without danger. The wires emerge from the annealing furnace and traverse the cooling rollers after which they are led down into a wash tank. This tank, which is identical in all dimensions with the lead pan, also is equipped with entrance and exit rollers and depression rolls. Such tanks are usually constructed from rough pine wood and are kept full of water. The water is relatively cool to the entering wires but at this point the metal is so cool as to not be affected by quenching. The purpose of the wash tank is to remove any foreign matter which might adhere to the steel and be carried along in the process.

The next step in the operation is an important one, viz., the cleaning of the wires. All metallic oxides formed on the wires during the annealing are removed in the cleaning tank. Commercial hydrochloric or muriatic acid of 22° Baumé strength is diluted with water to give an acid solution of 10.0 per cent. The best practice is to have the solution tank at least 24 feet long and of the same width and depth as the wash tank. Ordinary brick would not withstand the attack of the cleaning solution, so acid-resisting tile is utilized in the construction of the container. Steam pipe coils, composed of acid-resisting or non-corrosive metal, are laid horizontally along the bottom of the tank and serve to keep the solution at a temperature not exceeding 140° Fahrenheit. The wires are submerged in the cleanser by passing under micarta depression rolls, which turn in stainless steel bearings. The cleanser is tested for acidity at periodic intervals, using the titration with sodium hydrate test.

Following the cleaning, the wires are again washed in a tank about half the length of the previous bath. The water in this wash is kept at a temperature near the boiling point by means of exhaust steam from the pipe coils in the acid tank. An over-flow pipe is provided and all surplus water passes into a shallow trench which has an outlet into the sewer.

It is now assumed that the wires are properly annealed, free from oxide and ready to be fluxed for zincing. Just adjacent to the last wash tank is the flux-box, about ten feet in length and equipped similarly with rollers. The material from which this box or tank is constructed is also acid-resisting tile. The flux solution is heated to 170° Fahrenheit by steam pipe coils which exhaust into the previous wash tank.

Manufacturers in both England and Germany have found that only two substances are suitable for satisfactory fluxing. These are zinc chloride and sal-ammoniac. The former is made at the point where it is desired for use, by placing a quantity of hydrochloric acid in a stone cistern and 'killing' it with slab zinc. Zinc oxide or skimmings from the zincing pan sometimes are used for this purpose, although the author contends that the high percentage of iron found in this substance is detrimental to the solution so formed. Sal-ammoniac or ammonium chloride is purchased in the form of a deliquescent salt and is added directly to the flux box and diluted with water to a specific gravity of 1.040.

Zinc chloride is diluted with water until a solution of 1.150 specific gravity is secured. This substance is not as efficient as sal-ammoniac when fluxing because of the fact that often the acid radical is not entirely absent from the chloride and hence ferric chloride is formed on the steel. This chloride is carried over into the zinc pan where the iron increases the drossing tendency, i.e., the formation of a zinc iron alloy which contaminates the coating metal. About four pounds of iron will render ninety-six pounds of zinc practically useless for high grade galvanizing.

After dipping in the flux box the wires pass over a hot plate about ten feet long, which is in reality a portion of the flue which leads the products of combustion away from the fires of the furnace beneath the zincing pan. The moisture on the wires is quickly dried and there is no danger of the molten zinc spattering as the wires pass under its surface.

A wooden housing, leading to a louvre tower, is placed around the various baths so that objectionable fumes can be carried away.

There have been many attempts made in late years to better the practice outlined in the preceding paragraphs, but with little success. The writer has developed a unit which can be easily installed in any type of galvanizer mill; its chief function being to increase the toughness and quality of the zinc coat. At the time of writing, details regarding this process cannot be divulged, but it is hoped that such will be ready for publication shortly.

So much for the preparation of the wires, which are now in a position to be zinc coated. As was previously stated this coating can be applied in two different ways, and the wire is so classed according to the manner in which it is coated, viz., wiped and unwiped wires. The zinc pans used in the wiping units are from 18 to 28 feet long and about 16 inches deep, while the unwiped units incorporate pans of a much shorter length and greater depth. The zincing pan is heated in the same manner as the lead pan of the annealing furnace and a check on the temperature of the metal kept by a recording pyrometer. The average life of such pans varies between 5 and 7 months for tonnages between 4,500 and 6,000. The tendency for the zinc to oxidize on the surface of the bath is considerable. The formation of this oxide or skimmings is governed by the area of exposed surface and for this reason there is a greater accumulation of zinc oxide on the surfaces of pans used in wiping units than on those employed in the optional unit. The skimmings can be taken from the pan and sifted through a fifty mesh sieve which separates out the true oxide from the partly oxidized metal. The latter is again placed upon the hot metal and allowed to melt, while the finer oxide is stored and sold later to paint and pigment manufacturers.

Depression rollers, of the same design as those incorporated in the lead pan, are placed in the zincing pan in order to keep the wires beneath the surface of molten metal. The second roller, however, is adjustable in both horizontal and vertical directions, so that the distance of travel can be varied. This assures adequate control as regards thickness of coating.

In the wiping units, the wires are pulled out of the zinc through two asbestos wipes. There is one upper and one lower wipe to each wire and their purpose is, as the name implies, to remove any excess metal from the wires. The coating that remains is more or less high in iron, consequently the product of such units is not to be compared with unwiped wire as regards weathering. Two wipers look after the out-take, their duty being to replace the wads of asbestos when they become worn and to keep the correct tension on the wires after they pass the wipes. The asbestos must be kept saturated with a grade of lubricating oil which does not ignite easily. The purpose of this oil is to prevent any of the excess zinc from 'gumming' the wipes and to stop any tendency for this metal to oxidize. An annunciator system warns the wipers when a splice is coming, so that they may raise the upper asbestos wad and allow the hook-and-eye to pass through the aperture. This practice results in considerable scrap wire, since there is a portion of the material which has not been wiped smoothly, on either side of the splice. If the wipers exert too great a pressure on the wads the wires will break just behind the wipes, so it is important that the proper tension be kept on all wires. The unwiped galvanizer mill does not have any of these disadvantages, since the wiping is purely natural.

From the zincing pan the wires are drawn over individual sheaves and are immediately cooled in a water-box. This box is kept full of pure water and is exactly the same size as the wash tank between the acid and flux containers. The sudden cooling encountered by the wires assures a lustrous coating, but invariably affects its tightness and ability to withstand deformation. When a specification calls for a tight coating, i.e., one that will not crack off when the wire is bent, the water-tank is by-passed and the wires cool in air before coiling upon the reels of the take-up frame. This constitutes a rigid assembly supporting 30 reels which are driven on horizontal spindles. The power is secured from an adjustable speed direct current motor and is transmitted to each spindle by means of worm reduction gears off a main drive shaft. Clutches are provided for starting and stopping each reel or block. A system of individual sheaves of fairly large diameter guide the product into correct alignment with the reels.

Two blockers, each with one helper, strip the finished material from the reels and place the coils upon steel trucks. The tightness of coating as secured under this process is influenced by the speed of travel of the wires, the temperature of the zinc bath, length of immersion in this pan, quality of the cleaned surface and the method of cooling.

Unwiped galvanizing has been devised to overcome the natural tendency of the asbestos wipe in removing nearly all the pure zinc from the wire. The latter method secures a smooth coating by pressure while the former takes advantage of the surface tension of the metal to secure a satisfactory coating. In most units the wire is led almost vertically from the pan and passes over an elevated sheave system and thence travels downwards to the take-up frame. The vertical travel assures a smooth, easy flowing coating which quickly freezes as it passes upwards. The wiping is secured by means of a small cone of zinc which forms naturally at the point on the surface of the metal where the wires emerge. The system is most elaborate and would take more space than is available to adequately describe. From day to day the galvanizing industry is learning of newer and better methods of galvanizing under this system. To illustrate one point which clearly shows the necessity for proper construction in unwiped units; the wires being tightly stretched between the submerged roller in the zinc pan and the overhead sheaves, are free to vibrate in a manner similar to a violin string. Such vibration is undesirable since it will destroy the small wiping cone and thus result in a few feet of spoiled wire until a new cone forms. For this reason the speeds usually encountered in units of this type are considerably less than those found in wiping practice.

One man looks after the out-take of the pan since the wiping cones frequently oxidize and must be spooned out and replaced by pure metal. The operation is purely natural and does not affect the operation in any way. When a hook-and-eye tears out the wipe another quickly forms.

The question sometimes is asked just why some grades of unwiped wire have a bright lustrous coating and others a dull leaden gray finish. Obviously the latter condition is brought about by undue oxidation of the wires while the metal coating is assuming a solid state. This oxidation can be checked by sprinkling a quantity of nitrified petroleum coke which has been pulverized to pass 80 per cent through a 100-mesh sieve, over the portion of the pan's surface where the wires emerge. Sometimes this substance will give better results if it is saturated with a thin mineral oil. Various schemes have been devised to overcome the tendency towards oxidization which give more or less satisfying results.

To obtain a high quality zinc coating a good, reliable brand of zinc must be used. The American Society for Testing Materials has set a standard for the chemical composition of 'Prime Western Slab Zinc' which is that such shall not contain over 1.60 per cent of lead and 0.08 per cent of iron. It is important that such metal should be cadmium free since the presence of this element will affect the tightness of coating.

Wallace G. Imhoff, authority on metallic coatings, in his paper on "Obtaining a Satisfactory Zinc Coating" which appeared in the October 4th, 1928, issue of "Iron Age," has this to say in regard to impurities usually found in slab zinc. "Lead does not seem to be harmful in zinc for two reasons; first, it alloys with the zinc in small quantities only; second, any excess lead over the amount that will alloy with the zinc, settles to the bottom of the galvanizing pot and is not harmful unless it becomes too deep. If lead were lighter than zinc and thus remained at the surface, it would quickly oxidize at zincing temperatures thus producing an inferior coating." The article from which this extract was taken, referred to galvanizing of sheet metal products, but the same holds true in any process for obtaining a zinc coating. When the zinc becomes so contaminated with dross so that it floats to the surface, it is a good scheme to throw a few handfuls of finely divided lead into the pan. The heavy metal at once alloys with the iron of the dross, precipitating it to the bottom of the pan out of the way of the wires. The dross is removed at definite intervals depending upon the production and the celerity of the accumulation.

The vapour density of zinc is about 32.5 one half its atomic weight 65.0, since the molecule of zinc when in the condition of a gas consists only of one atom. Thus at ordinary zincing temperatures, between 800° and 950° Fahrenheit, zinc readily alloys with iron. The protective metal is not acted upon to any extent by either dry or moist air at ordinary temperatures, since a thin film of basic carbonate of zinc adheres closely to the metal and protects it from further change.

In testing galvanized wires for quality of coating the Preese copper sulphate test is usually employed. A solution of copper sulphate, specific gravity 1.186 and temperature 65° Fahrenheit, is used for this purpose. Test samples about 7 inches in length are taken from the end of each coil when it is removed from the reel. The number of tests, of course, rests entirely with the foreman of the galvanizing mill. It is often the case where a fewer number of samples are taken. Each test piece is wiped clean with cotton waste and gasoline before examining. As many samples up to seven or eight may be tested at once but care must be taken to prevent any of the samples touching when in the solution, otherwise an electrolytic action would hasten the removal of the zinc. After a thorough cleansing, they are immersed in the copper sulphate for a period of exactly one minute. At the expiration of this time the samples are removed, rinsed in cold water and wiped dry with a piece of waste. This removes the dark deposit from the wire. Such a deposit is termed ferrous zinc sulphate and results from a breakdown of the metallic coating. The samples are immersed again in the solution for one minute, then rinsed and wiped off once more. This operation continues, counting each one minute immersion as a dip, until copper is apparently depositing upon the steel base, showing that the zinc has been removed. When inspecting the samples the bottom portions for a length of one inch are disregarded. The number of immersions or dips withstood by the wire is a criterion of its thickness of coating. For example, the Western Electric specification for telephone and telegraph wire requires four such one minute immersions. This is a higher quality wire than that used for ordinary barbed wire fencing.

Another test which is quantitative is called the lead acetate test of determining ounces of zinc to the square foot of surface. This method of testing is too lengthy to outline here, but it may be said that it is the better of the two procedures.

Tightness or toughness of coating is examined by the wrap test. This consists of wrapping a sample of the finished wire tightly about a mandrel and observing the effect of the distortion upon the coating. An unwiped wire will if properly galvanized withstand high values when subjected to both the Preese and wrap tests. Very often specifications call for a wrap on the wires own diameter, which is a very rigid one indeed.

Micro-photographs of unwiped wire cross-sections show distinct layers of different chemical composition. The outer layer is composed of pure zinc and inside of this band is found a thin layer of zinc ferrite which is quite high in zinc. Next to the zinc-ferrite layer is an alloy of iron and zinc in which the former metal is predominant. Lastly the steel base is detected, which is composed of uniform grains.

It is not generally known in terms of years how long different classes of galvanized wires will last when exposed to the weather. Unfortunately sufficient time has not elapsed since the manufacture of the higher grade materials to give any idea of its weathering ability. Specimens are now under observation at the United States Bureau of Standards in Washington, where data in regard to their life in various localities is being compiled. In an interesting bulletin, R 10, the bureau makes public the results of simulated atmospheric corrosion tests which were carried on during the summer of 1928.

As for the future of the industry, very little can be said, except that the prediction might be made, since due to the ever increasing popularity of copper, bronze and cadmium copper wires, this class of wire will soon be discarded for communication work and be used entirely for the other purposes outlined in the opening paragraphs of this paper.

Graphs for Design of Reinforced Concrete Beams

C. G. Moon, A.M.E.I.C.,

Welland Ship Canal, St. Catharines, Ont.

The accompanying graphs are offered to designers who have not yet had the time or opportunity to re-arrange their own system of computations to agree with the C.E.S.A. 1929 specification.* One of the principal changes from the older methods is the determination of n or the ratio of the modulus of elasticity of steel to the modulus of elasticity of concrete. Formerly it was common practice to use 15 for 1:2:4 concrete and 12 or even 10 for mixtures of a higher ultimate strength. Under the new specification n has a varying value and is based upon the ultimate unit compressive strength of the concrete at the age of 28 days, or,

$$n = \frac{30000}{\text{ult. comp. strength}}$$

This straight line formula has the advantage of simplifying equations and is probably as close to the truth as other fundamental assumptions.

The maximum unit fibre stress in bending is taken as being equal to four-tenths of the ultimate compressive strength, and the primary equation $nf_c = 12000$, as shown on the graphs, is a direct result. If $f_s = 20000$ then $k = .375$ and $f_s' = 8800$ when the total depth is $1.1d$.

With the two graphs it is possible to arrive at a fairly rapid and direct solution of the bending moment problems commonly met with in the design of rectangular sections.

The symbols used are as follows:—

d = depth from compression surface of beam to centre of longitudinal tension reinforcement.
e = eccentricity in inches.
f_s = unit stress in tension steel.
f_s' = unit stress in compression steel.
f_c = unit compressive stress in extreme fibre of concrete.
M = moment in inch-pounds per inch breadth.
N = thrust in lbs. per inch breadth.
n = ratio of modulus of elasticity of steel to modulus of elasticity of concrete.
p = ratio of area of *tension* reinforcement to effective area of concrete.
p' = ratio of area of *compression* reinforcement to effective area of concrete.

$$c = \frac{d}{\sqrt{M}}$$

$$x = \frac{M}{d^2}$$

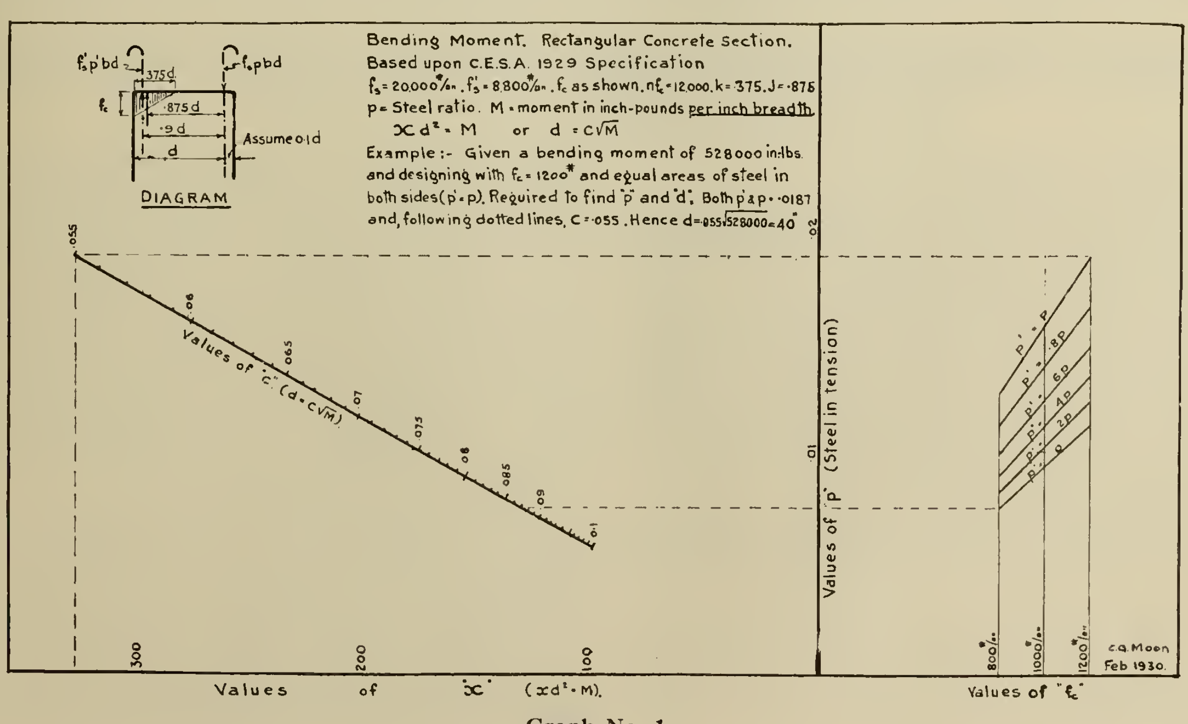
$$k = \frac{1}{1 + \frac{f_s}{nf_c}}$$

Graph No. 1 solves for moment, effective depth, and consequent ratio of steel, for conditions ranging from no steel in the compression side to an amount of steel equal to that in tension.

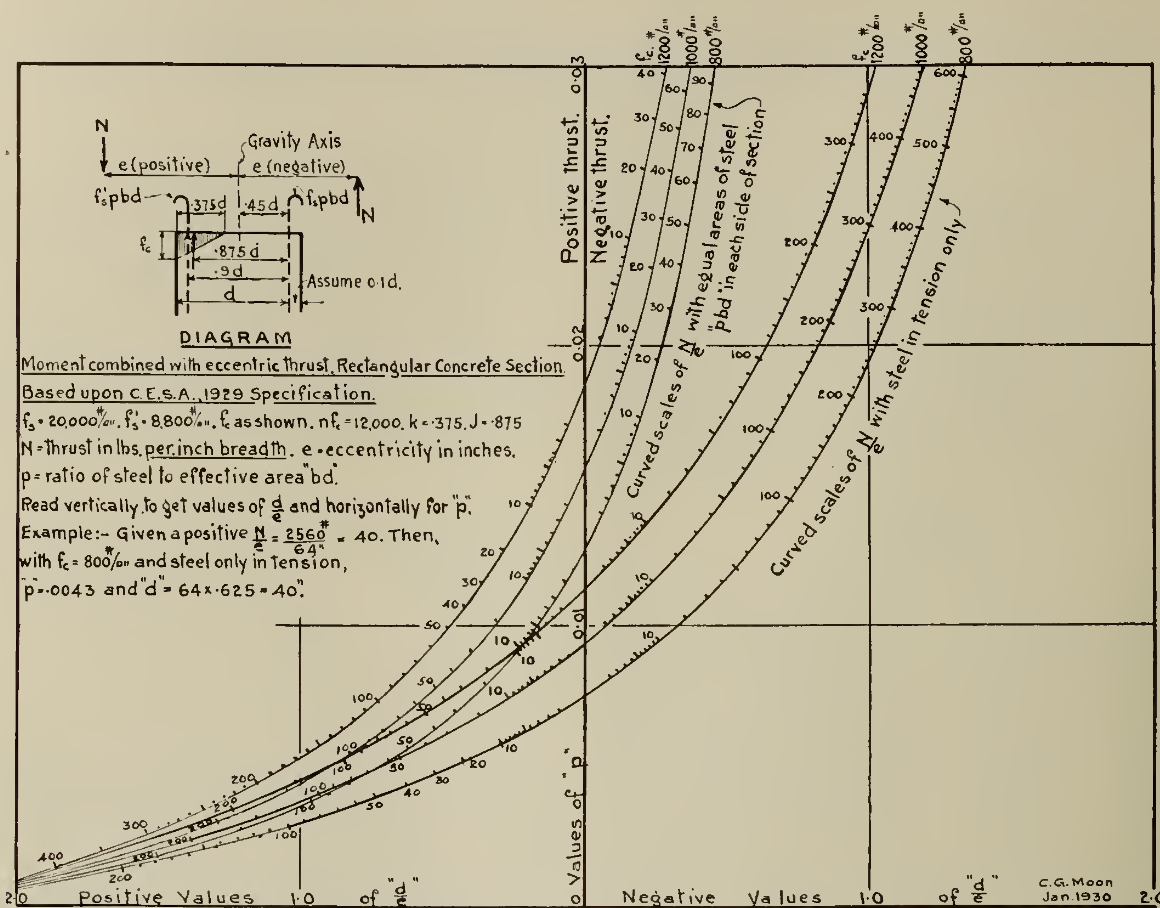
In using No. 1, select the desired value of f_c at the right hand end, and read vertically upward to the line giving the known ratio $\frac{p'}{p}$, thence horizontally to the left to get values of p and c. If x is desired, read vertically downward from the point giving the proper value of c.

Graph No. 2, gives a direct determination of d when bending is combined with an eccentric thrust. End walls or columns carrying fixed beams are subject to a combination of bending moment and "positive" thrust, while the

*Canadian Engineering Standards Association, Publication A23, 1929. Standard Specification for Concrete and Reinforced Concrete.



Graph No. 1.



Graph No. 2.

corners of cribs, bins or retaining walls resisting the load from an interior fill may be cited as examples of "negative" thrust.

In using No. 2, select the curve corresponding to the desired value of f_c, and follow it to the point marked with the known value of $\frac{N}{e}$. From this point read horizontally to get the value of p and vertically for the value of $\frac{d}{e}$.

Discussion of Paper on Recent Improvements in Mechanical Transport Vehicles by Captain N. G. Duckett (1)

Lieut.-Col. Frank Chappell, a.m.e.i.c. (2)

Colonel Chappell observed that the commercial motor vehicle did not develop to any great extent until roads became sufficiently improved to make this means of rapid transportation one upon which reliance could be placed. The cross country aspect of such travel naturally had at first no appeal to the commercial manufacturer of vehicles.

Now, however, the reliability of commercial vehicles on good roads having been assured, there was a reasonable possibility that such vehicles might be so durable as to be available for use under less favourable conditions than those for which they were originally designed.

Some of the problems involved in the original presentation of a vehicle in the field of commerce, included the development of an improved cooling system, due to the higher motor speed required. A different type of valve material had to be used in order to withstand the increased heat. A new drive shaft had to be designed, due to the excessive frame travel which affected the drive shaft angles. A reduction in the weight of the different assembled parts was necessary, otherwise the load capacity of the vehicle was reduced and operating economy thereby affected. The tire design was not satisfactory for high speeds. The development of the cord tire resulted in this latter handicap being very readily overcome, and rapid progress had been made in recent years in the development of other items of design, until now the operating economy was such as to make the commercial vehicle a practical, reliable and economical means of transportation.

This outstanding development included the six-wheel design, particularly the six-wheel flexible rear axle type. Owing to the assistance given by various war departments, development of this latter type had been most marked in Europe, since military requirements had called for a most comprehensive research in this style of construction.

However, in the United States, the six-wheel flexible rear axle unit was also in process of development, since there was evidently a commercial field for this type. To

(1) This paper was presented at the Annual General Meeting of The Institute, Ottawa, Ont., February 13th, 1930, and published in the February 1930 Journal.

(2) Assistant Factory Manager, General Motors of Canda, Oshawa, Ont.

quote one manufacturer alone, General Motors Truck Division had now progressed to the stage of actual production of such a heavy duty unit.

The 1929 Paris and London shows revealed the rapid progress made in the development and refinement of commercial chassis and motor design. Particularly interesting was the development of the motor unit, for in addition to the variety of six-wheelers shown at the recent shows, Mercedes, Renault, Junkers and Berliet displayed trucks motored by Diesel engines. Undoubtedly, there was a distinct trend toward the adoption of the Diesel engine for commercial vehicle work, and there was also no doubt that in due time refinements of design would result in the development of Diesel motors for the passenger and lighter car field.

It would appear that the improvement of transmission design had lagged somewhat behind the development of design of other essential features. During the later stages of the war, there had been developed a type of hydraulic transmission, something after the principle of the Hele-Shaw clutch, which had been used, according to personal observation, in certain types of tanks. Colonel Chappell recalled that Vickers had a motor omnibus in operation for their works purposes, which was equipped with a hydraulic transmission for test purposes, and while it was admittedly inefficient, it marked a trend toward an infinitely variable gear change.

Developments were now in sight that would enable gears to mesh more perfectly, and he believed that radical improvement in transmission design was at hand.

The problem of steering the type of vehicle under consideration, particularly when used for cross country and high speed purposes, merited very serious consideration. Great refinements had already taken place in this feature in commercial vehicles, resulting in a control that was both positive and sensitive. This had been brought to a high pitch of perfection on passenger cars, and the lessons learned had been applied to the truck field with materially advantageous results. The present stage of research development promised a wonderful improvement in this feature of design within a comparatively near future.

Visit of the R 100 to Canada

This ship, one of two built for the British government to test the possibilities of long distance passenger flight by rigid airships, has made the crossing from Cardington, England, to Montreal in seventy-nine hours, returning in fifty-nine hours. This is the fourth trans-Atlantic crossing from east to west, previous voyages having been made by the

R 34 (British) in 1919.............in 108 hours.
Los Angeles (built in Germany for the U.S. government) in 1924...in 80 hours.
Graf Zeppelin (German) in 1928....in 111 hours.

The leading particulars of the R 100 are as follows:

Capacity	5,000,000 cu. ft.
Length	709 feet.
Diameter	133 feet.
Total fixed weight	90 tons.
Total lift	156 tons.
Propelling engines	six, each 660 h.p., in three cars.
Electric generators	two, each 15 kw. d.c.
Fuel	gasoline.
Fuel supply	sufficient for 5,000 miles.
Cruising speed	about 70 miles per hour.
No. of passenger berths	100.
Cost	$2,250,000.

Through the kindness of the Minister of National Defence, members of The Engineering Institute of Canada were afforded an opportunity of visiting the airship at the mooring mast at St. Hubert, and a large number of members from Branches in eastern Canada took advantage of this privilege.

At a dinner given by the President and Council of The Institute in Montreal on August 7th, and also at a luncheon of the Ottawa Branch on August 8th, the officers of the ship related some of their experiences on the voyage and discussed informally a number of questions connected with rigid-airship construction and navigation. The views expressed on these occasions may be summarized as follows:

Wing-Commander Colmore stated that the present airship programme of the British government was based on experiments and investigations carried out since 1921, which had led to the conclusion that if success were to be attained in the construction of rigid-airships capable of making long trans-oceanic voyages with passengers, ships of much greater size and strength than any previously constructed would be necessary. When Major Scott crossed the Atlantic for the first time in 1919 with the airship R 34, he was able to make an average speed of only 40 miles per hour, and the fuel capacity of the ship imposed serious limitations. Such difficulties could only be overcome by increasing the size of the airship, but in doing so it was not sufficient merely to build a larger ship exactly similar to a previous smaller one, as the increase in size gave rise to entirely new problems. For example, in connection with the valves for the escape of gas from the bags, a different type of valve capable of discharging much greater volume had to be worked out. The R 100 and R 101 had taken three years to build after the conclusion of the experimental work on which their design was based. Two ships had been constructed, as it was felt that to demonstrate the possibility of passenger traffic it would not be safe to rely on one ship only, a minor failure in which might have brought the experiment to a premature conclusion. The R 100 and R 101 could certainly be regarded as a technical success, and the problem of mooring vessels of this size to masts in winds up to 35 miles an hour had been solved. They had at St. Hubert the most modern and efficient mooring mast yet constructed, and on the arrival of the R 100 it had only taken twenty-five minutes to bring her safely to the mast. He believed that as a result of the experience gained with the R 100 and R 101, much larger ships would be built, having a maximum speed of about 85 miles an hour and a regular cruising speed of over 70 miles per hour. He would leave to Major Scott the task of saying something about the actual experiences with the R 100 on the voyage across the Atlantic.

Major Scott thought it would be interesting to the members present to hear something about the voyage just completed, and the reasons which had led them to take the course they did. The ship left Cardington before dawn, the reason being the low temperature at that time, which would permit of making considerable progress with a minimum loss of gas, it being understood that when a rigid-airship rises in the air, when the temperature rises, or when the pressure falls, gas may have to be allowed to escape from the gas bags. They took a course well to the northward of Ireland, for the purpose of dodging a depression which the meteorological service informed them was centred around the south of Ireland, and in this way they obtained a fair wind from the south-east, afterwards changing to north-east, thus facilitating their progress. He stressed the importance of the receipt of constant meteorological reports during a voyage. Every six hours their meteorological officer had been able to furnish a complete chart of meteorological conditions over the north Atlantic, obtaining his information by wireless from ships, as well as shore stations. When off the north of Ireland with a favouring easterly wind there was, as a matter of fact, a strong unfavourable westerly wind only 200 miles to the south of them. It would be seen that an airship like the R 100 was like a sailing vessel in being largely dependent on the use of fair winds for economy.

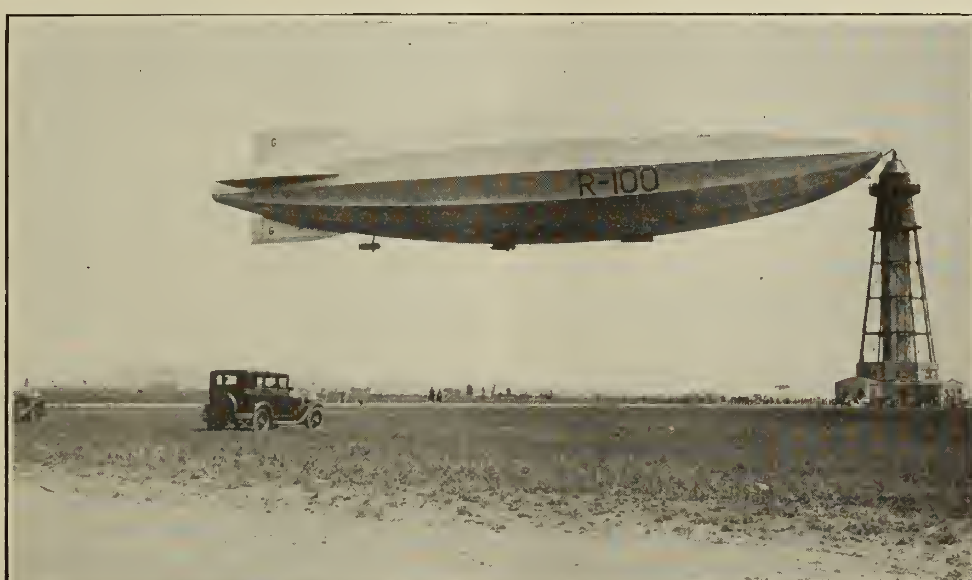
With regard to navigation, they received bearings from a number of ships on the Atlantic and also from the various radio direction-finding stations, and there was at no time any difficulty in determining the ship's exact position. This was evidenced by the fact that they made an accurate landfall, sighting the light at Belle Isle on the port bow, exactly where it should be, and continuing their voyage up the Straits without any alteration of course. In the Gulf of St. Lawrence they had experienced bad weather, particularly thunderstorms. It was desirable to keep a ship like the R 100 clear of thunderstorms, but not for fear of damage by lightning, as while a number of rigid-airships had been struck, no serious damage from lightning had yet been experienced. The chief danger from thunderstorms lay in the existence of violent up-currents of air in their neighbourhood. There were, of course, downward currents, but these were less dangerous. It was probably to such a violent upcurrent that the loss of the Shenandoah was due. The R 100 had been designed to be capable of rising 2,000 feet per minute, without damage to the gas bags or envelope, and the R 101 had been designed for an upward rise of 4,000 feet per minute.

Many believed that the most trying part of the trip was the passage over the ocean itself. As a matter of fact this portion of the run was the least difficult. Actually more fuel was used in coming from the strait of Belle Isle to Montreal than over the ocean portion. The few difficulties which the ship did experience occurred while coming up the St. Lawrence gulf and valley.

In one case a bump just before reaching Quebec caused a rip in some of the fabric of the starboard fin. This was by no means a serious affair and temporary repairs were made actually on board. These repairs allowed the ship to proceed at the rate of forty knots. Then, when off Three Rivers, they encountered violent air movements which dropped the ship to 1,200 feet, after which she rose to 3,000, dropped to 2,000 and then went up to 4,000 feet altitude. The whole of this rapid motion took place in a short time, which it was very difficult to estimate, but which probably did not exceed three minutes. The starboard fin, which had been previously damaged and repaired, withstood this, but the fabric gave way on the port fin. There was, however, no damage to any part of the structure of the ship, and they felt that in the R 100 they had a ship which was capable of weathering any normal disturbance which she was likely to encounter. The delay unfortunately prevented a landing being made in the evening and it was put off until morning. Had the crew been more familiar with the St. Hubert mast and surroundings, however, they would have landed during the night. Night landing, on account of favourable temperature and weather conditions, would undoubtedly be the rule in the future, as it could be much more advantageously effected.

Major Scott remarked further that when ocean navigation was in its infancy it was first developed by the Spaniards, who naturally made their regular voyages to portions of the globe where navigation was easy, and where steady trade winds could be found. It was largely the British who were driven to the development of the art of seamanship, since they had necessarily to make voyages across oceans like the north Atlantic where winds were more irregular and weather conditions frequently adverse. In a somewhat similar way it had fallen to the lot of the British to develop methods of handling and mooring large rigid-airships under adverse weather conditions.

He might mention that the mooring mast for airships had been essentially a British development. The Zeppelins had made their headquarters at Friedrichshafen, where wind conditions were much more peaceful than in Great Britain, and there was accordingly little difficulty in taking an airship in or out of its shed. In Britain, however, and in the province of Quebec, there was much greater risk in moving a large airship into or out of a shed, and the mooring mast was therefore a necessity. At Cardington, the R 101 had ridden out at the mast the severest gale of the winter, with a wind of 60 miles per hour and over lasting for many hours, and one exceptional gust of 83 miles per hour. During this gale the wind had shifted 120 degrees



R 100 at St. Hubert Airport.

in a minute, and the resulting loads upon the mast and the structure of the ship had been well within the limit, the ship having been designed to withstand a horizontal transverse force of 30 tons at the nose, whereas the actual load during the gale in question had not exceeded 15½ tons. At the St. Hubert mooring tower only fourteen men were required to moor the ship, and this could be done in any wind up to 30 miles an hour, a great contrast to the previous conditions, when hundreds of men were unable to control an airship of this size, even in a light breeze.

The experience of the present trip tended to show that, in addition to the main terminal at St. Hubert, the establishment of an emergency base nearer the Atlantic coast for use when weather conditions were adverse, might be advisable so that if strong head winds were encountered, the ship could land mails and take on extra fuel there before proceeding up the St. Lawrence. The mails and other urgent matter could be transported from this base by aeroplane to Montreal. The possibility of replenishing the fuel at an intermediate point would obviate the necessity of the ship having to carry on every trip the reserve of fuel necessary to meet the most adverse conditions. Her useful load could thus be materially increased. The airship could compete much more readily with steamship transport than with transport overland where fast railway and air services were available.

Mr. Giblett, meteorological officer, gave an interesting account of the researches which had been made in England on wind structure, for the purpose of obtaining information as to the size and intensity of eddies and other irregularities in wind, the data thus obtained being necessary for the design of airships like the R 100.

At both the dinner and the luncheon the visitors were warmly welcomed, and congratulated on their achievement. Hopes were generally expressed that they will meet with all success in the completion of their programme and will soon return to Canada.

The Centenary of the Liverpool and Manchester Railway

When the railway from Liverpool to Manchester was proposed in 1822 a grave difference of opinion existed between eminent authorities as to whether the passenger traffic on this road should be handled by steam locomotives, or whether it would be better to avoid these dangerous and new-fangled machines and haul the trains by means of ropes wound by stationary engines. The matter remained unsettled for some years, and finally, the directors having offered a prize of £500 for the best locomotive engine which should demonstrate its capacity for hauling a load of twenty tons at ten miles an hour, a competition took place in October 1829 over a level piece of the completed railway at Rainhill.

Four engines were entered for the prize, and each was required to make twenty runs over the course, a total of seventy miles, during the day. The "Rocket," made by George and Robert Stephenson, more than fulfilled the requirements; its competitors failed, and the prize was duly awarded to its makers. Further, the locomotive was definitely adopted as the motive power for the new line and eight engines were ordered from the Stephensons. The design of the "Rocket" included a number of features which have become standard in locomotive practice, particularly the multitubular boiler and the use of the exhaust steam in a contracted blast pipe for obtaining the necessary furnace draft.

The railway was not officially opened until the following year, when, on the 15th of September, the eight engines, of which one was the "Rocket," with trains accommodating about six hundred people, passed over the whole line in procession, one of them going at such "incredible speed" that it took only twenty-five minutes to go fifteen miles. The success of the steam locomotive on the Liverpool and Manchester Railway effectively terminated the dispute as to the adoption of locomotive or fixed engines, and established the steam locomotive as the standard means of handling railway traffic.

The Hundredth Anniversary of this opening is being celebrated this year in Liverpool in the third week of September, and gives a fitting opportunity to recall some of the achievements of the early railway leaders and engineers in Britain. The railways in England were really an outgrowth of the old tramways of the eighteenth century, on which traffic was hauled by horses, the wagons running on wooden rails. Iron rails were used for the first time in 1767. Trevithick built the first steam locomotive in 1804, but it was not until 1814 that George Stephenson's first engine at Killingworth Colliery hauled a train of eight loaded wagons weighing thirty tons at a speed of four miles an hour. In 1825, a railway having been built from Stockton to Darlington, a distance of thirty-eight miles, a train of thirty-four vehicles was drawn by one of Stephenson's locomotives, but in order to protect the public, the train was preceded by a signal-man on horseback. In spite of the success of this experiment, it was not thought prudent to use the locomotive for the conveyance of passengers, and for some years passenger traffic on this railway was carried on in coaches drawn by horses. The Liverpool and Manchester Railway, whose centenary is now being celebrated, was from the first a commercial success.

The achievements of George Stephenson as a civil engineer in surmounting the many difficulties encountered in the construction of this railway were not less remarkable than his development of the locomotive, and the railway which he made possible began a new era in land travel.

It is interesting to note that the first practical steam locomotive in use in America, the "Lion," was imported from England, and went into service on the 9th of August, 1829, on a line sixteen miles long in Pennsylvania. The first American-built locomotive was constructed in the following year, and worked for some time in South Carolina, but after a few months blew up, its attendant, annoyed by the noise of the escaping steam, having fastened down the safety valve. The first Baldwin locomotive, "Old Ironsides," was tried in 1832, and was modelled on one of Stephenson's successful engines. From that time the record of the steam locomotive has been one of continuous development.

OBITUARIES

Allen Hazen, M.E.I.C.

Deep regret is expressed in recording the death of Allen Hazen, M.E.I.C., which occurred on July 26th, 1930, at Miles City, Mont.

Mr. Hazen was born at Hartford, Vermont, on August 28th, 1869, and received his education at the New Hampshire College of Agriculture and Mechanic Arts, graduating in 1886. Subsequently he became a special student in chemistry at the Massachusetts Institute of Technology, where he came into contact with Dr. Brown, chief chemist of the Massachusetts state board of health, who in 1888 put Mr. Hazen in charge of the experimental station at Lawrence, where he was actively engaged on Boston sewage-disposal problems and those raised by typhoid epidemics in Lowell and Lawrence. In 1893 Mr. Hazen was in charge of the sewage-disposal plant at the World's Fair at Chicago, and the following year was spent in Europe on travel and study. During that time he wrote his first book, a review of European practice in water filtration. On his return to the United States in 1895, Mr. Hazen went into private practice, first in partnership with A. F. Noyes of Boston. In 1897 he went to New York and soon took charge of the design and construction of the filtration plant at Albany, N.Y. In 1904 Mr. Hazen went into partnership with G. C. Whipple, and in more recent years he was associated in sanitary engineering work with Chester M. Everett, Leroy N. Babbitt and Malcolm Pirnie. Mr. Hazen wrote a number of books on hydraulic and sanitary engineering subjects. It was he who introduced the probability concept into hydrology. His most recent work, a book on floodflow studies, has just been published.

Mr. Hazen joined The Institute as a Member on October 14th, 1911.

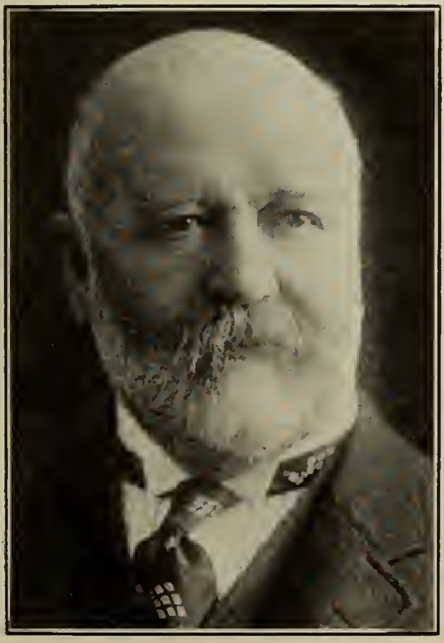
Frederic Lumb Wanklyn, M.E.I.C.

Members of The Institute will learn with regret of the death of Frederic Lumb Wanklyn, M.E.I.C., which took place at Grimsby, England, on August 3rd, 1930.

Mr. Wanklyn was born at Buenos Aires, Argentine Republic, on February 25th, 1860. He was educated at Marlborough College, England, and having decided on engineering as a profession, studied under the late Charles Sacre of Manchester.

His first position of importance was in Italy, where he became resident engineer of the Tramways and General Works Company s lines, Lombardy, and subsequently he acted as general manager and engineer of the Lombardy Roads Railway Company.

Upon coming to Canada, Mr. Wanklyn was appointed assistant mechanical superintendent and manager of the locomotive works for the Grand Trunk Railway. In 1897 he became general manager of the Toronto Street Railway. Then he entered the service of the Montreal tramways organization as manager and chief engineer of the Montreal Street Railway, remaining in that capacity until 1903. Since that date Mr. Wanklyn has been connected with the Canadian Pacific Railway, except during the periods when he assumed public service. In 1910 he was elected a member of the first board of commissioners of the city of Montreal under the charter changes which took active administration of the city from the aldermen, serving for two years. From 1903 to 1910 he was vice-president of the



Frederic Lumb Wanklyn, M.E.I.C.

Brian Douglas McConnell, M.E.I.C.

Dominion Coal Company, and remained as a director until 1920. Mr. Wanklyn was a governor of the Royal Victoria and Alexandra hospitals.

He was elected a Member of the Canadian Society of Civil Engineers on January 20th, 1887. He was a member of Council in the year 1909, and was a member of the Fuel Committee whose report was presented in 1925.

Brian Douglas McConnell, M.E.I.C.

Sincere regret is expressed in recording the death of Brian Douglas McConnell, M.E.I.C., one of the original members of The Institute, which occurred at North Bay, Ont., on July 13th, 1930.

Mr. McConnell was born at Gaspe, Que. on February 29th, 1836, receiving his education at Gaspe, Montreal, and Quebec.

He turned to engineering as a profession and was engaged on the construction of the Canadian Pacific Railway, being one of the party who made the first survey along the north shore of Lake Superior in 1878. At that time he was in the employ of the Dominion government, before the Canadian Pacific Railway Company took charge of the work itself. From 1874 to 1892 he was resident engineer, assistant superintendent and superintendent of the Montreal water works. In 1893 he became city engineer of Westmount, retaining that position until 1896, when he was with the Deep Waterways Commission on the Lake St. Francis and Lake Champlain canal project. In 1896 he entered private practice, which he carried on until 1916, being engaged on various municipal works, surveys and construction.

Mr. McConnell joined The Institute as a Member on January 20th, 1887, and was made a life member on January 9th, 1923.

PERSONALS

George R. Ewart Jr., A.M.E.I.C., who was formerly with Ynchausti and Company, Iloilo, Philippine Island, may now be addressed care of the Bishop Trust Company, Ltd., Honolulu, Hawaii.

William T. Pound, S.E.I.C., is now with the Ontario Paper Company at Thorold, Ont. Mr. Pound, who graduated from Queen's University in 1929 with the degree of B.Sc., was formerly with the Abitibi Power and Paper Company, Ltd. at Sturgeon Falls, Ont.

Bruce S. Taylor, s.E.I.C., is employed in the traffic department of the Bell Telephone Company of Canada at Quebec, Que. Mr. Taylor graduated from Queen's University in 1929 with the degree of B.Sc., and was for a time in the University's chemical engineering department.

Donald G. Robertson, Jr.E.I.C., is at present in the office of the city engineer, Hamilton, Ont. Prior to accepting his present position Mr. Robertson was with the E. B. Eddy Company at Hull, Que. Mr. Robertson is a graduate of Queen's University of the year 1924.

J. A. Rogers, s.E.I.C., has joined the staff of the Provincial Paper Limited, and is located at Port Arthur, Ont. Mr. Rogers, who is a graduate of the Nova Scotia Technical College of the year 1924, was formerly on the engineering staff of the Abitibi Power and Paper Company at Iroquois Falls, Ont.

O. J. McCulloch, A.M.E.I.C., is now with the Sydney E. Junkins Company, of British Columbia, Ltd., at Vancouver, B.C. Prior to accepting his present position Mr. McCulloch was with Porter Brothers and Robert Porter, at Detroit, Mich. He was for a time engaged on the construction of the Welland Ship Canal, at St. Catharines, Ont.

D. G. Geiger, A.M.E.I.C., a member of the staff of the Bell Telephone Company of Canada, has been transferred from Montreal, where he was in the engineering department, to Toronto, where he is transmission engineer, W.A. Mr. Geiger was lecturer in electrical engineering at Queen's University, Kingston, and resigned that position in 1928 to enter the service of the Bell Telephone Company at Montreal.

A. L. Dobson, Jr. E.I.C., is at present connected with the Jamaica Public Service Company, Ltd., at Kingston, Jamaica. Mr. Dobson, who graduated from the Nova Scotia Technical College in 1922 with the degree of B.Sc., was at one time on the staff of the Mound City Electric Light and Ice Company, later joining the staff of the Nebraska Electric Power Company at Broken Bow, Nebraska. Prior to accepting his present position, Mr. Dobson was with the Western Public Service Company at Broken Bow.

E. B. Patterson, A.M.E.I.C., has been appointed resident inspecting engineer for the Water Power Branch, Department of Mines and Natural Resources of the province of Manitoba, at Seven Sisters falls, Manitoba, during the construction of the Northwestern Power Company's development on the Winnipeg river. Mr. Patterson was formerly assistant engineer for the Dominion Water Power and Reclamation Service, at Whitemouth, Man. in connection with the same development. From 1909 to 1911, Mr. Patterson, who graduated from the School of Practical Science, University of Toronto, in 1909, was with Messrs. Smith, Kerry and Chace on concrete work at Pointe du Bois hydro-electric development. In 1911 he joined the Dominion Water Power Branch, being at first assistant engineer on power surveys on the Winnipeg river. From 1912 to 1913 he was resident inspecting engineer on the La Colle falls power development for the Water Power Branch. Following this he became assistant engineer attached to the Manitoba office of the Dominion Water Power and Reclamation Service.

Link Belt Company, Chicago, Ill., have recently issued a new data book No. 1615, entitled "The New Testament on Conveying Methods," containing 176 pages, on belt conveyors. This flexible covered book has been prepared to facilitate the selection and application of the proper type of belt conveyor for handling any material in quantities desired. Free copies will be mailed upon request.

BOOK REVIEWS

Water Supply and Utilization

An Outline of Hydrology from the Viewpoint of the Arid Section of the United States, together with an Outline of Water Law and its Administration as it has developed in the Arid States.

By D. M. Baker and H. Conkling. Wiley & Sons, New York, 1930, buckram, 6 x 9 in., 495 pp., front., figs., tables, charts, $6.00.

The authors of this book deal with the science of hydrology and primarily with its application to the solution of water problems of the arid and semi-arid states. While the book contains fundamental data and considerations applicable to particular areas, the elements of hydrology are fully and clearly set forth in a manner that will facilitate their general application.

The book opens with a history of the early irrigation works of the arid western states and a concise statement of the importance of water in the industrial and agricultural development of that area. The chapters immediately following deal in a very interesting way with water supply and its disposition.

That section of the book relating to administration and adjudication of water rights will undoubtedly be of particular interest to those engineers and administrators in Canada dealing with the contentious water problems of the prairie provinces and the dry belt of British Columbia.

The book is well written and should be useful to engineers having to do with the investigation of water supply, as a considerable portion of the material contained therein is not readily available elsewhere.

Shawinigan Water & Power
Company, Montreal.

Electroplating with Chromium, Copper and Nickel

By B. Freeman and F. G. Hoppe. Prentice-Hall, Inc., New York, 1930, buckram, 6 x 9 in., 212 pp., illus., figs. tables, $5.00.

The authors in the preface of this work say,—"An insistent demand has arisen for information concerning the process of chromium plating. This book has been written in the hope that it will serve, in some small measure, to meet this demand," and, "chromium plating is still in its infancy. New and better methods are constantly being devised. If this book helps others to a clearer understanding of the process, it will serve the purpose for which it is intended." The book very thoroughly covers the scope intended by the authors. It comprises eleven chapters, titled as follows:

I — Fundamental Electrical Considerations.
II — Chemical Fundamentals.
III — Applications of Chemistry.
IV — Plating Department.
V — General Remarks on Polishing and Polishing Compounds.
VI — Cleaning Surfaces for Electroplating.
VII — Specifications for Plating.
VIII — Deposition of Copper.
IX — Nickel Plating.
X — Chromium Plating.
XI — Testing Deposits and Solutions.

The authors cover their subject in a very logical way, as is shown from the titles of the chapters. They cover fundamental electrical and chemical considerations, then the plant itself and finally go into details regarding the processes of copper, nickel and chromium plating. They have wisely included copper and nickel plating because, as they state, no book on chromium plating could be considered complete without a discussion of these other two processes. The authors devote forty-eight pages to chromium plating and give quite a thorough story. Details are given regarding plating solutions, current densities, methods of racking, causes for defective work, etc. This chapter has numerous very good illustrations, which help to clearly bring out many of the points discussed. A very useful appendix and quite a thorough bibliography round off this book.

We consider this a very valuable and useful work. Anyone who is associated with chromium plating or who is contemplating going into this work will be well advised to have a copy of this book before him. Some time is given to theoretical considerations, but on the whole it is so written that it will be useful, not only to the chemist and engineer, but to the practical plater.

Limited, Montreal.

American Petroleum Refining

By H. S. Bell. D. Van Nostrand, New York, 1930, buckram, 6 x 9 in., 631 pp., figs., charts, tables, $6.00.

This is the second edition of a book intended for the use of engineers actively employed in the refining of petroleum. It is published seven years after the first edition and has been revised and augmented to bring it up to date, dealing with the latest developments in the technique of refining.

The author has fairly well fulfilled his purpose of preparing a book of reference for those actively employed in installing and operating refinery equipment. The data he has supplied permits one to obtain a good idea of what results can be obtained from existing equipment and also what can be expected from new installations or alterations to old plants based on the inclusion of new principles developed by research.

All branches of refining that have been carried on for the last few years are covered in the various chapters, with the exception of hydrogenation and the production of alcohols, etc., from refinery gases. These two processes, however, cannot yet be considered as regular refinery practice.

The co-authors, T. T. Gray and D. Drogin, have given a very comprehensive discussion on the chemistry of hydrocarbons, classifying these compounds in the well known series and giving the main characteristics of the members of each series. They have also given a good outline of the physical properties of petroleum and its products in Chapter IV.

The book is well written, highly technical language being avoided so that the ordinary refinery employee who is not acquainted with complicated formulae can appreciate and use it to the best advantage; at the same time the data supplied are sufficient to give the engineer direction as to correct design.

Since the technique of refining will probably develop in the future as rapidly as in the past, the information obtainable from this book of reference should be supplemented by consulting current papers submitted to technical societies and articles appearing in the technical journals. The volume will prove a valuable addition to a refiner's library.

Errata

In connection with paper on "A Short Monograph on Nomography" by F. M. Wood, A.M.E.I.C., which was published in two parts in the June and August issues of The Journal respectively, the following errors are noted:—

Page 373. Figure No. 5. Q scale on top shows value of 100 near the right end. This should read "1000".

Page 377. In the third determinant, the centre element of the top row should read $2.65 \log D + \log 1.272 - 0.80$.

Page 509. Centre element of last determinant should read $50 \frac{D}{D} \tan \phi$.

Page 510. Seventh determinant, first element of second row should be $\frac{B_3}{B_2}$.
Fifteenth line from end should read "point on the R scale", etc.

Page 518. Sixth determinant, first element should have minus sign, and read $\frac{-(1+k)}{\alpha - m - n}$
Thirteenth determinant, a_2 should read α_2.
Sixteenth determinant, a_1 should read α_1.

Waste Heat Boilers

A new bulletin describing waste heat boilers of an entirely different character from those used in the past has just been issued by the Foster Wheeler Corporation of 165 Broadway, New York City.

Several installations have been made in connection with the exhaust gases from Diesel engines and it has been found that in this service the boilers act as excellent mufflers.

Another interesting departure from usual boiler practice is that when operated with waste heat gases not exceeding 800° F., it is not necessary to by-pass the boilers for protection, even when dry. Repeated tests in operation have shown that the boilers are not damaged when used as mufflers alternately with and without water.

The boilers may thus be run as flash boilers, the steam production being controlled by setting the feed valve for the desired steam quantity.

The catalogue shows several designs, installations and details of construction which will be of interest to those having waste gases at temperatures above 500°. The bulletin is known as WB-30-2 and is available upon request.

Maximum Moments in Simple Beams, Plate Girders and Trusses of the Pratt Type

O. T. Macklem, A.M.E.I.C.,

Associate Professor of Engineering, Royal Military College, Kingston, Ont.

Table No. 1 gives the maximum moments, in thousands of pounds-feet, due to Cooper's E. 40. loading, at the one-tenth, two-tenths, three-tenths, four-tenths and five-tenths points of the even ten feet spans up to 300 feet and the maximum moments near the centre for the same spans up to 200 feet.

Plotting moments as ordinates, and span lengths as abscissae, there result curves giving the maximum moments at the 0.1, 0.2, 0.3, 0.4 and 0.5 points of all spans up to 300 feet.

To obtain the maximum moment at any point in a given span, lay off the span length to any convenient scale and mark the 0.1, 0.2, 0.3, 0.4, and 0.5 points on it. Through these points erect perpendiculars equal to the ordinates, for the given span, to the 0.1, 0.2, 0.3, 0.4, and 0.5 moment curves respectively. Joining the extremities of these perpendiculars gives the curve of maximum moments for the given span and the maximum moment at any point can be scaled from it.

Maximum Shears in Simple Beams and Plate Girders

Table No. 2 gives the maximum shears in pounds in a simple beam or plate girder due to Cooper's E. 40. loading at the 0.0, 0.1, 0.2, 0.3, 0.4 and 0.5 points of the even ten feet spans up to 200 feet.

To obtain the maximum shear at any point in a simple beam or plate girder, lay off the span length as before and at each tenth point erect a perpendicular equal to the ordinate, for the given span, to the corresponding shear curve. Joining the extremities of these perpendiculars gives the curve of maximum shears for the given span and the maximum shear at any point can be scaled from it.

Maximum Shears in Trusses of the Pratt Type.

Let AB represent a truss of n panels.

Let p be the panel length.

Assume the load to be moving from right to left, and draw the influence line $bgdha$ for shear in EF, the $(m + 1)$th panel from the right support.

$$\text{Then } DF = df = gf\frac{hk}{gk} = gf\frac{ef}{gf + eh} = gf\frac{ef}{gf + gf\frac{ae}{bf}} = bf\frac{ef}{bf + ae}$$

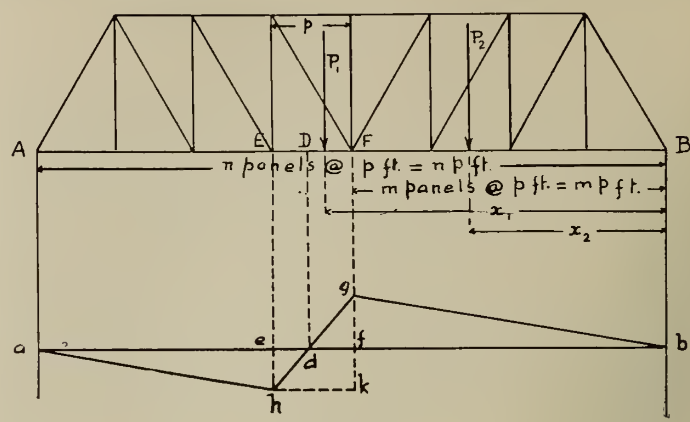

Figure No. 1.

$$\text{whence} \quad DF = bf\frac{ef}{ab - ef} = mp\frac{p}{np - p} = \frac{mp}{n - 1}$$

$$\text{Also } BD = bd = bf + df = mp + \frac{mp}{n - 1} = n\frac{mp}{n - 1} = n \,.\, DF$$

$$\text{Therefore} \quad DF = \frac{1}{n}BD \text{ or } \frac{DF}{BD} = \frac{1}{n}$$

Let P_1, distant x_1 from the right support, be the resultant of all loads in the panel EF.

Let P_2, distant x_2 from the right support, be the resultant of all loads on BF.

Consider the case in which $x_1 > BF$ and $=$ or $< BD$.

Then for a maximum shear in the panel EF, the load in EF must be equal to the average panel load on the span.

$$\text{Therefore} \quad P_1 = \frac{P_1 + P_2}{n}$$

190	250426	2	206547	2	166047	2	129347	2	96447	2	67226	2
200	261005	2	215205	2	173005	2	134885	2	100605	2	70400	2

And for a maximum moment at F in a beam of length BD, the average load to the left of F must equal the average load on the span.

Therefore $$\frac{P_1}{DF} = \frac{P_1 + P_2}{BD}$$

and $$P_1 = \frac{DF}{BD}(P_1 + P_2) = \frac{P_1 + P_2}{n}$$

Therefore, the position of the load for a maximum shear in the panel EF of the truss AB is the same as for a maximum moment at F in a beam of length BD.

Let M = maximum moment at F in the beam BD.

And S = maximum shear in the panel EF of the truss AB.

Then $$M = \frac{P_1 x_1 + P_2 x_2}{BD} DF - P_1(x_1 - BF)$$
$$= \frac{P_1 x_1 + P_2 x_2}{n} - \frac{P_1 n (x_1 - mp)}{n}$$
$$= \frac{P_1 (x_1 - nx_1 + mnp) + P_2 x_2}{n}$$

And $$S = \frac{P_1 x_1 + P_2 x_2}{AB} - \frac{P_1(x_1 - BF)}{EF}$$
$$= \frac{P_1 x_1 + P_2 x_2}{np} - \frac{P_1 n (x_1 - mp)}{np}$$
$$= \frac{P_1 (x_1 - nx_1 + mnp) + P_2 x_2}{np} = \frac{M}{p}$$

When $x_1 = BD$ then $x_1 - nx_1 = n\dfrac{mp}{n-1} - n^2\dfrac{mp}{n-1} = -mnp$

and therefore the P_1 term becomes zero.

When $x_1 > BD$, the P_1 term becomes negative and therefore, for a maximum shear in the panel EF of the truss AB, x_1 must be equal to or less than BD.

Therefore the maximum shear in the panel EF of the truss AB is equal to the maximum moment at F in the beam BD divided by the panel length, or $S = \dfrac{M}{P}$.

And hence, to find the maximum shears in a truss having n panels draw the influence lines for shear in each panel and scale the lengths db (or the lengths bd can be easily obtained from the equation $bd = n\dfrac{mp}{n-1}$). Plot the curve of maximum moments for each beam bd and from each of these curves scale the moment at the $\dfrac{1}{n}$th point. These moments divided by the panel length will be the maximum shears in the panels of the truss.

BRANCH NEWS

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Joint Luncheon to R 100 Officers

On Friday noon, August 8th, a joint luncheon with the United Service Institute of Ottawa was held in the banquet room of the Chateau Laurier, which was filled to overflowing. The speakers were Wing-Commander R. B. B. Colmore, O.B.E., Director of Airship Development, and Major G. H. Scott, C.B.E., A.F.C., Assistant Director of Airship Development (Flying). Among the guests at the head table were Colonel the Hon. D. M. Sutherland, new Minister of National Defence, and G. J. Desbarats, C.M.G., M.E.I.C., Deputy Minister of National Defence, through whose good offices the luncheon was made possible.

John McLeish, M.E.I.C., Chairman of the Ottawa Branch of The Institute, introduced Wing-Commander Colmore, who discussed briefly the progress in airship development since the present programme (of 1924) was commenced. This programme was approved by the British Cabinet in August of that year and the construction of the R 100 and the R 101 is in accordance with it. In this programme the work was to be limited only to the experimental stage, leaving the Government of the day free to consider the best method of future development in the light of experience gained.

In other words, the programme was to test out the practicability of airships in the light of post-war knowledge as vehicles of long distance transport. It was not intended with the present ships to inaugurate regular commercial services but rather to consider them in an experimental way so that from them a knowledge can be gained which will be beneficial in the establishment later of regular airship lines.

The R 100 and the R 101 are the largest airships ever built and have practically twice the capacity of anything heretofore. Both airships represent a radical departure from previous airships and are completely novel in many respects. They are not sister ships, the designer of each ship having had, subject to certain requirements, a free hand in the design.

The position today, according to Wing-Commander Colmore, is that these ships have been built and may be considered as fully satisfactory. They are stable in the air and their strength in the air has been proved; they are capable of landing in winds up to 30 miles per hour and it is expected it will be able to have them land in winds up to forty or forty-five miles per hour. They have travelled in winds up to eighty-five miles an hour and the knowledge and data obtained from the trial flights will be of great value in influencing the design for future ships. It is expected that in the next ship built there will be a far greater advance over the present ships than the present ships are over the previous ones.

One thing which the speaker stressed was the vital importance of meteorological data in conducting flights. These data are collected en route, correlated and made use of in determining the actual course of the flight.

The speaker expressed the hope that Canada would join with the Mother Country more closely in the matter of advancement of airship design and hoped that at the Imperial Conference next month the subject would receive favourable consideration. He closed with the thought that it was only a matter of time when airships would become a very practicable proposition for use on long voyages, particularly across large bodies of water.

Major Scott, who was introduced by Lieutenant Colonel C. B. Topp, President of the United Service Institute, outlined the course of the flight from the time that the R-100 left its mooring mast at Cardington, England, until it reached the St. Hubert mast near Montreal. The ship left England early in the morning with as much fuel as possible, and in this connection the speaker stated that on account of temperature conditions and the weight of fuel to be carried for a long flight, the take-off for such ships is always most favourable during the hours of darkness.

With regard to life aboard the airship, the speaker stated that many of the passengers had expected to receive a thrill from the trip, but on the contrary life aboard was very quiet and even boring at times. The ship was steady, there was no vibration, and eating and sleeping arrangements were all that could be desired. The trip in no way could be considered as a stunt but merely an effort to inaugurate a dependable and safe means of travel. There was no noise and—what is more to the point—no seasickness.

Trouble was experienced with a thunderstorm on the other side of Three Rivers. Certain conditions of the atmosphere during storms caused the ship to rise and descend vertically, but not to vibrate or wobble. This naturally caused a severe strain upon the ship; however in its construction, such contingencies are provided for. The experience near Three Rivers did no damage to the structure but caused a slight tear in the fabric of the fin.

Major Scott closed his very interesting discourse by expressing the hope that before long he would have the pleasure of entertaining aboard many of the members of the audience to whom he had spoken.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

MECHANICAL ENGINEERS. Two young graduate engineers with sales ability wanted by a well-known Canadian company. Apply, giving full particulars, to Box No. 562-V.

DRAUGHTSMEN—Preferably familiar with cruising, flotation and cyanide mill work. Men experienced in concrete, structural steel and plant layouts considered. Only Canadian citizens need apply. Work will be about eight months. Apply by letter. Location, Canada. Apply to Box No. 595-V.

ELECTRICAL ENGINEER, preferably with sales experience, to handle engineering equipment in Montreal and vicinity. Apply to Box No. 596-V.

ESTIMATOR OR QUANTITY SURVEYOR, required for a large building construction company. Must be experienced in this particular work and acquainted with Canadian methods of taking off and extending building quantities in detail. Apply giving age, experience and references to Box No. 597-V.

ESTIMATOR—One experienced in layout and estimating in reinforced concrete work. Location, Montreal. Apply, giving full particulars, to Box No. 599-V.

CHIEF DRAUGHTSMAN, experienced in design of pulverized fuel, pulp and paper mill and mining equipment. Location Ontario. Apply, giving full experience, to Box No. 600-V.

ESTIMATOR. Quantity surveyor and estimator wanted by a construction firm in Montreal. French and English preferred. Apply giving full particulars to Box No. 695-V.

CIVIL ENGINEERS. One or two junior instrumentmen on railway work. Location northern Ontario. Apply to Box No. 607-V.

MECHANICAL DRAUGHTSMEN, experienced in plant layout, required by a construction company with headquarters in Montreal. Apply at once to Box No. 610-V.

Situations Wanted

ELECTRICAL ENGINEER, M.Sc., A.M.E.I.C., graduate, seven years' experience in high tension calculation design and construction, seeks connection. Location immaterial. Age 30. Married. Apply to Box No. 7-W.

CIVIL ENGINEER, A.M.E.I.C., experience: highways, railways, drainage projects, stream diversion, earth, timber and concrete dams, laying large and small pipe, timber structures, concrete walls and pavements. Location, construction or maintenance. Desires position as engineer or superintendent. Location immaterial. Apply to Box No. 34-W.

ELECTRICAL ENGINEER, A.M.E.I.C., college graduate. Five years design and construction power house, substation and industrial plants. Two years operation and maintenance large substation. One year commercial experience. Age 32, single. Present location Montreal. Apply to Box No. 82-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years' experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Apply to Box No. 107-W.

COLLEGE GRADUATE, age 34, with over ten years experience in power developments and pulp and paper mill construction and maintenance, largely in direct charge of design or construction; desires new connection as chief or assistant engineer or construction superintendent. Apply to Box No. 167-W.

ENGINEER—Sales executive, A.M.E.I.C., age 37, presently employed as district representative, desires change in wider field. Experience (Canada and abroad), covers structural steel and iron foundry work as chief draughtsman, designer, etc. Available on reasonable notice. Apply to Box No. 227-W.

CIVIL ENGINEER, A.M.E.I.C., Canadian, 21 years experience, railways, highways, water power and conservation, concrete structures, electric transmission lines, etc.; field surveys, office engineering and construction. Working knowledge of French and Spanish. Available about October 1st. Now employed in Mexico. Prefer Canada, but willing to go anywhere. Apply to Box No. 327-W.

MACHINE DESIGNER. Experienced machine designer and draughtsman shortly open for position. A.M.E.I.C. Considerable experience in mining and winding machinery. Well up in steam power house equipment layouts and piping. Own design in successful operation. Accustomed to structural work. References good. Present location Montreal. Interview easily arranged. Apply to Box No. 329-W.

CIVIL ENGINEER, A.M.E.I.C., Reg. Pro. Eng. Ont. and N.B., age 47, married, twenty years experience in this country, twelve years in Scotland as construction and municipal engineer, specializing in roadway, water and sewer works, desires similar position, available forthwith. Just completed sewer and waterworks schemes for town in Maritime Provinces. Have also been engaged as engineer and superintendent with contractors on steam shovel excavation, concrete and caisson works for large buildings in Toronto, etc. Apply to Box No. 336-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., is open for engagement. Twenty-four years general experience both as engineer and as contractor. Has specialized in the construction of wharves, dams, foundations, etc. Apply to Box No. 358-W.

CIVIL ENGINEER, B.Sc., '24, Jr.E.I.C., C.P.E.Q., Canadian, age 30, married. Experience: Construction power developments, railways, highways, pulp and paper mills, maintenance pulp and paper mills, railways, desires permanent position with opportunity for advancement. Apply to Box No. 402-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), graduate. Eighteen years experience in survey and construction, railway, hydro-electric and buildings. Experience comprises both office and outside work. Desires responsible position. Would consider position with commercial or manufacturing firm. Available at once. Apply to Box No. 425-W.

ELECTRICAL ENGINEER, B.A.Sc., age 25 years, single; two five-month summer vacation periods on electrical construction and maintenance; three years and three months with large electrical manufacturing company, including twelve months standard test course, twenty-one months machine design, six months commercial experience. Apply to Box No. 426-W.

CIVIL ENGINEER, S.E.I.C., 1930 graduate of Nova Scotia Tech. with experience as plane table topographer, instrumentman and draughtsman and particularly interested in hydro-electric power development and reinforced concrete design, desires position. Willing to go to foreign fields. Available at a few weeks notice. Apply to Box No. 431-W.

SALES ENGINEER, B.Sc. (McGill, 1914), A.M.E.I.C., 37, married, presently employed in position of responsibility, desires to communicate with a prominent railway equipment supply house, with a view to becoming its Pacific Coast representative. Has a complete knowledge of railway locomotive equipment particularly. Excellent references can be furnished. Apply to Box No. 444-W.

CONSULTING ENGINEER. A member of The Institute with many years experience in general engineering is open for an engagement in consulting, advisory or inspecting capacity Would like to meet corporation or large contracting firm to whom such qualifications may be useful. Apply to Box No. 445-W.

Preliminary Notice

of Applications for Admission and for Transfer

August 23rd, 1930

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in October 1930.

R. J. Durley, *Secretary.*

* The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BARTLETT—OSWALD WILLOUGHBY, of Montreal, Que., Born at High Wycombe, Bucks., England, Sept. 16th, 1900; Educ., B.Sc., (Eng.), Univ. of London, 1924. Assoc. City and Guilds Engrg. College, London; 1917-18, engrg. ap'tice, Wm. Bartlett & Son, Ltd., High Wycombe, England; 1923-26, asst. engr., in charge of permanent way and overhead constrn., Reading Corporation Tramways, Reading, England; 1926-27, asst. to engrg. sales dept., Northern Electric Co. Ltd., Montreal; 1927 (Mar.-Oct.), asst. elect'l. engr., Lake St. John Power & Paper Co. Ltd., Montreal; Oct. 1927 to date, asst. elect'l. engr., Fraser Brace Engineering Co. Ltd., Montreal, Que.

References: J. B. D'Aeth, T. W. W. Parker, G. C. Clarke, J. C. Day, C. Bang, J. Stadler.

FEETHAM—LUKE BERNARD, of Halifax, N.S., Born at Halifax, N.S., Aug. 5th, 1897; Educ., B.Sc. (C.E.), N.S. Tech. Coll., 1921; 1917, concrete constrn. work, Quaker Oats Bldg., Saskatoon, Sask.; 1918, concrete constrn. work, Simpson Bldg., Halifax; 1919, machine shop, N.S. Steel Co., New Glasgow, N.S.; 1920, with Ballard, Sprague & Co., Quebec, engrs. and contractors, as engr. asst. in respon. charge of layout and part supervision of struct'l. steel and reinforced concrete paper mill in Nfld., street sewers and houses for small town, etc.; 1921-22, with Jackson & Moreland, Boston, Mass., and Pickings & Wilson, Halifax, on valuation work for N.S. Tramways and Power Commn.; 1922-23, with Doane Engrg. Co., Halifax, as res. engr. in charge of installing sewage and water systems for town of Middleton, N.S.; 1923-24, dfting and design of furnaces, W. S. Rockwell Co., New York; 1924, junior valuation engr., New York Edison Co., New York; 1924-25, asst. engr., Ballard, Sprague & Co., of New York, design, sales and supervision of constrn. of boiler settings, etc.; 1927, dfting and detailing struct'l. steel and concrete at main office, and 1928-30, asst. engr., on layout, design and supervision of constrn., Nova Scotia Power Commission, Halifax; at present, asst. engr., Halifax Harbour Commissioners, Halifax, N.S.

MATHEWS—HENRY MENDS, of Montreal, Que., Born at Alverstoke, Hamps., England, Feb. 16th, 1903; Educ., Diploma, Faraday House Elect'l. Engineering College, London, Eng., 1925; Assoc. Member, I.E.E.; 1925-26, asst. elect'l. engr., City of Winnipeg Hydro-Electric System; 1926-27, asst. engr., Messrs. Merz & McLellan, consltg. engrs., London, Eng. Preparation of reports, estimates, designs and schemes for the Electricity Commission and the Central Electricity Board, London, England; 1927-30, supervising engr., Messrs. Merz & Partners, Bombay, India (consltg. engrs. to the Govt. of India for railroad electrification). Supervising engr. for the constrn. and putting into operation of the 53,000 h.p. steam power plant at Kalyan, near Bombay, supplying power at 110 kv. for the operation of the electrified portion of main line of the Great Indian Peninsular Railway; at present, Canadian representative for Messrs. Merz & Partners, Montreal.

FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

O'CONNOR—GARRETT DAUNT, of Bridgeburg, Ont., Born at Niagara Falls, Ont., June 4th, 1895; Educ., B.Sc., Queen's Univ., 1921. M.S.E., Univ. of Mich., 1929; 1914-19, overseas, Lieut., Can. Engrs.; 1921-22, instr'man., and foreman on constrn. work for Prof. W. L. Malcolm, M.E.I.C.; Nov. 1922 to Feb. 1927, asst. to city manager, Niagara Falls, Ont., on design and layout of bldgs., pavements, sewers, sidewalks, etc.; 1927 (Mar.-July), res. engr., C.N.E.R. constrn. at Niagara Falls, Ont. for Roger Miller & Sons, Toronto; 1927-28, res. engr., on sewerage system as asst. to

M. F. Ker, A.M.E.I.C., Stamford Twp. Engr.; 1928 (Apr.-Sept.), private practice, Niagara Falls, Ont., air harbours, pavements, sewers, subdivisions, etc.; 1929-30, res. engr., for James Proctor & Redfern, Ltd., Toronto, at Capreol, Ont., waterworks and sewerage systems; at present, asst. to town engr., Port Colborne, Ont.

References: A. Macphail, W. P. Wilgar, W. L. Malcolm, M. F. Ker, W. B. Redfern, D. S. Ellis, T. S. Scott.

WEST—ARTHUR ELEMERE, of Walkerville, Ont., Born at Ridgetown, Ont., Oct. 21st, 1886; Educ., Night school, corres. school, and home study; 1908-09, blueprinting and tracing, Whitehead & Kales, Detroit, Mich.; 1909 to date, with the Canadian Bridge Co. Ltd., as follows: 1909-11, struct'l. dfting; 1911-14, checking struct'l. details; 1914-18, squad foreman; 1918-19, asst. mgr. of constrn.; 1919-23, chief dftsman.; 1923 to date, operating manager.

FOR TRANSFER FROM THE CLASS OF JUNIOR TO A HIGHER CLASS

BUDDEN—ARTHUR NAPIER, of Grand Mere, Que., Born at Montreal, April 28th, 1902; Educ., B.Sc. (Mech.), 1923, B.Sc. (Elec.), 1928, McGill Univ.; 1921 (summer), supernumerary engr., S.S. Victorian and S.S. Empress of Britain; 1922 (summer), fitter, mech. mtce, dept., Canadian Vickers Ltd.; 1923-24, testman, Gen. Elec. Co., Schenectady, N.Y.; 1924-25, office engr., International General Electric Co., Schenectady, N.Y.; 1925-27, engr., General Electric Sociedad Anonima, Mexico, D.F.; 1928, asst. supt., Laurentide Power Company, Grand Mere, Que.; 1929 to date, supt., Laurentide Power House, Shawinigan Water & Power Co., Grand Mere, Que.

References: C. M. McKergow, C. V. Christie, E. Wilson, E. B. Wardle, S. Svenningson.

COOIL—THOMAS REGINALD, of North Battleford, Sask., Born at Maple Creek, Sask., Mar. 1st, 1903; Educ., B.Sc. (Civil), Univ. of Sask., 1926; 1925, asst., surveys branch, Sask. Dept. Highways; 1926 (May-Nov.), instr'man and field engr., City of Saskatoon; 1927 (Jan.-May), signal office, Chicago & North Western Rly.; May 1927 to June 1930, engr., sewers and water dist. system, City of Saskatoon. Also special work on street rly. track, river bank protection, constrn. of concrete reservoir, and misc. engrg.; at present, city engr., North Battleford, Sask.

References: C. J. Mackenzie, J. E. Underwood, H. M. Weir, H. B. Brehaut, R. A. Spencer, J. G. Schaeffer.

COYNE—CLARANCE STANLEY, of 54 Boustead Ave., Toronto, Ont. Born at Ingersoll, Ont., Nov. 28th, 1888; Educ., Night classes, Toronto Technical High School, I.C.S.; 1909-16, clerk, rodman, dftsman., transitman, and asst. acct., C.P.R., Ontario Lines, Mtce. Dept.; 1916-17, transitman, and from Mar. 1917, asst. engr., G.T.R.; from Mar. 1928, asst. engr., C.N.R., and at present, asst. divn. engr., C.N.R., London, Ont., in charge of general mtce. work on the above mentioned railways.

References: G. H. Davis, S. G. Smith, E. Nicholson, A. R. Hannaford, H. B. Kippen.

DICK—VICTOR WILLIAM, of 140 Harvard Avenue, Winnipeg, Man., Born at Winnipeg, June 12th, 1897; Educ., B.Sc. (E.E.), Univ. of Man., 1921; 1918 (summer), Greater Winnipeg Water Dist.; 1920 (summer), City Hydro System, Winnipeg; 1921-23, student course, Canadian Westinghouse Co. Ltd.; 1923-26, sales engr., Canadian Westinghouse Co. Ltd., Calgary; 1926-29, dftsman., Manitoba Power Co. Ltd.; 1929 to date, elect'l. designer, Northwestern Power Co. Ltd., Winnipeg, Man.

References: F. H. Martin, E. V. Caton, R. Morham, E. P. Fetherstonhaugh, N. M. Hall, J. P. Fraser.

MAXWELL—EDWARD GERRARD, of Tarentum, Alleg. Co., Pa., U.S.A., Born at Halifax, N.S., April 8th, 1897; Educ., B.Sc. (Arts), Dalhousie Univ., 1922. B.Sc. (Civil), McGill Univ., 1924; 1924-25, cost. acct'g., Bell Telephone Company, Montreal; 1925-26, production tracer, Northern Electric Co. Ltd., Montreal; 1926-27, special studies and later in charge of alterations, production dept., Packard Motor Car Co., Detroit, Mich.; 1927 to date, with Pittsburgh Plate Glass Co., as follows: 1927-28, efficiency dept., Ford City, Pa.; 1928-30, asst. efficiency engr., and at present, plant efficiency engr., Creighton, Pa., in charge of wage incentive system, special studies, improvements in equipment and organization of labour.

POOLE—JOHN MAURICE, of 29 Preston Street, Halifax, N.S., Born at Scotch Village, Hants Co., N.S., Dec. 23rd, 1889; Educ., 1908-12 (inc.), 3 yrs., Kings College, and 2 yrs., N.S. Tech. Coll., special subjects in civil engrg. course; 1912-15, rodman and instr'man. on Can. Nor. Ont. Rly., Montreal to Hawkesbury; 1915 (June-Oct.), office, Public Works Dept., Halifax, N.S.; 1915-17, inspection and gen. engrg. work, Halifax Ocean Terminals; 1917-18, i/c survey party, N.S. Tramways & Power Co.; 1918-21, with Pickings & Roland, Halifax, i/c survey party, land subdivisions, etc.; 1922 (Feb.-July), survey for power line, N.S. Power Commission; 1922 (July-Aug.), inspr. on street pavings, City of Halifax; Sept. 1922 to Jan. 1923, i/c party survey for power line, N.S. Power Commn.; Summers 1923, 24, 25 and 26, office man, leveller, etc., topographical surveys, Dept. of the Interior; Winters 1923, 24 and 25, taught a short course in land surveying at N.S. Tech. Coll, Halifax; 1926, land surveying work for Dept. of Lands and Forests of Prov. Govt.; 1927-29, Dept. of Lands and Forests, (Crown Land Office), Halifax, N.S.; Sept. 1929 to date, dfting and outside engrg. work, with the Halifax Harbour Commission.

THE

ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

Published monthly at 2050 Mansfield Street, Montreal, by The Engineering Institute of Canada, Incorporated in 1887 as The Canadian Society of Civil Engineers.

Entered at the Post Office, Montreal, as Second Class Matter.

The Institute as a body is not responsible either for the statements made or for the opinions expressed in the following pages.

Volume XIII — Montreal, October 1930 — Number 10

Road Building in Ontario

E. L. Miles, M.E.I.C.,

County Engineer and Road Superintendent, County of Victoria, Lindsay, Ontario.

Paper read before the Montreal Branch of The Engineering Institute of Canada, March 20th, 1930.

Realizing that the progress of civilization, commerce and wealth is impossible without means of communication, we necessarily find highway construction prominently written in the history of Canada's growth.

During the early days of Canada, transportation was by water, portages being used between waterways; then came trails to inland forts and trading posts; then military roads for the transportation of troops; then the establishment of toll roads, and from then on the progress has been in widening, straightening, and bridging until we have arrived at the period when the combined efforts of the federal and provincial governments are linked with that of the counties, townships and towns, in the ever increasing movement of "Good Roads."

Railways, waterways and highways are the three great contributors to the development of Canada, as that development is applied to our national resources, population and industrial life. Nor should highways be considered the least of these, but rather the very arteries through which the life of the nation flows to the other two.

In the general organization of the roads of Ontario, there are three groups—township roads, or strictly farm roads acting as feeders to main transportation routes,—county roads leading from the agricultural districts to centres of population, and connecting our local towns and villages,—and the provincial highways connecting the larger provincial towns and cities.

The methods of financing the various systems of roads might be described as follows: The township road money is derived by direct taxation of the people in the townships, and forty per cent of the total annual expenditures is refunded by the provincial treasurer. The county road systems derive their money from the municipalities included in the systems and receive a refund of fifty per cent from the provincial treasurer on its annual expenditures. The provincial highways are built by the provincial highway department and twenty per cent of the cost is refunded to the provincial treasury by the counties benefited. (Previous to 1924 the province received forty per cent from the federal government through the Canada Highway Act.)

It is often said that the money that comes from the provincial treasury in the form of aids is contributed by everybody, but this is not the case as the term "everybody" is implied. The provincial revenue is derived mainly from lands and forests, mines, game and fisheries, public institutions, succession duties, automobile licenses, gasoline and amusement taxes, fines, etc.

Federal grants were derived from the consolidated revenue funds of Canada, which is made up largely of customs duties, crown lands, income and business taxes, etc.

Probably the oldest road building organization in Ontario is the Toronto and York Roads Commission dating from 1911. Then the Toronto-Hamilton Highway Commission started in 1914.

The first surveys were made in the county of York in 1791, and Yonge street was surveyed and partly cleared in 1794. In this year $900 only was spent in road improvement in the county of York, whereas upward of $750,000 is spent by the Toronto and York Roads Commission annually.

In 1894 the Ontario Good Roads Association was formed, which organization has brought about all the progressive road legislation since. In 1896 they had the late A. W. Campbell appointed as a road building instructor. In 1901 the Highway Improvement Act was passed. In 1915 the Department of Public Highways was formed. In 1919 federal aid was granted and in 1924 provincial aid was granted to county bridges.

Provincial Mileage (Southern Ontario)

Provincial highways	2,416 miles
County roads	8,095 "
Township roads	41,477 "
Total	51,988 "

Expenditures and Grants 1929

	Province	Counties
Provincial highways	$11,485,499	$ 2,280,973
County roads	4,321,162	4,700,000
		Townships
Township roads	1,802,640	4,500,000
	$17,609,301	$11,480,973

Grand total about $29,000,000.

Motor Vehicle Revenue 1929

Motor vehicle and gasoline tax	$16,346,042

The total highway expenditure for 1930 is estimated at $35,000,000.

Figure No. 1.—Lindsay-Downeyville Road (1928) Mixed Macadam 6 inches Thick, 18 feet Wide.

Economics of Highway Improvement

Railways and canals are necessary for the carrying of passengers and merchandise over long distances, but the primary channels of traffic are the rural roads.

The economics of highway improvement are of course the essential points which constitute the policies of the various provincial and federal highway schemes throughout Canada. It may be suggested that economy in highway transportation reacts to the detriment of rail transportation, that highway improvement increases the traffic of the pleasure vehicles to the detriment of production, or even that taxation resulting by the cost of the improvements, far exceeds the benefits derived. Be that as it may, it has long since been proven that the progress of civilization demands improvements in all things, and that competition is the life of trade.

From a financial point of view, good roads lower the cost of hauling; they widen the range of distribution; they increase the areas that may be devoted to the production of high priced products; they increase the value of lands and properties everywhere; they decrease the cost of operation of vehicles, and they foster to our lands our share of the biggest business in Canada today—the tourist traffic.

From a social point of view, good roads help the growth of rural populations; they develop the rural mail delivery service; they foster educational administrations; they increase school attendance; they better social conditions; they promote mutual understanding and union and allow for better health by minimizing the dust nuisance, and enable the medical and nursing professions to extend their fields of operation.

The highway branch of the Department of Railways and Canals made arrangements with the Dominion Bureau of Statistics in December 1919 to collect from the crop correspondents statistical information as to the cost of haul of crops and other products over the unimproved and the improved roads with the following results:

"The average cost per ton-mile of hauling over unimproved dirt or earth roads was found to be 37 cents, over the improved dirt roads 35 cents, over gravel roads 34 cents, and over macadam roads 25 cents. It will therefore appear that if, for instance, an improved dirt road over which the cost of hauling per ton-mile is thus shown to be 37 cents is to be graded, and given a surface, the gain to the users of every mile of the road so improved will amount for each ton carried, over each mile, to 12 cents or 32½ per cent.

"Most of the hauling of the crops in Canada is done at seasons of the year when the roads are best, hence the cost per ton-mile of hauling over unimproved roads is the lowest possible rate during the year. Still the extent to which the individual farmer is affected by high hauling costs may be seen from a single illustration:

"Supposing a farmer marketed during the season 10,000 bushels of wheat, in a town ten miles from home, his product as marketed, expressed in ton-miles, is 3,000. Consequently if the road now improved which he follows from his gate to the elevator were macadamized, his saving during the season would amount to 3,000 times 12 cents or $360.00."

The prodigious losses annually through poor highway transport facilities to the different agricultural sections of this country, and the possible gains from improvement of roads generally, may be seen from another calculation.

The Dominion Bureau of Statistics reported that the total yield of wheat in Canada for the year 1920 was 263,189,300 bushels, or 7,895,679 tons, and that the total yield of oats for that year amounted to 530,709,700 bushels or 9,022,064 tons. The total yield of these two grains alone in 1920 amounted to 16,917,743 tons. Now the average distance of haul is found by the questionnaire to be 7.6 miles. Assuming that all of this tonnage is marketed in the same form, the total ton-mileage for these grains amounted to 128,574,846. The average difference between hauling over unimproved and the improved roads is 4 cents per ton-mile. Consequently for this total ton-mileage, the possible saving to be effected by improving to the standard of the ordinary earth road, all the roads in the country used by agriculturists was $5,142,933.87 in 1920.

While the above deals only with the saving effected by team hauling it does not take into consideration the important question of upkeep cost as applied to the motor vehicle. The recognized average saving in the operation of every motor car over improved roads as against unimproved roads is 5 cents per mile, this item being made up of three important factors, depreciation of value, gasoline and oil consumption and wear and tear on tires.

Depreciation takes place by the crystallization and fatigue produced on all metal structures by constant shock and vibration and by the definite wearing of all movable parts.

Gasoline and oil consumption of heavy trucks are reduced 50 per cent while for lighter vehicles this waste is reduced 25 and 30 per cent. This fact shows the actual expenditure of energy involved in the continual raising of the vehicle out of pot holes and the diminished efficiency due to jerky motion.

Wear on tires is in direct proportion to their actual contact with the road over a given length of run. Broken contact under engine power means the destruction of the resistance of the rubber, and the bursting of the walls of the fabric or cords.

To this might be added the extra strain put upon the attention and endurance of drivers, and the tendency to accidents, but the results of this analysis will show that there is undoubtedly a waste going on all the time in the system of commerce as it affects human life, which can be reduced in the item of improved highway transportation.

Then considerable discussion is heard on the subject of highway transportation in competition with railway transportation, and as Canada has a vast system of public-owned railways, this question must be solved and the two methods of transportation co-ordinated. It is realized that transportation is the very blood-stream of civilization, yet there is evidence where the railroads have replaced the river and stage traffic, and once famous steam boat and stage routes are now no more. Even in summer resort communities it is found that lake traffic is struggling for its existence against the motor traffic which is found to be more convenient although not always more economical.

Railway transportation has for itself a distinct class of business, that of long distance haulage, which cannot be interfered with by highway transportation, while short distance haulage never was economically handled by the railroads, and perhaps never will be.

This is most apparent in congested railway terminals where delays are unavoidable, and the railway equipment not designed for L. C. L. class of business. The motor class of transportation for less than car load lots to suburban centres and country stores is desirable even at an increased transportation rate.

Suburban farms have flourished as a direct result of improved roads and land that could be bought for $500.00 per acre is sold for $10,000 or $12,000 per acre when subdivided into lots. The increased assessment of the land along the Toronto-Hamilton highway due to the highway improvement is about ten times.

Then again there are millions of men who must have work and the money with which to buy the products of the farm, and to this end the "Good Roads" movement is a God-send. The cost is distributed over the entire nation, giving employment in actual construction, in quarries, cement mills, and factories of all kinds producing road material.

Economics of Hill Cutting

That a definite economic value is derived from hill cutting is apparent in the item of transportation. Traffic census returns show that country roads are travelled by an average of 140 vehicles per day, 120 being motors and 20 horse driven, which will be assumed as correct for a period of 183 days. For the balance of the year, or 182 days, it is safe to assume this at one-half or 70 vehicles per day. It could also be safely assumed that the traffic on highways will increase from year to year at a rate of about 10 per cent.

The average speed of an automobile running on high gear is four times the running speed of low gear, and the wear and tear on the engine and parts is in about the same proportion.

As previously stated, if 4 horses can operate a 6 per cent grade, it takes 9 horses to operate a 15 per cent grade with the same load, so that the actual difference in the cost is 2¼ times.

Taking the average cost of operation of motor cars at 4¾ cents per mile and the depreciation value at about the same rate, or a total of about 9½ cents, there is an actual loss of 4¾ cents for every car that operates a 15 per cent grade on low gear for a quarter mile run. Also if the statistical value is taken of the cost to haul one ton one mile at an average of 31 cents as given by the Department of Highways, Ottawa, a loss occurs of 35 cents every time a horse drawn vehicle operates a 15 per cent grade for a quarter mile run.

Traffic

Motor traffic is created on a road after construction and not before, and the increase or decrease in the same is in direct proportion to the conditions of the driving surface. That is, the value of a traffic census in order to determine the importance of a road is comparatively nil, while the route and service rendered between established market places and beyond them are the essential features that determine the type, the status and the standards.

In the same manner also the proper widths of roadway should be determined, not in the light of what we see to-day, but within the economical life of the type of surface decided upon. Traffic does not even follow distance routes, but rather surface routes as practised by the tourist, and the owners of heavy motor trucks. Then again traffic does not produce a constant flow and may range from 100 vehicles to 1,000 per day at the different seasons or even different days. One day of heavy and particularly fast traffic will destroy the surface of a well graded gravel road if it is subjected to a 25-mile per hour gale at almost any angle across it.

Traffic in Relation to Road Surface

The traffic on highways is largely controlled, if not entirely controlled by the condition of the road surface, so that present day traffic over an unimproved surface becomes merely an indication of what might be expected over an improved surface. Narrow single track roads soon become obsolete, and the scheme of building half at a time is losing favour because of the additional cost when complete.

It is interesting to study the origin of traffic. County traffic might safely be classed in the following manner:—

50 per cent is from farm to town and return.
30 " " is from town to town.
20 " " is through traffic or from other countries.

In the manner of determining a suitable road surface to carry traffic the following table might be used as a guide:

1 to 10	vehicles per day	natural earth.
10 " 50	" " "	graded earth.
50 " 200	" " "	gravel.
200 " 500	" " "	macadams of various types.
500 and up	" " "	permanent pavements of various types.

Again in considering the ratio of traction on these various types of road surfaces, it is found that if natural earth requires 218 pounds pull on the draw bar, then it requires 92 pounds for graded earth, 78 pounds for gravel, 64 pounds for macadam of various types and from 30 to 50 pounds for various types of permanent pavements.

Also in considering grades; if one horse can draw a load on a 1 per cent grade, then it requires two horses to draw the same load on a 2 per cent grade, 3 on a 4 per cent, 4 on a 6 per cent, 6 on a 10 per cent and 9 on a 15 per cent.

Tourist Trade and Traffic

It is a difficult matter to establish the value of the tourist traffic in any particular section of the country, and therefore one must be content with the reflections received from observations, from the traffic census and estimates of the average spending power of the tourists.

From the report of the highways branch of the Department of Railways and Canals, Ottawa, for 1927, valuable information is obtained with regard to the highway, the motor vehicle and the tourist in Canada. For instance, the total amount spent on all roads for 1927 was $45,750,000, and 34,230 persons were employed on the work. This represents the construction of 6,020 miles, and the maintenance of 44,416 miles by the patrol method.

The total registration of all vehicles in Canada was 946,858, showing an increase of 107,933 or 13 per cent over the total for 1926, as compared with a 15 per cent increase in 1926 over 1925. Passenger vehicles numbered 827,518 and commercial trucks 101,421 for 1927. Imported vehicles are included in the figures above, and on such importations

Figure No. 2.—Lindsay-Little Britain Road (1928) Mixed Macadam 6 inches Thick, 18 feet Wide.

Figure No. 3.—Fenelon Falls-Lindsay Road (1929) Asphalt Mixed Macadam 6 inches Thick, 18 feet Wide.

of vehicles and parts the federal government has collected $21,649,778.68 in the same year, while the provincial governments have collected $22,994,424 in motor licenses, registrations, fines and gasoline taxes.

The parks branch of the Department of the Interior has calculated that the tourist traffic in Canada for 1921 represented an expenditure in Canada of $108,000,000 and for 1927 an expenditure of $276,000,000, or more than double in six years.

This figure $276,000,000 is greater than Canada's annual mineral production, greater then Canada's pulp and paper production, and next to Canada's greatest industry, export wheat.

Canada admitted 3,153,800 automobiles for touring purposes in 1927 and 4,508,808 automobiles in 1929 and sent out for touring purposes only 620,572.

The 1,076,819 automobiles registered in Canada in 1928 covered about 4,000,000,000 miles, and carried about 600,000,000 passengers. This showing represents twenty times that of the combined totals for the steam and electric railroads for the same period.

From the 145 ports of entry where "American" cars are recorded, in 1929,

1,206	cars entered for a 6-months visit.
1,091,014	" " " " 60-day visit.
3,416,588	" " " " 24-hour visit.
4,508,808	"

The first item shows a decrease of 65 per cent, the second an increase of 44 per cent and the latter an increase of 42 per cent over the 1927 figures.

The estimated value or outlay of the foreign motor tourists in Canada during 1929 is $397,806,760 figured on the basis of four persons to each vehicle, and a spending power of $5.00 per day for each person, considering that the 24-hour tourist stayed the full time, the six-months tourist stayed half time and the sixty-day tourist stayed one-quarter time. On the same method of calculation the Canadian tourist spent $90,000,000 in the United States.

Transportation

In adding to what has already been said on this subject under the heading of "Economics of Highway Improvement," it is interesting to note that about one-half the cost of the food supply is taken up in the item of transportation in which the motor truck plays a very large part, but the fact that 95 per cent of this road destruction is caused by 5 per cent of the traffic, and also that the value of the road construction to carry the 5 per cent is about double the value required to carry the other 95 per cent, is not considered in the problem of food supply.

Straight and wide roads, easy grades, and hard surfaces are therefore essential to the economic life of any country or district.

Of the three most rapid means of transportation, the aeroplane and airship take first place, the railway train second, and the motor car third. In comfort it depends entirely upon the length of the trip and the state of the road bed, but the ultimate order will probably be time first, comfort second and cost last, but for cost, the motor car is the most expensive for long distance travelling, the train second and the aeroplane the cheapest.

Commercial aviation dates from the Armistice in 1918 and is making wonderful strides, and while war flying was conducted regardless of cost and dangers, it is now settling down in the commercial channels of speed, economy, ease and safety.

Design

The increased volume of motor car traffic has gradually changed the design of our more important marketing roads, and methods that were of standard practice in the past have given away to more modern ideas.

A few years ago nearly all pavements were built to a crown of one-quarter inch to the foot of width, whereas they are now never over one-eighth and sometimes as light as one inch in twenty feet. Gravel roads were once given an inch to the foot whereas now they are seldom over one-quarter that amount.

Curves at corners seldom had more than a twenty-five foot radius whereas now they have seldom less than two hundred feet, and on provincial highways the radius is from three hundred feet up.

Alignment is becoming straighter. Crooked roads that were safe enough a few years ago are dangerous to-day, and the idea of deviation to avoid hills is giving away to extensive hill cutting in order to keep the roads straight.

Grades too are becoming more flat and regular, and the once familiar undulations of the road which conformed to the natural waves of the land are taken out by the cut and fill method. Nothing is more dangerous to a driver than an unexpected and sudden volume of bright light over the crest of a hillock at night.

Super-elevation and widening of curves are now practised for safety. At first the road was simply tilted by taking out the crown and affording drainage, whereas now a super-elevation of two feet and over is given on all curves of two hundred feet radius. Widening on curves is also practised, and stones painted white, or cable guard-rails are placed on the outer edge to mark the curves at night.

Guard railing along fills, deep ditches and at bridges are more common. Wire cable has taken the place of wood, and stones painted white are used to mark the shoulder where possible danger might exist.

Shoulders that at one time formed the bank of the ditch by a regular contour to the crown of the road, now have a distinct angle at the shoulder line, and cars are kept in an upright position when driving on them. The width of grade shoulder to shoulder has remained about the same for the past five years, but the width of pavements in the country has been increased.

Railway crossings are now before the public eye as the most important factor in the interest of public safety. The elimination of the grade crossings entirely is desirable but the improvement of the approaches and sight lines are constantly going on where improvement can be made. By-pass roads around towns and villages are now being talked of.

In types, the roads conform to the local conditions regarding materials, and the extent of the finances to build them. Traffic, of course, plays a big part, but it is found that the maintenance cost of gravel roads that carry from three to five hundred vehicles a day, are proportionately too high. Grading to uniform elevations and alignments, and metalling with local materials until a foundation is procured, and its value realized by use, is the popular method for the present at least.

Generally speaking, it is found that the various road organizations are keeping well up with the increased motor traffic from year to year. The average daily traffic has increased about one hundred per cent during the last five years, but the mileage of constructed roads has increased about four hundred per cent in the same length of time.

Construction

The construction of roads should be by stages. First, the grading to the proper and ultimate grade and final alignment which also establishes the drainage system. Second, a reasonable coat of gravel, followed by efficient dragging, patching and general maintenance. Then when the surface will no longer handle the traffic without resurfacing, it should be paved.

Pavements are undoubtedly the most economical, even on roads carrying as few as 500 vehicles per day. To maintain such a gravel road so that the driving surface is fit for the legal speed limit with comfort, it costs fully $750 per mile per year or $7,500 for ten years. To this must be added a cost of resurfacing twice in the ten years, say $6,000. At the end of ten years the cost has been $13,500 and the asset is a road worth about $1,500 and besides the public have had a dusty road in dry weather, and a sloppy road in wet weather, both uneconomical conditions. Now suppose the same mile is paved at a cost of $25,000 and spread the payments over ten years. The asset at the end of ten years is a road worth $20,000 and besides the public have had clean, pleasant and economical driving all the time.

In the first case $9,500 is lost by maintaining a gravel road (allowing $2,000 for grading common to both cases), and in the second $5,000 is lost by maintaining a pavement. A difference of $4,500 saved and maintaining the superior riding qualities of the road besides for ten years, to the credit of the pavement, not to forget the increased life of motor vehicles.

Severe climatic conditions is the most serious question Canadians have to contend with in the construction of permanent roads. Drainage of course must be adequate, but the best safeguard of all is a cushion of clean, fresh gravel or crushed stone under a new pavement. This cushion need only be a matter of two or three inches or just enough to take up the expansion of the frost. If the cushion is properly provided for no longitudinal side drains are required. Blind drains made of field stone or four-inch quarry stones from the edge of the pavement to the ditch are helpful in conducting the water that may flow along the edge of the pavement to the ditch, and in every case where small washouts occur in the shoulder, they should be filled with clean stones rather than dirt.

In the matter of general drainage it is not necessary to find outlets that may or may not mean the formation of the drainage district, but rather a matter of building the road up so that the crown will be at least eighteen inches above the high water in the ditches, and in no case should a road be paved that does not have this provision.

Farm drains crossing the road is another matter that should be carefully inspected, and if inadequate, or old, they should be relaid in concrete, and man-holes or catch-basins built at each fence line having the pipe line between laid in a straight line, and to a uniform grade. They can then be inspected by light reflection, and the annoyance of opening up the road and pavement at some future time avoided.

Figure No. 4.—"Standardite" on Concrete Base.

In general, highway construction along primary roads is rapidly becoming a matter of engineering, with definite plans and profiles, and more and more along the lines of railway building. Humps and hollows are being removed to allow the motorist to drive with ease and speed, without undue strain, or fear as to what the conditions ahead may be.

The Motor Car

In order that the road building programme may be continued in proper tune with what is going on, and what evidently must be expected as a result, first of all the automobile industry must be considered, for after all that industry is the one, if not the only one, that has thrown the road building game ahead by leaps and bounds.

Within the past twenty-five years, the motor car has revolutionized roads, and in itself has grown from an eccentric luxury to a vehicle of necessity in every day life. The motor industry has grown until it has become an economic factor in the commercial life of the country, and so too the roads must keep pace with the requirements of the motor industry in order that that industry shall flourish.

Then again, to the credit of this industry must be added the development of oil, cement and other industries which derive a large percentage of their trade from the automobile, and which when all taken together make up the prosperity of the country. Even with regard to railways the automotive freight is one of the most important, if not second in importance, to the grain shipments of Canada.

All this has been written to point out the tremendous strides in rapid transportation, in order that one may learn the lesson that an organization for road building must keep abreast of the times and realize that the future means of transportation will be more rapid than ever, that the motor car will be more powerful, and roads must be built more closely along the lines of railroad construction and of a better and more lasting type than ever before.

Traffic follows the best roads from one point to another, regardless of distance, and there are examples of the division of traffic from old established routes to better constructed roads, even miles away. Therefore there are primary and secondary roads in every part of the country, and every organization should recognize this fact and lay down the policy of road building to meet these requirements. Continuity of service is therefore essential as no man can render his best service to a community or cause by one year of service, and no organization can be expected to function with any degree of efficiency if it is broken up and changed from time to time.

There is both a need and a necessity for strong road organizations throughout the length and breadth of Canada and more particularly just now when the country needs the best that is in the individual to see that expenditures are classed as investments and not as foolhardy speculations.

The Construction, Operation and Maintenance of Unit Cars

T. H. Dickson, A.M.E.I.C.,
Supervisor of Unit Cars, Canadian National Railways, Moncton, N.B.

Paper read before the Moncton Branch of The Engineering Institute of Canada, December 12th, 1929.

A unit car might be defined as any self-propelled rail car which can operate in regular revenue train service either alone or coupled to one or more trailer cars. In some cases the car circuits are so designed that two or more unit cars may be operated coupled together, and controlled from one car, usually the leading one.

Outline of Causes for the Development of this Equipment

There is an old law which states that every effect must have a cause, and this applies to the particular case under discussion. Among the causes for development of unit cars we will mention:

(1) Losses in operation of most branch lines with steam train operation.

(2) Increased cost of ton mile operation due to:
- (*a*) Increasing wages of train crews.
- (*b*) Increasing cost of repairs.
- (*c*) Increasing cost of new rolling stock.
- (*d*) Increasing cost of fuel and water.
- (*e*) Improved service demanded by the public, both in type of equipment and frequency of service.
- (*f*) Increasing taxation.

Revenue has failed to keep pace with the increasing costs, due to:

(*a*) Failure of freight, passenger and express revenue to increase in proportion to the increase in operation costs. (Average freight rates in this country are stated to be less than in the United States where conditions are such that costs are usually less than in Canada.)

(*b*) Decrease in passenger revenue due to increasing competition from busses and private autos: the bus competition often being quite unfair as the bus does not usually pay a tax, or license, which represents the actual wear and tear on the road, and, in a case of unprofitable service the bus company can abandon the service while the railway cannot do so without permission of the Board of Railway Commissioners.

(*c*) Canal, and other water-borne traffic for freight, and to a lesser extent for passengers. This is also an unfair competition as canal charges are not paid, therefore, the canal traffic travels on a roadbed, if one might call it so, that they do not have to keep in condition.

Due to the above, and other causes, it becomes increasingly difficult to make earnings balance expenses.

A continuous effort is made to improve the efficiency of the motive power in use or being built. This has produced numerous changes in locomotives, both in size and in gadgets, as they are sometimes called. Labour-saving, and fuel-saving equipment, have been added to all modern locomotives, and boiler pressures have increased considerably, as a result of the development of special alloy steels; however, it would seem that the limit in size has almost been reached, and, when we consider the efficiency of the average steam locomotive, we can readily see that this type of equipment must either be improved enormously or it will eventually be superseded by something better. It is considered that the overall efficiency of the modern steam locomotive is in the vicinity of 5 per cent and its availability for service is just over 40 per cent.

Steam turbine locomotives are being experimented with in Europe.

For main line service the problem was solved, at least in districts of heavy traffic, by the adoption of electric locomotives and the multiple-unit car. This results in a much heavier train being hauled by a locomotive that is quite simple, of high efficiency, and capable of increased efficiency due to regenerative braking.

For the branch line and local main line service, various types of equipment have been tried with varying amounts of success.

(1) *Gas-Mechanical.*

This is a type of car using an engine similar to an automobile engine, in fact, in some cases it was an auto engine with a gear drive to one or more axles. Not many cars of this type are now being sold in the smaller sizes, but the J. G. Brill Co. of Philadelphia are still making a four-cylinder and a six-cylinder engined car of this type, using a four-speed gear shift with a drive to both axles on the forward truck. This type of car has been quite a success where used in a service that is suitable. A four-cylinder car of this type is in service between Stellarton and Sunny Brae and a six-cylinder one on the line between Mont Joli and Matane. These cars require little attention and are quite economical, giving an average of about eight miles per gallon of gasoline.

(2) *Gas-Electric.*

As the gas-mechanical car, in the hands of inexperienced or careless drivers, can produce an objectionable jolting during gear shifting, and, as the acceleration could be quite uneven, the electric drive was considered, and we find that, as far back as 1907 this drive was being used. It differed from the straight gas-mechanical drive in that it had the mechanical connection between the engine and the driving wheels replaced by an electrical drive made up by coupling a direct current generator to the engine; the current from this generator was supplied to series motors mounted on the axles and geared to them through a gear and pinion; the current being carried through the necessary control equipment, so that the proper connections might be made, and proper supervision exercised over the operation of the power equipment. This method of connection of the power to the driving axles resulted in a smooth jar-free acceleration, as there was no mechanical gear-changing to do, the variations in speed being obtained by varying the voltage on the motors, either by varying the engine speed or by varying the generator field excitation, or both. On some types of cars a regrouping of motor connections to provide various series and parallel arrangements is also used. It might be noted here that the speed of a series motor is directly proportional to the voltage impressed on it. For this reason, and also for its high starting torque, it is admirably adapted to traction service.

This addition of the electric drive made the car much more expensive and also caused an increase in maintenance, as motors, generators, exciters, compressors and a number of other control devices, as well as much wiring, had to be maintained; however, the drive proved much more satisfactory than the gear type, although it did not become very popular until after 1918, as the manufacture was discontinued during the war. Shortly after, however, a few enterprising young men who saw the possibilities of this type of car developed a much more reliable engine, and a

Figure No. 1.—Gas-Electric Car, Canadian National Railways.

very simple type of electrical control, and have now been marketing a very satisfactory car for some years. Other manufacturers have followed with somewhat similar equipment, some being very elaborate internally, with all sorts of gadgets to add to the first cost and to the worry of the maintainer and others, but which add little to the efficiency and reliability, while one company eliminate everything they possibly can and provide a wonderfully reliable car with little excess material to keep up.

Complete figures have not yet been received for 1928 but, in 1927,

150 gas-electric cars were purchased for use in the United States.
8 gas-electric cars were purchased for use in Cuba.
2 gas-electric cars were purchased for use in Canada.

and in 1929,

117 gas-electric cars were purchased for use in the United States.
1 gas-electric car was purchased for use in Canada.
9 gas-electric cars were purchased for export.

At that time the B. & O. had 17 in service and other roads nearly as many. Recently the General Electric Co. announced a total of 383 gas-electric cars equipped by it were in service, and, of this number, the Burlington leads with 46 and the Chicago and Northwestern follow with 37.

Cars of this type are turned out with double power plants rated at 550 horse power, and it is understood they can now be obtained with 800 horse power rating if desired.

(3) *Storage Battery Cars.*

While the gas-electric car was in its infancy, the electric storage battery car was developed, and it has been quite a success in its limited field. It was a somewhat radical departure, as it carried no engine of any sort and depended for its propulsion on the energy stored in a large battery. This battery is charged before the start of the run and the car is then operated by using current from the battery to turn the traction motors. The first available record of this type of car dates back to 1911, and it appears that the type originated about that time. There is in service in this region a car of this type which entered railway service in 1913 and has probably operated over half a million miles and is good for a few more miles.

The standard car of this type has a battery of 250 cells of Edison nickel-alkaline battery of 450 ampere-hour rating, which on good roadbed should provide about 80 miles operation on one charge of the battery.

The cleanliness and quietness of this car make it attractive, but it has some disadvantages. Its charging supply has to be direct current, and, to obtain this, some type of converter is usually necessary, as there are few places where direct current can be purchased. This conversion entails some loss, and, usually power rates are rather excessive, making the cost of operation high. The speed is limited and the mileage is also limited, and, as the car usually operates over a run where her battery capacity is nearly all needed to make the trip in fair weather, there is little reserve of power for bad weather.

Until the cars had been in service some time, their capabilities were not well known, and some of them were badly abused by excessive mileage and continuous service which kept the battery temperature so high that the plates rapidly deteriorated and the expected six or seven years' life did not materialize. The cost of a replacement battery is quite high, as is the cost of new battery solution.

As the batteries operate at a fairly high temperature, a large quantity of water is driven off from the cells, and this has to be replaced with distilled water, and, when it is known that as much as 90 gallons of distilled water may be used in one battery in one week, it can readily be seen that, if the water is not 100 per cent pure, the impurities will gradually increase in the cells, thus causing loss of efficiency and other battery ills. For this reason every effort is made to keep the distilled water pure.

(4) *Distillate Electric Cars.*

The cost of fuel for various gas cars has always been a deterrent to their use in Canada especially, and also to a less extent in the United States, and we find one western road experimenting with a distillate engine. They use a modified gas engine and fit it with a carburetor for each cylinder, and they find that their fuel costs are much less, but it is also understood that what they have been saving in fuel costs has, so far, been nearly balanced by the increased cost of maintenance, as the engines have more valve trouble, require more frequent decarbonizing and require very accurate setting of the carburetors.

(5) *Oil-Electrics.*

Canadian National engineers realized the limitations and disadvantages of these various cars, especially for long runs and for heavy service, and decided that something more economical and satisfactory should be available and so a search was instituted.

It was known that a Swedish firm had been producing an oil-electric equipment since 1913, and had had good success with it. Three leading electrical and mechanical officials of the Canadian National Railways went to Sweden and examined this car, and found it quite satisfactory for the type of service it was used in, but not at all suitable for conditions here.

They found that a very heavy slow speed engine was used and they decided that the engine was too massive to be useful here. They were operating their cars with several trailers, but their trailers were rigid axle types with only four wheels, and very light bodies. A search was then made for a Diesel type engine that would be satisfactory, and, when it looked as though they were not going to be success-

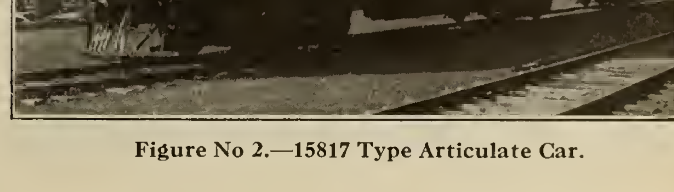

Figure No 2.—15817 Type Articulate Car.

Figure No. 3.—"9000" Type Oil-Electric Car.

ful, they heard that the Wm. Beardmore Co. of Glasgow and London were developing an engine for lighter than air craft. On looking into this development they found an engine that, with slight modifications, appeared to offer a solution of their difficulties. Beardmores, who had been making Diesels for submarines for the British Government, had had excellent experience with the Diesel, and the result was that they made a very satisfactory job of remodelling their aero engine. The resulting engine was somewhat heavier per horse power developed, but much more rugged and reliable for service. As a result, in 1925, the Canadian National manufactured 7 four-cylinder cars and 2 eight-cylinder ones, the four-cylinder ones being 60 feet long and the 8-cylinder ones being articulated cars of 120 feet length. The Beardmore engine is a 4-cycle engine cold starting, with solid injection, and with ignition of the fuel obtained by the temperature of compression (1,200 degrees F.) Each cylinder head is fitted with 2 inlet and 2 exhaust valves as well as a fuel atomizer, which sprays the fuel in to the cylinder in a fine mist.

In the four-cylinder type, which is the only type in service in this region at present, the engine is direct-connected to a 105 kw. direct current generator and an exciter. The main generator leads are carried to a controller in each end of the car where the various connections to the motors are made. The motors are two of about 100 h.p. each mounted on the forward truck.

The engine room contains the necessary fuel, water and lubricating tanks, and switch gear. The driver's cab, in the right hand forward corner of the engine room, contains the air gauges, voltmeter, a pilot light connected to the lubricating and cooling circuits (this light only lights when the water or oil pressure drops); headlight and number light and marker and cab light switches, valve for air-operated bell ringer and one for horn; master controller, engine throttle and engineer's valve for operation of the air brakes. The air for brakes, bell and horn is provided by a motor-driven air compressor operated from the main generator current. The operator's cab in the rear end is similarly fitted.

In this car the motors are connected in series for starting, thus giving maximum starting effort, the engine is gradually speeded up by the throttle, then, when the speed has reached about 15 m.p.h., the throttle is closed and the controller moved to the second notch connecting the motors in parallel, the speed is again increased by the throttle; for still higher speeds the throttle is again closed and the controller moved to the third notch, called the field shunting position. In this position, the motors are still in parallel, with the fields shunted with a resistance. This weakens the field and the weaker the field, the higher the speed. With the controller in this position, the throttle can be opened again and the car's speed increased to its maximum, which is about 65 m.p.h. on level tangent track with normal adjustment of the electrical circuits and with new wheels. A slightly higher speed can be obtained by certain adjustments but it is not considered advisable to make them for a car in ordinary service.

The eight-cylinder car has a slightly different type of control, and has four motors, but the engine is similar except that it is a straight eight.

It might be interesting to note that the R 101 is powered with Beardmore 8-cylinder engines, using superchargers, which increase the output considerably.

Many outstanding records were made by the first lot of cars, which is all the more wonderful when it is considered that this particular equipment was new and untried. The first and most spectacular record was the non-stop run of unit car 15820 from Montreal to Vancouver, 2,937 miles in 67 hours non-stop, a transcontinental record made in November 1925 and still unbroken.

Another record that is really more important but not so spectacular, is that of 15822 on this region. This car made a record of over twenty-one months of 100 per cent service, i.e., was not out of service one day in that time, and hopes were entertained of making it a two-year record, but the Maritime Express put an end to those hopes by side-swiping the car.

These first cars were scattered from the prairies of western Canada to the wilds of Prince Edward Island and spare parts were mostly carried at Toronto, but, in spite of this and also of the fact that nobody knew a lot about the equipment and the troubles that might be expected, the record made and savings shown were so great that a new order of five 73-foot 9-inch cars powered with a six-cylinder engine of the same type was placed in 1927 and, early this year, an additional seven six-cylinder cars were ordered and will soon be delivered, while a shunting engine is also being built.

The biggest development, of course, is the 9000 class locomotive, which, of course, is not a unit car, but which must be touched on as it is a development of the oil-electric car. This locomotive is a two-unit engine, 4-8-2 and 2-8-4 type, each unit containing a V-shape 12-cylinder engine of 12-inch bore and 16-inch stroke, each engine developing 1,330 h.p. at normal rating, but designed for the use of a supercharger should it be considered necessary. The locomotive has a maximum tractive force of 100,000 pounds, while the 6000 steam locomotive is rated at 49,600 pounds. Many new and radical ideas are embodied in this engine, among which might be mentioned an exhaust muffler, which is also a boiler for generating steam for train heating. The exhaust gases pass through this boiler and give up their heat and at the same time they lose their velocity and this results in a very quiet operating engine.

To come back to cars again, some of these cars operate over 300 miles a day, and some have now operated a total mileage of over 200,000, and the total mileage of 4, 6 and 8-cylinder cars is now over 2,250,000.

The average miles per gallon of fuel oil is between five and six for the 4-cylinder cars, although some cars have a frequent consumption of over 7, and, when it is considered that the type of fuel used costs less than half the cost of gas one can well see that the fuel charges are the small part of the cost of the service; in fact, the average cost per mile of operation is roughly 28 cents of which 19 cents is for the crew's wages. The cost of operation of a gas-electric in similar service would be 38 to 40 cents and a storage battery car 40 to 42 cents, and of a steam train about $1.35. (NOTE:—These figures are approximate and are given for comparison.)

The average availability for service is considerably over 80 per cent while that of a steam engine is generally given as about 40 per cent.

The oil-electric car is admirably adapted to branch line and main line local service, while the 9000 locomotive is suited for either freight or passenger service on main line.

Figure No. 4.—Installation of 50,000-pound Engine in the New Oil-Electric Locomotive.

Figure No. 5.—Car 15830, 6-Cylinder Engine.

The oil engine has many points of superiority over the gas engine, not only for traction, but stationary and semi-portable power plants, ship propulsion, etc. In marine service the Diesel is rapidly displacing the steam engine and turbine, so much so that about 65 per cent of the tonnage under construction at the present time is designed for Diesel engine operation. Is it reasonable to expect that the oil engine will gradually retire the steam engine from railway service?

In passing it might be mentioned that some other unit car developments have also been tried: namely, the steam car. At one time a high pressure steam car was tried out in this region, and at the present time the International Harvester Co. are manufacturing a unit car using a high pressure boiler to generate steam, which operates an 8-cylinder uniflow engine mounted under the car frame. It appears complicated and it does not appear to have a very bright future.

An English company, the Sentinel-Cammell, manufacture a unit car using a small upright self-feeding boiler, which supplies steam to a small vertical two-cylinder engine, which drives through a silent chain to the two axles of the forward truck. Cars made by this firm have been marketed throughout the Empire and are giving satisfactory service, but are not designed to suit Canadian conditions.

In case the impression is conveyed that the Canadian National Railway has developed the only oil-electric, it should be mentioned here that the Ingersoll-Rand, in conjunction with the General Electric and the American Locomotive, developed an oil-electric locomotive about the time Canadian National first cars were being designed. Their first locomotives were 300 h.p. shunters. They then developed a 600 h.p. main line and freight transfer locomotive and they have now made additional types in 750 and 880 h.p., but none of them compare with the Canadian National No. 9000 in size.

The Putnam division of the New York Central has in service a locomotive with a V-12 MacIntosh and Seymour engine with cylinders 14 inches by 18 inches. This engine is rated at 900 h.p. and the locomotive is used in fast passenger service.

The New York Central uses a locomotive that is a very wonderful combination of all types of electrical equipment. It is called a storage battery oil-electric locomotive, and is used in terminal service. It has an Ingersoll-Rand engine with the usual generator and motors; in addition to this it has a large capacity storage battery, an overhead collector shoe and a third rail shoe. This locomotive is designed in this manner so it may be operated from the overhead trolley wire in sections electrified with that type of line, and the third rail shoe is used for collecting its propulsion current in sections using an electrified third rail; the oil engine is used in non-electrified sections to provide the necessary power for operating, while the battery is used to assist the engine on peak loads and it is the sole means of propulsion while shunting in many of the enclosed sheds around the New York terminals. The New York Central must be well satisfied with this engine as they have placed one of the largest single equipment orders for 35 more of similar design. The original locomotive was fitted with metering equipment which showed the total amount of power used from each source. Incidentally it might be mentioned in passing that this locomotive will probably be a nightmare for the maintenace staff as it will have very complicated wiring.

Fuel

As the fuel pumps on all oil engines using mechanical injection are very finely adjusted mechanisms, a very clean grade of fuel with little variation in viscosity is necessary, and it must be free from water.

A business man recently criticized the Canadian National Railway for using oil engines in a coal mining country, and being dependent on a foreign country for fuel supply. However, the author is glad to hear that his fears will soon be groundless, as the Bergius process of low temperature reduction of coal to produce fuel oil etc. is in a fair way to be successful, and Canada may in time produce most of her fuel in this way. It is understood about 35 gallons of fuel oil are produced from one ton of coal and there are other more valuable by-products including 30 gallons of gasoline.

Maintenance

A maintainance man is assigned to each car, and he has to be that combination, not easily found, of a first class electrician and a good fitter. The regular maintenance is governed by a set of rules which outline the daily, weekly, and monthly work, and the work is usually so organized that each day brings about the same amount of work, accidents excepted.

When heavy repairs, which cannot be done at the car's terminal are necessary, the car is taken to the nearest roundhouse or shops, and when it is realized that every day out of service means a loss of probably $50.00 to the road, it is evident that the work should be rushed.

Remarkably few large troubles have developed and this is the more astonishing when it is considered that any new development usually has to have numerous changes before it is really satisfactory.

In conclusion the author would say that this is the day of the oil engine and it will make rapid strides in the future, and it may not be long till the oil engine for autos will be common.

It might be added that an effort has been made to sketch the development of the unit car and its descendant the oil-electric locomotive, without the necessity of quoting many figures, as a multiplicity of figures tends towards confusion.

The order of seven Westinghouse-Beardmore 6-cylinder, 350-h.p. cars have been delivered to the Canadian National Railways and also one switching engine powered with a similar engine and some additional cars of a similar type are under construction.

The Westinghouse Company have recently turned out in the United States a new car of 800 h.p. fitted with two 6-cylinder power plants and are now demonstrating it on the Erie railway.

During the early summer the Canadian Pacific Railway purchased two gas-electric cars of 400 h.p. which are stated to give an economy of one mile per gallon of gasoline. No definite operating statistics on these two cars are yet available.

Coal Mining — Past, Present and Future

T. L. McCall,
Chief Mining Engineer, British Empire Steel Corporation, Limited.

Paper read before the Cape Breton Branch of The Engineering Institute of Canada, March 11th, 1930.

One of the earliest references to coal is that of Theophrastus, a Greek writer who lived about two hundred years before the Christian era. He published a work entitled "The Book on Stones," in which he discusses an earthy material that would burn and which was used by smiths.

The early inhabitants of Britain appear to have had knowledge of the value of coal, for in Monmouthshire a flint axe stuck in a vein of coal was discovered on the crop of a seam. Again, axes and picks of solid oak have been found in old excavations near Stanley, in Derbyshire, and at Ashby-de-la-Zouch stone hammer heads and wedges of flint have been found in ancient coal workings.

The object of all these workings was to obtain fuel for warmth and in the old Roman camps in parts of England heaps of cinders have been found. One of the first records of coal mining in England dates back to 853 A.D. and is to be found in a deed in which the Abbey of Peterborough made a grant of lands.

By the year 1281 it is reported that Newcastle had a considerable trade in coal, although its use met with opposition as witness when in 1306 the citizens of London petitioned King Edward I to prohibit the use of coal in London.

During the Elizabethan period the ruling powers began to be alarmed at the rate at which the forests of oak were being devastated for use in the iron industry and the best brains in the country set to work to devise ways and means of using coal for smelting. Lord Dudley spent a lifetime experimenting on this, but it was not until some seventy-five years later that his dreams were realized, when Abraham Darby in 1735 first successfully used coke for the smelting of iron at Colebrook Dale Iron Works in Shropshire.

So far coal had been obtained from shallow workings usually driven in the side of a hill where free drainage could be obtained but with the exhaustion of coal accessible through level tunnels, recourse was had to shallow shafts up which women carried the coal in baskets strapped to their heads and backs.

Shafts with adit drainage were next used and horse-gins were introduced and the coal, still loaded into baskets at the face, was trammed out to the pit bottom on flat cars with iron rim wheels running in stone tracks.

With the deepening of shafts, the water problem became more and more pressing and, in 1698, Savery developed his steam engine for pumping water. This pump acted on much the same principle as the present day pulsometer, with the exception that, steam pressure being absent, the pump acted as a suction pump only. Thus its application was very limited.

In 1711 Newcomen devised his improved atmospheric engine driving spear rods which lifted the water out of the mine. The valves on this engine were operated by hand for each stroke of the engine, but in 1713 a youth named Humphrey Potter, being apparently lazy by nature, devised

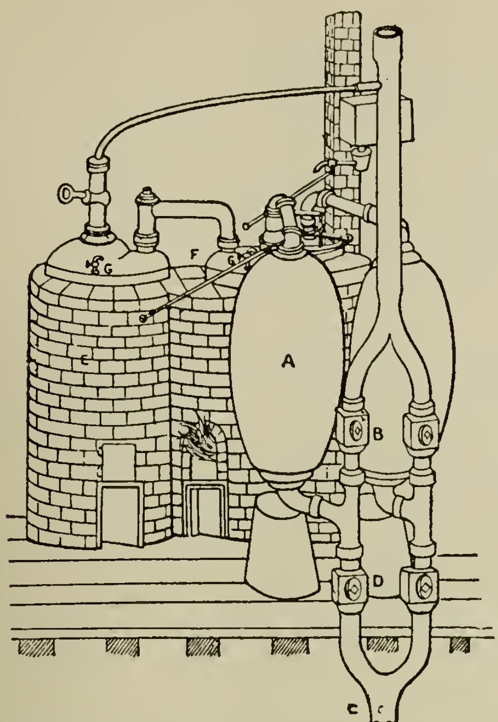

Figure No. 1.—Savery's Pumping Engine, 1698.

a rig of cams and ropes which did the work for him. This engine in its improved form continued in common use and held the field until about 1800.

Thus with the introduction of power derived from fuel, coal came into industrial use and the first real impetus was given to its production, which increased so marvellously during the nineteenth century.

With the power now available, science began to devise ways and means of lightening the manual labours of the miner and in 1761 Michael Menzies proposed to replace the miner by a machine swinging a heavy pick actuated by power transmitted from the surface through spear rods and chains. Thus was conceived the first mechanical coal cutter, but it was not until the use of compressed air became available that this branch of the industry made any progress.

Mines were now getting deeper and more extensive through the conquering of the water problem, but the miner was again faced with a fresh difficulty—that of preventing explosions of gas. For some time now the mines had been ventilated by furnaces placed at the shaft bottom, but gas would continue to accumulate and explode. At first these small accumulations of gas were cleared out of the places by the simple expedient of setting fire to them. The "fireman," as he was then known, would enter the mine before the miners and, clad in padded heavy clothes and armed with a long pole with a torch tied to its end, would go about the mine and at any place where the presence of gas was suspected, would lie down and in that position poke the torch up to the roof and so ignite any gas which happened to be present.

Numerous were the safety devices tried to light mines. Mirrors were used to reflect the light from the surface; the glow of fish skins was also tried, and the steel mill, which consisted of a steel disc made to revolve rapidly against a piece of flint so as to produce a shower of sparks. In 1815 Sir Humphry Davey and George Stephenson, independently and almost simultaneously, hit upon the principle of the safety lamp, which, with modifications, still holds good to this day. Of late years electric lamps have been introduced to the great advantage and greater safety of the miner, due to the improved illumination. Rapid strides have been made in increased candle power and more rugged construction of these lamps.

With safety lamps coming into more general use, explosions became less frequent, though more devastating when they did occur due to the larger scale of operations, but it was not until the eighties that scientists began to realize that the disastrous explosions in mines were in many cases due to something more than gas. Eventually this agency was traced down to coal dust and Sir W. E. Garforth originated the idea and put into practice the use of stone dust as an agent to dilute the coal dust down to an extent to render it inert and harmless.

The first method of working coal was developed on the pillar and stall system, in which roadways were driven in the seam with pillars of coal left in for support. These roadways were braced against falls of stone with the most readily available material, namely, wood.

Later on the extraction of these pillars was undertaken and mining had made a further advance. With the gradual exhaustion of the thicker and accessible coals, recourse was had to the thinner seams and frequently the superior quality of these thin seams rendered their prior working desirable even with the thicker seams available. This development led to the introduction of longwall mining, with the object in view of complete extraction of the coal and reduced costs of mining.

Subsequently in the deeper mines it was found that roadways could not be maintained in the solid workings and the operators were driven to use the total extraction method whereby the roadways leading to the coal faces were formed in the rock in the excavated areas. For many years after the inception of longwall, the coal at the working face was shovelled out to the cars at the roadhead, the roadways being spaced to suit conditions, but usually about thirty to forty feet apart. To give the necessary height to these roadways the rock in the roof was blown down (brushed) or else the pavement was shot up and in either case the waste rock was packed or stowed away in the excavated area next to the roadway. These packed areas formed a support for the roof which, gradually settling, squeezed them tighter and tighter until they resisted further settlement of the strata and owing to the close spacing of these packwalls control of the roof presented few difficulties.

In the thicker seams, especially those containing bands of dirt, rail tracks were laid right along the face of the working and the coal was loaded straight from the face into

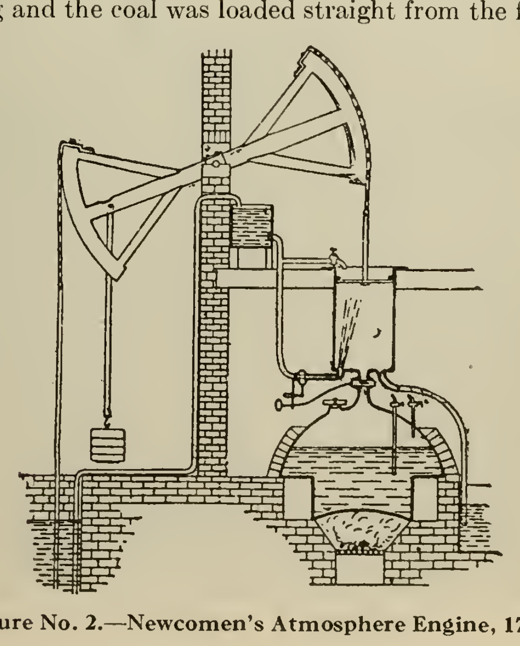

Figure No. 2.—Newcomen's Atmosphere Engine, 1705.

Figure No. 3.—No. 2 Colliery, Dominion Coal Company Limited, Glace Bay, Cape Breton, N.S.

mine cars. This system worked well, provided there was enough dirt in the seam or coming away with the seam to stow the waste.

In recent years mechanically driven face conveyors have been introduced on to which the miner shovels the coal direct from the face. The coal then passes down the conveyor to the cars at the loading point. This system embraced conveyors up to three hundred feet in length and advantage was taken of this fact to dispense with all the brushed roadways through the waste into the face. The roof had now no supports on which to rest and gradually settle, with the result that the face timbers had to bear the whole brunt of the load and not being strong enough collapsed, allowing the roof to fracture right up to the coal face. Under these conditions roof control was non-existent, roof troubles over the face were endless and the conveyor system got a bad name. Pioneers, however, persevered and finally evolved the method of building packwalls in the waste from the fallen roof stone and so the roof, now having supports on which to rest and gradually settle on, behaved better and roof control was re-established. The latest development of roof control at the face is the use of steel props of such strength that they will resist the first bending movements of the roof and will sustain the roof until the face is sufficiently advanced to permit of one or two rows of props being drawn, those remaining in place being strong enough to hold the roof, whilst the unsupported area breaks off in the waste at the last row of props.

The conveyor system has been extended beyond the coal face and mines now exist in which all the coal mined is brought out to the surface by conveyors. Such an installation is extremely costly and necessitates large outputs to justify the outlay.

As the shallow seams have been worked out it has been necessary to search deeper and deeper after coal and each increase in depth implies a concomitant increase in capital expenditure for shaft sinking and equipment. This capital increase requires a larger mine output and this in turn necessitates a larger area being made tributary to the mine than was formerly the case. In short, the deeper the mine the larger must be the scale of operations.

The method of supporting main roadways has undergone changes to meet the altered conditions brought about by the greater depth at which mining is now being carried on. The plain wood timbering, consisting of a horizontal member supported by an upright leg at either end, which sufficed for the shallower workings, was found to be too light for the deeper mines and the cost of replacing broken members became an exceedingly heavy burden on the industry. Various modifications of wood have been worked out, but the trend is towards something more substantial. Some roadways, especially those near the pit bottom, are supported by brick or stone arches, but this is expensive and serves only for roadways which will be required for the lifetime of the mine. Steel cross members supported by wooden legs are now in frequent use and in many mines the wooden legs are replaced by brick walls running the whole length of roadways. Of recent years shaped steel girders of H-section are being used. These are made of the horseshoe shape, or semicircular with straight legs. They are spaced along the roadway and the intervening spaces are frequently filled with brickwork or concrete. Their use has been attended with most satisfactory results. Contemporaneously with this has been developed a system

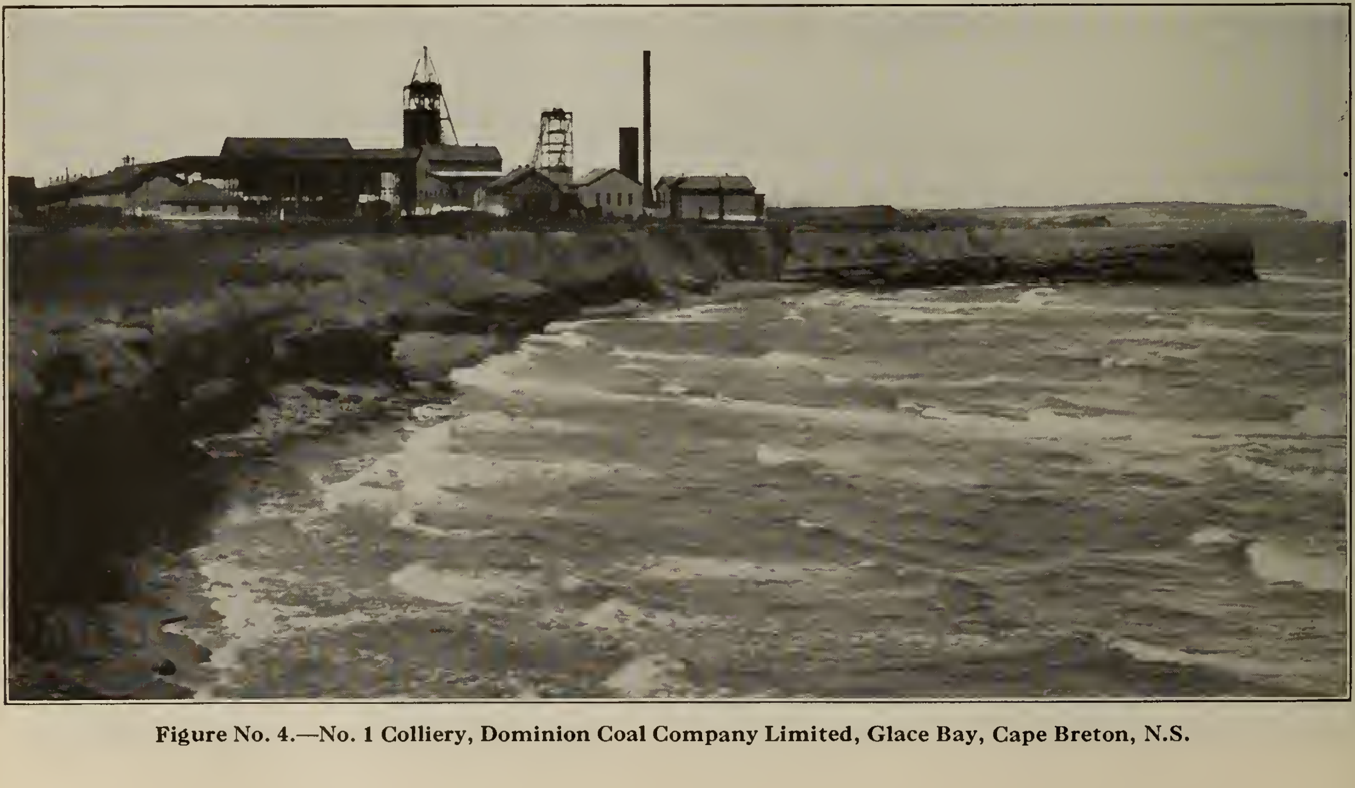

Figure No. 4.—No. 1 Colliery, Dominion Coal Company Limited, Glace Bay, Cape Breton, N.S.

of lining roadways with pre-formed reinforced concrete blocks. This method has also yielded good results.

The mechanization of underground equipment began with the introduction of compressed air which still, in spite of its low efficiency, holds a large place in mining, though it had to yield to the ever growing improvements in the use of electricity underground.

The machines for producing compressed air have undergone radical improvements and have grown from small reciprocating machines to the giant turbo-compressors producing no less than 45,000 cubic feet of free air per minute.

Each year sees some improvement in the design of machines for undercutting or shearing the coal, the boring of the holes for blasting, the machines for loading the coal and the design of the conveyors, etc.

Machines, known as entry drivers, are now made which dig and load out the coal, but these are large and cumbersome and require excellent physical conditions in the mine.

The underground haulage systems have kept pace with the march of science. We have shown how coal was first of all carried out of the mine, then wheeled out in small corves running on stone tracks. Then the corves were hoisted bodily. Horse haulage began to replace manual labour, which in turn was displaced by rope haulage or, where possible, now by electric trolley or electric storage battery locomotives. The mine cars from holding only a few hundred weights of coal have increased to cars of 4 to 5 tons capacity. Roller bearings are replacing the old open type bearing and nowadays the underground haulageways in a large modern mine are run with the precision of modern railways.

With the ever increasing size of mines the transportation of men to and from their work is receiving closer attention—especially is this the case in our submarine areas where workings extend for three miles seawards.

Ventilation has grown from natural ventilation, through the furnace shaft up to the present day large fans electrically operated on the surface, the largest which has come to the author's notice being one in South Africa, which passes no less than 900,000 cubic feet per minute.

The explosives used in mines for bringing down coal or rock have been steadily improved from the black powder days to the modern permitted explosive.

Some of the explosives, on detonation, have been found to yield nitrogen peroxide and recently it has been discovered that small quantities of this gas when added to

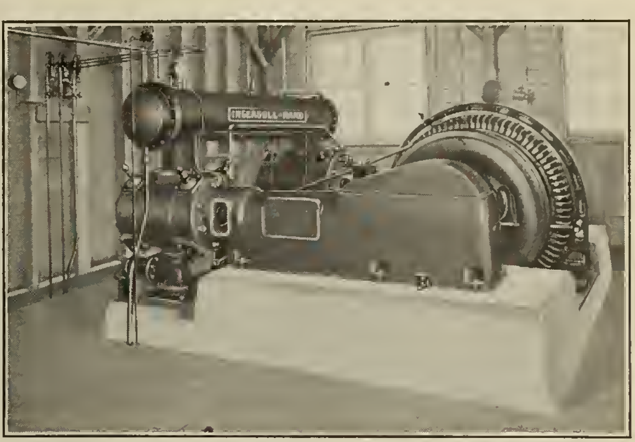

Figure No. 5.—A Direct-Connected Synchronous Motor-Driven Air Compressor of the Type Found in Canadian Collieries.

an air-methane mixture render that mixture more sensitive to explosion or, in other words, act as an accelerator. This is now being closely investigated and as an accelerator has been found, why should not a retarder be discovered!

Liquid gases are being tried out as explosive agents, the two outstanding examples being liquid oxygen and liquid carbon dioxide. These gases are held in a container and exploded by electrically fired detonators.

To sum up briefly, modern practice is all towards obtaining the largest possible outputs from the smallest possible amount of development work, or what is known now as "intensive mining." This is obtained by the thorough mechanization of the mines and establishing a system of work in which workers are allotted special duties to perform, in a similar manner to mass production in a factory. These duties or cycles of operations are repeated day after day and eventually the workers become highly skilled in the performance of the allotted duties.

With regard to the future of mining there can be no doubt that intensive mining will be further and further developed as means are devised for the more rapid execution of the deadwork, such as brushing, making roadways, etc., which must keep pace with the extraction of the coal. Indeed, it is beyond doubt that systems of working will be evolved which will materially decrease this amount of deadwork.

Actual manual labour will be continuously lightened as machines are invented to replace human muscle and ultimately fewer and fewer men will be required per unit

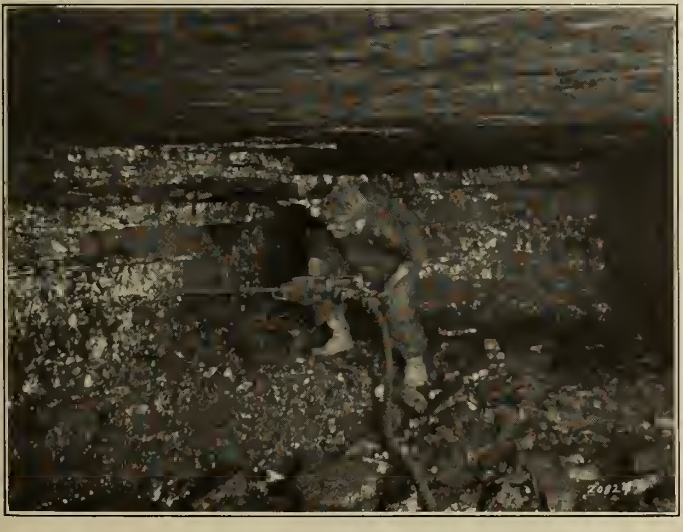

Figure No. 6.—Jackhamer Drill of the Type Used in Coal Mines.

Figure No. 7.—Overcutting with a Radialaxe Type Coal Cutter.

of tons produced but such men will require to have a continuously improving technique of the handling of machinery. These machines must of necessity be smaller, lighter, and highly flexible in operation to permit of their working in mines whose physical conditions do not lend themselves to the use of present day machines.

One of the difficulties already encountered in intensive mining is the evolution of large bodies of gas due not to the greater amount of gas liberated by the coal, but to the larger tonnage of coal produced in a limited time from a limited area. This serious factor is already causing concern to mining men. It is suggested that sooner or later science will evolve a catalyst—which could be placed at various points in the mine—that will change this dangerous gas into its innocuous components of carbon dioxide and water.

Coal dust, as we have already pointed out, can be rendered harmless by dilution with stone dust. Were such a catalyst as above found for gas, then mines could be rendered safe from devastating explosions.

Along with the problem of gas goes that of ventilation or of conducting air for long distances underground —a problem that is now beginning to rear its head in our own coalfield in Cape Breton. One solution is, of course, large airways and plenty of them, but that would involve prohibitive capital expenditures, for after all coal is only worth what it can be sold for. Several solutions offer themselves. One would be to pump the air through large air mains at high pressure and then release it when in the workings, or the air might be liquefied, transmitted through pipes and again released in the workings. Yet again, it is possible that science may evolve simple and economical methods of purifying the air and after supplying the deficiency of oxygen keep it recirculating in the mine. Along with this problem would go that of cooling the air in deep mines where the natural temperature of the strata is high. This is already being done in one deep ore mine. None of these problems are beyond the reach of science.

Electricity will continue to play its part increasingly in the mining of coal, though compressed air will still hold its own for years to come in many operations about the mine, especially where large volumes of gas are to be found.

It is also suggested that in mines whose physical conditions are such as to prohibit the profitable extraction of coal that a use will be found for the coal by burning it *in situ* and collecting the produced gases so formed by means of boreholes. These gases will be employed in gas engines for the production of electrical energy.

Discussion on "A Short Monograph on Nomography" Paper by F. M. Wood, A.M.E.I.C.[1]

H. B. Muckleston, M.E.I.C.[2]

The author's treatment of the alignment nomograph is complete as far as it goes; but, by considering particular types instead of analyzing the general case, he has made the subject appear to be a much more complex business than it really is. By attacking the general case, the whole subject can be boiled down into a few very simple formulae.

Any formula can be plotted as an alignment nomogram, provided it can be made to plot in the cartesian system of co-ordinates as three families of straight lines. This condition is satisfied if the expression can be tortured into the form

$$f_1g_3+f_2h_3+f_3=0 \qquad (1)$$

in which f_1 is any function whatever of the variable Z_1; f_2 is any function whatever of the variable Z_2, and g_3, h_3 and f_3 are any functions whatever of the variable Z_3. In order to plot this equation in any system of co-ordinates, it is first necessary to choose a modulus for each of the functions f_1 and f_2. The modulus is defined as the scale length of the variable when the value of the function is unity, *e.g.* log 10 or sin 90°. Let these moduli be M_1 and M_2; the equations of the three families of lines in the cartesian system will be

$$x-M_1f_1=0;\quad y-M_2f_2=0;\quad \frac{g_3x}{M_1}+\frac{h_3y}{M_2}+f_3=0$$

each of which, being in the first degree in x and y, will plot as a family of straight lines. Equation (1) will, therefore, plot as an alignment nomogram.

In determinant notation, the three equations are

$$x\begin{vmatrix} 1 & 0 & -M_1f_1 \\ 0 & 1 & -M_2f_2 \\ \frac{g_3}{M_1} & \frac{h_3}{M_2} & f_3 \end{vmatrix}=0 \qquad (2)$$

To reduce this to the required form for alignment plotting, add the second column to the first, divide through each row by the quantity in the first column, multiply column two by L and column three by minus one, giving:

$$x\begin{vmatrix} 1 & 0 & M_1f_1 \\ 1 & L & M_2f_2 \\ 1 & \frac{h_3M_1}{g_3M_2+h_3M_1}L & \frac{-M_1M_2f_3}{g_3M_2+h_3M_1} \end{vmatrix}=0$$

in which L is any arbitrary distance. The co-ordinates of the three systems of points forming the alignment nomogram are:

$$\left.\begin{array}{lll} \text{For variable } Z_1; & X_1=0; & Y_1=M_1f_1 \\ \text{For variable } Z_2; & X_2=L; & Y_2=M_2f_2 \\ \text{For variable } Z_3; & X_3=\dfrac{h_3M_1L}{g_3M_2+h_3M_1}; & Y_3=\dfrac{-M_1M_2f_3}{g_3M_2+h_3M_1} \end{array}\right\} \quad (3)$$

It will be seen that the systems Z_1 and Z_2 plot on two parallel lines at the arbitrary distance L measured on the axis of x. The support for Z_3 will be straight or curved depending on the nature of the functions of Z_3 which appear in the expressions for X_3 and Y_3. In more general terms, Z_3 plots on a curve of which the radius of curvature may be infinite. Some of the functions of Z_3 may be unity or missing altogether. If g_3 and h_3 are both unity, X_3 is evidently a constant and Z_3 plots on a straight line parallel to Z_1 and Z_2; which is generally called the "III" type. If f_3 is zero, Y_3 is zero and the nomogram is the so-called "N" type, though it sometimes appears in the form of I L or H. From inspection of the expression for X_3, it is evident that Z_3 will come between the other two if $\frac{g_3}{h_3}$ is positive. This position can always be assured, if required, by proper attention to the signs of g_3 and f_1 or of h_3 and f_2.

When the expression to be plotted is put into the form of equation (1), f_1 and f_2 may appear as reciprocals, in which case, the scale value of the variables will be very short and the graduations very close together as the functions approach zero. In such a case we may write:

$$\frac{g_3}{\phi_1}+\frac{h_3}{\phi_2}+f_3=0; \qquad (4)$$

The three equations will then be

$$x-\frac{1}{M_1\phi_1}=0;\quad y-\frac{1}{M_2\phi_2}=0;\quad g_3M_1x+h_3M_2y+f_3=0$$

---

(1) This paper was published in two parts in the June and August 1930 issues of the Journal.

(2) Consulting Engineer, Vancouver, B.C.

From which

$$x\begin{vmatrix} M_1\phi_1 & 0 & 1 \\ 0 & M_2\phi_2 & 1 \\ \dfrac{-g_3M_1}{f_3} & \dfrac{-h_3M_2}{f_3} & 1 \end{vmatrix}=0$$

And the co-ordinates of the three systems of points are:

$$\left.\begin{array}{ll} X_1 = 0; & Y_1 = M_1\phi_1 \\ X_2 = M_2\phi_2; & Y_2 = 0 \\ X_3 = -\dfrac{h_3M_2}{f_3}; & Y_3 = -\dfrac{g_3M_1}{f_3} \end{array}\right\}\quad\ldots\ldots\ldots\ (5)$$

Evidently, Z_1 is on the axis of y; Z_2 is on the axis of x, and Z_3 lies between the axes. This type is frequently known as the "broad arrow" type. There is nothing in either equations (3) or (5) which defines the angle between axes of co-ordinates in plotting as an alignment nomogram. It may be anything we choose, which, in most cases, means whatever will make the whole drawing nearly square.

The above two sets of equations (3) and (5) contain the whole mechanism of the alignment nomogram. The difficulties in their practical application arise mainly in recognizing that the expression to be plotted can be twisted into one of the forms (1) or (4) and in the choice of the best values for the moduli. These moduli determine the length of their respective scales for the ranges required and, together, they fix the position and size of the system of points for Z_3. No useful rules can be laid down; cut-and-try is the only precept and experience the only effective teacher. Occasionally, there is a choice of type; formulae which finally appear in the shape $g_3f_1-h_3f_2=0$ can be plotted in either the III or N types. The form of the functions involved will generally dictate the choice.

While the above sets of formulae give the co-ordinates of the Z_3 system, it is seldom necessary to calculate them as simpler and less laborious methods of plotting that system are available. The most generally applicable is the method by cross isopleths. For every possible value of Z_3 there is an infinite number of pairs of values for the other two and the isopleths for all these pairs must intersect in the correct position of the point representing the particular value of Z_3. Unless f_3 is zero, there is an obvious advantage in choosing Z_1 (or Z_2) so that f_1 (or f_2) will be zero. This gives one easily calculated series of isopleths and a similar treatment of the other will give a second series. However, the intersections may be so flat as to be useless, in which case, some other method must be used. In many cases, one co-ordinate is simple and the other complex. The simple co-ordinate can replace one series of isopleths. Many commonly used formulae have been tabulated; if Z_3 is an argument, the data for cross isopleths are ready to hand. The same is true if a cartesian nomogram for the formula is available.

A formula containing four variables will plot as two scales for two of the variables with a net or grid for the other two if it can be put into the form

$$f_1g_{34}+f_2h_{34}+f_{34}=0\ \ldots\ldots\ldots\ldots\ldots (6)$$

in which g_{34}, h_{34}, f_{34} are simultaneous functions of the two variables Z_3 and Z_4. To plot such a formula, let Z_3 be given any selected value; the formula reduces to a three variable formula and could be plotted as such with the usual system of points for Z_4. Of course, a separate nomogram for Z_4 would be required for every selected value of Z_3 but as scales for Z_1 and Z_2 would be the same for the whole collection, all these nomograms might be combined into

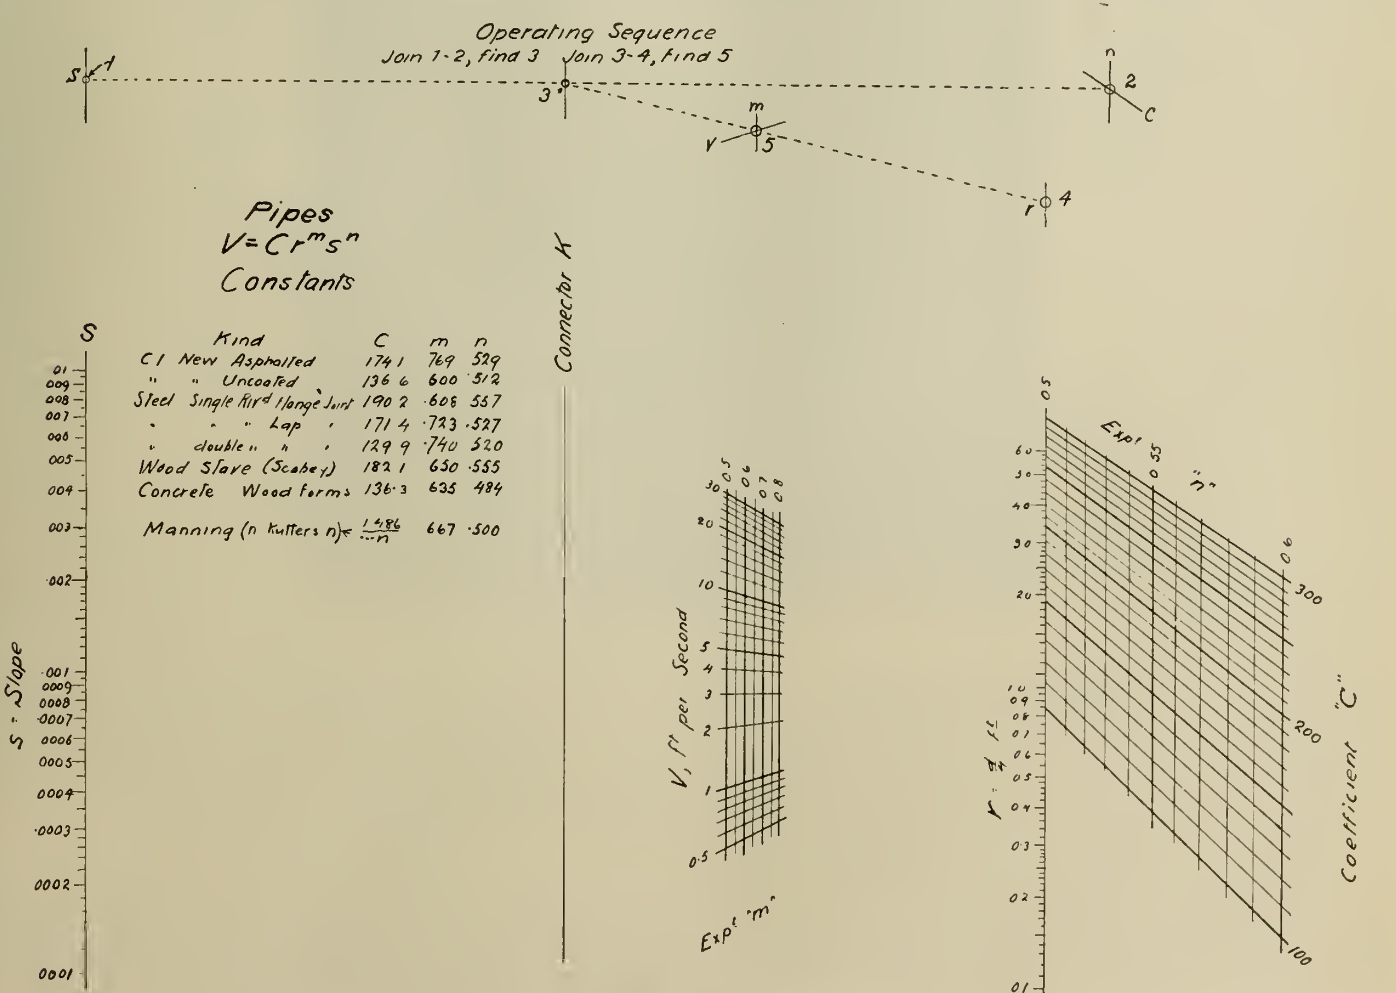

Figure No. 19.

one with the usual scales for Z_1 and Z_2 and a family of scales for Z_4. We could obviously do the same thing treating Z_4 as the constant and get another nomogram with a family of scales for Z_3. As the scales for Z_1 and Z_2 would be alike in both nomograms, the two might be superimposed and the lines for Z_3 would then form the graduations for Z_4 and vice-versa. That is, such a formula will plot as a grid or net.

As an illustration of what can be accomplished with the alignment nomogram, consider the formula

$$V = Cr^m s^n$$

a general formula for the flow of water in closed channels containing six variables.

This formula can be split into

$$\log K + m \log r - \log V = 0$$

and

$$\log K - n \log s - \log C = 0$$

Both are in the form of equation (6) and will therefore plot with a net. They are alike in form and the description of one plotting will serve for both. K is an arbitrary auxiliary and serves as a connector between the two.

Let $M_1 = M_2 =$ any convenient log scale.

Taking the first expression, put

$$Z_1 = K \quad f_1 = \log K \quad X_1 = 0 \quad Y_1 = m \log K$$
$$Z_2 = r \quad f_2 = \log r \quad X_2 = L \quad Y_2 = m \log r$$
$$\left.\begin{matrix} Z_3 = V \\ Z_4 = m \end{matrix}\right\} \begin{matrix} g_{34} = (Vm)^\circ = 1 \quad h_{34} = V^\circ m = m \\ {}_{34} = -m^\circ \log V = -\log V \end{matrix}$$
$$X_{34} = L\frac{m}{1+m} \qquad Y_{34} = \frac{m \log V}{1+m}$$

X_{34} does not depend on V so that the lines for m are parallel to Z_1. When r is unity, $\log r$ is zero and $\log V = \log K$. The lines for V are all straight and all pass through $r = 1$ and $K = V$.

The other plots in the same way except that, in this case, K is the unknown and is, therefore, best made the middle scale. This requires that X_{67} be negative, wherefore the negative sign of the second term is given to n and $X_{67} = \frac{-nL}{1-n}$. The complete nomogram is shown in figure No. 19.

With some formulae, all attempts to reduce them to the form of (1) result in an expression with Z_1 appearing in two terms instead of one and plotting as an alignment nomogram is apparently not possible. The difficulty can often be by-passed by treating the extra appearance as if it were a separate variable and plotting as a four-variable formula. It is a mistake to try for too great a range in one chart. For instance, 4,000 second-feet and a twelve-inch pipe could not possibly occur in the same problem, and there is no very good reason why they should ever appear on the same chart. It is far better to make a number of charts, each of which covers only those ranges which can occur together, and to let the various charts overlap about half the range of each.

F. M. Wood, A.M.E.I.C.[3]

With reference to the discussion by H. B. Muckleston, M.E.I.C., the author felt when he was preparing the original article that the average reader might not be familiar with the determinant notation, and would in any case appreciate some refreshing of memory. He therefore arranged the paper with a view to leading up progressively from the simpler examples to those more complex. Much of the apparent complexity is due to the discussion of choice of moduli, and of the position of the various scales, to suit particular requirements. When the significance of the determinant method of attack has been grasped, the keys given in Appendix B should materially simplify the labour involved in studying the more elementary formulae.

The author agrees with the statement made in the second paragraph that any formula may be plotted as an alignment chart provided it can be expressed as three families of straight lines. He does not agree, however, that Mr. Muckleston's equations (1) and (4) represent the general case. The general form for such formulae may be expressed.

$$\begin{vmatrix} f_1 & g_1 & 1 \\ f_2 & g_2 & 1 \\ f_3 & g_3 & 1 \end{vmatrix} = 0,$$

as was mentioned in the article. Expressing this as a "collinear" chart, we see that this gives the three families of straight lines

$$\begin{cases} f_1x + g_1y = 1 \\ f_2x + g_2y = 1 \\ f_3x + g_3y = 1 \end{cases}$$

each family representing one of the variables Z_1, Z_2, and Z_3.

Equation (1) is seen to be a particular case of this more general form, in which $g_1 = f_2 = 0$. If we consider this general formula as an alignment chart, we find that each variable is represented by a curved line, whereas equation (1) gives us two straight lines and one curved line. It should be noted also that functions of Z_1, Z_2, and Z_3 each appear in more than one term, instead of functions of Z_3 alone. Mr. Muckleston refers to this type of equation in his last paragraph. Examples of this general type for three variables were not studied in the monograph, because they are not very tractable, and do not lend themselves willingly to the application of moduli. A simple example like

$$\begin{vmatrix} P & P^2 & 1 \\ Q & 0 & 1 \\ R & R^3 & 1 \end{vmatrix} = 0$$

where P, Q, and R are the three variables, will serve as an illustration of this statement.

The use of isopleths in plotting the functional scales, as mentioned by Mr. Muckleston, furnishes indeed a more simple and rapid method than that of calculation of co-ordinates. The author must confess, however, that he seldom uses this method except in conjunction with the method by calculation, i.e., he generally calculates at least one of the co-ordinates, and obtains the other co-ordinate by either analytical or graphical means, using isopleths as a final check on the work. Some engineers may disagree with this, but the author has found that in most cases more time is wasted in obtaining good intersections for the isopleths, or in changing from one method to another when the intersections become poor, than if calculations were made in a straightforward way. The author is also naturally sceptical as to the accuracy of the chart when completed in the purely graphical way. Firstly, there is the chance of error in marking the end points of the isopleths; secondly, in obtaining the intersections; and thirdly in the operation of inking in; in addition, there is the final opportunity afforded (in all charts) of exercising the human privilege to err, when coming at last to the actual solution of specific problems.

Mr. Muckleston's treatment of the equation $V = Cr^m s^n$ shows what may be accomplished by the use of auxiliary or "pivot" scales in cases involving a great many variables. It is interesting to compare this chart with one that would be obtained when no pivot scale is used. The elementary determinant form for such a chart is

$$\begin{vmatrix} 0 & \log V - \log c & 1 \\ 1 & \frac{1}{2}\, m \log r & 1 \\ 2 & -n \log s & 1 \end{vmatrix} = 0$$

This will give three binary scales along parallel straight lines; one of the scales is dependent on a network for the variables V and C, the second scale is dependent on a network for the variables m and r, and the third scale is dependent on a network for the variables n and s.

[3] Lecturer, McGill University, Montreal, Que.

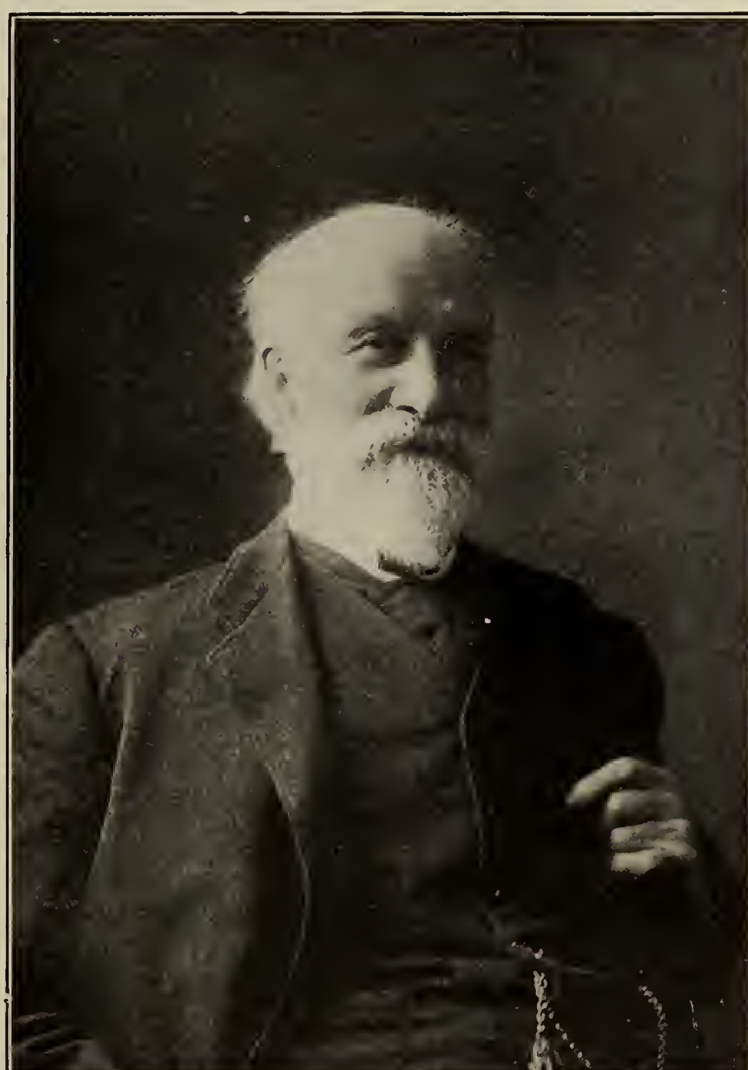
Sir Sandford Fleming — A Biography

By the late Professor Peter Gillespie, M.E.I.C.

Presented before the Niagara Peninsula Branch of The Engineering Institute of Canada, May 19th, 1925.

How often has it been said that while the engineer as a technologist may be capable, he is not usually a citizen in the enlarged sense of the word! His structures may be safe, his work may display an ingenuity that compels admiration; his integrity may be above question, but outside of his professional work his influence is not felt. Those engineers who have received recognition are the exceptions, and they have won it largely through widening their contact with the pulsating life of their time. They made their contribution in service but in addition they added something to the life of their day in constructive thought or needed reform. The thanks of a grateful posterity were often their sole reward.

Of Canadian engineers, the most outstanding in this exceptional class is perhaps Sandford Fleming—Fleming the product of a Scottish parish school who became the chancellor of a great university; Fleming the youthful surveyor who became the chief engineer of the Intercolonial and the Canadian Pacific Railways; Fleming the founder of the Canadian Institute, promoter of standard time and the "All Red Line," advocate of parliamentary reform, apostle of a united empire, scientist, plenipotentiary, litterateur, publicist, citizen. And while it is true that few engineers can be what Fleming was, there must be in the contemplation of his unique career, some measure of inspiration for all.



SIR SANDFORD FLEMING

Sandford Fleming was born in Kirkcaldy, Fifeshire, Scotland, in 1827. Until he became apprenticed in his early teens to John Sang, an engineer and surveyor of Kirkcaldy, he attended the local parish school. In 1845, seized with the desire for adventure in the New World, he sailed for Canada in a sailing ship, landing in Quebec after a six weeks' passage on June 5th. A few weeks later he had arrived in Peterborough by way of Ottawa, the Rideau canal and lakes, Lake Ontario and Cobourg. Peterborough at that time contained about 2,000 people, and it was here that young Fleming obtained his first employment. This was as draftsman with a local surveyor, Richard Birdsall. The next year he compiled and published a map of Peterborough town, the lithographing work having been done by his own hands. In 1847 a similar map of Cobourg was issued by Fleming, although this latter, singularly enough, bears no date. In 1849, he obtained his commission as a surveyor of lands after presenting himself for examination by the then commissioner of lands in Montreal. After this he made Toronto his permanent residence.

Fleming at 22 was one of that small number of enthusiasts who in 1849-50 launched the Canadian Institute. Intended originally as a professional society for engineers, surveyors and architects, it was first proposed and its organization discussed at a small meeting in the office of the late Mr. Kivas Tully at the corner of King and Yonge streets, Toronto, on June 20th, 1849. After many vicissitudes, a meeting to adopt a constitution was called for February 8th, 1850. At this meeting only two were present, Mr. Fleming and Mr. Passmore. After much silence and waiting in vain for a larger attendance, it was decided that Fleming should take the chair and Passmore should act as secretary, and with rather more unanimity than regularity, they proceeded to adopt a series of resolutions one of which provided that the first subject for discussion at the proposed weekly meetings "be the act for regulating the admission of land surveyors and the survey of lands throughout the province."

In the work of the Institute for over fifty years Fleming maintained the keenest interest. To its transactions he contributed at least thirty papers, and to his influence exerted in a hundred ways, a very considerable measure of its success was due. His address at that meeting in 1899 which commemorated the completion of fifty years of the Institute's history concluded with an expression of the hope, so characteristic of Fleming the Canadian and Imperialist, that Canada's contributions to letters, science and art would enable her to take her place worthily among the nations constituting the British Empire.

From the Canadian Society of Civil Engineers, organized in 1887, the predecessor of The Engineering Institute of Canada, Fleming appears to have remained aloof until 1908, when he became an honorary member.

Fleming believed that the Canadian Institute because of its character as a scientific and literary body, was in a peculiarly favourable position to consider the question of electoral and parliamentary reform. In 1892, he addressed to that society a note in which he pointed to the majority vote method of electing legislators and the party system of government as the two outstanding evils of the parliamentary system. In relation to the former, he averred that electors who vote for defeated candidates, together with those who do not vote or have no vote, remain unrepresented; that thereby one-half of the population is disfranchised, and that in effect there results government of the major part by the minor, instead of government of the whole by the whole. The party system in addition makes for instability and militates against continuity of policy; through it passions are inflamed, antagonisms are stimulated and relentless warfare results; the expression of independent conviction is stifled because devotion to party replaces devotion to the state.

The problem was to devise a method of electoral representation by which the whole electorate might be duly recognized in one deliberate body, so that every interest within the nation might be fairly represented in its government; where representatives would not be expected to echo conclusions dictated by whim, passion or party exigency, or formed on immature judgment or insufficient evidence, and where each member would feel himself free to speak and vote as his clear convictions directed. He quoted from the author of "The British Commonwealth" to the effect that "party is a rude and barbarous instrument of legislation only less bad than legislation by despotic power which it supplanted." The author looked for the dawn of a new day when in place of the evils above referred to "there would be scope and encouragement for the awakening of a calm patriotism" and when "men of capacity, wisdom, and of good conscience, with minds evenly balanced, would be preferred and generally would be chosen as representatives." In place of "divisions and weakness and instability with a long train of evils, there will be unity and strength and security which proceed from wisdom and peace and concord."

Fleming had previously given expression to similar sentiments in an article entitled "A Problem in Political Science" published in Volume VII of the Transactions of the Royal Society of Canada, in 1889, and in an address on "Parliamentary vs. Party Government" delivered at Queen's University in 1891. These views, so vigorously expressed over thirty years ago, are of special interest today in the light of recent tendencies in practical politics in Canada.

To none of the causes which received his support did Fleming devote himself with more patience and determination than to reform in the reckoning of time. It was in 1876 that he began his advocacy of standard time and for over twenty years he continued it. In his first paper, among other things, he illustrated the inconvenience and confusion arising from the then unsatisfactory methods of time keeping by the case of a traveller proceeding from Halifax to Detroit by rail. He stops at Saint John, Quebec, Montreal, Ottawa, Toronto and Hamilton. At the beginning of the journey he sets his watch by Halifax time. As he reaches each place in succession, he finds a considerable variation in the clocks by which the trains are run and he discovers that at no two places is the same time used. It was to regularize these differences that standard time was proposed.

In a subsequent paper, he pointed out the advantages, geographically and commercially of selecting as the universal prime meridian the anti-meridian of Greenwich through the Pacific ocean since such a line would avoid practically the land of all nations.

On the initiative of the Canadian Institute, Mr. Fleming's proposals were officially communicated to the leading governments of the world with a view to securing an international unification of the method of designating time for common use. In 1881 he attended an international geographical congress in Venice as a representative of Canada and the United States, and there read a paper on "The Regulation of Time and the Adoption of a Prime Meridian." In 1883 he brought the question before the American Society of Civil Engineers, which body responded by appointing a special committee on standard time of which Fleming was chairman.

Largely as a result of his indefatigable work, the railways of Canada and the United States adopted standard time in 1883. In 1885 Greenwich observatory adopted the 24-hour system and a similar action was taken by the Canadian Pacific Railway with respect to its entire system the following year. By 1890, standard time was in general use in Canada, the United States, Mexico, Great Britain, Sweden and Japan and was on the eve of adoption in Austria-Hungary, Germany and Belgium.

Fleming's first large-scale engineering undertaking was the completion of the construction of the Northern Railway between Toronto and Collingwood, the position of chief engineer of which he assumed in 1855 and retained until 1863. His engagement with this road, known at first as the Ontario, Simcoe and Huron Railway, began in 1851.

In 1853, when he was assistant engineer, he prepared a paper on the geology of the valley of the Nottawasaga river describing the location of various ancient lake beaches which pointed to a time in the distant past when Lake Huron stood at much higher levels than now. His theory was that this condition obtained until the waters of Lake Erie had forced a passage between that lake and Lake Ontario after which the water in the upper lakes subsided to something like their present levels. The Nottawasaga beaches, he thought, therefore antedated the beginnings of the Niagara river.

It should be mentioned that this theory is not now accepted in the form in which Fleming advanced it, that the phenomena are more complex than he had supposed, and that present-day belief in the influence of great overburdens of ice in what is now eastern Ontario on lake and land levels does not seem to have been entertained by him.

Fleming's second engineering undertaking of magnitude was the location and construction of the Intercolonial Railway to connect Quebec with the Maritime provinces, which project had been under consideration since 1827. The first survey of a line had been conducted in 1837 by Captain Yule, but as this was through disputed territory, now the state of Maine, opposition to the proposed location developed in certain sections of the United States, and nothing further was then attempted. In 1846-8 other surveys were completed by Captain Pipon and Major Robinson, but mainly because of the difficulty experienced by the provincial legislatures and the Imperial government in reaching an understanding, the enterprise was advanced but little. In 1863 the project was again revived, and for the position of chief engineer Sandford Fleming was the common nominee of the provinces of Upper and Lower Canada, the provinces of New Brunswick and Nova Scotia and the Imperial government. This position he held until the completion of the work in 1876.

The conflict between Fleming and his commissioners respecting the material of which the Intercolonial Railway bridges were to be constructed illustrates the unrivalled pertinacity of the man. These commissioners were appointed in 1868 to assume the management of the railway, Mr. Fleming still retaining the post of engineer-in-chief. At the first meeting following their appointment, they announced their intention of constructing the bridges of wood instead of iron as recommended by Fleming. To Fleming it appeared advisable to employ metal, so that fire hazard and natural decay might be eliminated. For although the first cost might be greater, the heavy repair and replacement charges to be expected where timber is employed would not have to be met. In addition, the location of the line permitted the delivery of material from sea-going vessels at several convenient points. The commissioners however dissented, and decided that the bridges should be built of wood.

Fleming's opinion had not been hastily formed and the more he considered the matter, the more convinced he was of the correctness of his position. In January 1869 he made his first appeal to the then Prime Minister, Sir John A. Macdonald, in which he submitted at length the arguments as to why iron and not wood should be used. This letter was referred in due course to the commissioners but was never replied to and remains unanswered to this day. The commissioners notwithstanding were sustained and the order was given that all bridges should be built of wood. In the following year Fleming in a statement prepared for Parliament gave a list of all the bridges on the line and their estimated cost in wood and in iron, which showed that the cost of the latter would be only slightly in excess of the cost of the former. He again recommended that iron be used. The commissioners in a majority report reiterated their former ruling that wood should be used, but excepted therefrom five structures which they conceded might be built of iron. Fleming appealed again to the Premier and again to the commissioners. In reply one of the latter, Mr. C. J. Brydges. addressed a communication to the Privy Council in which he stated that the fear of wooden bridges catching fire was groundless, and that in his experience of 18 years as a railway manager no instance of a wooden bridge having been injuriously affected by fire had come under his notice, and that the cost of iron bridges would be $300,000 to $500,000 more than the cost of wooden structures. Fleming's reply cited two instances of bridges on the Grand Trunk Railway under the management of Mr. Brydges himself which had been very recently destroyed by fire, and challenged examination as to the accuracy of his estimates of cost. The commissioners then conceded the point partially, and recommended that all bridges over 60 feet span should be built of iron. But this did not satisfy Fleming. He believed he was right and refused to compromise. He persisted and in 1871 an order-in-council was passed authorizing that all bridges even to the shortest span of 24 feet be built of iron, and all but three were so constructed. The actual cost of the iron superstructures was some $19,000 less than Fleming's estimate.

As stated above the first reconnaissance for an Intercolonial Railway passed through what is now the state of Maine, then disputed territory. Subsequent to this, the Ashburton award, interpreting the treaty of 1783, decided this as United States territory. In the "Concluding Remarks" of the "History of the Intercolonial Railway" 1876, the chief engineer in his characteristic way, refers to this unpleasant event in Canada's national history as one which "converted undoubted British territory into foreign soil, which alienated the allegiance of thousands of British subjects and made a direct connection between central Canada and the Atlantic impossible." Further on he asserts that no Canadian can reflect on this sacrifice of British interest without pain and humiliation, and attributes the fault, not to the Washington government, but to the "ignorance of the merits of the case and an indifference to the interests at stake on the part of the Imperial representative who had been entrusted with the protection of the rights and the honour of the Empire." Fleming's moral sense rebelled against what he considered to be great national injustice.

Elsewhere in the same volume, Fleming eloquently and somewhat prophetically says "I feel that I am performing the last act of duty in the office I have long held, and that I am separating myself from a work to the prosecution of which, with many friends and fellow-labourers, I have devoted for many years the best energies of my life. A connection of this kind is not broken without an effort, but any personal considerations must disappear in view of the completion of a work which realizes the national aspirations of half a century by bringing within a few hours, the old fortress of Halifax and the older citadel of Quebec, and which must form an important section of the railway, destined ere long to extend from east to west through the entire Dominion."

Fleming's greatest engineering undertaking was as chief engineer of the Canadian Pacific Railway, which position he assumed in 1871. On the 20th of July in that year, British Columbia entered confederation, one of the conditions being that a railway should be constructed within ten years from the Pacific to a point of junction with the existing railways of Ontario and Quebec. On the same day survey parties left Victoria for various points in the Rocky Mountains, and from the upper Ottawa westward and all along the line surveys were begun. The reports of these were laid before the Canadian House of Commons in April 1872. In the summer of the same year, the chief engineer, in order to see the main features of the country with his own eyes, travelled across Canada by such facilities as were then available. His party included Dr. Moren, physician, Mr. John Macoun, botanist, and Rev. Geo. M. Grant, Presbyterian clergyman of Halifax, N.S. who was the secretary of the expedition, and who afterwards became Principal of Queen's University, Kingston, Ont.

They travelled from Toronto to Collingwood by rail, and by steamboat from Collingwood to Prince Arthur's Landing, then a settlement of a hundred houses. "Silver Islet" in Lake Superior was then the world's most wonderful silver camp, producing, it was said, $1,200,000 worth of silver per year, and this was considered by the travellers a circumstance worthy of extended remark. The existence of a Cobalt silver camp in the same province which a generation subsequently would produce fifteen times as much annually was not then suspected. The road from Prince Arthur's Landing, now the flourishing city of Port Arthur, to Fort Garry, now the city of Winnipeg, was over the famous Dawson route, in the history of which more of the romantic has probably been found that in that of most of Canada's early highways. The first white man known to have travelled it was Radisson, who in 1663 passed eastward from Lake of the Woods to Lake Superior on his way to Montreal. In 1731 Verendrye, while commandant of a trading post at Nipigon, traversed it from east to west as far as Lake Winnipeg. It was over this route by canoe and portage that the North West and Hudson's Bay Companies for many years were wont to transport their supplies and furs. In 1860 Mr. Simon J. Dawson, an engineer in the employ of the Department of Public Works, Canada, was commissioned to find a waterway from the head of Lake Superior to Fort Garry, to constitute a link between the east and the west. The thought of a railway across that rock-ribbed land was almost too bold then to be entertained. Mr. Dawson selected the route which Verendrye and the fur traders had followed, and ten years later the government endorsed his decision. Dams were built, roads cut and corduroyed, steamers and other craft supplied, and rest houses erected. It was over this route that Sir Garnet, afterwards Lord Wolseley, conducted the Red river expeditions 1,200 strong in 1870 for the suppression of the first Riel rebellion.

The first 45 miles from Lake Superior to Lake Shebandowan was by wagon to a height of land 1,000 feet high. After this, the route was by steamboat, canoe and portage through the Rainy lake, Rainy river, and Lake of the Woods to the "North West Angle" of the latter, thence by wagon road to Fort Garry.

At the banquet given to Chancellor Beatty and Principal Taylor three years ago by the Queen's University Alumni Association of Montreal, Professor John McNaughton told the following story respecting a single incident of that historic journey through the wilds of Canada fifty-three years ago.

"One night in the course of their toilsome journeys, it is said, they had put up their tents on the shores of one of those innumerable lakes of ours, whose waters they were the first white men to stain with the crimson glow of their camp-fires. A storm blew up during the night and loosed all the boats from their moorings. Without boats nothing could be done. So there was nothing for it but to swim out after them. Grant, you remember, had only one arm that was fully serviceable. But that one was as good as most people's two arms. He could wield it like a flail. With it he swam out and brought one of the boats in, then another and another. How did he attach himself to the boats having but one arm? In a very primitive way. He took the rope in his teeth and struck out for the shore. Fleming then and there made up his mind once for all that this man could bite his way through anything, and from that time, I fancy, there was nothing at all that came into Grant's head that Fleming did not support and push with the whole weight of all his body."

At Winnipeg the travellers were astounded by the amount of drunkenness, and the remark was made that while the clergy do all in their power by precept and example to check it, the saloons appear to be stronger than the churches. Manitoba then had a population of fifteen thousand people. At Silver Heights, six miles up the Assiniboine from Fort Garry, lived Mr. Donald A. Smith, M.P., head of the Hudson's Bay Company in America, afterwards Lord Strathcona.

From Fort Garry to Edmonton, via Fort Ellice, Fort Carlton and Fort Pitt, was by pony and Red river cart through the lands of the Cree, Blackfeet and Salteaux Indians. At Fort Edmonton there were noted with much interest the outcrops of coal from the river bank two feet thick, and an attempt to burn it was attended by some measure of success. From Edmonton to Jasper House at the entrance of the Yellow Head Pass required two weeks. Here they were met by Mr. Moberly, who was in charge of the British Columbia surveys, and who had come up from Victoria with pack trains and supplies for his various parties. From the Yellowhead to New Westminster, the route was via the Thompson river to Kamloops and Lytton, thence by the Fraser to tide water. This is substantially the route through British Columbia which Fleming, after nine years of exploration, finally recommended, but which was not adopted by the Canadian Pacific Railway after his resignation. It is, however, practically the one selected by the Canadian Northern Railway now the Canadian National. From Toronto to the British Columbia coast consumed exactly three months.

On Sundays, worship was conducted from a service compiled especially for survey parties, at the instance of Fleming, by clergymen of the churches of Rome, England and Scotland. From its pages such sacred songs and canticles of the Christian faith as Gloria Patria, Adeste Fideles, Hursley and Old Hundred were sung in camps on the windswept plains of the great lone land, in the fastnesses of the Rocky Mountains, and the desolation of the Ontario hinterland, by men of all faiths and no faith at all, whose sense of things spiritual had been quickened by their very isolation.

It should be remembered that in 1872 no complete surveys of Canada west of Ontario existed, and that both latitude and longitude could be known only approximately. Fleming carried a watch which kept local time for Montreal whose longitude is 73° 33′ west of Greenwich. By observing the hours of sunrise and sunset, he was able to determine his own local time on the plains and thence his longitude with respect to Montreal whose time he knew. The following illustration will make clear his method:

Time of sunset 9h. 34m.
Time of sunrise 7h. 26m.
Interval of daylight 14h. 08m.

Adding half of this to the time of sunrise will give the local noon as indicated on Montreal timepieces. This is seen to be 2h. 30m. p.m. But 2h. 30m. is the equivalent of 37° 30′ since 15° is equivalent to one hour. The longitude of the observer is therefore 73° 33′ plus 37° 30′ or 113° 03′ west. The method of course takes no account of sun time being either fast or slow.

The greatest difficulties in the location of the Canadian Pacific were encountered in the province of British Columbia, eleven routes in all having been examined by the engineers up to the year 1877. These eleven lines all came through the Yellow Head Pass, at which point they separated more or less, and terminated at various places on tide water from Port Essington at the mouth of the Skeena, the most northerly, to Port Moody on Burrard Inlet the most southerly. These surveys were attended by all kinds of difficulties, many of them due to the exceptionally rugged character of the country, some to the difficulty of transporting supplies, some to the severity of the climate, and some to the attitude of the native Indians. The reports of the engineers who directed these explorations are stories of adventure and heroism hardly surpassed in fiction anywhere. The names of Smith, Moberly, Jarvis, Hunter, Cambie, Horetsky, Macleod, Ruttan and others, as long as the thrilling story of the location of the Canadian Pacific continues to be read, will stand for courage, endurance, resourcefulness and fidelity. The various reports by the engineer-in-chief up to and including that of 1880 are filled with stories of the successful completion of tasks of almost superhuman difficulty in a way that is well-nigh inspiring. An illustration is taken at random from Fleming's report for 1877.

In the autumn of 1874, Mr. Jarvis was selected to make a winter exploration of the Smoky River Pass through the Rocky Mountains, roughly in the latitude of Athabasca Landing and the mouth of the Skeena river. His assistant was Mr. C. F. Hanington and Alec. Macdonald was engaged to take charge of the dog trains. As this was the only way of transporting supplies, it was necessary to limit the number of the party and to dispense with all unnecessary commodities. The outfit for each man consisted of a pair of snow-shoes, a pair of blankets and some spare moccasins, while a piece of light cotton sheeting was taken in lieu of a tent, the latter having been considered too cumbersome. The supplies consisted of dried salmon for the dogs, and bacon, beans, flour and tea for the men, and were intended to last for two months. The start for the pass was made from Fort George on the upper Fraser early in January 1875 with the thermometer on occasions registering 53° below zero. The narrative as told by Jarvis then continues:

"The party now consisted of three white men, three indians, and three trains of dogs, and the order of march was as follows: two men in front to 'break track' or beat down the snow with the snowshoes to make a road over which the dogs could travel, then the three trains, with a man driving each—the lightest being placed first—and, lastly, Hanington or myself alternately bringing up the rear and making what is called a 'track survey' of the route travelled. The bearings were taken with a pocket compass, and the distance measured by pacing, forty paces to the chain being found a good average on level ground or ice, and this was continued the whole of the distance to Lake St. Anne, fifty miles above Fort Edmonton. The intense cold continued until the third week in January, and camping out under these circumstances had its drawbacks. Many were the frozen noses and ears during the day's march, but then the exercise helped to keep us warm; while in the camp at night the largest and most roaring of fires scarcely did more than burn the side turned towards it, the other being made thus more susceptible to the cold. One curious effect of the extreme lowness of the temperature was to cause the fire to steam rather than smoke, and this with the very driest wood that could be found.

"The cold was also not without its effect on our four-footed companions; they frequently had frozen toes, and we were obliged to make moccasins of flannel and leather to protect their feet. One old dog, the leader of the Cariboo train, suffered a great deal from frost-bite, and on the third day out he was noticed to be very lame all the morning. A halt was called at noon to drink a cup of tea, and 'Marquis' lay down with the rest, but when a start was made the poor dog made a feeble effort to rise, gave one spasmodic wag of his tail and rolled over dead. His legs were frozen stiff to the shoulder; the minimum thermometer, exposed to the sun on top of the sled at the same time, registered forty-six below zero. A hole in the snow on the bank was the only grave we could make for him, and a spare dog being harnessed in his place the expedition pushed on, not without sincere regret at our loss. The travelling was good on the main river, there being only four or five inches of snow on the new and smooth ice, and we made pretty long marches, but the snow began to get deeper when we turned up the north branch of the Fraser, at the head of which it was hoped that a pass through the mountains would be found. Six days after leaving Fort George, the cache was reached, and found not to have been disturbed either by Indians or wild beasts. Here the sleds were unloaded, and Hanington, with two trains and two Indians, went back to the main river, thence to go to Bear river, where one of the Indians had a salmon cache, and to bring two sled loads of dried fish—about six hundred—back with him. Alec. and I, with the other train, went forward up the north branch to explore and break track; and six days later the whole party reunited at the cache, less the one Fort George Indian, who, having handed over the salmon, had returned overland to his village. A heavy fall of snow during two days rendered the return journey tedious, and Hanington had to adopt the old plan of doubling up. The snow falls soft and moist here, and has a wonderful faculty of adhering to the sleds, as well as piling up under the bows, making killing work for the dogs." And so the story continues page after page in a similar strain. The party reached Winnipeg on May 21st, having been five and a half months on the trip.

By 1880, nine years after the commencement of the work, the line had been located westward from Fort William to the Red river, which it crossed at Selkirk, a branch extending therefrom to Winnipeg. West of the Red river, the location of 1877 which crossed the narrows above Lake Manitoba had been abandoned for one lying south of that lake. Thence, the direction was generally northwesterly to Battleford and Edmonton, crossing the south Saskatchewan river not far from the present city of Saskatoon. It crossed the Rocky Mountains via the Yellowhead Pass, descended the North Thompson to Kamloops, thence by way of the Thompson and Fraser rivers to the Pacific.

From 1871 until 1880, when Sir Sandford severed his connection with the enterprise, the work had been carried on as a national undertaking. Some sixty-seven separate contracts had been entered into comprising grading and ballasting, steel rails, station buildings, wooden ties, bridges, rolling stock, etc., on account of which some $9,486,000 had been paid. The cost of explorations, surveys, engineering and supervision of construction was nearly $5,000,000, so that the cost to the country up to December 31, 1879, was over fourteen million dollars.

A comparison of the prices paid over 40 years ago with those obtaining to-day is very interesting. In 1879 John Ryan was paid 16 cents per cubic yard for earth embankments on the Manitoba prairie. Steel rails weighing 57¼ lbs. per yard, supplied by the West Cumberland Iron & Steel Co. Ltd., cost the country $24.05 per ton in 1879 delivered at Montreal. It may be remarked here that the present-day steel rail weighs nearly twice as much as that purchased for the Canadian Pacific Railway in 1879. On the Fort William-Shebandowan section, Messrs. Sifton & Ward, contractors, were paid in 1875 $1.25 per cubic yard for solid rock excavation, $22.00 per M for bridge timber 16″ by 12″, $20.00 per M for hard wood and pine plank, and 26 cents apiece for wooden ties. In 1880 Andrew Onderdonk was paid the following prices for work in the province of British Columbia:

Solid rock, $1.50 per cubic yard
Concrete, $6.00 per cubic yard
Bridge timber, 12″ by 16″, $18.75 per M
Wooden ties, 30 cents apiece.

In the same year, James Crossen Cobourg was paid $4,746 each for first class passenger coaches carrying sixty-four passengers each. In comparison with this, it may be remarked that a modern steel passenger coach seating seventy-nine persons will cost today something like $33,000.

The locomotive which was adopted for passenger and way freight had cylinders 17 inches by 24 inches, four driving wheels 62 inches diameter, and weighed loaded 75,000 pounds. It had an overall wheel base of 44 feet 6 inches. It is interesting to note that the weight of the locomotive used at the present day is nearly seven times as great as that proposed for the Canadian Pacific Railway in those early days. This gives some conception of the changes that have taken place in the weight of rolling stock in the interval.

That Fleming realized to the full the great responsibility resting upon one entrusted with the selection of a route for a great railway is quite apparent from his reports. With a desire to be quite sure that no reasonable uncertainty existed as to the conditions existing in British Columbia, he prosecuted his explorations in that province for nine years, examining in all as said above, some eleven routes.

Respecting this particular problem he states in his report on the Canadian Pacific Railway for 1880—"It was a serious responsibility for any engineer to assume to recommend that construction should be commenced on the line to Burrard Inlet without first having exhausted all the sources of enquiry open to us. I felt that we should clearly and unmistakably understand the capabilities and possibilities of the northern region, that we should obtain data to determine if a railway line could be obtained through it, that we should know the characteristics of the route and that we should possess full information with regard to the climate, soil and capability for settlement, before the government became irrevocably committed to the large expenditure attendant on the adoption of any route."

"It is easy to understand that if, subsequently to construction of the railway on the southern route, it should be discovered that a northern line could have been undertaken at a greatly reduced cost and through a country in respect of soil and climate suitable for prosperous settlement, a gross and irremediable error would have been committed, possibly ever to be deplored."

In June 1880, the government of Canada appointed a commission to enquire into the facts connected with the prosecution of the Canadian Pacific Railway from its inception. This enquiry was a result of discussions in and out of parliament respecting the propriety of and responsibility for the large expenditure incurred and of certain allegations as to irregularities on the part of officers and others employed in connection with the explorations, surveys and construction. The commission consisted of Judge Clark of Cobourg, Samuel Keefer, civil engineer, and Edward Miall, assistant commissioner, Department of Inland Revenue of Ottawa. Two years later this commission, after having conducted a rather searching enquiry into the matters of reference, issued its final report. This report took exception to many of Mr. Fleming's methods of conducting his work. It contended for example that more reconnaissance and less detailed survey in the early stages of exploration would have cost less and would have produced quicker and better results; that when contracts were let the data respecting quantities were not available in sufficient detail for estimating purposes; that a special class of excavation for muskeg should have been created; that information as to the character of the soil generally was very meagre, and that the work had been carried on "at a sacrifice of money, time and efficiency."

It must be remembered, however, that the undertaking was one of stupendous magnitude, that the chief engineer was hampered by a pernicious patronage system, that he was obliged to obtain his information in a hurry, that his work was often hampered and delayed until parliamentary appropriations were forthcoming, and that he was overworked because he was obliged to divide his time between the Intercolonial and the Canadian Pacific during the first five of his nine years of service on the great transcontinental enterprise. These circumstances were recognized by the commission, as indeed they will be by all reasonable persons. And while there were differences of opinion as between Mr. Fleming and the commission, and while he, being human, doubtless made mistakes, no shadow of doubt as to his integrity ever existed. In one place in the report, referring to the engineering staff and its service generally, it is stated that they "have shown ability, zeal and the strictest integrity in the supervision of the work. . . . They have fought inch by inch and day by day against what they thought to be attempted encroachments on the part of the contractors' engineers."

In the same year the Canadian Pacific enterprise was taken over by a syndicate headed by George Stephen and Donald A. Smith, and the route west of Winnipeg was entirely changed, the line running much farther south and crossing the Rocky Mountains by the Kicking Horse Pass. The last spike on the through line was driven in 1885 at Craigellachie by Sir Donald Smith. At this ceremony Fleming was an interested spectator.

To Fleming the Pacific cable, with the larger related project of a world encircling state owned British telegraph system, was primarily a means of uniting the scattered members of a great and powerful empire. In addition it was a sound commercial enterprise and for upwards of twenty-five years he gave himself unsparingly to its advocacy. Of his services in that regard, Earl Grey, Governor General of Canada, said in Ottawa in 1907 that their recital suggested the missionary fervour of Saint Paul. "He has without hope of personal gain visited five continents; he has traversed all the great oceans, the Atlantic many times, and has given himself, his time and his substance ungrudgingly and without stint to the service of the Empire." Fleming hoped for an Imperial intelligence system serving the press of the Empire, whereby all its readers would be supplied with trustworthy information on all matters of prime concern to Britishers the world over. Fortunately he lived to see the realization of many of his fondest dreams.

It was in 1758 that the first meeting of the legislative assembly of Nova Scotia was held. The matter was brought to the attention of the members of the legislative council of that province during the session of 1908, noting that that was the one hundred and fiftieth anniversary of that important historic event, and of the beginning of autonomous government in the overseas possessions of the British Empire.

The significance of this fact appealed to Fleming's imperialism. Then a resident of Halifax, he addressed to the mayor of that city a public letter in which he suggested the marking of the event by the erection through popular subscription of a monument in the city of Halifax which to succeeding generations would stand as a tangible reminder of their inestimable heritage of self-government Subsequently he took the matter up with the lieutenant-governor of the province, suggesting that it be undertaken as a provincial enterprise, and offering a suitable site on his own estate for the purpose. Further reflection led to the belief that its erection should be made a national rather than a provincial matter, and finally that its historic importance warranted its being undertaken as an Imperial affair. The various governments of the self-governing possessions of the Empire were communicated with. Their response was hearty and general and on August 14, 1912, the monument was formally dedicated on behalf of the people of the British Empire by His Royal Highness the Duke of Connaught, Governor General of Canada, "as an embodiment of the spirit which animates the people of the Empire in both hemispheres—an attestation of the partnership of the sisterhood of nations all under one Crown." "We may rest assured," says Fleming, "that the British Empire, built up on the principles of freedom, justice, equal rights and the self-government of all its autonomous parts, is not destined to pass away like the empires of history. The new empire is inspired by a spirit unknown to the empires founded on absolutism. It is a union of free and enlightened communities, dedicated to the cause of commerce, of civilization and of peace; and who can doubt that such a great political organization is destined to endure. Every improvement in transportation, in postal arrangements and in telegraphy by land and sea, is calculated to facilitate inter-communications and to foster friendships among kindred people, and thus to perpetuate their attachment to the cradle of the British race, to the source of that unequalled constitution which is their highest inheritance "

Fleming's views as to the function of a modern university were expressed in his first address as Chancellor of Queen's University which position he assumed in 1880 and held until his death in 1915. University federation as against independence so far as Queen's was concerned, mental discipline as against the imparting of knowledge, the humanities as against the natural sciences were all discussed in succession, and after asserting that the aim of education is "to ennoble the propensities and tastes, to strengthen the moral sense and to fit man to discharge his duties as an intelligent being," he concluded by expressing his own opinion that a curriculum in which Latin and Greek do not predominate is one best suited to the needs of a young nation.

During the seventy years of his active life in Canada, Fleming witnessed the growth of the impotent colony of British North America into a proud and self-reliant nation. When he arrived in 1845, it possessed sixteen miles of steam railroad; when he died, it had completed three lines of transcontinental railway, which lines were exchanging traffic with Canadian-owned steamships on both oceans consigned to the ports of the seven seas. He saw the laying of the first trans-Atlantic cable to Canada in 1858, the construction of the Victoria tubular bridge at Montreal in 1859, and its replacement by a series of through trusses in 1898. He saw the Niagara suspension bridge erected in 1855 and its replacement by a magnificent steel arch 42 years afterwards. He witnessed the completion of two successive enlargements of the Welland canal in 1850 and 1883 respectively, and the commencement of the Welland ship canal whereby the usefulness of this historic waterway is to be still further extended. He saw the completion of the Sault Ste. Marie canal in 1895, the opening of the St. Clair tunnel in 1891, and the Detroit river tunnel in 1911, and those important improvements in internal navigation through terminal elevators, harbours, lake carriers and deepened canals which facilitate the transport of Canada's wheat to the markets of the world. He saw the beginnings of national conservation in Canada, a very material progress made in the utilization of the nation's magnificent waterpowers; and observed the stimulus given thereby to Canadian industry. He even lived to see the Great Lakes and deep waterways project within measurable distance of realization.

He witnessed the evolution of the electric telegraph and the telephone, the beginning of wireless, the introduction of electricity for illumination and power, and the perfection of its economical long distance transmission. The development of the internal combustion engine and its application to vehicle and aircraft propulsion in peace and in war was another epoch-making incident of his times. He observed the development of the superdreadnought, the submarine and the modern explosive. He saw the scientific method supplant empiricism in medicine, agriculture and industry, and observed the development of a sense of community responsibility in such matters as prison reform, child welfare and industrial relations. In all of these, he maintained an active and intelligent interest, and to many of them he made substantial contributions.

He lived through the stormy times preceding and following confederation, the Fenian raids of 1866, the north west rebellions of 1870 and 1885, and followed the acrimonious controversies respecting commercial union with the United States with which the names of Richard Cartwright, Erastus Wiman and Goldwin Smith were associated, but lived to see the day most gratifying to his Imperial sympathies, when this country became a united Canada and when sentiment favouring annexation with the great nation to the south had practically ceased to exist.

To what endowments of nature, habits of mind or traits of character did this career owe its success? What was there in the personality or abilities of Sandford Fleming that distinguished him from hundreds of engineers who have done good and honest work in the development of this country but who have won no place in science, in statecraft, or in epochal and national affairs? There are many things that might be mentioned. Fleming was a man of prodigious energy and indomitable perseverance and possessed almost limitless capacity for arduous work. His interests outside of his daily work were innumerable. In the furtherance of his objects he possessed endless patience, most of his major accomplishments being the result of years of persistent effort. He was an easy and comfortable speaker and possessed a facile pen. He was not hampered by undue modesty, for he knew his capabilities and used them to the full. In rather strange but probably unconscious contrast with this characteristic were some of his remarks concerning the work of engineers generally, on the occasion of a dinner given him in Ottawa by the engineers who had been associated with him in the survey and construction of the Canadian Pacific Railway. "Silent men such as we are" said he "cannot hope for profit or peace in law, cannot look for fame in press or pulpit, and above all things must keep out of politics . . . . Although we deal largely with figures, they are not figures of speech." His mind was of the analytical, incisive type which detects the impractical features in every scheme and never espouses a visionary one.

Like J. J. Hill, he possessed boundless industry and a capacity for handling large scale undertakings; like George Stephen and Donald Smith, he had, fifty years ago, a vision of and a faith in Canada's future which few men of the time possessed; like Cecil Rhodes he believed the British Empire to be a force in world politics making for ordered liberty, human progress and international peace—something to be consolidated, extended and perpetuated at almost any cost. His mentality however, was of a more delicate texture than that of any of the four. His tastes were catholic, his sympathies broad, his patriotism inspiring, his imagination magnificent, and no finer ideal for the young engineer aspiring to serve his time and country, is to be found in the history of Canada's material development than the career of this illustrious Empire builder.

VOLUME XIII OCTOBER 1930 No. 10

Recent Progress in Steam Production

The advance in steam power engineering practice during the last twenty years has been a striking one. In order to take advantage of the possibilities of the steam turbine, permitting a great increase in the size of individual power units and the employment of steam of high pressure and temperature, radical changes in boiler construction and operation have been necessary. Their introduction has involved prolonged experimental work, for the practical difficulties experienced in handling steam at 1,500 pounds pressure and at temperatures up to 1,000 degrees F. have not been easy to surmount. Designs and methods of construction which formerly gave acceptable results fail completely under the new requirements, and the problem of burning successfully the large amount of fuel required for a boiler evaporating as much as 400 tons of water per hour (the capacity of the units installed in a recent station) and the handling of the resulting ash requires very different treatment from that customary in the smaller units of the past.

As a result, there are many boilers now in operation which utilize in steam production from 85 to 90 per cent of the available heat of the fuel. This greatly increased efficiency has been made possible by adopting more scientific methods of combustion, by using more effectively the radiant heat of the fuel, by developing satisfactory methods of air preheating, and more particularly by the employment of very large boiler units.

At present the limit of pressure to be used commercially on a large scale in North America is about 1,500 pounds per square inch, although in Europe pressures considerably higher than this have been successfully employed. At such pressures special materials and methods of construction have been necessary, particularly as regards superheaters and steam drums, and it is possible that in the future for pressures of 2,000 to 3,000 pounds per square inch, drumless boilers will be developed. The seamless forged steel steam drums now in use for large high-pressure boilers present difficulties in construction and are costly. A drum* recently made for a working pressure of 1,405 pounds per square inch had to be forged from an ingot weighing over 300,000 pounds. The finished drum, 60 inches outside diameter, 52 inches inside diameter and over 40 feet long, weighed more than 106,000 pounds when machined to its finished dimensions.

Developments as startling as those in the steam-containing parts of the boiler have been made in the furnace. The principles governing the combustion both of pulverized and solid fuel are now better understood, and the economy to be obtained from air preheating is fully realized. Troubles arising from ash and flue-gas dust in large units have been successfully overcome, and progress in these respects has not been confined to boilers for stationary service. Several successful installations using pulverized fuel have been put in service for sea-going vessels.

It is well to note the present extended use of oil firing for boilers, experience with which has thrown light on many questions of combustion and heat transference which were previously imperfectly understood. Marked advances have been made in the difficult task of increasing the power and efficiency of the locomotive boiler, in which the unavoidable limitations of space and weight make it particularly difficult to secure the large output of steam required to haul modern passenger and freight trains. Locomotive boilers are now in daily use capable of evaporating as much as thirty tons of water per hour, with pressures up to 500 pounds per square inch, and using mechanical stokers.

Reference may also be made to the wider appreciation by steam users of the necessity for adequate records of boiler performance, and the resulting more general use of measuring instruments, such as thermometers, pyrometers, flowmeters and CO_2 recorders. All these factors have contributed to the general improvement in boiler operation and practice which is becoming evident.

There is still room for improved economic performance in many of the smaller boiler plants for heating and industrial purposes, in which so large a proportion of the world's fuel consumption takes place, but it seems certain that in the near future increasing use will be made in these installations of the experience obtained in the larger plants, thus leading to more scientific and careful operation, and more satisfactory results for the owners.

The Chute-à-Caron Obelisk

The Chute-à-Caron power plant is being constructed in a rocky section of the Saguenay, and in order to complete the large dam across the gorge it was necessary to excavate a diverting canal and turn the river through this new channel, while the dam foundations were constructed across the deep original channel. This diversion naturally required the damming of the original channel and local conditions and the extreme depth and high velocity of the water rendered the construction of a cribwork dam impracticable. It might be mentioned here that the Saguenay

*See Mechanical Engineering, August 1930, p. 751.

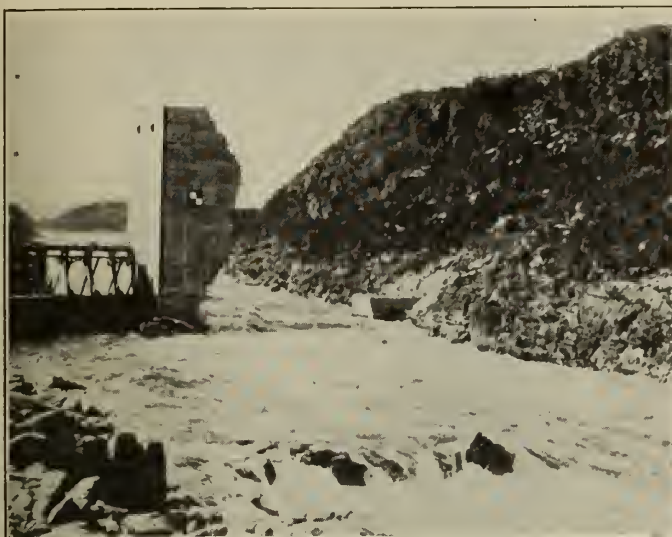

Figure No. 1.

Figure No. 3.

river has a flow varying from 35,000 to 225,000 cubic feet per second. It was therefore decided on the suggestion of James W. Rickey, M.E.I.C., Chief Hydraulic Engineer of the Aluminum Company of America, to close the channel by dropping a large reinforced concrete tower or obelisk into the channel. This operation has now been successfully completed and is illustrated in the accompanying photographs, furnished through the kindness of Mr. Rickey.

The obelisk was 92 feet high, 45 feet wide, and contained 5,500 cubic yards of concrete; one side was shaped so as to fit as nearly as possible the bottom of the river, and figure No. 1 shows the obelisk in its vertical position, a few moments before it was tipped into the river, which at that time was discharging about 35,000 cubic feet per second, with a maximum depth of 25 feet. The ragged edges on the contour side of the obelisk are pieces of heavy form timber that were left in place.

The obelisk was built several months beforehand and rested on the top of a concrete pier arranged so that by means of suitable blast holes the river side of the pier could be shot off, thus leaving the obelisk unsupported on that side. It was necessary to leave a heavy stream of water flowing down the old channel in order to form a cushion for the obelisk to fall into so as to avoid breakage. This precaution worked perfectly.

Figure No. 2 shows the obelisk in an inclined position, about three seconds after the supporting pier was shot away.

Figure No. 3 shows the conditions after a few seconds, when the obelisk had either just come into contact with the bottom of the river or was just about to do so. The small specks are the form timbers which were carried nearly 200 feet into the air as the water shot out from under the obelisk. The water was shot upward nearly 300 feet and went over the hill shown at the right of figure No. 1.

Figure No. 4 shows the obelisk in its final position, and was taken about five minutes after figure No. 3.

The obelisk landed in its final position within one inch of its calculated location. It was practically undamaged, there being only hair-line cracks on the top face in the prone position and on the downstream vertical face. One of the construction joints opened up about one-thirty-second of an inch. The obelisk was about 3 feet out of level, measured along a diagonal from the highest to the lowest point.

It will be noted that water is passing from the opening at each end of the obelisk. The opening at the left was unavoidable owing to the configuration of the supporting piers. That on the right was about 6 feet wide and was intentionally made so, in the absence of any previous experience of a similar type. As a matter of fact, in similar work in the future it would not seem necessary to allow more

Figure No. 2.

Figure No. 4.

than a two-foot opening, in which stop-log grooves could probably be left. There was, however, no difficulty in stopping the openings and within 72 hours of the felling a railway trestle had been built across the obelisk, both of the end openings were closed and the obelisk cofferdam was practically tight.

The total cost of the operation was less than $75,000, whereas, owing to the depth of the water, i.e., 25 to 40 feet deep, depending upon flood conditions, and the velocity of the current 20 to 30 feet per second, building the usual type of crib cofferdam would have involved a cost of some three to four hundred thousand dollars, and the cribwork might have been washed out by floods of 100,000 second-feet which have occurred since the obelisk was felled. In other words, the cost of cofferdamming a stream by this method can be determined in advance very accurately, whereas under the former methods one could not even make a shrewd guess as to the cost of cofferdams, particularly where heavy floods must be encountered after the building is commenced.

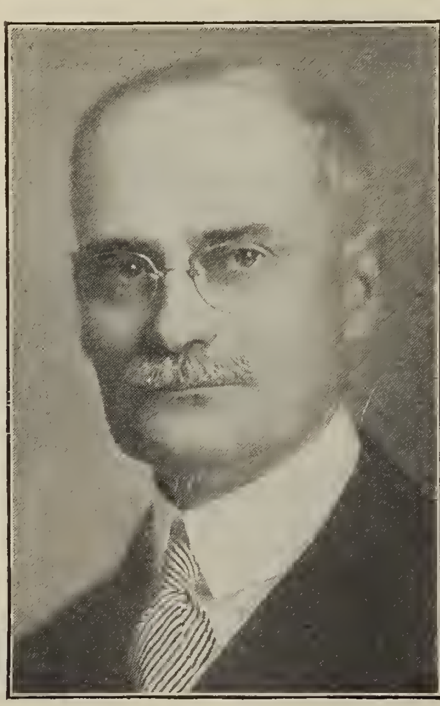
Application has been made for patent covering this operation in construction.

OBITUARIES

George Frederick Porter, M.E.I.C.

Members of The Institute will learn with regret of the death of George Frederick Porter, M.E.I.C., which occurred in Detroit, Mich., on September 19th, 1930.

Mr. Porter was born at Detroit, Mich., on October 7th, 1862, and received his early education at Detroit public schools. In 1886 he entered the engineering office of Mason L. Brown, and until 1894 was in charge of surveying parties. In 1894-1895 he was employed on a survey of the St. Clair and Erie ship canal, and in 1895-1896 he was with the Detroit Bridge and Iron Works as draughtsman. The following year was spent with the Keystone Bridge Company of Pittsburgh, Penn., after which time he returned to the Detroit Bridge and Iron Works for three years. In 1900 Mr. Porter became one of the founders of the Canadian Bridge Company, Ltd., at Walkerville, Ont., remaining there in charge of draughting until January 1909, at which time he joined the staff of the board of engineers appointed by the Dominion government in that year to design and supervise the construction of a bridge across the St. Lawrence river near Quebec to replace the one that collapsed during construction in August 1907. Mr. Porter remained in charge of the draughting department until the official design was completed in June 1910. In 1911 he was named as engineer of construction of the St. Lawrence Bridge Company, a corporation organized to carry out the construction of the Quebec bridge. In 1919 Mr. Porter returned to the Canadian Bridge Company at Walkerville, Ont., as chief engineer and in 1927 he was appointed consulting engineer of the company.



GEORGE FREDERICK PORTER, M.E.I.C.

On October 13th, 1921, on the occasion the of centenary celebration of McGill University, Mr. Porter was awarded the honorary degree of Doctor of Laws. In 1919 he was awarded the Gzowski Medal of The Institute with G. H. Duggan, M.E.I.C., and the late Phelps Johnson, M.E.I.C., for a paper entitled "The Design, Manufacture and Erection of the Superstructure of the Quebec Bridge."

Dr. Porter was a member of the Detroit Athletic Club, the Grosse Isle Golf Club, the Detroit Automobile Club, the American Society of Civil Engineers and the American Railway Bridge and Building Association. He joined The Institute as a member on April 17th, 1909, and took a keen interest in Institute affairs, having represented the Border Cities Branch on the Council in 1923.

William Grant Matheson, M.E.I.C.

It is with much regret that the death of William Grant Matheson, M.E.I.C., which occurred at New Glasgow, N.S., on September 12th, 1930, is reported.

Mr. Matheson was born at Albion Mines, N.S., on August 1st, 1848, and received his education at the public schools of Chatham, N.S., and the University of New Brunswick. In 1868 he went to Scotland, where he was apprenticed as a machinist to Baxter Brothers, Dundee, and to R. Napier and Sons, Glasgow. Returning to Canada in 1871, he entered the employ of I. Matheson and Company, New Glasgow, in January 1872. In 1874 he became manager of this firm, holding this position until June 1914, at which time he joined the Nova Scotia Steel and Coal Company. In 1921 Mr. Matheson's health compelled him to give up all active work and he retired.

Mr. Matheson took a great interest in steam boilers, which he made his specialty, and as the representative of Nova Scotia, he took a prominent part in the formulation of a uniform code of regulations for their construction and inspection in the various provinces of Canada. He took an active part in municipal affairs, particularly in connection with the construction of public works, and also in connection with the school board on which he served for ten years. Mr. Matheson was a member of the American Society of Mechanical Engineers and of the Association of Professional Engineers of Nova Scotia.

He was one of the oldest members of The Institute, having joined as a Member on February 3rd, 1887. He was placed on the retired list in April 1922.

William Falconer McKnight, A.M.E.I.C.

Members of The Institute will learn with deep regret of the death of Professor William Falconer McKnight, A.M.E.I.C., which took place in the Jordan Memorial Sanatorium, Riverglade, N.B., on August 25th, 1930.

Professor McKnight was born at Douglastown, N.B., on May 30th, 1884. From the local schools at his home he went to normal school, following which he taught school for

WILLIAM FALCONER McKNIGHT, A.M.E.I.C.

one term. Becoming interested in electricity, he served an apprenticeship with the Robb Engineering Works at Amherst, N.S., and entered the engineering school at Mount Allison in 1905. After two years he continued his studies at McGill University where he took the degree of B.Sc. with honours, in 1909.

Following his graduation Professor McKnight was associated with the Canadian General Electric Company in electrical design and transformer testing. He was next engaged with the Northern Electric Company in sales work and was later appointed director of the Educational Department of that company in Montreal. Following a year's recuperation from illness, in August 1921 he was appointed head of the electrical department of the Nova Scotia Technical College at Halifax, a position which he held until his death.

In addition to the general field of his activities, from time to time he took up special research and installation work which gave scope for his many interests and abilities. He served as acting secretary to the Board of Engineering Standards under the Research Council of Canada and helped to compile the first edition of the Canadian Electrical Code. Professor McKnight was a member of the American Institute of Electrical Engineers, the Association of Professional Engineers of Nova Scotia, and the committee on engineering physics of the National Research Council.

Professor McKnight joined The Institute as an Associate Member on April 27th, 1920, and took a keen interest in Institute affairs. He represented the Halifax branch on the Council in 1929 and was chairman of the same branch in 1925.

Arthur Knox Mitchell, M.E.I.C.

It is with regret that the death is recorded of Arthur Knox Mitchell, M.E.I.C., on April 27th, 1930.

Mr. Mitchell was born at Marietta, Ohio, on June 9th, 1887. He received his early education at preparatory schools in Massachusetts, and graduated from the Massachusetts Institute of Technology in 1909 with the degree of B.Sc.

Following graduation Mr. Mitchell was for a short time engaged on sewage disposal investigations with the Sanitary District of Chicago, later being connected with the Central Foundry Company, New York City, as engineer of pipe lines. He was for a time in charge of sewerage installation at Puebla, Mexico, and in 1910-1911 he was chief engineer in connection with the Ashcroft, B.C., irrigation project for the Quaker Oats Company, Ill., and in 1901 he became a member of the firm of Canavan and Mitchell, consulting engineers, Victoria, B.C. During the World War Mr. Mitchell was secretary of the War Industries Board and in 1919 he became associated with the St. Joseph Lead Company, New York, which position he held at the time of his death. In 1920 he invented an underground shovel used in mining and subway excavating.

Mr. Mitchell joined The Institute as an Associate Member on October 14th, 1913.

John MacKenzie Moore, M.E.I.C.

Deep regret is expressed in recording the death of John MacKenzie Moore, M.E.I.C., which occurred at London, Ont., on June 19th, 1930.

The late Mr. Moore was born at London, Ont., on October 1st, 1857. He received his early education in that town and serve five years' apprenticeship in the offices of Robinson and Tracy, architects and provincial land surveyors. From 1891 to 1910 Mr. Moore was engineer in charge of the waterworks system of the city of London and from that time on was engaged in private practice as a consulting engineer and architect.

Mr. Moore was a member of the Ontario Association of Architects and the Royal Architectural Institute of Canada, and was responsible for many prominent buildings in London. He took an active interest in civic affairs, having served as city controller for the year 1916-1917 and as mayor in 1926 and 1927.

Mr. Moore joined The Institute as an Associate Member on April 18th, 1922, and was transferred to the class of Member on October 24th, 1922.

PERSONALS

W. A. Madeley, S.E.I.C., is now a draughtsman with the Pacific Great Eastern Railway at Squamish, B.C.

Arthur Fraser, A.M.E.I.C., is now located at Launceston, Tasmania, Australia. Mr. Fraser was at one time with the Geodetic Survey of Canada, Department of the Interior, Ottawa.

Ezra B. Rider, A.M.E.I.C., formerly engineer with the Water Department of the City of Los Angeles, Calif., is now assistant engineer of the Metropolitan Water District of Southern California, Los Angeles.

J. A. Simmers, A.M.E.I.C., has joined the engineering staff of the Ontario Paper Company, Ltd., and is located at Thorold, Ont. Mr. Simmers was formerly structural engineer in the office of the architect, city of Toronto.

C. R. Townsend, Affil.E.I.C., formerly of the forestry department, Canadian Power and Paper Corporation, at Three Rivers, Que., is now chief forester of the Anticosti Corporation at Port Menier, Anticosti Island, Que.

H. R. Montgomery, S.E.I.C., who graduated from McGill University in 1929 with the degree of B.Sc., is with the Atlas Construction Company, Ltd., and the Standard Dredging Company, Ltd., on the West Saint John, N.B., harbour improvements.

Clyde B. Joy, Jr.E.I.C., is now designing engineer and estimator with the London Structural Steel Company, Ltd., London, Ont. Mr. Joy was formerly estimator with the Austin Company, Philadelphia, Pa. He is a graduate of the University of Toronto of the year 1924.

A. G. Graham, A.M.E.I.C., has been appointed city engineer of Nanaimo, B.C. Mr. Graham was at one time assistant engineer in the municipal engineer's office at Point Grey, B.C., and prior to his present appointment was on the engineering staff of the city of Vancouver, B.C.

W. S. McDonald, A.M.E.I.C., is now with the chief engineer's branch, Department of Railways and Canals, Ottawa, Ont. Mr. McDonald is a graduate of the University of Alberta of the year 1915, and prior to accepting his present position was with the Department of the Interior at Calgary, Alta.

D. C. Bryden, S.E.I.C., has joined the staff of the Winnipeg Hydro-Electric System, Winnipeg, as power sales engineer. Mr. Bryden, who graduated from the University of Alberta in 1928 with the degree of B.A.Sc., has been with the Canadian Westinghouse Company, Ltd., at Hamilton up to the present time.

A. T. Perrin, A.M.E.I.C., has been appointed chief engineer of the Whiting Corporation (Canada) Ltd., Toronto. Mr. Perrin was at one time with the mechanical department of the Dominion Bridge Company at Lachine, Que., and prior to accepting his present position was with E. A. Turner and Company, Toronto.

John H. Legg, S.E.I.C., has joined the staff of the Hudson Bay Mining and Smelting Company, Ltd., at Flin Flon, Man. Mr. Legg graduated from McGill University in 1929 with the degree of B.Sc., and since that time has been with the British Metal Corporation (Canada) at Montauban, Que., and Stirling, N.S.

Donald E. Burnham, S.E.I.C., has accepted a position as assistant engineer with the Hydro-Electric Power Commission of Ontario at Hamilton, Ont. Mr. Burnham, who graduated from the Nova Scotia Technical College in 1928 with the degree of B.Sc., was formerly with the Canadian Westinghouse Company at Hamilton.

T. H. Winter, A.M.E.I.C., has been appointed lecturer in engineering at the Memorial University College, St. John's, Nfld. Mr. Winter graduated from the Nova Scotia technical College in 1923, and prior to accepting his present position was with the New Jersey State Highway Department, Metropolitan Division, Newark, N.J.

D. H. McDougall, M.E.I.C., is president of the McDougall Engineering Company, Ltd., Toronto. Mr. McDougall was at one time president of the Nova Scotia Steel and Coal Company, Ltd., New Glasgow, N.S., and vice-president of the British Empire Steel Corporation, but has more lately been located in Toronto where he has been carrying on a practice as a consulting engineer.

Major C. A. Scott, A.M.E.I.C., for many years first assistant engineer, roadway section, Department of Works, and since 1928 with the contract department of the Robert Simpson Company, Ltd., of Toronto, has joined the staff of the Adams Furniture Company Ltd., Toronto, as manager of the contract department. Major Scott is a graduate of the School of Practical Science, University of Toronto, of the year 1909.

A. F. Bryant, M.E.I.C., who since 1927 has been manager of the Nashwaak Pulp and Paper Company at Saint John, N.B., is now technical director and adviser of the Canadian Pulp and Paper Association, and is located in Montreal. Mr. Bryant is a graduate of the University of New Hampshire, and has been in Canada for the past sixteen years. From 1914 to 1918 he was with the pulp and paper division of the Forest Products Laboratories of Canada, in 1918-1920 he was chemical engineer with Bennett Ltd., at Chambly Canton, Que., and from 1920 to 1927 Mr. Bryant was chemical engineer for the Laurentide Company Ltd., at Grand'Mere, Que.

W. H. Abbott, A.M.E.I.C., has become connected with the Newfoundland Light and Power Company, on the Pierres brook development, and is located at St. John's, Newfoundland. Mr. Abbott, who was formerly with the Foundation Maritime Company at Montreal, was at one time assistant superintendent for the Foundation Company of Canada, Ltd., on the construction of the Ghost power development for the Calgary Power Company. He was overseas from 1914 to 1919, and following his return to Canada in 1919 he was chief engineer of the Hull Electric Company. In 1922-1923 Mr. Abbott was on the engineering staff of the Gregory Commission on the Ontario Hydro-Electric enquiry, and from 1923 to 1927 he was principal assistant engineer with Beaubien Busfield and Company of Montreal, and later with Busfield, McLeod Ltd.

ELECTIONS AND TRANSFERS

At the meeting of Council held on September 5th, 1930, the following elections and transfers were effected:

Members

BREED, Charles B., B.S. in C.E., (Mass. Inst. Tech.), consulting engineer. 6 Beacon Street, Boston, Mass.

KAYSER, Nicholas James, B.Sc., (Univ. of Wis.), director, Fraser Brace Engineering Co. Ltd., Montreal, Que.

McCALL, Thomas Lockhart, (Heriot Watt Coll.), chief mining engineer, British Empire Steel Corporation, Ltd., Glace Bay, N.S.

Associate Members

‡BUCHANAN, Walter S., gen. supt., elect'l. contractor, Goulet & Belanger, Quebec, Que.

FERGUSON, William Patterson, B.Sc., (McGill Univ.), in charge of Sydney office, Peacock Bros. Ltd., Post Bldg., Sydney, N.S.

‡MacMILLAN, Kenneth L., engrg. dftsman., Canada Cement Company, Ltd., Montreal, Que.

‡PLATOU, Otto Stoud, concrete designer, Power Corporation of Canada, Montreal, Que.

WEICKER, Julius John, B.A.Sc., (Univ. of Toronto), consulting engineer, Cobourg, Ont.

Juniors

BRUMBY, Walter William, (City and Guilds of London), engrg. student, Canadian General Electric Co. Ltd., Peterborough, Ont.

COBBOLD, Robert James, (Assoc. City and Guilds Inst.), students' test course, Canadian General Electric Co. Ltd., Peterborough, Ont.

EVANS, Charles Durward, B.Sc., (McGill Univ.), 303 Milverton Boulevard, Toronto, Ont.

JONES, Arthur R., B.Sc., (Univ. of Alta.), test dept., Canadian General Electric Co. Ltd., Peterborough, Ont.

MORRISON, George Hawley, B.Sc., (N.S. Tech. Coll.), 27 Rupert Street, Halifax, N.S.

Transferred from the class of Junior to that of Associate Member

‡BRADLEY, Robert A., 65 Lowell Avenue, St. Catharines, Ont.

COOKE, Norman Melville, B.Sc., (Queen's Univ.), district engr., municipal roads, Department of Public Highways, Ontario, Ottawa, Ont.

‡HOLDER, George William, in charge of hydraulic dept., Abitibi Power & Paper Co., Sturgeon Falls, Ont.

HVILIVITSKY, Jakov, B.A.Sc., (Univ. of Toronto), struct'l. engr., Truscon Steel Co. of Canada, Montreal, Que.

PARKE, Charles Sager, B.Sc., (McGill Univ.), chief engr., The Harshaw Chemical Company, Cleveland, Ohio.

PLOW, John Foss, (Grad. R.M.C.), asst. to the secretary, The Engineering Institute of Canada, Montreal, Que.

Transferred from the class of Student to that of Associate Member

ARMSTRONG, Lawrence Henry, B.Sc., (McGill Univ.), in charge of operation of Madrid-Buenos Ayres radio telephone link, Compania Telefonica Nacional de Espana, Madrid, Spain.

McINTOSH, John Cameron, B.Sc., (Queen's Univ.), asst. to res. engr. on constrn. of Cedar Rapids storage dam on Lievre River, Notre Dame du Laus, Que.

SMITH, Hamilton Ellesmere, B.Sc., (McGill Univ.), secretary and engr. in charge of constrn. work for F. H. McGraw, 51 East 42nd Street, New York, N.Y.

‡Elected after passing Institute's examinations under Schedule "C."

Transferred from the class of Student to that of Junior

SCADDING, Simcoe Crawford, B.A.Sc., (Univ. of Toronto), statistician, The Bell Telephone Company of Canada, Montreal, Que.

Students Admitted

GRANT, Donald Seafield, estimating dept., Eugene F. Phillips Electrical Works, 5795 de Gaspe Avenue, Montreal, Que.

FOSTER, Eldon Barry, B.Sc., (Univ. of N.B.), student engr., Canadian General Electric Co. Ltd., Peterborough, Ont.

HAWKE, Charles Edison, (Undergrad., Univ. of Toronto), 1206 Mackay Street, Montreal, Que.

MIDDLETON, Oliver, B.A. (Eng.) Cambridge Univ., (Undergrad., McGill Univ.), 3559 University Street, Montreal, Que.

PERLSON, Ellsworth Hartland, (Grad. R.M.C.), (Undergrad., McGill Univ.), 99 Cedar Avenue, Pointe Claire, Que.

BOOK REVIEWS

Industrial Accounting for Executives

By J. R. Bangs, Jr. McGraw-Hill Book Company, New York, 1930, buckram, 6 x 9 in., 449 pp., figs., tables, $5.00

This book deals principally with features of industrial accounting relating to the manufacturing and cost problems confronting the factory accountant, and also contains several chapters on corporate accounting dealing with the structure of balance sheets and the fundamental book entries necessary to set up typical financial transactions.

The subject of distribution of factory expense is concisely and fully covered, with particular reference to the operation of machine rates. The relationship of factory cost systems to the financial books is also explained and standard costs, the use of which are being more generally adopted, are dealt with at some length. The various methods of accounting for depreciation, obsolescence and depletion are also discussed and the advantages and disadvantages of each method set forth.

That part of the volume dealing with corporate accounting illustrates in a very simple manner the various accounts common to the majority of industrial organizations, and the book entries and principles of double-entry bookkeeping are explained by the use of chart illustrations. The preparation of a balance sheet and the explanations of fixed assets, current assets and liabilities, capital, etc., are dealt with and the procedure necessary to close the financial books of a business at the end of a fiscal period is outlined. The methods of analyzing balance sheets so as to determine the financial standing of a company are also touched upon. Other chapters deal with various phases of accounting practice of general interest.

This book can be recommended as being a presentation of the fundamentals of accounting, drawn up in a concise manner suitable for those desiring a text-book free from detailed explanations found in more comprehensive volumes on accounting practice.

K. W. Dalglish, C.A.,
General Auditor,
Northern Electric Company, Limited,
Montreal, Que.

Strength of Materials

Part I: Elementary Theory and Problems.
Part II: Advanced Theory and Problems.

By S. Timoshenko. Van Nostrand Company, New York, 1930, buckram, 6 x 9 in., 735 pp., figs., tables, Part I, $3.50, Part II, $4.50.

The preface to Part I states that "the first volume contains principally material which is usually covered in required courses of strength of materials in our engineering schools. The more advanced portions of the subject are of interest chiefly to graduate students and research engineers, and are incorporated in the second volume of the book. This contains also the new developments of practical importance in the field of strength of materials."

" .... in deriving the theory of the deflection curve, the area-moment method is used .... in discussing statically indeterminate systems, the method of superposition is applied.... For explaining combined stresses, use is made of Mohr's circle .... "

Part I contains ten chapters covering tension and compression within the elastic limit, combined stresses, torsion, stresses in beams, deflection of beams, statically indeterminate problems in bending, beams of materials which do not follow Hooke's Law and beams of two materials, stresses due to direct and bending loads, combined bending and twist, and energy of strain. An appendix deals with moments of inertia of plane areas.

Part II consists of seven chapters. Six are devoted to about fifty problems encountered in structural design and machine design. The seventh chapter discusses mechanical properties of materials.

There are an author index and a subject index to each volume.

Frequent footnotes contain references to sources (mainly European).

The preface to Part II contains the suggestion that this part may be used as a basis for three advanced courses: one for students interested in structural engineering, one for students interested in machine design, and a third in testing of materials of construction.

The author has maintained throughout the point of view of *applied* mechanics.

Topics are presented in concrete form which enables the student to appreciate in each case its applications to practical design and makes the book a valuable one for the reference shelf of the designer.

There is a good variety of practice problems without useless repetition.

R. S. L. Wilson, M.E.I.C.,
Dean, Faculty of Applied Science,
University of Alberta,
Edmonton, Alberta.

Photoelectric Cells

By N. R. Campbell and D. Ritchie. Sir Isaac Pitman & Sons, London, Eng., 1929, buckram, 5½ x 8½ in., front., figs., charts, 15/- net.

This book is a comprehensive treatise on the theory, uses and practical application of the photoelectric cell, and is written in such a way that it can be read with pleasure by any one interested in the subject. The authors have dealt with all the phases of this novel and interesting device, and have subdivided the theoretical and practical aspects in such a way as to make the book useful both as a text and as a work of reference. A considerable amount of experimental data is given which would be useful for any one engaged either in development or research. There are numerous reference to articles on allied subjects so that fundamental information dealing with almost any phase of photoelectric emission can be found very readily. There is also considerable information dealing with methods of associating photoelectric cells with such auxiliary devices as amplifiers or recording instruments.

With the advent of sound pictures and television the photoelectric cell has found a wide field and, in fact, cannot be replaced by any other device known at the present time. As yet, the average layman, like a good many engineers and physicists, has not had much occasion to delve into the technical aspects of the photoelectric cell, which will undoubtedly find application in a great many places where present needs are served by crude and inadequate devices. Electron emission from light sensitive surfaces provides a phenomenon which is ideal for effecting remote control by changes in light intensity, and a number of recording devices, other than for sound recording on films, have already found practical application. This book, therefore, comes at a very opportune time and engineers, physicists and amateurs will find in its pages a large amount of useful information.

H. J. Vennes, A.M.E.I.C.,
Transmission Engineer,
Northern Electric Company, Ltd.,
Montreal.

Kempe's Engineer's Year Book for 1930

Revised under the direction of the Editor of "The Engineer." Morgan Bros. (Publishers) Ltd., London, W.C. 2, 1930, morocco, 4¾ x 7 in., 3042-xlv pp., figs., tables, £1-11s.-6d., net.

A single volume of over three thousand pages, which is well bound, opens easily for reference, lies flat, is adequately indexed and contains a compendium of data on "civil, mechanical, electrical, marine, gas, aero, mine, and metallurgical engineering" is something of an achievement in bookmaking. Such is the 37th annual issue of "Kempe." Its principal difference from earlier editions is the omission of Section I, containing mathematical tables readily found elsewhere, and the use of the space thus saved for additional purely technical information. The work is now published under the direction of the Editor of "The Engineer," and fully maintains its high original standard.

The sources from which the information has been drawn are given in most cases, but in some instances, as for example the article on detonation in automobile and aero engines, the date of the article is not stated, though it could of course be ascertained from the reference. The selection of subjects is admirable and the book can be recommended as an excellent work of reference on almost every conceivable engineering topic.

American Railway Signaling Principles and Practices

Chapter XII: Semaphore Signals.
Chapter XIII: Light Signals.

Published by the Signal Section, American Railway Association, New York, 1930, paper cover, 6 x 8¾ in., 84 and 47 pages, respectively, figs., charts, tables, $0.25 each.

The American Railway Association Signal Section have now published two additional chapters, XII and XIII, in their series of Manuals of American Railway Signal Practice. This series was reviewed in the July number of The Engineering Journal, and, when complete, will cover all phases of American Signalling Practice. A complete list of the chapters now available is as follows:

Chapter II: Symbols, Aspects and Indications.
" V: Batteries.
" VI: Direct Current Relays.
" VII: Direct Current Track Circuits.
" VIII: Transformers.
" X: Alternating Current Relays.
" XI: Alternating Current Track Circuits.
" XII: Semaphore Signals.
" XIII: Light Signals.
" XXIII: Highway Crossing Protection.

The chapters now issued deal respectively with semaphore and light signals, and give the latest authoritative information on the equipment for these which is now standard on American railways. They are, of course, descriptive, and are fully illustrated so as to give those concerned in the use of this apparatus all necessary instructions for erection and operation.

Semaphore signalling on railways dates from 1841, when its development began in England, the mechanically operated type of semaphore having been gradually replaced by power operated signals actuated either by compressed air with electrically operated valves, or by electric motors operating on either direct or alternating current.

The obvious advantages of a signalling system having the same aspect by day or by night led to prolonged experiment on light signals of various types, and the efficient means of illumination now available have led to the development of luminous signals, lamps of sufficient brilliancy, with lenses and reflectors of proper design, making it possible to use such signals in daylight as well as at night. All the regular types of light signals are discussed, and the pamphlets form a striking illustration of the remarkable change in railway signalling methods which has taken place during the past ten years.

Like the other pamphlets in the series, the chapters now published are provided with a series of questions covering the principal topics dealt with, thus making the booklets very useful for instructional purposes.

Piping Handbook

By J. H. Walker and S. Crocker, with contributions by others. McGraw-Hill, New York, 1930, leather, 4¾ x 7¼ in., 763 pp., figs., tables, $5.00.

This volume adds another to the long list of handbooks dealing with specialized branches of engineering, its purpose being to provide authoritative and accurate information for the engineer interested in piping work. It is no mere collection of rules and tables. For example, the authors, in chapter II, have dealt briefly but adequately with such portions of the theory of the flow of fluids as are needed in the design of piping systems, and have given in chapter VII an excellent résumé of the elastic properties of straight piping and bends, giving methods for computing the expansion stresses and anchor thrusts in pipe lines. On some of the subjects treated, such as oil piping (chapter XIV), but little information has hitherto been available.

The authors have been aided by other contributors, whose assistance is duly acknowledged in connection with their specialized subjects, and free use has been made of the more recent specifications for material, valves, fittings, etc. The illustrations are numerous and clear, and include many charts and nomograms. References to authorities quoted are given throughout. There is a good index, and the volume is not too large or heavy for convenient use.

The general scope of the work is wide, covering, in addition to the topics already mentioned, such branches as the metallurgy of piping materials, the requirements due to high temperature and pressure, heating insulation, pipe supports, heating and plumbing systems for buildings, underground steam piping, piping for fire protection and water supply, and gas plant piping.

The book can be recommended as a work of reference for any engineer responsible for the design or construction of modern piping systems.

Arrol's Reinforced Concrete Reference Book

By Ernest A. Scott. E. & F. N. Spon, Ltd., London, S.W. 1, 1930, buckram, 5½ x 8½ in., 283 pp., illus., diagrs., formulae, graphs, tables, 16s. net.

Any manual summarizing the methods of calculation, and giving the specifications and tables for detail designing, which are employed in regular practice by a contracting firm of the standing of Sir William Arrol & Company, Limited, is worthy of attention. The book under review deals with reinforced concrete construction, and is a companion volume to the Bridge and Structural Engineer's Handbook, now in its second edition, embodying the same firm's practice in steel construction and issued by the same publishers. These books, of course, deal particularly with British methods and are intended to assist designers and constructors in carrying out their work; incidentally, they illustrate the firm's methods and achievements.

Section I of the Reinforced Concrete Reference Book consists of a series of photographs of typical reinforced concrete structures; Section II gives the formulae to be used for members subject to flexure; Section III deals with standard specifications and regulations; and Section IV contains a series of Tables for use in detail designing.

It is interesting to note that in Britain, with the exception of the British Standard Specifications and certain reports of the Institution of Structural Engineers, there are at present few authoritative publications regulating the use of reinforced concrete. In drawing up the volume now published the author has, therefore, consulted the most recent regulations elsewhere, covering both European and American practice, and including the building codes of New York, Chicago, and Sydney, N.S.W. Documents such as the United States Report of the Joint Committee on Standard Specifications for Concrete and Reinforced Concrete, 1924, and the Canadian Engineering Standards Association's Standard Specification for Concrete and Reinforced Concrete have also been drawn upon and those provisions selected which appear best suited to British requirements.

The volume thus contains in accessible form and reasonable compass a body of information required in reinforced concrete design. If due allowance is made for the differences in local conditions, it will be found of considerable utility as an office reference book.

Electric Light and Power*

The electric light and power industry grows faster than the population of the country. It is inevitable that the size of the industry should attract attention. Indeed, for many years, close observers have predicted that, notwithstanding great economies and public benefits, the danger which confronts the industry is that its phenomenal growth will outgrow public understanding. Yet all the canons of economics indicate that in the public utility business, consolidations and mass production are prerequisites to sound growth and low cost of service.

The policy of effecting physical interconnection of electric systems to embrace widespread geographic areas has been continuously advocated. It is basically sound and economically unassailable. The lower costs and better service which have accompanied interconnection amply justify the continuance of the policy. Without interconnection and co-ordination of the facilities by merger or through the common control by the holding company, high-grade electric service would not have been available to the small towns and villages or to the farms of the country. Reliable, abundant, and low cost power is vital to the nation's industries, communities, homes and farms. This quality of service is in turn dependent on large-scale production and on the managerial, financial and technical ability which large companies alone can command.

Large productivity, higher wages, shorter hours, better working conditions, position in world's markets and maintenance of general prosperity depend in a great measure on the application of electricity. It is doubtful if any economic or social force has exerted a more positive influence on the daily lives of so many people and certainly none has contributed more to comfort, convenience and to the fullness of life.

In the last five years:

1. The use of electricity in American homes has increased 70 per cent including that used in homes added to the systems in the period.
2. The unit price of household electricity has decreased 15 per cent, effecting an aggregate estimated saving of 230 million dollars.
3. Although the average home has increased its consumption of electricity by 27 per cent, the monthly bill has gone up but 7 per cent. Of the total expenditures made to meet living costs, those for electricity take less than 2 per cent.

Public regulation, by commissions devoting their time exclusively to this work and staffed with competent technical and legal advisers, has brought benefits to the public, and economic values to the nation. Regulation should be established on such a sound and equitable basis as to commend itself to the public served and not deny to the public utility the opportunity to earn that reasonable rate of return on the value of the facilities devoted to the service necessary to enable it to secure the additional capital needed to make the improvements and extensions requisite to provide increasingly efficient and economical service to ever-expanding territories.

The best judgment is that during the next ten years, to adequately meet the requirements of the nation, the output of electricity will have to be doubled. The benefits accruing to the whole national life—economic, industrial and social—attainable from this larger use of electricity, are beyond visualization.

It is clear that to raise the large sums of money required now and year by year, the utility companies must merit and receive the high degree of confidence which has enabled them to finance these large programmes of expansion. Investors in the business, now numbering more than three millions, have shown this confidence.

Obviously, if by unduly restrictive legislation, political abuse, or unjustifiable attacks on the utilities, public confidence is disturbed, electrical development will, as a consequence, be rendered more difficult, less economical, and wider extension will be restricted. In such a situation, the utilities will be injured beyond question, but the injury and the deprivation to the public will be infinitely greater.

**Abridged from the report of the Public Policy Committee of the National Electric Light Association. Presented at the fifty-third convention of the N.E.L.A. at San Francisco, 1930.*

Dodge Manufacturing Company, Toronto, are issuing a new publication entitled "Material Handling News," the first issue of which appeared in July of the current year. Although this is primarily an advertising medium, it is being edited and published by the company's engineering department, with the idea of putting into the hands of those interested a monthly paper on materials handling. In each issue the first two or three pages will be devoted to an article on materials handling copied from one of the leading technical or trade journals setting forth the latest developments in this field, and the remainder of the paper will contain items relating to the company's own product and its own advertising. Copies of the Material Handling News may be obtained by addressing the Dodge Manufacturing Company, Ltd., Toronto, Ont.

Graphs for Design of Reinforced Concrete Beams

(Blue Prints Available)

The graphs for the design of reinforced concrete beams, by C. G. Moon, A.M.E.I.C., published on pages 559 and 560 of The Engineering Journal for September 1930, were necessarily reproduced to a somewhat small scale. Through the kindness of the author a limited number of large scale blue prints of these, taken from the original tracings, have been placed at the disposal of members who desire them, and copies can be obtained on application to the General Secretary.

The full-size blue prints, of course, permit of much more accurate readings than is possible with the small scale reproductions.

A New Method of Gathering Peat

Peat is a valuable fuel when properly dried and handled. Methods of treating it hitherto devised have been found so expensive, however, that in many localities which contain peat deposits these are not utilized at all. Many efforts have been made to develop cheaper and more efficient methods of preparing peat for the market, but these usually require expensive machinery, or large amounts of space, or have other drawbacks which have prevented their general adoption. A method which has been recently devised and applied successfully in some large peat bogs in Russia includes features not previously used and may prove of interest in Canada. It is based on sun-drying, the only economical means of separating moisture from peat. Methods hitherto employed require the excavation of the entire depth of the bog. The wet peat is brought to the surface and spread out to dry, and after about a month, when dried to 30 or 45 per cent moisture content, is cut up and stored in piles. This treatment requires a good deal of power and labour for excavating the peat and transporting it with its high percentage of moisture; the peat prepared by these methods has so far been unable to compete effectively with other forms of fuel.

The essential feature of the Russian method consists in gathering the peat as a fine powder, which is dried out from the surface of the bog in thin layers. This drying of the peat in the open air is accelerated by its pulverization. In working a bog by this method the peat is prepared for working by draining by means of open ditches. The top layer of moss and turf is first removed, and as a rule the portion of land to be dealt with is surrounded by a deep trench, into which the water is led from a system of drains covering the area to be worked. The prepared bed of peat is cut up on the surface by a suitable tractor-driven cutter to a depth of about four inches, and this milling is done on alternate strips about seven feet in width. Care must be taken to avoid the danger of breaking the cutter on stumps. After cutting the milled peat is piled on the strips left unmilled for that purpose, forming pointed rows in the centre of the strip. Under the action of the sun and wind, the peat is quickly dried on the surface of the rows. The dried part is raked off to the depth to which it has dried and piled in two new rows on the sides of the original row. The uncovered wet peat in the original hill then continues drying, and during the working day the removal of layers is repeated many times. When completed the dried peat is piled in cone-shaped heaps. If necessary the peat in these heaps can be subjected to further drying by means of repeated removing of dried peat layers. This process takes about four days in favourable weather, and ten days in bad weather, and the finished peat has a moisture content of from 25 to 50 per cent.

This process, known as the Korelin method from the name of its patentee, has been employed in the United Soviet States of Russia on a large scale and the cost is stated to have been only about half that of peat prepared by the older processes.

The milled peat is not briquetted or compacted, but is burned in special furnaces like those for pulverized coal. Briquettes can, however, be prepared from it at a very low cost.

Additional information regarding this development may be obtained from the Amtorg Trading Corporation, New York City, the American representatives of the new Russian industrial developments.

The North York Hydro-Electric Commission have recently completed a test panel for the accurate and convenient testing of all types of watthour meters.

Variations of current on ¼ ampere steps to 10 amperes may be obtained either direct through the meter under test or through the primary of the step-up loading transformer.

For testing 3-wire meters, a three-pole double-throw switch transfers the load from one series coil to the other and at the same time retains line-side connection for the potential coil.

A 0-110/220/550 volt auto-transformer furnishes voltage for meters of various ratings. Convenient terminals for connecting a rotating standard are provided. Two hanger straps support a small front panel upon which the meter under test is placed. These can be seen in the photograph and serve to keep the meter away from stray fields and within convenient distance of the operator. Leads to the meter are flexible and weighted below like those on a telephone switchboard, keeping them out of the way when not in use.

A separate test rack provides for ten meters under dial test.

An adjunct to the panel is a small air compressor and trigger nozzle which facilitates removal of dust from working parts of the meter.

BRANCH NEWS

Cape Breton Branch

S. C. Mifflen, M.E.I.C., Secretary-Treasurer.
Louis Frost, Branch Affiliate, Branch News Editor.

The Cape Breton Branch of The Institute staged a very successful picnic on September 9th. The arrangements for the outing, the first of its kind attempted in Cape Breton and somewhat in the nature of an experiment, were under the capable direction of the past-president of the Branch, Mayor Michael Dwyer, of Sydney Mines.

The largely attended party of members and their ladies congregated in Sydney, whence they proceeded to Mira Ferry, where a delightful afternoon was spent in games. Toward evening the company gathered around an old fashioned campfire where all joined in a happy singsong and in story telling, the ladies enhancing the happy occasion by serving a delicious luncheon.

The outing concluded with a dance at the Mira Ferry pavilion, which continued until a late hour, those present having a very enjoyable time.

Hamilton Branch

John R. Dunbar, A.M.E.I.C., Secretary-Treasurer.
J. A. M. Galilee, Affiliate E.I.C., Branch News Editor.

EXECUTIVE MEETING, AUGUST 27TH.

A luncheon executive meeting was held on Wednesday, August 27th, at the Wentworth Arms hotel, to arrange for the opening meeting of the Branch in September. A. J. Grant, M.E.I.C., having promised to address the Branch on Institute affairs for the first meeting, it was decided to hold it in the Royal Connaught hotel on September 11th.

It was further decided to instruct the Secretary to get in touch with the A.S.M.E., Ontario Section, to see if a joint meeting of that body and The Institute Branch might be arranged.

Including the chairman, there were six present.

OPENING MEETING, SEPTEMBER 11TH

The first meeting of the 1930-31 season of the Hamilton Branch was held in the grill room of the Royal Connaught hotel. It was a happy thought that the President of The Institute, A. J. Grant, M.E.I.C., should be the speaker for this opening meeting and that there should be such a good turn out of members from the Niagara Peninsula Branch. During the evening Mr. Anderson sang. Those seated at the head table were Messrs. W. F. McLaren, M.E.I.C., A. J. Grant, M.E.I.C., E. G. Cameron, A.M.E.I.C., R. K. Palmer, M.E.I.C., E. H. Darling, M.E.I.C., F. L. Haviland, M.E.I.C., C. G. Moon, A.M.E.I.C., H. A. Lumsden, M.E.I.C., J. K. Davidson, Jr.E.I.C., and W. L. McFaul, M.E.I.C.

Mr. Palmer, who had to leave early, spoke in favour of the Hamilton resolution.

"That section 5 of the By-laws be deleted:

Section 32 delete "Affiliates $10.00" and add "Affiliates" to last sentence.

That section 34 read as follows:—

The annual fees shall be as follows:—

		If paid on or before Mar. 31st.
Members	$13.00	$12.00
Associate Members		
First 10 years	11.00	10.00
After 10 years	13.00	12.00
Juniors	7.00	6.00
Students	2.00	1.00
Affiliates	9.C0	8.00

That the first paragraph of section 56 be deleted and the following substituted:—

The secretary of The Institute shall each year remit to each branch an allowance of $150.00 and in addition a rebate of 10% of the annual fees, current or arrears, received from the members of that branch during the year, payments being made quarterly.

That copies of this resolution be forwarded to headquarters and to each Branch."

THE FUTURE OF THE INSTITUTE AND HOW TO IMPROVE FINANCES AND INCREASE MEMBERSHIP

Mr. McLaren, in introducing the speaker, thanked the members for honouring him by electing him chairman of the Hamilton Branch.

Mr. Grant, whose subject was "The Future of The Institute and How to Improve Finances and Increase Membership," expressed himself as being not only pleased to be present at Hamilton, but that he was fulfilling a duty by being present. The more exchanges that take place among the branches, as exemplified by the presence of the Niagara Peninsula Branch, the better it would be for The Institute at large.

He then proceeded to outline some of the points that are to be discussed at the forthcoming Plenary Meeting of Council. The primary question is—Increased membership is necessary or else the subscriptions will have to be increased. The source of revenue is from the members alone. The fees, in comparison with those of other societies, are extremely small. The council, however, is on the horns of a dilemma because the members have been canvassed twice, and on the last occasion only 946 members voted out of about 3,300 who were eligible, the ayes getting 627 votes, the nays 319. The motion was therefore lost by 4 votes which were necessary to obtain a two-thirds majority. This small interest was disappointing to the council. However, Mr. Grant was emphatic in his statement that by some means or other, revenues must be increased.

One solution of the problem of increased revenues is by increasing the membership. There are eight separate professional associations with standings varying in quality; their members should be members also of The Engineering Institute of Canada.

One of the points to be brought up at the Plenary Meeting of Council is the question of the formation of professional sections. The two sections proposed are, Aeronautical and Radio. In Ottawa alone there are 10 aeronautical and 25 radio men eligible for membership. These men at the present time are members of foreign societies. They would obtain the same facilities that they now enjoy if these sections were incorporated. It is estimated that there is a strong potential membership available in the personnel of aeronautical and radio companies throughout the Dominion.

Mr. Grant then went on to discuss some of the proposed financial changes, that the grade of Branch Non-Resident be abolished and that the Associate Members should pay the same as the Members. He urged that very serious consideration be given to this point, as, in his opinion, a decrease in membership would inevitably follow. His own opinion was that there should be no category of Members.

The question of size of the Journal was touched on as well as the advisability of publishing Transactions.

The chairman in thanking the President for his analysis of the situation concurred that increased membership is a necessity. He stated that the Hamilton Branch were of the opinion that the Journal should be kept the same size.

The meeting was then thrown open for discussion, a synopsis of which follows:—

Mr. McFaul. The confederation of the professional societies and The Engineering Institute of Canada is absolutely essential. Data should be completed showing how many members of the one are members of the other. The Institute members should use their influence to push forward this confederation.

Mr. Grant. The basis of confederation is to arrive at a uniformity of qualification of members.

Mr. McGill. We should pay someone to go after new members. Many did not realize the benefits of membership.

Mr. Lumsden. Something must be wrong when a man who is an engineer is not interested in The Institute. The whole question of grade is complicated, and often a man would prefer to drop out when a question of transfer was brought up.

Mr. Moon (St. Catharines). In the old days of the Canadian Society of Civil Engineers, the idea of the society was to select the membership and when the public engaged any civil engineer, the work was guaranteed. Mr. Busfield's classification of the function of the professional societies as protectors of the public and The Engineering Institute of Canada as being interested in the education of the engineer, is a good one. No examinations should be held for entrance of middle aged men. If a man can earn his living by his professional work, he should be eligible for membership.

Chairman. If we are to increase membership we should widen the scope and take more of this class.

Mr. Cameron. Thanked the Hamilton Branch for their hospitality and hoped that more inter-Branch meetings would be held. The individual members should be the logical men to impress membership on others. The confederation of The Institute and the professional societies is desirable. Mr. Adams' committee was going to recommend that no action be taken re change in size of the Journal, that the Transactions be issued in the 9 inch by 12 inch size. He presented a very strong argument for the 6 inch by 9 inch size showing exhibits carefully prepared that had been submitted to Mr. Adams' committee.

Mr. Darling. There are other points not touched on by Mr. Cameron which should receive consideration.

Chairman. Recommended that a straw vote be taken, and out of a show of nine hands, eight expressed an opinion that the size should be 6 inch by 9 inch, and one 9 inch by 12 inch. Forty members were present.

The discussion then became very general, the opinion of the meeting fairly generally came to the following conclusion:

That, waiving all financial questions, the size of the publication should be 6 inch by 9 inch, provided that the papers were so arranged that they could be taken out by the members and either filed or bound separately. The Transactions then would be unnecessary.

Mr. Lumsden. Paid a tribute to Mr. Cameron and complimented him on the splendid work he had done in studying the question of Journal size. He stated that the Hamilton Branch was honoured by the presence of so great an engineer as Mr. A. J. Grant.

Mr. Darling then proceeded to enumerate what he considered to be the feelings of the Hamilton Branch, to be presented at the Plenary Meeting of Council, under the following headings:

Transfer Fee
Provincial Professional Societies
Rebate System
Publications.

It was decided to get the requisite number of signatures of corporate members on the Hamilton resolution in time for submission to council before October 1st.

The meeting then adjourned with the singing of "Auld Lang Syne."

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

By kind permission of the Minister of National Defence, members of The Engineering Institute were given an opportunity of visiting the British dirigible R 100 at the St. Hubert Airport on August 7th.

A special train was run by the Canadian National Railways from their Guy street station and approximately 250 members took advantage of this opportunity of seeing the great airship at close range.

Every courtesy was extended by the officials in charge at the mooring mast and as a result of this it was possible for practically all of the party to inspect the interior of the ship. An electric elevator carried the passengers to the top of the mast and access to the gangway was had by means of an ingenious revolving platform carrying flights of steps. From the opening in the nose a long suspended gangway led to the living accommodation amidships. This consisted of a combined dining room and lounge surrounded by a gallery. Opening off this were the cabins for passengers and officers and on the outside of the cabins were observation verandas and sun-rooms commanding a view of the country beneath, through large windows in the outside fabric of the ship. The crew's quarters were directly forward of the general accommodation and a second gangway led to the stern of the ship and the three engine room gondolas. The control cabin was directly below the living quarters but as members of the crew were on duty there at all times, it was not possible for any of the visitors to enter and inspect it.

Taken all round, the trip was an extremely interesting one and it was very gratifying that so many members were able to avail themselves of their opportunity.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.

A joint meeting with the Hamilton Branch was held on September 11th to discuss certain business matters connected with The Institute.

About twelve members of the Niagara Branch motored to Hamilton and enjoyed dinner at the Connaught hotel after which the discussion blazed into full force.

The principal subjects to be dealt with were three, namely, a proposed amendment to the By-laws revising fees, another proposed amendment dealing with rebates to Branches, and a proposal by the Niagara Branch to reduce the size of the Journal and make it available for loose leaf binding, or the issuance of transactions.

President A. J. Grant, M.E.I.C., opened the meeting with a review of some of the activities during the past year. He deplored the fact that the increase in fees had been lost by such a narrow margin but stated that The Institute would carry on and retrieve the financial condition by certain retrenchments combined with a determined drive to interest and obtain new members. Regarding the Hamilton proposed amendments he thought the Branches to be the greatest contributing factor to the present success of The Institute and a revision of the rebate system might very well be given serious consideration. The other proposal to alter the scale of fees for different grades however was complicated by the fact that the present grading was not acceptable to many members. The proposal to charge heavier fees to Associate Members of more than ten years standing might result in numerous resignations unless they were given the grade of Member. It is a question as to whether or not The Engineering Institute should have only one grade of membership in a manner similar to that of the medical or legal professions.

There followed a lively discussion participated in by Messrs. W. F. McLaren, M.E.I.C., chairman, L. W. Gill, M.E.I.C., H. A. Lumsden, M.E.I.C., W. L. McFaul, M.E.I.C., H. B. Stuart, A.M.E.I.C., and others. Many phases of Institute affairs were covered and many good suggestions were advanced for improvement. It appeared to be the general impression that energetic, perhaps even radical, measures were desirable in order to arouse the seeming lethargy of the membership. One note stood out rather prominently in some of the speeches indicating that Hamilton Branch opinion was strongly against any change in the size of the Journal as it would surely jeopardize the financial status of that publication.

E. G. Cameron, A.M.E.I.C., felt that this opinion should not go unchallenged and asked for the protection of the chair while he endeavoured to illustrate some of the high lights on the other side of the picture. In a very able manner he pointed out that the publications of an Institute were more important than any other single activity. They were the tangible evidence that The Institute was giving something in return for the yearly fee and upon their popularity or utility depended much of the good will of the membership. The monthly Journal is a very valuable publication and a great step ahead of the older system of advance pamphlets and transactions. If however it could be improved in such a manner as to simplify the filing of individual papers and at the same time enable Transactions to be printed for permanent record, or for sale, then why hesitate? The question of cost was important but not so important as utility. Too much stress had been laid upon giving service to the advertisers rather than upon giving service to the membership. As a matter of fact the latest advice from Mr. Adams' committee was to the effect that it would cost no more to print the Journal in the small size than in the large size and no concrete evidence had so far been presented that the revenue from advertising, after the initial adjustment, would be any less than it is at present.

At the conclusion of Mr. Cameron's speech the chairman remarked that the Hamilton Branch had voted upon this question last spring but they were then distinctly under the impression that such a change would dislocate the finances of The Institute. The question was to come up at the nearby Plenary Meeting and he was sure that Councillor Darling would like to be instructed as to the feeling of the members present. A show of hands was then asked for and the majority shown were in favour of the Niagara proposals—one vote alone was cast in favour of keeping to the present size of the Journal. E. H. Darling, M.E.I.C., Councillor for the Hamilton Branch, thanked the members for this expression of their opinion and stated that he had no pessimism as to the future of The Institute when he noted the remarkable interest which was indicated by the discussion during the evening. In connection with the proposals to confederate or affiliate with the provincial organizations, which had been mentioned by Mr. McFaul and other speakers, he wished to point out this difference: the Provincial Associations had no power to debar any man if he could pass the qualifying tests whereas The Institute still retained that power when an applicant was deemed undesirable for any reason. This is a very valuable safeguard in preserving the integrity and high standing of its membership.

A total of forty were present.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

ELECTRICAL ENGINEER, with experience in sales, manufacturing and advertising, with company selling to railways and general industrials. Apply giving full experience to Box No. 613-V.

INDUSTRIAL ENGINEER, qualified to reorganize a factory employing 500 to 1,000 operators, manufacturing electrical and radio apparatus in a modern, efficient manner and to direct its activities for most economical results; who possesses initiative and the ability to direct employees. Application must state complete qualifications, including history, education, and salary expected. Apply to Box No. 620-V.

ARCHITECTURAL DRAUGHTSMAN, capable of getting out details and experienced in the design of fireproof buildings. Must be thoroughly experienced and able to take charge of a small drawing office. Apply to Box No. 621-V.

CHEMICAL ENGINEER. A pulp and paper mill in the province of Quebec has an opening for an assistant chemical engineer. Must be a graduate and have some experience in pulp and paper mill work. Good opening for right party. Apply to Box No. 623-V.

PLANT ENGINEER, experience in plant maintenance and construction, not over 35 years, for an industrial company in Montreal. Apply to Box No. 624-V.

MECHANICAL ENGINEER, recent graduate, for large pulp and paper mill in the province of Quebec. Will be required to do draughting and design in connection with the maintenance of mill equipment and alterations. Experience in pulp and paper mills not essential. Apply to Box No. 627-V.

Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., married, desires employment with manufacturer of industrial products, selling to industrial and other markets. His experience includes engineering and building construction, administration and operation of utilities, municipal works, etc. Record of integrity; moderate salary; location immaterial. Apply to Box No. 14-W.

CIVIL ENGINEER, A.M.E.I.C., experience: highways, railways, drainage projects, stream diversion, earth, timber and concrete dams, laying large and small pipe, timber structures, concrete walls and pavements. Location, construction or maintenance. Desires position as engineer or superintendent. Location immaterial. Apply to Box No. 34-W.

ELECTRICAL ENGINEER, B.Sc. (McGill '26), Can. Gen. Elec. Co. test course, with experience in testing and maintenance. Apply to Box No. 39-W.

ELECTRICAL ENGINEER seeks connection with Montreal engineer or architect for part time work involving the design and specification for industrial and public buildings. Experienced and capable of complete responsibility. Apply to Box No. 40-W.

CIVIL AND MECHANICAL ENGINEER; aggressive, practical engineer, with background of experience in design, construction, maintenance and operation of pulp and paper mills. Especially qualified to reduce mill costs. Apply to Box No. 53-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Apply to Box No. 107-W.

COLLEGE GRADUATE, age 34, with over ten years experience in power developments and pulp and paper mill construction and maintenance, largely in direct charge of design or construction; desires new connection as chief or assistant engineer or construction superintendent. Apply to Box No. 167-W.

CIVIL ENGINEER, B.Sc. (McGill), M.E.I.C., P.E.Q. and B.C., with broad experience in hydro-electric power investigations, studies and exploration of forest lands, including design and construction driving and storage dams, wharves, flumes, piers and booms and loading plants, as well as general engineering and contracting, is open for engagement. Location immaterial. Now engaged but available on short notice as projects are nearing completion. Speak French fluently, physically fit, active and energetic, and can get results. References can be furnished if required. Apply to Box No. 177-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., R.P.E. Ont., with twenty-four years experience embracing dams, wharves, grain elevators, foundations, pile driving, highways, municipal engineering, water power surveys, road locations, inspections and estimating is open for engagement as engineer or superintendent in construction, operation or maintenance. Location immaterial. Apply to Box No. 358-W.

CIVIL ENGINEER, A.M.E.I.C., university graduate, O.L.S., married, twenty years experience city surveys, calculations for curved surveys, design, layout and supervision, sidewalks, pavements, sewers and water systems. Acted in capacity of chief engineer for large engineering and surveying firm for five years. Best of references. Available on short notice. Apply to Box No. 413-W.

CIVIL ENGINEER, S.E.I.C., 1930 graduate of Nova Scotia Tech. with experience as plane table topographer, instrumentman and draughtsman and particularly interested in hydro-electric power development and reinforced concrete design, desires position. Willing to go to foreign fields. Available at a few weeks notice. Apply to Box No. 431-W.

SALES ENGINEER, B.Sc. (McGill, 1914), A.M.E.I.C., 37, married, presently employed in position of responsibility, desires to communicate with a prominent railway equipment supply house, with a view to becoming its Pacific Coast representative. Has a complete knowledge of railway locomotive equipment particularly. Excellent references can be furnished. Apply to Box No. 444-W.

ELECTRICAL ENGINEER, McGill graduate. Thoroughly experienced in the sale of mechanical and electrical industrial equipment. Has carried responsibility and prepared publicity campaigns and technical studies. Commands both French and English and can handle French-Canadian clientele. Available at short notice. Go anywhere. Single. Apply to Box No. 457-W.

ELECTRICAL ENGINEER, graduate '26, University of Manitoba, Canadian General Electric test course; also three years as assistant to industrial control engineer. Available for a position at once. Apply to Box No. 462-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (McGill Univ. '27), age 26. Fifteen months outside plant engineering with large public utility. Twenty months sales engineering experience with electrical manufacturing company. Available on reasonable notice. Apply to Box No. 463-W.

ELECTRICAL ENGINEER, B.Sc. (McGill), Jr.E.I.C., age 28, graduate Canadian General Electric Company, test course, with two years experience in the design of induction motors and direct current machines. Previous experience includes electrical installation in large paper mill, and assistant to engineer in charge of small utilities company. Married. Location immaterial. Apply to Box No. 466-W.

CIVIL ENGINEER, experienced in road construction, mine surveying, transmission line survey and construction; paper mill construction; age 27. Available on short notice. Apply to Box No. 468-W.

Preliminary Notice

of Applications for Admission and for Transfer

September 19th, 1930

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in November 1930.

R. J. Durley, *Secretary.*

* The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

DENMARK—DONALD ERNEST, of 983 Jessie Ave., Winnipeg, Man., Born at Montreal, Aug. 29th, 1897; Educ., Matric. in Arts, Univ. of Man., 1914; D.L.S., 1926; Man. L.S., 1927; 1920-22, chainman and instr'man. on subdivision and baseline surveys; 1923-26, control traverse surveys as articled pupil, Topog'l. Surveys Branch, Dept. of the Interior, Ottawa; 1926 to date, with McColl Bros., Surveyors and Engineers, Winnipeg, as follows: 1926-27, location and survey of Great Falls-Central Manitoba Mines, transmission line; 1927-28, reconnaissance work and prelim. surveys in connection with Seven Sisters power development; 1928, location and survey of Manitoba Eastern Railway; (1929, location and survey of Seven Falls-Winnipeg transmission line, City of Winnipeg Hydro); 1929-30, location and survey of Seven Sisters-Winnipeg transmission line; also various land, road and drainage surveys in connection with municipal work.

The Tanna Tunnel in Japan

The long-expected completion of the Tanna tunnel of the Japanese Government Railways has been further delayed by an accident that happened towards the end of June, when there was a cave-in and a great inburst of water. The engineers estimate that the accident will cause a delay of nine months, which means that it will be three years—the official estimate—before this difficult piece of engineering work is completed.

Work on the tunnel was commenced in April 1918. Difficulties were anticipated, owing to the geological conditions known and suspected, but it is doubtful if the great enterprise would have been started had the true characteristics of the area been fully known. However, it would not be fair to say that the Tanna tunnel, as was said of the Simplon, is the grave of the geologist's reputation, for opposition was heard from more than one source before the work was begun, but the obvious economic advantage of the new route was probably a greater incentive to action than the assurances of men learned in the nature of this volcanic land. In the years intervening since 1918 several serious accidents entailing heavy loss of life have occurred, but in the most recent mishap, owing to the experience gained, there were no casualties of any sort.

The object of this cut-off, which is known as the Atami line, after the famous hot spring at the eastern portal of the tunnel, is to avoid the tortuous 37 miles in the many-tunnelled section between Kozu and Numazu, which was completed in 1889. It is worthy of note that the highest point on this section, at Gotemba station, is 1,240 feet above sea level, while the highest point on the cut-off, near Atami, is only 259 feet. In other words, the train rises 1,200 feet in the short run of 18 miles from Kozu at the seaside to Gotemba, and descends 19 miles to Namadzu, also a seaside town. Therefore, there is every inducement from an economic point of view for abandoning the old route, which is, moreover, 7 miles longer than the new one.

The traffic capacity of the Kozu-Numazu section will be increased threefold by th new cut-off, the limited express will save 30 minutes, and the railways in the course of a year will save many thousands of yen, represented by coal bills and wear and tear. This is held to justify the expenditure of over seven million sterling on 30 miles of double track, with several stations and one great tunnel. The cost of the atter is estimated at £2,600,000.

A general description of the terrain through which the tunnel is bored has been published by the director of the Bureau of Construction, Railway Department, Japan, who points out that the difficulties encountered are due to a combination of three bad conditions, "many faults, great inflow of water and soltafaric clay of bad composition."

The accident in June was due to the tapping of a huge interior reservoir. The cave-in occurred at a point 11,980 feet from the western portal, and water and mud rushed out at a rate estimated at 45 cubic feet per second, the mass of detritus blocking the tunnel being estimated at 4,000 cubic yards. The torrent was brought under control and many tons of cement injected into the area to solidify it, after which the work of excavation proceeded. The existence of this reservoir was ascertained in 1926, when a boring was made, and at a depth of 80 feet water was encountered which spurted 40 feet into the air. At this point the tunnel was to run 600 feet below the surface, and the drillers striking a great transverse fault crossing the main island of Japan at this point, running south-north coming from the bay of Sagami and entering the sea of Japan, tapped the subterranean lake. Between four and five thousand feet now separate the heads of the excavations from the eastern and western portals, but the engineers in charge are confident that the worst obstacles have been encountered and overcome.

—*The Engineer.*

The Horton Steel Works, Limited of Bridgeburg, Ontario, has acquired from the Canadian Barking Drum Company, Limited the rights to sell and serve, as well as to manufacture, U-BAR barking drums and accessory equipment. Formerly, the Horton Steel Works, Limited handled only the fabrication of the equipment.

The Sao Paulo-Parana Railway Company

In April 1930 the section of the Sao Paulo-Parana Railway from Cambara to Inga was opened to traffic by the representative of the president of Parana. Much progress has been made by the railway company since 1928, at which time the railhead was at Cambara Km. 29, and one could only travel west of that point by road, ferrying across the Cinzas and Laranginha rivers. This year there is a solid railway bridge over the Cinzas river and the railhead has reached Bandeirantes, Km. 82.

The contractors on the work are Messrs. Macdonald, Gibbs and Company (Engineers) Ltd. of which Lieut. Colonel A. C. Macdonald, M.E.I.C., is managing director. Captain C. B. R. Macdonald, M.E.I.C., is in charge of the survey and construction of the project in question.

The railway is well sited and solidly built. Construction of the 96 kilometres to Km. 125 is due for completion by the end of this year, and it seems clear that it will be completed about three months ahead of time, and for a figure which will show some saving on the estimates. Km. 125 is on the top of the ridge between the Laranginha and the Congonhas rivers, which is the highest ridge the railway has to cross. In the next section of 61 kilometres from this point to Jatahy, and particularly on the descent to the Congonhas river, the work will inevitably be heavier and the cost of construction per kilometre will be higher than in the sections so far constructed. No pains have been spared by Macdonald, Gibbs and Company in the study of alternative routes for this section, and some modifications have resulted from recent surveys which will effect some slight reduction of cost.

Frost Heaving

A recent paper on the "Freezing and Thawing of Soils as Factors in the Destruction of Road Pavements,"* by Stephen Taber, Professor of Geology, University of South Carolina, draws attention to the information now available on this subject as a result of considerable experimentation by the author and others.

Soils, when frozen under natural conditions, generally behave as open systems with respect to water. The extent of heaving may be either greater or less than that encountered when freezing occurs in a closed system. Some soils, under certain conditions, freeze with no appreciable uplift of the surface, while others give uplifts as great as 60 per cent of the depth of freezing. Soils that are very impermeable because of high colloid content behave in laboratory tests essentially as closed systems. These include certain muck and gumbo soils, and soils containing bentonite.

Laboratory experiments show that excessive heaving is always accompanied by the segregation of ice in layers or lenses. Similar segregations have been observed when excavations were made in badly heaved ground. The factors which chiefly affect ice segregation are texture of soil, composition of soil, supply of water, rate of removal of heat, and surface load.

Various measures are suggested for the elimination or reduction of damage due to ground freezing, thawing, and alternate freezing and thawing. Proper drainage is always essential. Placing a thick layer of coarse material under the pavement, extending to the extreme depth of ground freezing, is an effective but expensive method. Addition of sand to the subgrade will prevent ice segregation. Uniformity of texture in subgrade soils is essential to the avoidance of differential heaving.

Extensive research in the problems of ground freezing is recommended.

*Published in "Public Roads," Vol. II, No. 6.

Gypsum, Lime and Alabastine, Canada, Ltd., announces the appointment of Robert S. Wright as European representative of the company with headquarters in London, England, where he will be particularly concerned with acoustical and insulation engineering in connection with the uses of the Canadian building materials on British and European construction projects.

Increase of Steam Power Facilities of The New Brunswick Power Company

John D. Garey, A.M.E.I.C.,

Chief Engineer, New Brunswick Power Company, Saint John, N.B.

Paper read before the Saint John Branch of The Engineering Institute of Canada, December 12th, 1929.

In 1928 the old steam power plant of the New Brunswick Power Company at Saint John, New Brunswick, had become inadequate for its increasing load, and inefficient according to modern standards. It had grown in size to fill entirely a long narrow block between city streets, (figure No. 1), so that the usual procedure of adding a new turbine and boiler could not be followed. The equivalent of a new plant with greater capacity, reduced operating labour and costs, and freedom for expansion was needed.

The above were the principal elements in the situation. In addition, it was desired that plans for securing more power should make use of the old building but keep the new equipment entirely free of dependence on the old, should avoid any possible interference with continuous reliable operation of the full capacity of the old station during the construction period, and should permit future reconstruction under the same conditions.

The engine room of the old station was situated between two boiler rooms, one containing old hand-fired boilers and the other somewhat newer stoker-fired boilers. This required a considerable operating force and restricted the purchase of coals to those which could be burned on the stokers with reasonable efficiency at the rating required by the station load. The old engine room contained engines and turbines of a total capacity of 3,700 kw. alternating current and 650 kw. direct current, 600 volts, and about 1,200 kw. in motor generator sets for railway and elevator service. It was desired that the new equipment should be suitable for operation by a minimum number of men and with any coal which might be economically available, and that the operating force should be able to ascertain readily that the high efficiency of the new equipment is continually maintained.

A considerable reduction in first cost and operating costs could be obtained by the installation of a relatively large new turbine and boiler unit. Since the old plant would be kept in reserve, dependence on a single unit would not unduly jeopardize continuous power supply until considerable increase in load had taken place. The new unit must not be much larger than needed for the near future, partly to avoid idle investment, but principally because it would unduly postpone the installation of a second unit, which should preferably be a duplicate, until the load had grown so large that failure of the first unit would overload the reserve equipment in the original engine room. It was also desirable that the second installation should not encroach too much on the space devoted to the railway equipment, which would involve a material expenditure for its relocation.

Studies indicated that a turbine with maximum rating of 7,500 kw. and a boiler of equal capacity would meet these conditions. The length required would be just about equal to that of the older (hand-fired) boiler room. By omitting the usual division wall between the boiler and turbine and placing the firing side of the boiler toward the turbine, the entire equipment, including the necessary auxiliaries to give high efficiency and convenient operation, could be placed within the limits of the narrow building. This compact arrangement also furthered the plan to reduce operating labour to a minimum by making all apparatus accessible, visible, and largely controllable from a central point. Figure No. 2 shows the relative locations of the equipment and figure No. 3 shows a cross-sectional elevation. The new layout forms the beginning of a single row of turbines and a single row of boilers, which may be extended into the old section as the load grows.

The day-by-day performance of the completed new equipment is shown in figure No. 4. The solid straight line is the "Parsons line." To obtain this the weights of coal burned for each of 121 consecutive 24-hour days, including Sundays, between December 10, 1929, and April 9, 1930, were plotted against the kilowatt-hours generated each day. During this time the daily average circulating water inlet temperature was 40 degrees F. or below. Above this temperature the effect of reduced vacuum in increasing the coal consumption is noticeable. Each point shows the operation for one day. The outputs were divided into groups of 40,000-50,000 kw.hrs., 50,000-60,000 kw.hrs., etc., and the straight line was drawn through the circles representing the averages of these groups. Since the daily generated output did not fall below about 40,000 kw. hrs., a point at about 27,000 was obtained by the summation of a number of low-load night periods, to assist in fixing the position of the lower part of the line. The curve of b.t.u. per kilowatt-hour was calculated from the Parsons line. Both are plotted against generated, rather than distributed kilowatt-hours, because it has been impossible so far to separate the auxiliary power for the new plant

Figure No. 1.—Steam Power Plant of the New Brunswick Power Company at Saint John, N.B.

from that for the old. Indications are that the energy used for auxiliaries in the new plant ranges from about 9 per cent at monthly capacity factor of 50 per cent, to 7 per cent at 80 per cent capacity factor.

As most of the old hand-fired boilers were in use, it was necessary to start the new work by the installation of the boiler and put it into operation before the remaining old boilers could be removed from the place where the turbine would stand. The only changes in the building consisted of deepening the basement. The stack for the old hand-fired boilers is outside the limits of the new work and is used for the new boiler until a second new boiler is put in.

The old circulating water pump-pit, because of the tide range of about 28 feet, was situated outside the building line under the street toward the harbour, its floor being below low tide level. It remains unchanged except for the replacement of the old pumps with units of larger capacity.

Circulating water for both the new and old parts of the plant is obtained through a concrete intake tower standing in the harbour about 450 feet from the power plant. The large and rapid change in tide level necessitated special methods of construction for this intake. After driving and cutting off piles for a foundation at the tower site, a timber mat was suspended from two derrick boats until sufficient concrete was added so that when landed on these piles, the concrete was above low tide level. Divers were used in subsequent form work and in placing the 42-inch intake pipes.

Trash racks are used at present, but provision is made for the later installation of revolving screens, should future harbour water conditions cause rapid plugging of the condenser tubes. The two 42-inch pipes from the new intake to the old intake, and the concrete tunnels from the old intake to the pump-pit are entirely submerged at extreme low tide level and there is no lift on the pumps.

On the discharge side of the condenser the circulating water passes through a 30-inch cast iron line, running through a concrete tunnel from the turbine basement to the dock, a distance of about 275 feet. At this point it drops vertically into the harbour and ends in a bend with the outlet facing up at an elevation 11 feet above extreme low water. This provides a seal and maintains a siphon on the outlet line, reducing the head on the circulating pumps. The circulating pumps are driven by variable speed motors, maximum speed being used to develop a total head of 58 feet for the condensers in the old plant and to lift the water to the highest point of the circulating water system. After the discharge pipe is filled, the siphon is, of course, established, decreasing the head and permitting the pumps to run at a lower speed.

In fixing the elevation of the basement floor it was desired to reduce as much as possible the amount of excavation, all of which was in rock, because of difficulty with seepage into it, the necessity for waterproofing, and uplift forces at high tide. The deepest excavation was therefore confined to the small area beneath the boiler ash-pit required for feeding the ash into the steam jet vacuum conveyor. This method of ash removal was very well adapted to the conditions because of the small space required. The ash passes directly into the conveyor through gates in the bottom of the ash-pit, preventing the escape of any dust.

The old building was reconditioned and concrete basement walls were carried up to the street level, with pilasters for the crane columns. A large door at the end of the building opens onto a platform within reach of the crane. The space between the turbine platform and the boiler firing floor gives the crane access to equipment in the basement. The compactness of the new layout is indicated by the building volume required for the complete new equipment, 34 cubic feet per kilowatt of capacity.

The Nova Scotia coals usually ignite easily and give an ash containing considerable iron. These characteristics pointed to the desirability of a furnace largely water-cooled. Fin tubes were therefore provided on rear and side walls and arch, and two rows of plain tubes on 12-inch centres in each row, across the ash-pit. At an output of 90,000 pounds of steam per hour the rate of heat release is 18,500 b.t.u. per cubic foot. During a year's use of the boiler this furnace, with only one brick wall exposed to the flame, has required no attention.

The boiler is designed for operation at 448 pounds drum pressure and 250 degrees superheat. It is fired by two horizontal, turbulent short-flame burners using primary air at a maximum pressure of 4 inches, and secondary air at 480 degrees F. and 7 inches maximum, the latter supplied through a duct passing around the side and across the front of the boiler. Because of the very rapid ignition of the coal used, it was found necessary to make several minor burner changes and adjustments with the result that the flame from the two burners now fills the furnace very well at maximum load, without impinging sharply on the furnace walls. Figure No. 5 shows the modified burner. A small accumulation of friable ash on the ash-pit screen-tubes against the rear wall occurs under sustained heavy load, but otherwise the furnace remains quite clean

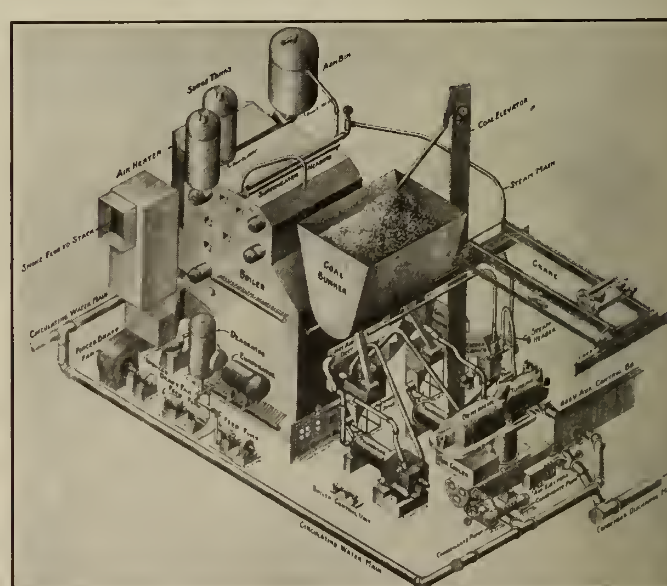

Figure No. 2.—General arrangement of plant.

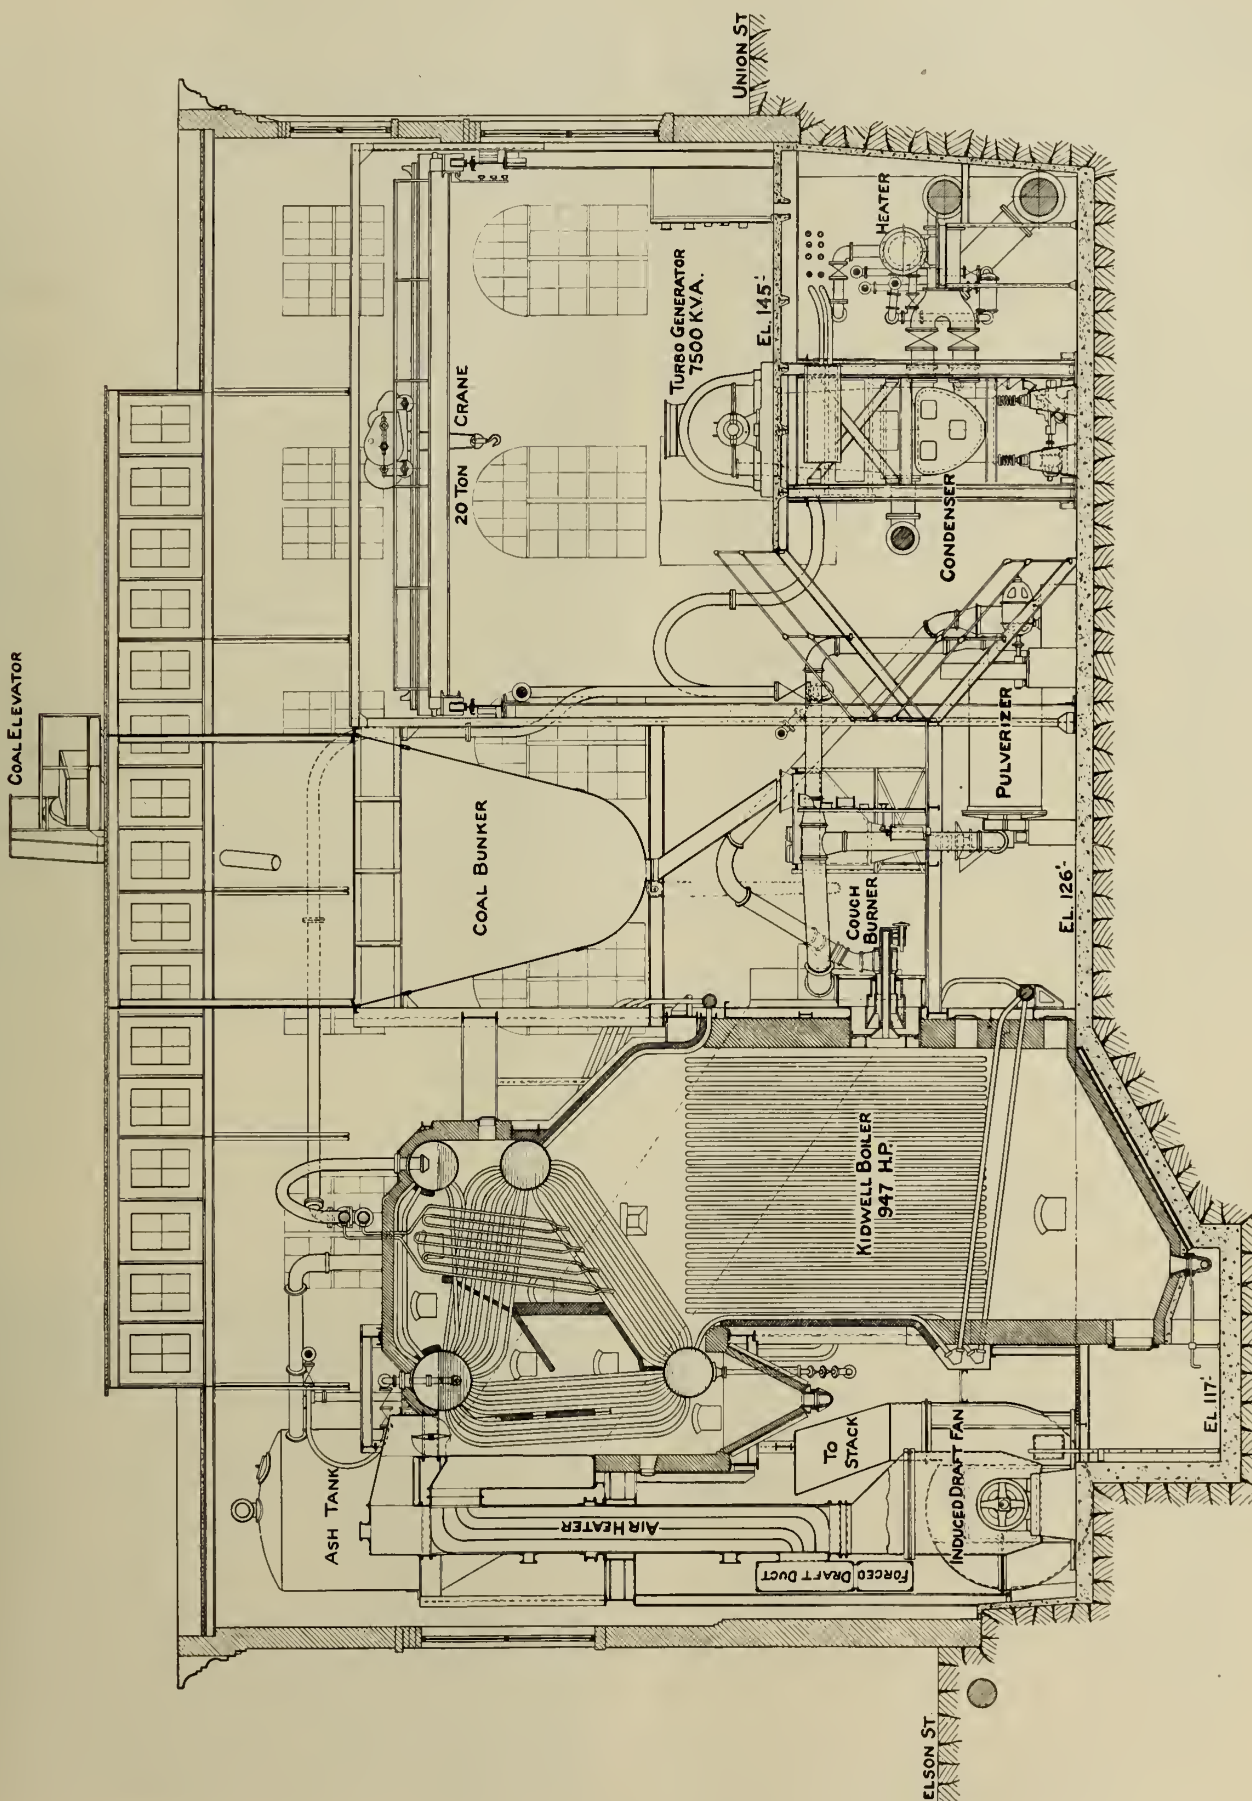

Figure No. 3.—Sectional elevation of plant.

except for the usual very thin film of ash on all metal surfaces. There is a notable absence of "sparklers." The boiler is equipped with soot blowers. No difficulty has been experienced with slag accumulations between the tubes since making the burner alteràtions. It was found necessary to cut sections from the soot blower cams to shut off the steam while they pointed directly at the burners during rotation, to prevent disturbance of the flame.

The gases pass from the top of the boiler down through the plate-type air heater back of the boiler to the induced draft fan placed on the basement floor level. This fan is driven by a variable speed motor and discharges into a flue leading to the brick stack in the old engine room.

The forced draft fan, also driven by a slip ring motor, stands on the basement floor level near the induced draft fan. It takes air from near the boiler and forces it through the air heater in a direction counter to that of the boiler gases. The following table shows the expected performance of the boiler:—

Evaporation, lb. per hr.	15,000	25,000	50,000	70,000	90,000
CO_2 entering air heater, per cent	14.0	15.0	14.8	14.5	14.0
Temperatures, deg. F.:					
Gas leaving boiler	445	470	545	625	710
Gas leaving heater	323	319	338	374	414
Air entering heater	70	70	70	70	70
Air leaving heater	413	407	404	431	479
Draft losses, in water:					
Boiler (incl. superheater)	0.05	0.07	0.37	0.67	1.03
Heater, gas side	0.07	0.17	0.61	1.26	2.21
Heater, air side	0.03	0.12	0.49	1.07	2.07
Superheater:					
Pressure drop, lbs.	....	2	5.5	10	16
Superheat, deg. F.	....	180	212	235	250
Efficiency boiler, superheater and air heater, per cent	....	....	83.1	82.1	80.4

Tests indicate that the boiler, as well as the other equipment, has met expectations.

Coal is received by truck or wagon and dumped into a hopper at street level. From this an apron feeder takes it up a slight incline to a high speed swing-hammer crusher from which a vertical bucket elevator takes it through the roof to a sufficient elevation to spout it into the suspended steel bunker running across the front of the boiler. The low grade coal now burned contains such a large proportion of fines that removal of some and shortening of the other crusher-hammers was necessary to avoid coal so fine that it would pack in the bunker when wet. This change was readily made and has the advantage of increasing the capacity and reducing the crusher power required.

When future boilers are installed, a horizontal conveyor will be placed across the top of the bunker, receiving coal from the bucket elevator.

From the bunker the coal passes through spouts to two automatic scales placed accessibly on the firing floor. Openings are provided so that any stoppage of coal can be immediately seen and corrected. Directly below the scales, and at about the floor level, are the two disc feeders for the mills. In this position they can be seen by the operator either in front of the control board or near the burners, and the manual adjusting mechanisms can be reached from the firing floor.

The two pulverizing mills, with their primary air fans, are placed on the basement floor in front of the boiler. The ball mills used, giving a uniform fineness of grind with little attention required for adjustments or repairs, contribute materially to the ease of operation of the station. The energy required for the ball mills per ton pulverized becomes quite high at low outputs, and to care for possible low night loads the installation of a third small capacity mill and burner was kept in mind and provision was made so that it could be added without great difficulty.

A steel ash tank of 33 cubic yards capacity is installed about 30 feet above the street level near the boiler. A high

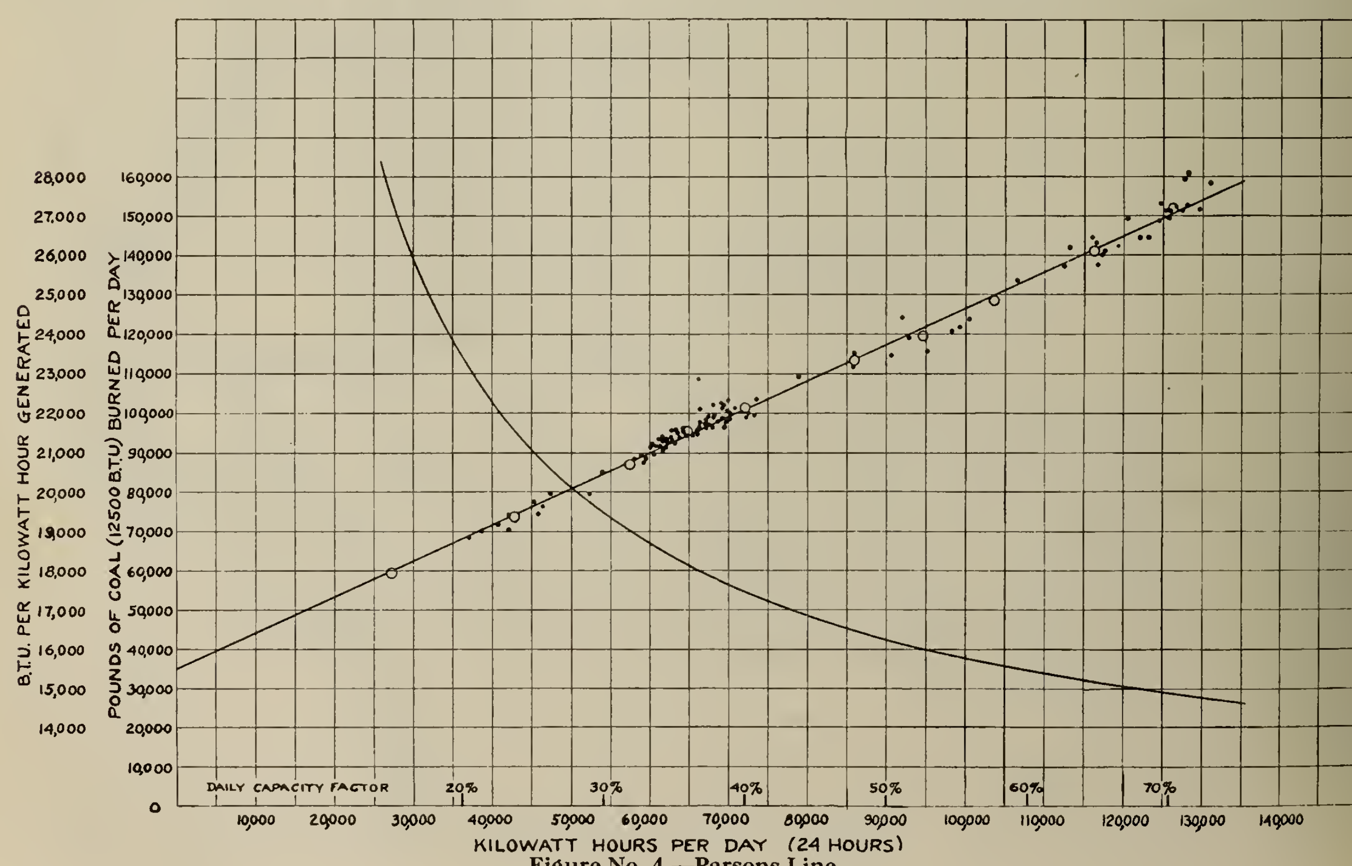

Figure No. 4.—Parsons Line.

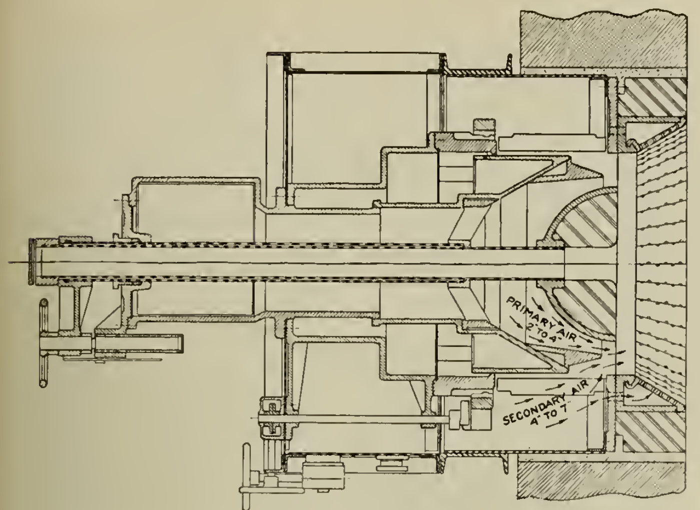

Figure No. 5.—Modified Pulverized Coal Burner.

pressure steam jet produces a partial vacuum in the tank, lifting the ash and cinders from the ash-pit and hoppers under the last passes of the boiler. From the tank the ash is delivered through a chute to trucks in the street.

By facing the boiler toward the turbine, the pulverizer mills are within reach of the turbine crane and the scales, feeders and burners are visible and accessible from a central operating position between the boiler and turbine. There is, of course, some noise from the mills, although the lagging around them deadens that from any parts but the gears. To offset this, the forced and induced draft fans are placed at the rear of the boiler where their noise is not objectionable. No more dust is found in the turbine section than in plants having the usual division wall between the boiler and turbine. The enclosure between the top of the bunker and the roof is dust tight. Pressure above atmospheric does not exist in any of the powdered coal equipment except the two primary air pipes to the burners.

A rather complete system of automatic control of the pulverized coal and fan equipment has been provided to maintain proper efficiency and output under the rapidly fluctuating demands caused by the railway load, and also to free the operator for other work. The master controller is placed on a board with practically all boiler instruments and controls, and also sufficient turbine and condenser instruments to allow the operator at that point to supervise the operation of all equipment and control most of it (figure No. 6). There is, of course, a main electrical

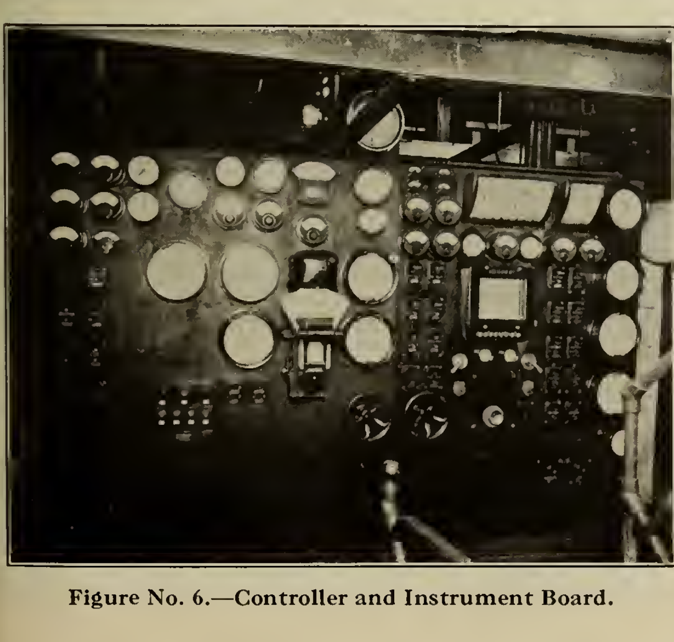

Figure No. 6.—Controller and Instrument Board.

switchboard placed along the wall nearest the turbine, where panels can be added as the number of feeders or generators increases, but it is necessary for the operator to go to this only occasionally for switching. The central control board is near the stairway from the basement to the turbine floor, on the firing floor level, and midway between the boiler and turbine, and hence is quickly reached from any part of the room. Its position parallel to the boiler front will line up with future similar boards when the station is further enlarged. All the important auxiliary motors are provided with ammeters mounted on this board, and most of them can be started and stopped from it.

The scheme of combustion control is shown diagrammatically in figure No. 7. The control equipment automatically adjusts the speed of the mill feeder, primary air fans, and induced draft fan to maintain the proper steam pressure in the main header at all loads. The forced draft fan speed is then automatically adjusted so that a slight suction is maintained in the furnace, and a damper in the suction line to each of the mills prevents positive pressures inside the mills. Fan motor speeds are controlled through adjustment of secondary resistance by motor driven controllers. The boiler uptake damper and the forced draft fan discharge damper are so interconnected with the automatic control as to cause them to move just sufficiently to smooth out the fluctuations in the flow between the steps of the induced and forced draft fan motor speeds.

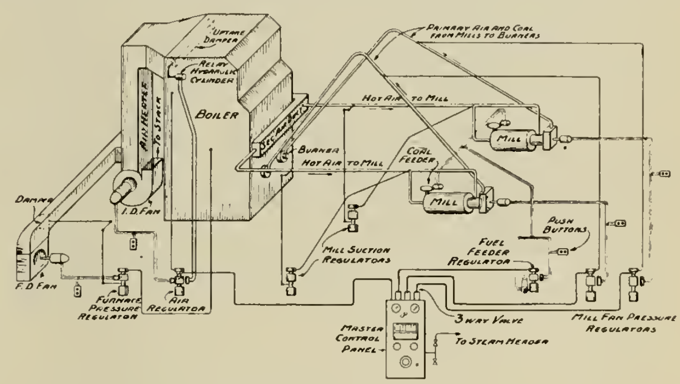

Figure No. 7.—Combustion Control System.

This automatic equipment can be quickly rendered inoperative and the individual motors controlled manually by push buttons on the central board. The equipment is found to give good control over a range from 18,000 to 90,000 pounds evaporation per hour.

As it is obviously undesirable to permit the building up of air pressure in the furnace with the induced draft fan shut down, electrical interlocks are provided so that the induced draft fan, forced draft fan and the two pulverizer fans must be started in the order named. These interlocks also function on failure of any fan motor.

The turbine is a combined impulse-reaction unit, operating at 3,600 r.p.m. and rated at 7,500 kv.-a., with 0.8 power factor. It was made in Baden, Switzerland. Sufficient spare parts are carried either at Saint John or in the manufacturer's American factory to insure against long outage. The following table shows the expected steam rates of the turbine at 375 pounds gauge pressure, 700 degrees F. steam temperature and 29-inch vacuum, with direct excitation:—

Load, kilowatts at terminals	3,000	4,500	6,000	7,500
Power factor, per cent	80	80	80	100
Steam rates, lb. per kw.hr.:				
Without steam extraction	10.45	10.07	10.0	10.45
With extraction at two points, to heat condensate to approximately 212 degrees F., and make-up	11.2	10.8	10.6	11.2

Figure No. 8 shows both turbine and generator.

The generator is star connected, 2,300 and 4,000 volts, and supplies a three-phase, four-wire system with a grounded, interconnected neutral. It is equipped with differential protection relays of the modern percentage type and with thermo-couple type temperature detectors. The generator ventilating air circulates in a closed system in which is installed a tubular air cooler connected to the circulating water system in parallel with the condenser.

No main generator field rheostat is provided, since the direct connected exciter is designed to be stable at all required excitation voltages, which permits manual adjustment of the generator voltage by means of the exciter rheostat. Normally the excitation voltage is automatically adjusted to maintain the required generator voltage, by a Brown Boveri rheostatic regulator connected in the shunt field of the exciter. The main field circuit of the turbine generator can be transferred to a spare exciter in the old power plant. Since this emergency exciter might not be stable at the lower voltages required, provision has been made for transferring its field to the control battery. Under this condition the spare exciter operates as a separately excited machine and is, of course, stable at any output voltage.

A very compact single pass condenser with 4,600 square feet of surface is installed inside the steel turbine foundation. The low temperature of the harbour water allows high vacuum to be obtained with very little surface. The normal summer maximum is 56 degrees F. with an extreme of 62 degrees F. on low tide. The condenser has the usual equipment of steam jet air ejectors, and two motor driven condensate pumps. The latter are so designed as to maintain positive water pressure on both stuffing boxes to prevent in-leakage of air. The condenser has horizontally divided water boxes to permit cleaning one-half with the other in use. The table following indicates the expected performance:—

Steam condensed per hr., lb	67,000	67,000	33,000	33,000	35,000
Temperature circulating water, deg. F	55	40	55	55	40
Quantity circulating water, imp. g.p.m	10,000	8,330	8,330	4,110	4,170
Condenser friction, ft. of water	11.5	8.5	8.5	3.5	3.9
Vacuum, referred to 30 in. barometer	29.0	29.25	29.22	29.6	29.25

To keep the turbine lubricating oil in condition, two 420-gallon tanks are provided, into one of which a used charge of oil may be drawn for settling. The other contains a new charge ready for use.

The system for heating the condensate or feed water was designed to give fairly high efficiency without introducing complications unwarranted in a relatively small plant. Figure No. 9 shows the principal piping. Steam is extracted from the turbine at two points; the lower one at a maximum pressure of about 9 pounds absolute, to heat the condensate passing through an extraction heater, and the upper one at about 70 pounds gauge pressure to furnish pure make-up by the evaporation of city water in the evaporator. The vapour from this latter process also enters the de-aerating heater and provides the second stage of heating to give a water temperature of about 212 degrees F. entering the boiler. Sufficient excess steam is withdrawn from the de-aerator to the vent condenser to de-aerate the condensate. Since an economizer is not used with the new boiler, this provision is not strictly necessary at present. The de-aerator, however, is designed to handle both the present and an additional future unit, and the possibility of the future use of an economizer makes the slight additional expense and complication of the de-aerating features seem warranted.

The water leaving the condensate pumps passes successively through the air ejector condensers, the de-aerator vent condenser, the extraction heater and into the de-aerating heater through a float valve which allows any excess or deficiency to be cared for by the surge tanks. Here it meets the evaporator vapour and steam line and other drips and passes to the boiler feed pump suction header below. A second float valve on the de-aerator will admit city water if the level goes unduly low.

This arrangement of the condensate piping permits the new de-aerating heater and the old open heater to be cross connected and provides insurance against low water in the boilers in the form of a 4,200 gallon reserve of condensate in the roof surge tanks. It also is well adapted, without special preparations, to the making of turbine and boiler tests by the operating force, to ascertain that the original efficiencies of the main equipment are maintained. This is accomplished by providing two roof surge tanks instead of one, piped so that for a turbine test the condensate may be discharged alternately into the two, for volumetric measuring—one filling while the other is emptying into the de-aerator. The method of accomplishing this can be seen from figure No. 9. Feed water is measured for a boiler test in the same manner. This allows accurate determination of either turbine steam consumption or boiler evaporation to be made without interrupting the continuous flow of water to the feed pumps, and with very few changes from normal operating conditions. The surge tanks are provided with bottle shaped tops to reduce the test error from a wrong determination of water level. The other data required during such tests are provided for by coal sampling taps, test thermometers wells, and connections for test gauges, and by a small plant laboratory.

There are two boiler feed pumps, each with more than sufficient capacity to supply the new boiler. Both operate at 3,550 r.p.m. This high speed reduces the size and cost of the units and makes them well adapted to direct drive by either motor or turbine. The pump ordinarily used is driven by a squirrel cage motor, and the reserve pump by a turbine which exhausts either to the atmosphere, or into the de-aerator if the evaporator should be out of service. For a 250 imp. g.p.m. pump the constant speed drive was found to be more economical in total cost than variable speed. The reserve pump is controlled by a governor maintaining a fixed difference between the pressures at the pump and in the main steam header.

The feed and steam piping is fabricated in accordance with the American engineering standard for 400 pounds working steam pressure, and presents no special features other than arrangements for connection to future new installations. The piping allows the boiler to be fed at one side through an automatic regulator preceded by a valve whose function is to limit the differential pressure across the regulator. The boiler may be fed at the other side through an entirely independent manually operated valve.

An 8-inch tie line from the new steam header passes into the old engine room where there is installed an equipment for reducing the pressure and temperature of the steam to about 160 pounds and 500 degrees, for the old units. Sufficient safety valves are provided on the outlet side of the reducing valve to prevent dangerous rise in pressure due to any improper functioning of the equipment. Under the very rapidly fluctuating loads the pressure is maintained within a range of 4 pounds or less.

With reference to the electrical connections, the main 4,000-volt generator-leads go directly to circuit breakers in an outdoor substation, situated on a wharf about 175

Figure No. 8.—Turbine and Generator.

feet from the power house. From a station service bank of transformers in this substation, leads return to a 3-phase bus at the rear of a 440-volt steel auxiliary panel board in the turbine room. The main switchboard, of the standard vertical type, adjoins the auxiliary board. It is fitted with the usual switches, instruments, and relays for controlling all the generator and feeder circuits connected to the bus in the outdoor substation. The 1,000 kv.-a. station service transformer bank has sufficient capacity to carry the present load when operating in open delta when any one of the transformers is out of service. This bank probably will be duplicated when additional generators are installed, but for the present it is considered that sufficient provision for the continuity of the auxiliary supply has been made by providing for open delta operation.

The station service board carries safety type knife switches and primary contactors for the individual auxiliary motor circuits. This arrangement of the auxiliary motor equipment conforms to the present tendency to group similar apparatus wherever practicable. It was particularly desirable at Saint John by reason of the limited available space adjacent to most of the motors.

Each of the primary motor contactor circuits is provided with two interconnected push buttons for starting and stopping the motors, one button of each pair being located adjacent to the motor and the other button mounted on the boiler control panel. This panel also mounts other buttons for speed control of certain motors, speed indicators, etc., as well as the boiler instruments previously described. By this grouping it is possible for one man at the boiler control board to control and supervise all the principal motors during normal operation, while the push button adjacent to each motor makes emergency control possible without going to the boiler control panel.

Wherever frequent speed adjustment is required, the motors are of the slip ring type and are fitted with motor driven secondary drum controllers. In all cases these controllers and the accompanying secondary resistors are mounted adjacent to the motor, which minimizes the length of interconnecting leads. For each of these motors a pair of "fast-slow" push buttons is also provided, one button being placed adjacent to the motor and the other on the boiler control board. Contrary to common practice, the motors for driving the secondary drum controllers are all supplied from a 110-volt, 3-phase source rather than at 440 volts, since this lower voltage permits this equipment to be maintained with less hazard. The 110-volt supply is secured through two small transformers fed from the 440-volt bus.

Wherever speed control is not required and where the starting duty will permit, squirrel cage motors of the full voltage starting type are used. The coal handling motors, which are of this type, are interlocked electrically through extra contacts on the primary contactors so that the coal elevator, coal crusher, and apron feeder motors must be

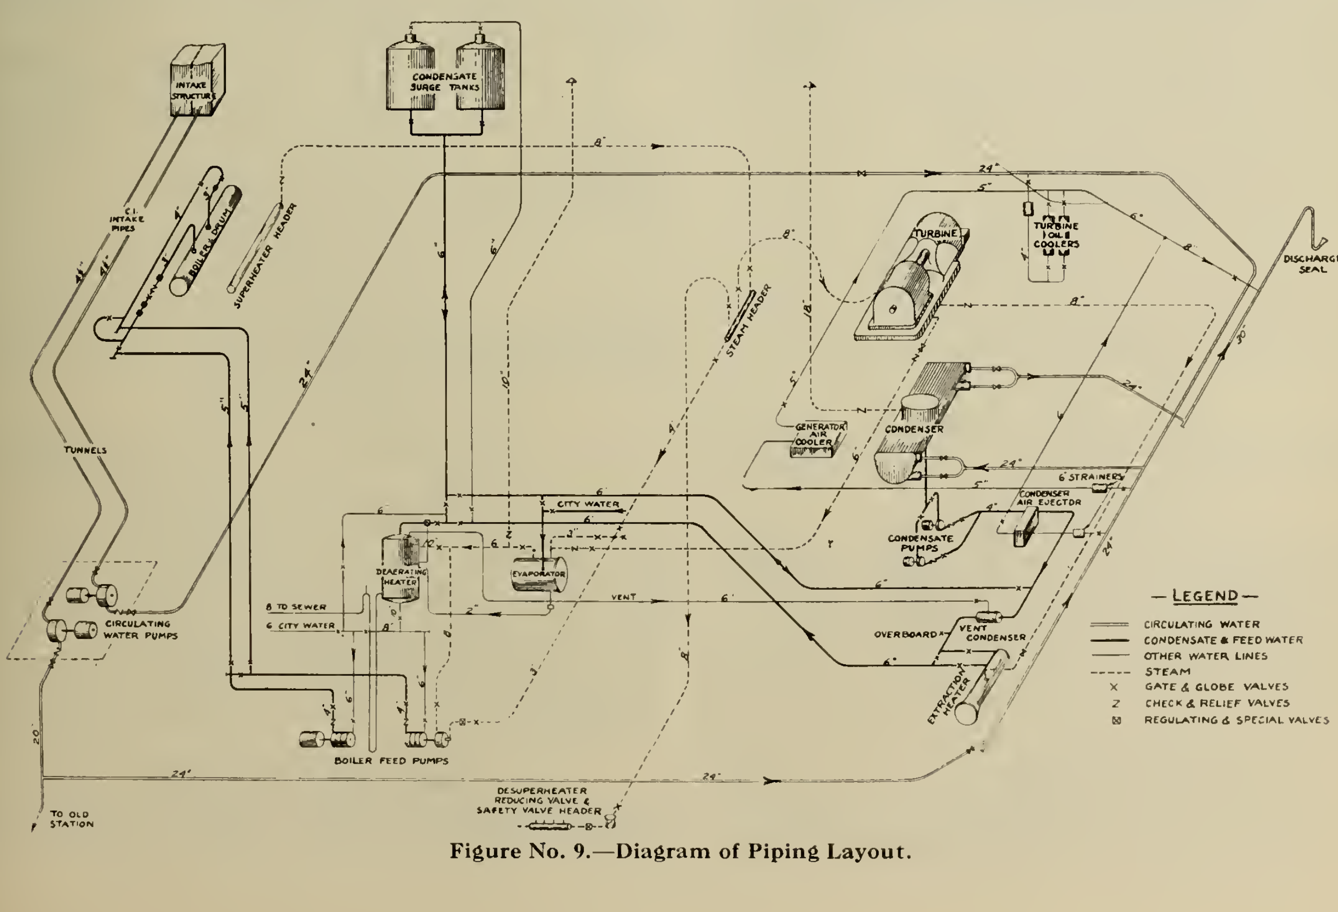

Figure No. 9.—Diagram of Piping Layout.

started in the order named, or shut down automatically in case of any motor failure in such sequence as will prevent delivery of coal to equipment not running. For supervision of operation from the control board, it was deemed desirable to install an ammeter for each important motor to give a positive indication when the circuit is closed. As the slip ring circulating pump motors are located in a pit at a remote corner of the station, a Selsyn transmitter has been provided on each of the two secondary drums with indicators on the boiler control board which show the position of these drums at any time.

Coal is fed to each pulverizer by a one-quarter horse power, 125-volt, direct-current motor supplied from the station control bus. The speed of these motors is controlled simultaneously by a motor-operated rheostat controlled by manually operated push buttons near the motor, on the control board, or through contacts on a Smoot regulator. Preliminary operating experience showed the desirability of an indication of speed on the coal feeder motors and on the pulverizer fan motors; therefore, speed indicating magnetos were added to these motors with electrical indicators on the control board.

The outdoor 4-kv. substation controls the new generator, 6 regulated outgoing feeders, station service bank, and one tie feeder to the system of the New Brunswick Electric Power Commission. This last feeder also is tied to the 2,300-volt bus in the old substation through two transformer banks having a total capacity of 3,000 kv.-a.

The steel structure for the substation is of the conventional type, except that a roof has been installed. The structure mounts the main and transfer bus, together with the necessary disconnecting switches. The electrically operated circuit breakers and instrument transformers are mounted in individual sheet metal houses with the leads carried through roof bushings. This arrangement permitted the utilization of a number of indoor oil breakers which were available at Saint John. Three single-phase outdoor type induction regulators are installed on each of the outgoing feeders. The current and potential transformers for the regulator control have been mounted inside the regulator top housing, which has greatly simplified the installation.

A roof was incorporated in the substation design because the unloading plant of a large coal company is situated adjacent to the substation site, which makes this location subject to a great deal of coal dust under certain wind conditions. For this reason it was considered advisable to cover the substation structure to minimize the necessity for cleaning insulators, bushings, etc., and to insure increased reliability.

The main 4,000-volt generator leads are carried in fibre conduit, encased in concrete, through a tunnel under the street adjacent to the power house. This tunnel was cut through rock. The leads then continue through a concrete enclosed passageway built through the warehouse situated on the wharf, where they terminate in a concrete manhole. From this point the conduits run to the generator switch in the outdoor 4,000-volt substation.

All control cables are carried from the switchboard in iron conduit through the tunnel and passageway above. They terminate in a separate concrete manhole from which the conduits lead to the various breakers, etc. The 4,000-volt feeder cables are carried in iron conduit through the tunnel and terminate at poles in the street for connection to the overhead distribution system, which was changed from the 2,300-volt three-wire arrangement, to 4,000-volt four-wire. All iron conduits in the yard are encased in concrete for protection against corrosion occasioned by the ash fill.

This station of the New Brunswick Power Company at Saint John, N.B., was designed and constructed by Sanderson and Porter, in cooperation with J. D. Bowles, chief engineer of the Federal Light and Traction Company.

Data on Plant and Equipment

Building (Section Containing the New Equipment)

Width inside of building—48 ft. 6 in.
Length inside of building—93 ft. 0 in.
Area per kw. capacity based on 7,500 kw.—0.6 sq. ft.
Volume per kw. capacity based on 7,500 kw.—34.0 cu. ft.
Elevation of extreme low water—100 ft.
Elevation of high water—128 ft.
Elevation of pump room floor—97 ft.
Elevation of condenser floor—126 ft.
Elevation of turbine floor—145 ft.

Circulating Water Intake and Discharge

Gross area screen chamber extreme low water—140 sq. ft.
Intake lines—Two, each consisting of 112 ft. of 42 in. c.i. pipe and 290 ft. of 3 ft. 10 in. by 4 ft. concrete tunnel.
Discharge line—One 30 in. c.i. pipe 280 ft. long.
Elevation of seal on discharge line—111 ft.

Fuel

Kind and source—Dominion—Sydney, Nova Scotia.
Proximate analysis, as fired—volatile matter 28.8%, fixed carbon 54.8%, ash 13.1%, moisture 3.3%. b.t.u. per lb. 12,610.

Boiler and Furnace

Type of boiler—Class 22-36 D, Kidwell, steel cased.
Steam pressure—448 lb. gauge maximum drum working pressure.
Steam drums—36 and 42 in. diameter, approximately 25 ft. long.
Other drums—Two 36 in. diameter, approximately 25 ft. long.
Boiler tubes—3¼ in. diameter, No. 8 b.w.g., 36 tubes wide.
Fin wall tubes—Sides 4 in., arch and rear 3 in., all No. 6 b.w.g.
Ash-pit screen tubes—4 in., No. 6 b.w.g., two rows, 12 in. centres each.
Boiler heating surface—9,472 sq. ft.
Projected area water cooled surface in walls, arch and screen—1,400 sq. ft.
Furnace volume above screen tubes—7,050 cu. ft.
Manufacturer—Canadian Vickers Limited.

Superheater

Tubes—1⅝ in., No. 9 b.w.g., 4 loop, 1,650 sq. ft. total surface.
Type and manufacturer—Elesco—Superheater Company.

Air Heater

Elements—3 ft. by 25 ft., 10,260 sq. ft. heating surface.
Spacings—Air side ¾ in., gas side 1 in.
Type and manufacturer—Vertical plate—Combustion Engineering Corporation, Ltd.

Forced Draft Fan

Capacity at 8.75 in. static pressure—31,800 cu. ft. per minute at 100 deg. F.
Type and size—Double inlet, 48 in. RB design C2.
Manufacturer—Green Fuel Economizer Company.
Drive—75 h.p. slip ring motor, 580-1,160 r.p.m.
Speed control—Secondary resistance, 13 points.

Induced Draft Fan

Capacity at 6 in. static pressure—68,500 cu. ft. per minute at 414 deg. F.
Type and size—Double inlet, type SA, No. 8.
Manufacturer—Green Fuel Economizer Company.
Drive—125 h.p. slip ring motor, 248-495 r.p.m.
Speed control—Secondary resistance, 13 points.

Stack (Built for Old Boilers)

Dimensions—175 ft. above burner floor, 7 ft. 6 in. inside top, brick.

Raw Coal Handling Equipment

Receiving hopper with grating—8 ft. by 8 ft., opening 6 in. by 6 in.
Apron conveyor—18 in. wide, 15 ft. centres, 25 tons per hour.
Apron conveyor drive—3 h.p. squirrel cage motor, 870 r.p.m.
Crusher—30 in. by 24 in., type A, 1,160 r.p.m., 25 tons per hour.
Crusher drive—40 h.p. squirrel cage motor, 1,160 r.p.m.
Elevator—Single strand bucket chain, 64 ft. centres, 25 tons per hour.
Elevator drive—5 h.p. squirrel cage motor, 1,160 r.p.m.
Manufacturer—Jeffrey Manufacturing Company.
Coal bunker—⅜ in. unlined copper steel, capacity 135 short tons.
Automatic coal scales—Two, 200 lb. scale, capacity 12,000 lb. per hour, Richardson.

Pulverized Coal Equipment

Mills—Two 6,000 lb. per hour ball mills, 4 ft. 6 in. by 9 ft., herringbone gear drive.
Mill drives—Two 50 h.p. slip ring (starting duty) motors, 575 r.p.m.

Feeders—Two 30 in. diameter, disc type.
Feeder drives—Two ¼ h.p. direct current motors, 300-1,200 r.p.m., 120 points.
Primary air dans—Two 30 in., plate type.
Primary air fan drives—Two 15 h.p. slip ring motors, 580-1,160 r.p.m., 13 points.
Manufacturer—Canadian Kennedy Manufacturing and Engineering Company, Ltd.
Burners—Two 30 in. Couch type D—Combustion Engineering Corporation, Ltd.

Combustion Control Equipment

Equipment—One 8 element master controller, power unit, and 7 regulators—Smoot Engineering Corporation.

Ash Handling Equipment

Type and capacity—Steam vacuum, 5 tons per hour.
Sizes—8 in. ash-pit line, 6 in. soot hopper line.
Manufacturer—George J. Hagan Company.

Main Generating Unit

Turbine—2 impulse stages, 23 reaction stages, 3,600 r.p.m.
Generator—3-phase, 60 cycles, 4,150 volts, star connected.
Capacity—7,500 kv.-a., 0.8 power factor,—7,500 kw., 1.0 power factor maximum.
Steam conditions—375 lb. gauge, 700 deg. F. (450 lb. 750 deg. maximum).
Direct connected exciter—37 kw., 125 volts, shunt wound.
Manufacturer—American Brown Boveri Electric Corporation.

Generator Air Cooler

Tubes—⅝ in. Admiralty metal, 1,100 sq. ft. total.
Ventilating air—24,000 cu. ft. per minute at 104 deg. F.
Cooling water—56,700 lb. per hour at 77 deg. F.
Manufacturer—American Brown Boveri Electric Corporation.

Turbine Lubricating Oil System

Oil coolers—Two, 130 sq. ft. each, American Brown Boveri.
Settling tanks—Two, 420 imperial gallons each.

Main Condenser

Type and size—Surface, single pass, horizontally divided, 4,600 sq. ft.
Tubes—¾ in. No. 18 b.w.g., 17 ft. 6 in., rolled one end, admiralty.
Packing—1 fibre ring, corset lace, and 1 lead ring.
Circulating water—Salt harbour water, 8,330 imp. g.p.m. (10,000 maximum).
Manufacturer of condensing equipment—Canadian Ingersoll-Rand Company, Ltd.

Circulating Water Pumps

Number and type—Two, single-stage, 16 in. discharge.
Capacity each—8,330 imp. g.p.m. at 25 ft. head, 3,000 imp. g.p.m. at 58 ft. head.
Drive—125 h.p. slip ring motor, 435-870 r.p.m.
Speed control—Secondary resistance, 13 points.

Condensate Pumps

Number and type—Two, two-stage, 2½ in. discharge.
Capacity each—133 imp. g.p.m., 80 ft. discharge head.
Drive—10 h.p. slip ring motor, 875-1,750 r.p.m.
Speed control—Secondary resistance, 11 points.

Condenser Air Ejectors

Number and type—3 primary and 2 secondary steam jets.
Capacity—5 cu. ft. per minute with 2 primary and 1 secondary jet.

Extraction Heater

Type and size—Horizontal, 6 pass, floating head, 410 sq. ft.
Tubes—¾ in., No. 18 b.w.g., Admiralty metal.

Evaporator

Type and size—Horizontal shell, submerged admiralty coils, 126 sq. ft.
Steam pressures—53 lb. gauge (400 lb. maximum)—vapour 2 lb. gauge.
Capacity—3,000 lb. make-up per hour.
Manufacturer—Riley Engineering and Supply Co., Ltd.

De-Aerating Heater

Type and size—Vertical, 5 ft. 3 in. diameter by 8 ft. 6 in.
Operating pressure and capacity—1 lb. gauge, 170,000 lb. water per hour maximum.
Vent condenser—25 sq. ft., 82,000 lb. condensate per hour.

Condensate Surge and Measuring Tanks

Number and size—Two, 7 ft. diameter by 10 ft., 2,100 imperial gallons each.

Boiler Feed Pumps

Number and type—Two 3-stage Cameron; one motor, one turbine driven.
Capacity and head—250 imp. g.p.m. each, 1,200 ft. total head.
Drive—200 h.p. squirrel cage motor, type FT, 3,550 r.p.m.
Drive—190 h.p. non-condensing turbine, type 2-MD, 3,550 r.p.m.
Speed controls—Motors; constant speed. Turbine; Fisher excess governor.
Manufacturer—Canadian Ingersoll-Rand Co., Ltd.

High Pressure Steam and Feed Water Piping

Flanged joints—400 lb. American Engineering Standard, Van Stone.
Valves—400 lb. American Engineering Standard cast steel, Reading.
Piping fabricator—Walworth Manufacturing Company.

Low Pressure Piping

Flanged joints—125 lb. American Engineering Standard, Durabla gaskets.
Valves—Jenkins Bros., Ltd.

Miscellaneous Valves

Boiler safety valves—Three 4½ in. Crosby.
Superheater safety valve—One 4 in. Consolidated.
Boiler non-return valve—One 8 in. Edward.
Drum stop-check valves—Two 3 in. Edward.
Blow-off valves—Six 2½ in. Edward, two in tandem.
Turbine atmospheric relief valve—18 in. Atwood-Morrill.
De-aerator back pressure valve—10 in. Cochrane multi-port.
Circulating water valves—16 in.-24 in. Jenkins Bros., Ltd.

Heat Insulation

High pressure steam lines—3 in. thick except small sizes.
High pressure feed lines—Double standard magnesia except small sizes.
Manufacturer—Johns-Manville Corporation.
Hot air duct covering—1½ in. Rockwool blankets and hard finish.

Steam Pressure Reducing Equipment

Type—Master controlled 8 in. reducing valve, 400-160 lb.
Manufacturer—Swartwout Company.

De-Superheater

Type—Copper cartridge.
Manufacturer—Elliott Company.

Crane

Type and capacity—3 motor, 20 tons, type NE, pendant operated.
Motors—Hoist 30 h.p., bridge 7½ h.p., trolley 10. h.p.
Manufacturer—Northern Crane Works, Ltd.

Mechanical Instruments

Steam flow meters—Indicating recording totalizing—Republic.
Feed water flow meter—Indicating recording totalizing—Republic.
Boiler water level recorder—Differential pressure type—Foxboro.
CO_2 recorder—Ranarex—Permutit Company.
Draft gauges—P9F and P4F—Bailey.
Surge tank level indicator—Industrial Jr.—Liquidometer.
Pressure and temperature recorders—12 in. Class III—Foxboro.
Indicating pressure-vacuum gauges—Form IR-SP—Ashcroft.
Indicating thermometers—12 in. Tag-Hespe—Tagliabue.
Feeder and fan tachometers—Electric—Weston.

Laboratory Equipment

Chemical testing set—Lab-Rette—Babcock and Wilcox.
Sieve shaker and sieves—Ro-Tap—Tyler.
Dead weight gauge tester—Type 1300—American.

Miscellaneous Mechanical Equipment

Air compressor—12 by 10 in., 368 c.f.m., 100 lb., Ingersoll-Rand.
Sump pump—210 imp. g.p.m., 20 ft., vertical, 1,150 r.p.m., Rumsey.
High pressure steam traps—Inverted submerged bucket, Armstrong.
Boiler soot blowers—14 half-width elements—Diamond.
Boiler feed water regulator—Type SM and type S—Swartwout.
Boiler water column—Reliance.

Main Switchboard

Type—7 panel 90 in. vertical remote control, ebony asbestos.
Manufacturer—Canadian General Electric Company.

Station Service Switchboard

Type—10 panel 90 in. vertical safety board, steel.
Manufacturer—Empire Switchboard Company.

Generator Voltage Regulator

Type—Quick acting, controlling exciter field, Brown Boveri.

Control Storage Battery

Type—60 cell, Exide KXF-13, sealed in glass jars.
Capacity—13 amperes for 8 hours, 150 amperes for 1 minute.
Manufacturer—Electric Storage Battery Company.

Battery Charging Equipment

Type and capacity—Induction motor-generator, 1½ kw., 140 volts, shunt.
Manufacturer—Canadian General Electric Company.

Station Service Transformers

Rating—Three 333 kv.-a., single phase O.I.S.C., 4,150/460-230 volts.
Manufacturer—Canadian General Electric Company.

Feeder Induction Regulators

Rating—48 kv.-a, single phase self-cooled automatic outdoor.
Voltage—2,400 volts primary, 10/5 per cent buck or boost.
Manufacturer—Canadian General Electric Company.

Outdoor Substation

Type—Galvanized steel structure, asbestos protected metal roof.
Manufacturer—Canadian General Electric Company.

Oil Circuit Breakers

Generator and tie breakers—Type FK-55, solenoid operated.
Feeder breakers—Type FK-12, solenoid operated.
Mounting—Individual weatherproof houses, with instrument transformers.
Manufacturer—Canadian General Electric Company.

The Electric Trolley Omnibus

E. G. Cullwick, Jr.E.I.C.,
Assistant Professor of Electrical Engineering, University of British Columbia, Vancouver, B.C.

The last few years have seen an unprecedented increase in motor traffic in the United Kingdom. The automobile has ceased to be a rich man's luxury, with the result that roads which were comparatively unfrequented before the war have become more and more congested. Side by side with the increase in private motoring has been a similar growth of heavy vehicular traffic on the roads, consisting of both freight movements and the development of the large passenger coach. The congestion of the roads has naturally concentrated in the towns, in many of which the narrow streets have proved totally inadequate to deal with the increasing volume of traffic, with the result that costly reconstruction has become necessary.

This increased congestion of traffic, coupled with severe competition from motor buses, has made it more and more difficult in the smaller towns to operate tramways satisfactorily. The difficulty has been accentuated by the decrease in money values since the war, so that many tramway undertakings have not only found their passenger returns decreasing, but have also found their renewals funds insufficient to keep the systems in good repair. Consequently the last few years have seen the complete removal of many tramway systems, and their replacement by motor buses or by trolley buses.

The latter vehicle has proved so successful and popular with the public, being less expensive to operate than the motor bus, and much more comfortable due to its smooth and high acceleration and absence of noise and smell, that its status has changed from that of a cheap substitute for the tramcar to that of an extremely important and popular means of transportation.

It is the purpose of this paper to give some account of the development and use of the trolley bus, both in Europe and on this continent, together with its more important technical features.

Early Development in Europe

By the end of the nineteenth century considerable progress had been made in electric street railways on the continent of Europe, especially in Germany. The more important technical features, such as current collection from overhead wires and track, and the series-parallel control of two series motors, had become fairly standardized and many systems were in operation in cities and towns.

The new system having proved successful in areas of fairly dense population, it was natural that electric traction should be looked upon as the possible solution of transportation problems in less thickly populated districts such as the outskirts of cities and rural areas, but here the street railway was found to be unprofitable due to the cost of constructing and maintaining the steel track.

It was in order to eliminate this latter expense that the idea was conceived of constructing a road vehicle driven by electric motors and supplied with power from two overhead wires, the collecting device being such as to allow considerable lateral freedom of movement of the vehicle. It is this type of vehicle that has come to be known as the "trolley bus" or "trackless trolley."

The first working example of a trolley bus seems to have been the vehicle which was shown at the international exhibition of Paris in 1900, which was fitted with steering gear and driven by electric motors (*Note 1*). Power was supplied by means of two overhead wires, connection being made to the bus by the use of an electrically driven "contact carriage" which ran on the overhead wires, from which carriage a flexible cable conveyed current to the motors. The system attracted considerable attention, but only two or three further installations were made, one being at Eberswalde near Berlin and one near Monte Carlo, and none of them were in operation for any length of time.

Meanwhile a German engineer, Max Schiemann, had been developing a trolley bus in which the current was collected from the overhead wires by means of two trolley poles, with under-running sliding contacts. His first installation was in the Biela valley and provided both a passenger and goods service. The line was opened in July, 1901, and was in use for several years (*Note 2*).

Figure No. 1 shows one of the passenger buses. These vehicles had seating space for eighteen passengers, while there was standing room for six more on the rear platform. The average running speed was 12 kilometres per hour. Motive power was provided by two series motors arranged for series-parallel control, with short-circuit braking. A tramcar controller, with vertical drum and operated by hand, was used.

The new system was only advocated for use where conditions did not warrant the expense of a track; there was no suggestion that it might supersede the tramway, but in rural districts where traffic was comparatively light or where it was desired to develop a traffic route to be served ultimately by street cars it had the great advantage of low capital cost (Schiemann gives the initial cost as about one-quarter of that of a track system).

Another use to which the new trackless system was put was that of connecting factories and warehouses with railway stations, such an "industrial line" being shown in figure No. 2 which shows a passenger bus passing a train of goods wagons near Monheim-on-Rhine (*Note 3*).

Schiemann's system with trolley poles had better success than the cable-collection method, and during the following years many installations were put into operation. Figure No. 3 shows a bus at Mülhausen, where it is seen that the two poles have been replaced by a single one, with a double-pole sliding contact. Many of these early buses had front-wheel drive.

An example of a trolley bus using alternating current was shown at the electrical exhibition at Leipzig in 1912; built by Schiemann, it was driven by a brush-shifting repulsion motor at 1,000 volts and 50 cycles, and had a free-running speed of 20 kilometres per hour (*Note 4*).

Schiemann's buses had a lateral freedom of movement of about three metres on either side of the centre line of the wires, and it was to obtain greater mobility that other engineers used the more complicated cable collector. After an experimental stage this idea was successfully developed, and an important example was the system used in Italy, where by 1909 there were about 60 miles of route in operation in the neighbourhood of Lake Como. The Italian buses were built with a short wheelbase of 8.5 feet so that they could negotiate the sharp bends which were so prevalent in the roads. On the two overhead wires ran a four-wheeled contact truck, which was connected to a trolley pole on the bus by a flexible cable, so arranged that the vehicle could turn round without any manipulation of the collecting gear, which advantage was common to all cable

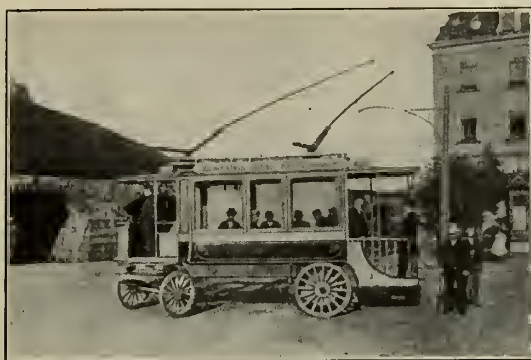

Figure No. 1.—Trolley Bus in Biela Valley, Germany, 1901.

systems. The passing of two buses using the same pair of overhead wires was, however, more difficult when a cable was used; with trolley poles, those on one of the buses could easily be pulled down from the wires while the other bus passed by, but with the over-running contact trucks of the cable systems it was necessary to arrange some method of disconnecting the cable from the truck and then exchanging trucks. On the early systems, with comparatively infrequent service, the economy of using but one pair of wires for two-way traffic justified the slight delay which took place when two buses met. With the heavy services in use at the present time two pairs of wires are always used.

In Germany the cable system was developed principally by the engineer Stoll, whose installations, at Dresden in 1903 (*Note 5*), and in a few other places, were not so successful at first as those of Schiemann. However, the largest use of Stoll's system was in Austria, where the Austrian Daimler Company built buses which were installed quite widely in that country (*Note 6*).

Figure No. 4 shows a type of bus in use near Vienna about the year 1908 which has several interesting features including a back-wheel drive, the motors being incorporated in the wheels themselves, thus eliminating all transmission problems and, it was claimed, prolonging the life of the motors. The cable was attached to the bus on a spring drum, which automatically wound up any superfluous length, while its other end was attached to the four-wheeled contact truck, which had a hanging arm with a heavy weight on the end whose purpose was to prevent the carriage being pulled off one of the wires by the lateral pull of the cable. The total length of the cable was about ten metres, so that the bus had a large freedom of movement.

A similar type to this was also used, except that the motors were built into the front wheels. These buses, seating twenty-four passengers, were operated at a cost of

Figure No. 2.—Passenger Bus passing Goods Train at Monheim-on-Rhine.

from 7 to 9.5 cents per mile, while their energy consumption was about 80 watt-hours per ton-mile in fine weather.

Another example of cable collection was that installed in Bremen in 1911, where the two overhead wires were placed in the same vertical plane, 30 centimetres apart. A contact carriage with two contact wheels ran on the upper wire, while connection was made with the lower wire by means of sliding contacts; the carriage was connected to the bus by a flexible cable. The system, which consisted of two lines each two kilometres long, was constructed by Köhlers of Berlin and Bremen. The buses seated twenty, weighed 3.2 tons empty, and took about 0.4 kw.hr. per bus-mile.

Progress in the development of the trolley bus was naturally cut short by the war, though many miles of temporary route were used by the military in Italy during the conflict. During the post-war years of reconstruction, it was Great Britain that first took full advantage of the economies of the system, so it is to that country we must now look for its further development. During the last few years, however, several deputations of continental engineers and municipal men have visited the systems in England,

Figure No. 3.—Trolley Bus with Single Trolley Pole at Mülhausen.

and the trolley bus would seem to be starting on a new lease of life on the continent.

Development in England

In the first decade of this century the use of the tramcar had been steadily growing in Great Britain, and so long as the area served was one of fairly dense population the undertakings proved successful. It was soon found, however, in the smaller towns and outlying districts of the larger ones that it was much more difficult to operate at a profit. The high cost of operation was due, firstly, to the high cost of the track and its maintenance; secondly to the high rates paid on the track; and lastly, to the fact that the tramway companies had to maintain a disproportionately large area of paving, this being an unwelcome legacy from the old horse trams.

Naturally in these circumstances any system which could dispense with the track was bound, sooner or later, to find favour, and in 1910 we find a delegation sent by the city of Bradford to the continent for the purpose of inspecting the existing trolley bus systems there and reporting on their suitability for use in England. Their report was favourable, and in 1911 the first trolley bus line in the United Kingdom was opened at Bradford. Figure No. 5 shows one of the two buses which were put into service. They had seating capacity for twenty-eight, and required two men, a driver and a conductor, to operate them. Two 20 h.p. series motors, with shunted field control, supplied the motive power, and it will be noticed that current was

Figure No. 4.—Trolley Buses near Vienna, 1908.

collected by means of two trolley poles with under-running contact wheels, a method which had been used for tramcars in Great Britain and which now has become standardized in trolley bus practice (*Note 7*).

There were also four buses put into service about this time at Leeds, but these differed from the Bradford vehicles in having a front entrance and requiring only one man to operate them.

Other corporations now followed the lead of Bradford and Leeds; during the year 1912 the Rotherham corporation opened a route from Rotherham to the village of Maltby, and Dundee also commenced a trolley bus service. Considerable interest was aroused in tramway circles and not a little opposition from the rapidly growing motor omnibus companies. Altogether at the outbreak of hostilities in 1914 there were seven installations of trolley buses in operation in Great Britain, and though the vehicles were somewhat primitive in mechanical and electrical equipment the experiment seemed to be successful. The technical press of that time bears witness to the keen discussions which took place as to the possibilities of the new system. The trolley bus had to defend itself against both the motor bus interests and the firmly established tramcar, but the newcomer proved its worth at least from an economic standpoint on light traffic routes where the tram was definitely unsuccessful: the day had not yet come when road vehicles could surpass the tramcars in riding comfort.

The war put an end, for the time being, to any further development, but the growth of the use of the trolley bus in the years of reconstruction which followed can be traced to some very definite effects which the war produced. The smaller towns had let their track systems get out of good repair and now found that their renewals funds, due to the change in money values, were insufficient for the purpose. Road vehicles had been developed enormously and consequently the roads and especially the narrow streets in towns began to suffer from congestion, and finally the improvement in the construction of road vehicles enabled a trolley bus to be developed which completely surpassed the pre-war examples in comfort, speed, economy and reliability.

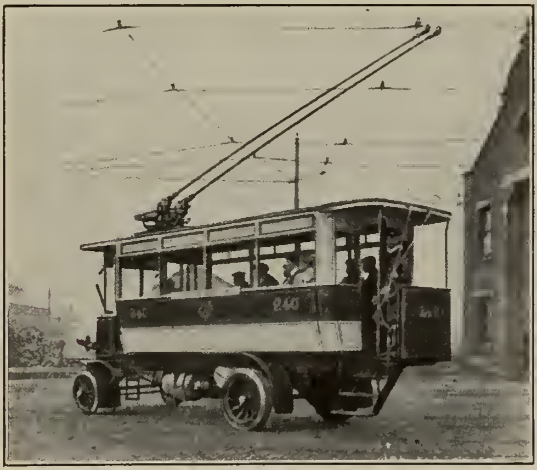

Figure No. 5.—Trolley Bus at Bradford, England, 1911.

Many of the smaller towns have now entirely removed their old track systems, and the movement would seem to be spreading to the larger cities. The latter naturally have a much greater amount of capital sunk in their tramway undertakings, and were better able to keep their systems in good repair during the war; having much heavier traffic to deal with, the tramcar, in these cases, has been quite successful financially. The congestion of traffic and the intense competition of motor bus companies, with the increased use of the private motor car, have, however, helped to decrease the popularity of the trams even in the large cities. It should not be forgotten, however, that great efforts are being made at the present time by the manufacturers to improve the riding comfort and to increase the speed of tramcars so that, with their superior carrying capacity, it would be unwise to say that they have not a very definite and important place in city transportation.

Figure No. 6.—Six-wheeled Double-deck Trolley Bus at Wolverhampton, England, 1926.

Some of the towns have replaced their trams by trolley buses, others by motor buses, while still more have adopted both types of vehicle. The advantages of the motor bus lie solely in its independence of route and overhead fixtures. On the other hand the trolley bus is very much quieter and smoother in motion, due to the absence of reciprocating parts, clutch, and gear box; its acceleration is high and smooth, due to the characteristics of the series motor and its control, while there is entire absence of smell. Use can be made of existing overhead material and of the old tramway power supply and distribution system. Provided that the route is permanent, as are most routes in towns and cities, it is just as flexible in traffic as the motor bus. Unless the service is so infrequent as to require a headway of twenty minutes or more (the exact limiting headway is a matter of local circumstances and cannot be taken as any definite figure to suit all cases), the trolley bus is considerably more economical to operate than the motor bus.

Although the two types of vehicle are often rivals when the removal of trams is considered, it is the enterprise of the motor car industry which has produced a trolley bus seating as many as sixty-five and capable of serving large towns and cities. In figure No. 6 is seen the modern type of

Figure No. 7.—Open Top Double-deck Trolley Bus at Hastings, England.

double-deck, six-wheeled pneumatic-tired vehicle which was first put into use at Wolverhampton in December, 1926.

This bus seats sixty-one and weighs approximately fourteen thousand pounds. It was built by Guy Motors, Ltd., of Wolverhampton. The adoption of the six-wheeled principle, with four driving wheels, has enabled a large capacity bus to be constructed without excessive axle weight. Since the pair of driving wheels on either side are locked together by the transmission gearing, wheelspin is almost impossible since both wheels on one side are very unlikely to leave the road surface at the same instant; thus one of the chief causes of skidding is removed. The two driving axles are situated at the ends of double springs which are slung from the frame at their centre, so that any vertical movement of a wheel only causes half that movement in the frame. Actually, the springs absorb a considerable amount of any such movement, so that the bus is delightfully smooth in motion.

Wolverhampton, with a population of about 134,000, is now served entirely by trolley buses, while motor buses, both single- and double-decked, run to the surrounding rural districts. Trolley buses also connect Wolverhampton with neighbouring Black Country towns, the population of the total area served being about 360,000. During the year ended March 31st, 1930, 23,176,000 passengers were carried by trolley buses alone, which ran a total of 2,419,762 miles. The gross profit of the trolley buses was £75,271 with an average fare per mile of 1.171d. The motor buses ran 2,251,607 miles, carried 16,522,400 passengers, and earned a gross profit of £26,236 with an average fare per mile of 1.196d. There are nearly 30 miles of trolley bus route, and plans are under way for the construction of an additional 13 miles; the system is one of the best examples of the success of these vehicles in a large industrial centre. The schedule speed of the service has increased by over twenty per cent, and the removal of the tracks has been a great boon to motorists. One of the greatest advantages to residents near a route has been the elimination of the often distressing noises of the tramcars.

At the present time, trolley buses are in operation in the following places in England:

Ashton-under-Lyne	Leeds
Birmingham	Maidstone
Bradford	Mexborough and Swinton
Chesterfield	Nottingham
Darlington	Oldham
Grimsby	Ramsbottom
Hastings	Rotherham
Ipswich	St. Helens
Keighley	Southend-on-Sea
Tees-side Railless Traction	Wolverhampton
West Hartlepool	York.
Wigan	

During the present year a great many additional installations will be started, one of the most important being the scheme of the London United Tramways Company who are abandoning some forty-six miles of tramways to the west and south-west of London and are substituting trolley bus routes covering at first about twenty miles in Twickenham, Teddington, Hampton, Kingston, Surbiton, Malden, and Wimbledon. This company has not paid any dividend on its ordinary shares since 1907 or on its preference shares since 1914, and since the war has had to spend £878,000 on track and road maintenance.

Among other places where trolley buses will be installed include Birkenhead, Cheltenham, a route from Atherton to Haydock in South Lancashire, Bournemouth, Newport, Leicester, Liverpool, Derby, and Pontypridd, the latter being the first example of trolley buses replacing street-cars in Wales. Aberdeen, Southport, Preston, and Manchester are also considering the adoption of these vehicles. Altogether twenty-three applications for trolley bus powers were before Parliament this year.

British firms have supplied trolley omnibuses to Christchurch, New Zealand, Bloemfontein, Orange Free State, and also to Italy and Belgium. It is interesting to note that continental opinion is now leaning more to the use of double-deck buses instead of single deckers with trailers, such as were supplied by a British firm to Copenhagen.

As a result of the visit of a delegation of German engineers to England a trial service of trolley buses has been put in operation between Mettmann and Gruiten, near Dusseldorf, this year.

Mechanical Features of the Trolley Bus

Figure No. 9 shows a typical example of a six-wheeled trolley bus chassis (*Note 8*); its outstanding feature is the "dropped" frame, which enables the floor of the bus to be within about twenty-four inches of the ground. The two rear axles are slung at the ends of double cantilever springs and are each fitted with a differential gear. The transmission is through propellor shafting through universal joints. All six wheels are fitted with brake drums, a foot-operated Westinghouse air brake acting on front and rear wheels and on two brake shoes on each of the middle wheels, these being fitted with duplex brakes with four shoes each, the

Figure No. 8.—Four-wheeled Single-decked Trolley Bus at Chesterfield, England.

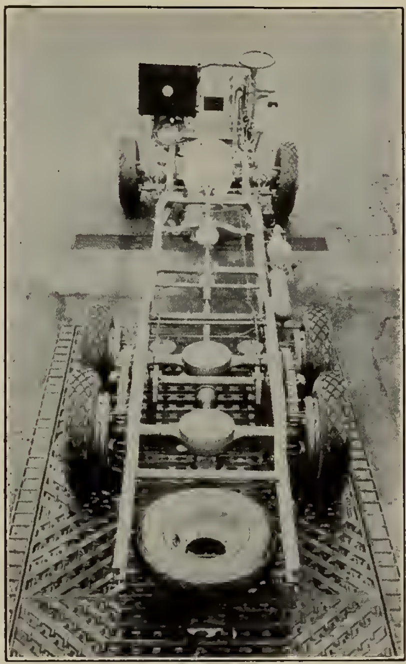

Figure No. 9.—Six-wheeled Trolley Bus Chassis.

other pair in each drum being operated by the hand-brake. In an emergency braking test at Hastings in 1929 on a bus with this chassis, at which the writer was present, retardations of over eleven feet per second per second were obtained by the simultaneous use of all the mechanical brakes. The road surface was dry, and of good macadam, and it was found that with a retardation of twelve feet per second per second the wheels just commenced to slip, thus giving a co-efficient of adhesion under these conditions of 0.40.

The following are representative figures for the type of six-wheeled bus in use at the present time, with covered upper deck:

Weight, complete............from 13,000 to 17,000 lbs.
Mean wheel-base............16 ft
Overall length...............26.5 ft
Height to top of roof........14.5 ft
Overall width...............7 ft 2 in.
Length of trolley poles......18 ft
Tires, pneumatic............36 ins. to 40 ins. by 8 ins.
Seating capacity............54 to 65
Maximum capacity.........85 approximately.

The seats in the latest buses are all of the bucket type and upholstered. Except for two side seats which cover the driving wheels on the lower deck all seats face forward. Unfortunately, it is not possible to use bodies wider than about seven feet, on account of the limited width of the roads; an extra foot in width, which would bring the buses up to the usual dimension on this continent, would entirely overcome the slight lateral overcrowding which takes place.

Single-deck buses, which are used on routes where the traffic is not so heavy, usually have only four wheels, a typical example being shown in figure No. 8. This bus is one of the Chesterfield fleet, and was constructed by Clough, Smith and Company, London. It seats thirty-two passengers, and weighs 12,700 pounds. It is 26 feet long and 7 feet 4.5 inches wide. Nearly all single-deck buses have a centre entrance. The trolley poles are somewhat longer than those on double-deckers, usually being about twenty-one feet.

With an 18-foot pole a trolley bus has an extreme lateral movement of about fifteen feet from the centre line, or about thirty feet in all; for ordinary running a deviation of about ten feet to either side is quite usual. Thus the electric bus is just as flexible in traffic as the motor bus, and is indeed superior in this respect on account of its high acceleration.

Electrical Equipment and Control

In the early days of the trolley bus, as the number of vehicles in operation was comparatively few and as the future of the new method of transportation was uncertain, it was not considered necessary to design equipment *de novo* when existing street-car apparatus could be employed. Consequently in the first buses we find vertical tramway controllers and heavy tramcar motors. As the trolley bus developed, it was realized more and more that in order to obtain the best possible results it would be necessary to build equipment specially designed for the purpose.

Both single-motor and double-motor equipments are used in the latest buses, the usual one-hour ratings being, for a six-wheeled double-decker, either 60 to 80 h.p. if a single motor is used or two 35 to 40 h.p. motors if the older method of series-parallel control is adopted; for a single-decker the ratings are in some cases the same, but a single 50 h.p. motor is also used.

The majority of buses are fitted with series motors, series-parallel control being used with double motor equipment, and shunted or tapped field control for the higher speeds if only one motor is fitted. A popular arrangement for series-parallel control is the "twin" motor, both armatures being mounted on the same shaft.

An interesting application of the compound-wound motor is found on the buses manufactured by Guy Motors, Ltd. The electrical equipment on these vehicles is manufactured by the Rees Roturbo Company, of Wolverhampton. A single 60 h.p. compound motor is adopted with a strong series field which supports the shunt field when taking power from the line. The bus is started on full shunt field with resistance in the armature circuit; when this is cut out in steps by contactor control the bus runs at about 11 miles per hour when taking full-load current of 85 amperes, whereupon further movement of the controller puts resistance into the shunt field circuit, finally bringing the vehicle up to full speed of about 25 miles per hour.

This system is also interesting in being the only example of regenerative braking in use on trolley buses. When the power pedal, which operates the master controller, is allowed to return from its lowest (full speed) position shunt field resistance is cut out and the back e.m.f.

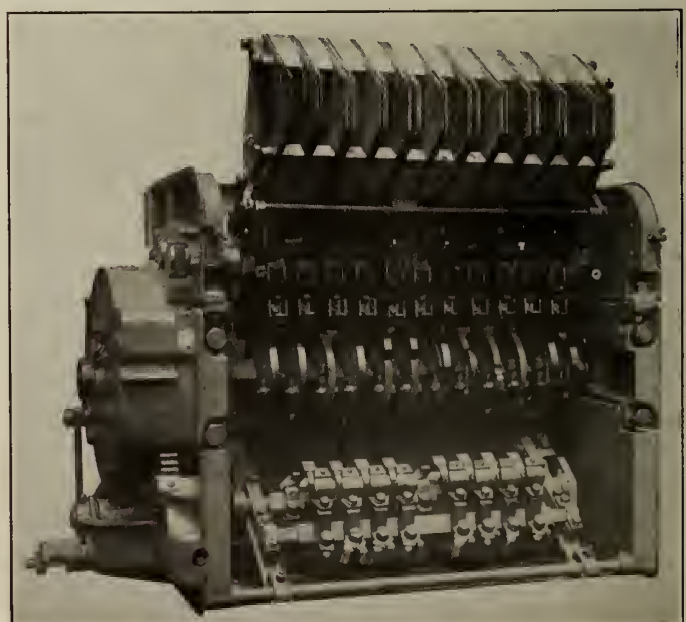

Figure No. 10.—Foot-operated Main Controller for Trolley Bus with series-parallel Control.

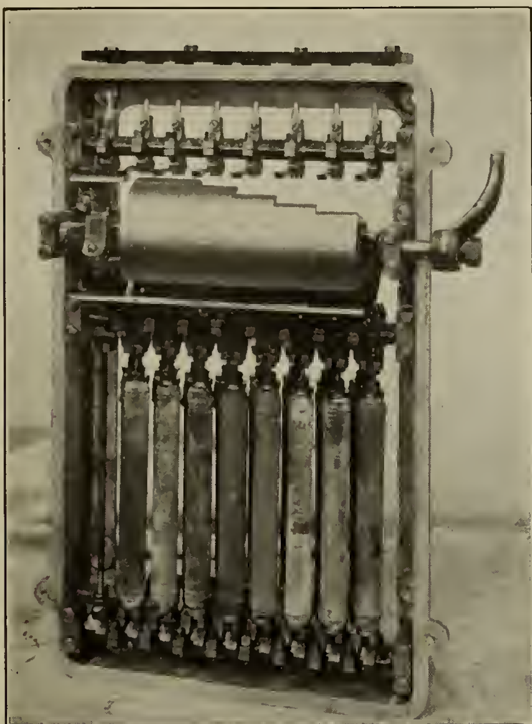

Figure No. 11.—Master Controller for Compound Motor with regenerative Braking.

of the motor rises to a value higher than the voltage of the supply. Under these conditions the machine generates power which is returned to the line, and the bus is braked due to the transformation of its kinetic energy into electrical energy. When regenerating, the series field opposes the shunt field, which prevents any violent or excessive braking effects due to variation of line voltage or careless operation.

The operation of this equipment has been found to be entirely satisfactory, and has proved by experience to effect a saving in current consumption and brake wear. In Hastings, where the routes are hilly, it is said to reduce the energy consumption by about 0.3 kw.hrs. per bus mile. It is only effective above a speed slightly in excess of that corresponding to full shunt field, or about 12 miles per hour. As the energy destroyed while braking varies as the square of the speed, if a bus is brought to rest from 24 miles per hour by regenerative braking down to 12 miles per hour, and by the mechanical brakes below that speed, three-quarters of the energy of motion will have been absorbed during regeneration and only one-quarter remains to be dissipated in the brake drums.

Another type of equipment, constructed by Messrs. Bull Motors, of Ipswich, makes use of an "eddy current" brake, which is operable down to very low speeds. It consists of a short-circuited rotor on the armature shaft which revolves in a field system which is energized by the application of the brake pedal. Its operation is smooth and satisfactory, but all energy is dissipated as heat in the rotor, while the additional weight is quite considerable.

In all cases a foot-operated controller is used. Figure No. 10 shows a foot-operated main controller for series-parallel control of two motors, in which the main motor currents are directly controlled. This is the product of the English Electric Company (*Note 16*).

Figure No. 11 shows the master controller on the Wolverhampton buses. It is operated from the "power pedal" through cranks and rods, and a complete movement from "off" to "full speed" operates consecutively the contactors which cut out the series resistance and then cuts in steps of resistance in the shunt field circuit. The shunt field resistance is seen beneath the controller drum.

All control pedals push downwards to operate, being analogous to the accelerator of a motor bus. A spring returns the controller to the "off" position when the driver's foot is removed.

A reversing controller or switch is always provided which reverses the direction of motion by reversing the connections of the armature alone. This switch is interlocked with the power pedal so that it can only be operated when the main control is in the "off" position.

In order that the whole of the electrical equipment may be isolated from the line, and to protect against overloads, two circuit breakers, one in each lead, are usually situated in the driver's cab. A signal lamp in the cab goes out if the poles come off the wires, while in some cases a system of small lamps informs the driver how far the bus is from the centre of the overhead conductors, this being of great use in foggy weather.

Energy Consumption

At first sight it might seem that the energy consumption of a trolley bus must of necessity be much higher than that of a street-car of similar capacity, due to the greater resistances to motion experienced with a rubber tire on a road surface compared with a steel wheel on a steel track.

The specific energy consumption (i.e., watt-hours per ton-mile) must always be higher in the case of a trolley bus, but the discrepancy decreases as the frequency of stops on a route increases. This is due to the fact that with more stops to the mile a greater proportion of the total energy required is taken up in accelerating the bus, and less in overcoming the resistances to motion.

By keeping the weight of the trolley bus as low as possible the energy consumption per bus-mile can be brought to a very economical figure. For the year 1927-1928 the average consumption for all the trolley buses operating in Great Britain was 1.48 kw.hrs. per bus-mile, with an average seating capacity of 40.4. This figure includes many old buses whose consumption is relatively high; taking particular cases of modern six-wheel double-deck buses, two examples are:

Doncaster — Six-wheel, double-deck, with double motor equipment and series-parallel control: 1.47 kw.hrs.

Wolverhampton — Six-wheel, double-deck, with single compound motor, regenerative control: 1.38 kw.hrs.

Comparing the two cases, the seating capacity is practically the same in each (sixty and sixty-one respectively). There is a slight difference in weight in favour of the Wolverhampton bus, but the difference in energy con-

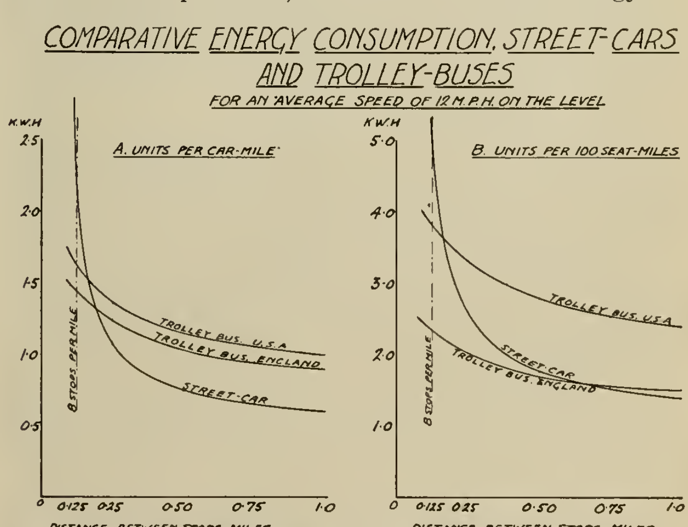

Figure No. 12.

sumption would seem to be due mainly to the electrical systems used. In addition to the saving produced by regenerative braking, there is less loss in the series rheostats in the case of the compound motor, since the greater part of the speed variation is obtained by control of the shunt field, with the series resistance all out. With series-parallel control approximately one-third of the energy supplied during uniform acceleration is wasted in the rheostats, but this is reduced somewhat by shunting the field in the full parallel position to obtain the maximum speed. With shunt field control of the compound motor only about one-quarter is dissipated in resistance.

In order to illustrate the influence of the frequency of stops on the relative energy consumption of trolley buses and street-cars, the curves in figure No. 12 have been calculated from the following assumptions:

American street-car. Light-weight double-truck car.

Seats	42
Weight unloaded	30,000 lbs.
*Weight loaded	32,240 lbs.
Average resistance to motion	12 lbs. per ton (2,000 lbs.)
Average resistance to motion while coasting	15 lbs. per ton
Acceleration	1.5 m.p.h.p.s.
Braking retardation	2.0 m.p.h.p.s.

English trolley bus. Six-wheel, double-deck.

Seats	61
**Weight unloaded	13,000 lbs.
Weight loaded	16,080 lbs.
Average resistance to motion	44 lbs. per ton (2,000 lbs.)
Average coasting resistance	46 lbs. per ton
***Acceleration	2.0 m.p.h.p.s.
Braking retardation	2.0 m.p.h.p.s.

American trolley bus. Four-wheel, single-deck.

Seats	42
Weight unloaded	16,000 lbs.
Weight loaded	18,100 lbs.

Other figures the same as for the English trolley bus.

Note *: The weight loaded has been taken to be the weight when one-third of the seats are filled at an average weight of 140 pounds per passenger. Statistics show that the average load is roughly one-third of the seating capacity. The American street-car and the English trolley bus are assumed to have a staff of two men while the American trolley bus is taken to be a one-man vehicle.

Note **: This represents the lightest weight of a six-wheeled double-deck trolley bus under present conditions.

Note ***: This is a very conservative estimate. The acceleration of modern trolley buses is usually as great as three miles per hour per second or more, while the braking retardation is often greater.

The energy for the short runs is calculated on the assumption of a period of constant acceleration, one of constant coasting retardation, and one of constant braking retardation. The long runs have a period of free-running (constant speed) instead of coasting.

Series-parallel control is assumed in each case, and the loss in the rheostats is taken as 50 per cent of the energy required for acceleration only. An overall efficiency of 80 per cent is assumed to cover all other losses, electrical and mechanical.

The effective weight of the street-car is taken as 5 per cent greater than the dead weight, and the effective weight of the trolley bus 3 per cent above the dead weight, due to the absence of heavy gears, heavy steel wheels, and fewer motors.

The curves give the energy consumption for a run on the level at an average speed (excluding stops) of 12 miles per hour in kilowatt-hours per vehicle-mile and also per 100 seat-miles, the latter figure taking into account the seating capacity and being a fairer method of comparison than the former.

The following general conclusions may be drawn:

(1) For stops as frequent as every 220 yards (an average figure for city service), the street-car cannot compete with the trolley bus if such a high average speed as 12 miles per hour is required. Of the two trolley buses considered, the English one has the advantage due to its slightly lower weight and larger seating capacity.

(2) When a basis of 100 seat-miles is used the advantage of the English bus with stops every 220 yards is greatly increased, and this vehicle keeps the advantage until the distance between stops is over half a mile.

(3) For long periods of running without a stop the street-car is superior to the trolley bus in energy consumption.

In hilly districts the advantage of the trolley bus is increased, due to the lighter weight of this vehicle.

Thus it is seen that for city transportation with fairly frequent stops and a high schedule speed the trolley bus is more economical in energy consumption than the present street-car, due to the practicability of building a bus very much lighter than the modern "light-weight" double-truck street-car.

Actually, with modern traffic control and the rapid acceleration of city traffic, the trolley bus is the only passenger vehicle which can conform economically with conditions of high acceleration.

The figures for double-truck street-cars as used on this continent are often extremely high, due to the use of out-of-date equipment. For instance, the average consumption per car-mile in a certain large Canadian city for the year 1929 was 5.4 kw.hrs. with an average seating capacity of 42.5.

The Overhead Equipment (*Note 9*)

Trolley buses require two overhead conductors for the supply of power to the motors. The usual practice in Great Britain is to space them 18 inches apart and 21 feet above the ground, and the most common size of wire is No. 4/0 s.w.g., which has a cross-sectional area of 0.1257 square inches and a resistance per mile of 0.347 ohm. The weight of such a pair of wires, 40 yards long, with their hangers and insulators, is about 130 pounds. The distance between the wires and the curb is usually about ten feet, which enables the buses to pull into the curb when stopping.

The negative wire is placed next to the side of the road, and triple insulation is placed between it and the positive wire: the insulators on the hangers and a strain insulator in between. A strain insulator should also be used between the negative wire and the pole, so that double insulation exists between the negative wire and ground. This protects the steel pole from electrolytic effects should one of the insulators become faulty. Also, though the present practice

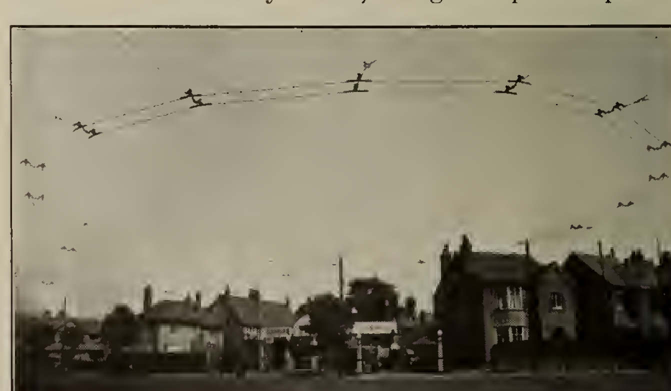

Figure No. 13.—Turning Circle for Trolley Buses.

is to ground the negative side of the line at the power station, there is no reason why the mid-point of the system should not be earthed, giving a maximum voltage to ground of 250 on a 500-volt system.

The positive wire is split into half-mile insulated sections, supplied from feeders as in standard tramway practice. The question of providing negative feeders has to be decided when converting from a track system, and this naturally depends on the circumstances of each case. In Hastings the feeder problem has been solved by the unusual method of using No. 6/0 s.w.g. wire for the overhead conductors (*Note 17*).

Where the two lines cross, it is necessary to insert an insulated crossing wherever a positive wire crosses a negative one. Where a branch line joins a main route, the wires of the latter should be unbroken, and it should be arranged that the wires on an uphill route should be as continuous as possible.

A six-wheeled bus requires a turning space of from sixty to seventy feet in diameter, and the overhead conductors are constructed in a corresponding loop, as illustrated in figure No. 13. Where space is not available triangle turning may be used or the line taken round a block.

Operating Expenses

The advantage of the trolley bus from an economic standpoint was shown long before the new type of vehicle captured the approval of the riding public. Mr. T. G. Gribble, in a paper read before the Institution of Civil Engineers in London in March, 1914, showed that even with a two and a half minute service, representing heavy traffic conditions, the operating costs should be less than those of a track system by about 7 per cent, while the construction costs should be less by about 44 per cent. With a light service of thirty minutes headway these figures would be increased to 36 per cent and 70 per cent respectively.

The economy of the trolley bus may best be verified from the published accounts of the Wolverhampton municipal transport undertaking, and reliable comparisons can be made between all three methods of transportation. For the years 1925-1926, which were the last years of service of the main portion of the tram system, the operating costs averaged 29.58 pence per 100 seat-miles, with an average number of seats per vehicle of 46. For the years 1928-1929, during which trolley and motor buses have been in full operation, the operating costs per 100 seat-miles were:

Trolley buses (average seats 46)	23.76 pence
Motor buses (average seats 38.5)	31.43 pence

Taking the trolley bus figure as 100 per cent, we have:

Trolley buses	100 per cent
Tramways	124 per cent
Motor buses	132 per cent

A more detailed comparison of trolley and motor buses yields the following relative figures:

	Trolley buses	Motor buses
*Maintenance and repairs	1.0	1.53
Traffic expenses	1.0	1.35
Power or fuel	1.0	1.69
General expenses	1.0	0.61

*Includes overhead equipment.

The rates payable on the overhead equipment make the "general expenses" higher in the case of the trolley bus.

The total number of passengers carried by each type of vehicle for the two years in question were:

Trolley buses	32,562,672
Motor buses	25,069,624

Mr. C. O. Silvers, manager of the undertaking, has published the following figures for the period from April 1st, 1929, to January 5th, 1930:

Trolley buses:	operating expenses per bus-mile	10.48 pence
	operating expenses per 100 seat-miles	21.4 pence
Motor buses:	per bus-mile	12.148 pence
	per 100 seat-miles	29.63 pence

The above figures are operating costs only, and do not include any contribution to the renewals fund, which in the case of tramways would require about $15,000 per mile per annum for the track alone.

General Remarks

Wherever the modern trolley bus has been substituted for street-cars a quicker and more popular service has been the result. The overall schedule speed (including all stops and shedding) of the trolley buses in Wolverhampton for the year 1929 was 9.274 miles per hour against about 7.5 miles per hour for the trams. Motor buses had an average schedule speed of 8.53 miles per hour.

The six-wheeled buses, with their balloon tires, are distinctly more comfortable to ride in than the average street-car with its noisy vibration of unsprung weight and often nauseating oscillation of the body. One important factor of the popularity of the trolley bus is its almost complete absence of noise. This is a great boon to the passengers and to the residents along the route, while the nerve-racking medley of city noises is greatly reduced.

In every case of the installation of trolley buses, traffic has been speeded up and congestion relieved. The buses load and unload at the curb and leave the crown of the road to fast moving traffic. The appearance of the road is greatly improved by the removal of the tracks, while the extra overhead wire is hardly noticeable.

Those transportation undertakings which were unable to operate tramways at a profit and which have adopted the trolley bus have found their passenger receipts go up and are now on an economically sound footing.

The ultimate status of the trolley bus is difficult to foresee; at the present time it would seem to be superior to the street-car on all but the heavy traffic routes. Many transport undertakings which serve densely populated areas are renewing their track and replacing their rolling stock by the most up-to-date tramcars, in which great efforts have been made to reduce noise and vibration and to increase speed.

At the same time it should be noticed that in areas of exceptionally heavy traffic, such as in the hearts of London and Paris, the track systems have naturally given way to more flexible road vehicles while the great bulk of the city transportation is carried on underground, where the electric railway can have its own right-of-way and can develop to the full the advantages of steel track. The question naturally arises as to how far it is advisable to attempt to carry the population of a large city on the streets alone. So long as no other method of public transportation is available in such a city then the tramcar, provided that it is an up-to-date vehicle and has a double track in wide and well designed streets, would seem to be the best solution of the problem; but as soon as the density of traffic necessitates the construction of a high-speed electric railway with its own right-of-way, whether underground or not, then the operation of tramways is only duplicating an expensive service, and the local traffic of the streets can be carried much more effectively by the trolley bus. In a rapidly growing city which is destined to have a population of several million it would seem advisable to consider the use of trolley buses before the track system has grown to such an extent that it would be a costly matter to replace it.

Figure No. 14.—Four-wheeled Trolley Bus, Chicago Surface Lines.

It is assumed in the above that street-cars, if used, would have a capacity considerably greater than that of a double-deck trolley bus. The usual single-deck street-car of this continent, seating between forty and fifty, has no advantage whatever over the sixty to sixty-five seater trolley bus.

So far as the smaller towns and cities are concerned, the trolley bus has proved itself to be definitely superior to both the tramcar and the motor bus, and it now seems certain that in such cases the track system is obsolete. It has already been seen that the trolley bus has the advantage over the gasoline vehicle in operating costs, efficiency of operation, and comfort. It is only in rural districts where the service is infrequent, or in developing a new traffic route, that the motor bus is of real advantage in transportation.

The Trolley Bus in North America

The history of the trolley bus on this side of the Atlantic dates from the year 1903, when an experimental line was successfully operated at Scranton, Pa. Other lines were planned following the same system, but it would seem that none of them were actually put into service. In 1910, however, we find a route in operation in Los Angeles, one and a half miles long, which was the only trolley bus system in use in the United States at that time.

Little progress was made in the development of the new vehicle until after the war. Mention should be made however, of a trolley bus which was operated at Merrill, Wis., in 1913 and abandoned the same year. This same vehicle was sold to the West End Street Railway, Boston, where it was in operation for a short time in 1916.

After the war it was found that the cost of installing and operating street railways had increased considerably, so that during the years 1920 to 1924 great interest was shown in the possibilities of the trolley bus (*Note 10*), and a number of systems were put into service in Canada and the United States. This was the first concerted effort on the part of the manufacturers to develop the new type of vehicle, but as the venture was largely experimental, no very serious attempt was made to design equipment specially for the purpose. In consequence, these early post-war buses, with their truck frames, solid tires, and heavy street-car motors, were found in general to be expensive to operate and uncomfortable to ride in. In four cases only have these early buses survived to the present day—in Baltimore, Md., Philadelphia, Pa., Rochester and Cohoes, N.Y. Those systems installed in Staten Island, N.Y., Toronto and Windsor, Ont., Minneapolis, Minn. and Petersburg, Va., have all been abandoned (*Note 11*).

The failure of these systems brought the principle of trackless trolley operation, quite illogically, into disfavour: the failure was due to the fact that the principle had not been developed along sound engineering lines. A committee of the American Electric Railway Association visited Europe in 1924 and inspected trolley bus systems there. At this time the vehicles in use in England were of the old type with solid tires and heavy equipment; apart from their advantage of low capital cost, they were looked upon as having a certain sphere of use where the service was too heavy for the motor bus, but lighter than that necessary to make a track system successful. It is therefore not surprising that the Committee reported that they considered the trolley bus to have too narrow a field to justify its further development. An editorial in the Electric Railway Journal in 1927 summed up the situation with the words: "Whatever the ultimate fate of the trackless trolley may be abroad, it certainly appears to have passed the crest of its popularity in this country" (*Note 12*).

We have seen how improvements in large passenger motor buses enabled the trolley bus to increase in popularity in England; exactly the same thing now happened in the United States, and a new interest was aroused when on September 9th, 1928, a service of trolley buses commenced operation in Salt Lake City (*Note 13*).

For some time previously it had been found that the cost of maintaining track and paving was preventing the successful operation of the street-car system, and during the three years 1925, 1926 and 1927 the company had to abandon over twenty-seven miles of track. One stretch of single line, over four miles in length, was in need of reconstruction and as the route was a profitable one there was no question of abandoning it, but the cost of renewing the track was prohibitive. It was therefore decided to operate trolley buses, and the success of the venture has started a new era in trolley bus operation in the United States.

The new vehicles, 10 in number, are six-wheeled, pneumatic-tired, single-deck buses seating 43. Manufactured by the Versare Coach Corporation, they are a very great improvement on any hitherto used in that country. Weighing about 16,000 pounds, they have a length of 31 feet 7 inches and a mean wheel-base of 18 feet 9 inches. With cushion seats upholstered in leather they bear no resemblance whatever to the uncomfortable vehicles which have previously called forth so much adverse criticism.

The electrical equipment is of Westinghouse construction, and consists of two 50 h.p. series motors, weighing approximately 800 pounds each, arranged for series-parallel control, with rheostatic braking. A pedal operates a master controller, which actuates contactor gear under the rear seat. There are six notches in the series connection, and five in parallel.

Figure No. 15.—Latest type Double-deck Trolley Bus supplied to Birmingham by Guy Motors, Ltd.

Trolley poles 19 feet long connect the buses to the overhead wires, which are 18 feet 6 inches above the ground. The positive is placed 24 inches from the negative wire, while the centre line of the two is 13 feet from the curb.

The operating experience of the line has shown very clearly that the trolley bus in its more perfected state is a most important contribution to transportation problems. The traffic on the route increased by about 30 per cent after the conversion, which increase has been maintained. At rush hours the buses carry from seventy to eighty passengers.

The comparative operating costs of the new buses, motor buses, and street-cars have been given as:

Trolley buses	100 per cent
Street-cars	125 per cent
Motor buses	159 per cent

(compare with figures for English buses)

The energy consumption for the winter months is given as a little over 2.2 kw.hrs. per bus-mile, compared with 4.3 kw.hrs. for street cars.

It is interesting to note that the six-wheel principle is considerably hampered in the United States, due to the more important details being protected by British patents (*Note 8*). Consequently the trend of development seems to be towards a four-wheeled vehicle with dual tires on the rear wheels, as is shown in figure No. 14.

Two such vehicles were put into service in New Orleans on December 2nd, 1929 (*Note 14*). One, built by the American Car and Foundry Motors Company, and fitted with General Electric electrical equipment, weighs 19,000 pounds and has a nominal seating capacity of 40. The other, built by the Twin Coach Company and fitted with Westinghouse equipment, weighs 16,500 pounds and seats 42. Both are fitted with two 50 h.p. series motors, each driving a rear wheel through a separate propellor shaft with a gear reduction of eleven to one. A foot-operated master controller and contactor gear under the rear seat give series-parallel control and automatic acceleration by means of an accelerating relay, which allows a step of resistance to be cut out only when the motor current has dropped to a definite value. In the General Electric equipment the resistance contactors are closed by cams on a shaft driven by an air engine.

A perfectly smooth acceleration of over 3 miles per hour per second can be obtained, while retardations of about 6 miles per hour per second are common. The manufacturers give 1.7 kw.hrs. per mile as the average energy consumption.

In the course of a few months Chicago will have the largest trolley bus installation in the United States (*Note 15*). A total of 41 buses will serve five routes with an aggregate mileage of seventeen. The first route, 3.75 miles in length, was opened on April 17th, 1930, and 13 buses maintain a three-minute service in rush hours and a seven-minute service at other times. The buses are four-wheeled forty-seaters; see figure No. 14.

Among places where the most recent type of trolley bus has been installed are Manila, P.I., Knoxville, Tenn., and Detroit. Other cities are now taking an interest in the system.

It would therefore seem that the trolley bus is finding a definite place in American city transportation. As the forty-seater single-decker has a smaller carrying capacity than large up-to-date street-cars, its sphere of use is naturally not on the heaviest traffic routes, but rather in residential districts where traffic is not so heavy and its comfort and absence of noise are particularly appreciated, or in any situation where it is found that the density of service is insufficient to warrant satisfactory maintenance of track.

Though this would seem to be the situation at the moment, the trolley bus has proved so popular and successful in the few years that have elapsed since it was first made a comfortable vehicle, and since any change in street-car practice must necessarily be gradual on account of the large amounts of capital invested in track and cars, it is not improbable that the trolley bus will come to be used much more widely and in situations where the street-car is considered to be supreme. In all but the large cities the profitable operation of street-cars is often very doubtful, while the trolley bus has great advantages over the motor bus except where it is quite impossible to erect overhead wires or where the service is temporary or very infrequent.

In a large city it is an advantage to the riding public to have a homogeneous service; that is, a service that only uses one type of vehicle. If the major part of the system is served by the street-car, as happens in the typical Canadian city, the density of traffic is really only great enough to justify street-cars in the concentrated business areas, and this is the point where track vehicles contribute most to traffic troubles and congestion. On the extensive routes which serve the residential portions of the city the traffic must in many cases fall below the economical limit for track maintenance. At the same time, in a growing city the existing track system is always lagging well behind the real traffic requirements of the population, whereas a trolley bus system, on account of its low capital cost, could easily keep pace with the growth of a city and at the same time would alleviate troubles of traffic congestion in the business areas.

With the ever-increasing number of private automobiles, it becomes more and more important to provide an efficient and comfortable method of mass transportation, in order to stem the inevitable congestion of the streets produced by vehicles which take up an extremely large road-area per passenger carried. It is obviously extremely difficult, if not impossible, to limit the use of private cars by law, so that it is necessary to provide a public service which will be attractive enough to compete with the automobile.

The increased comfort, speed and economy of the modern trolley bus have shown that it is no longer necessary to have a steel-tired car running on expensive track in order to provide comfortable city transportation. The street railways are already in existence and have an enormous amount of capital invested in them, so that no sudden change is possible or desirable except when companies are faced with necessary track reconstruction; it is then that a bold policy of scrapping the old and adopting the new may make all the difference between financial success and failure.

A Method of Equalizing Stresses in Masonry Arches with Particular Reference to Arched Dams

H. B. Muckleston, M.E.I.C.,

Consulting Engineer, Vancouver, B.C.

Paper read before the Vancouver Branch of The Engineering Institute of Canada, March 27th, 1930.

General

In the normal course of things, a masonry arch is built on centring and, after being keyed up, is swung by gradually lowering the falsework until the arch is self-sustaining. When the centres are struck, the arch is at once put under stress due to its own weight and during its ordinary service is subjected to further and varying stresses by whatever live load may come upon it. If the material in the arch were perfectly rigid, that is, not subject to strain as a result of stress, it would be possible, at least in theory, to design the curve of the neutral axis and the profile of the ring so that the dead load stress would be of uniform intensity over every radial section. The unit stress at any point would be the same as at any other point and there would be neither moment nor shear anywhere in the ring.

Since, however, every material of which we have knowledge is subject to strain as a result of stress, it follows that the size, or the shape, or both, of the arch ring under its own weight must differ from that of the unloaded arch. If the arch is built without hinges, as most masonry arches are, the ring must change its shape under load. The tangent to the neutral axis is fixed at the abutment, or practically so, and hence the change in shape must involve a shortening of the radius of curvature there and a lengthening of the radius at the crown. At two intermediate points there will, of course, be no change. These changes in curvature must involve bending moments in one direction or the other with the consequent result that the stresses over any cross section, except at the two points mentioned, are no longer uniform. In other words, the line of thrust no longer coincides with the neutral axis, and, since the maximum fibre stress is limited to a definite figure, it follows that the material is not being used to the maximum advantage.

In addition to the change of shape due to dead load, there is a further change due to the shrinkage of the concrete in setting. Most of this is really a thermal effect caused by the dissipation of the chemical heat developed in the hydration of the cement, but a small part is due to the evaporation of the surplus water not needed for hydration. If the arch were free in space, this shrinkage would merely result in a change in dimensions, but as it is not free, shrinkage must result in a change of shape as well. This deformation is in the same direction as the deformation due to dead load and the two must, therefore, be considered together.

It is impossible to prevent these deformations, but if it were possible to neutralize them in some way, we could effect a material saving in the masonry of the ring which would be reflected in a further saving in the abutments and piers. Obviously, too, the saving in weight of the ring would extend the field of the masonry arch to spans otherwise considered impracticable. This compensation cannot be effected by any jockeying with the curve of the neutral axis, in fact, any such attempts usually result in making a bad matter worse. The necessary compensation can only be accomplished mechanically, by introducing stresses of opposite sign to those set up by the deformations caused by dead load and shrinkage. One method of doing this forms the subject of this paper. The method will be described as it would be applied to arch dams, but it will be realized that it is perfectly general in its application and can be applied to masonry arches of any kind. Indeed, it also has application to structural elements other than arches should the need be apparent.

Mechanics of the Arch Dam

In figure No. 1, the solid lines are a cross-section of a hollow cylinder exposed to uniform radial inward pressure all round the circumference. If the thickness of the cylinder wall be small in proportion to the outside diameter, we may assume that it would be subjected to uniform circumferential compression; the circumference would be shortened and every point would move inward on radial lines so that A would move to A' and B to B'. There would be a change in size but no change in shape.

In figure No. 2 we have a segment of a cylinder, fixed at the abutments A, B, and G, H, and subjected to radial pressure. Since the segment is fixed at the abutments, no movement can occur at those points, but elsewhere it is free to move radially, and D will move to D' and E to E'. The tangent at the abutment being fixed, the radius of curvature there must be shortened which will involve a compensating increase in the radius of curvature at the

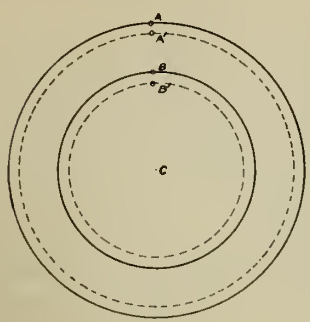

Figure No. 1.

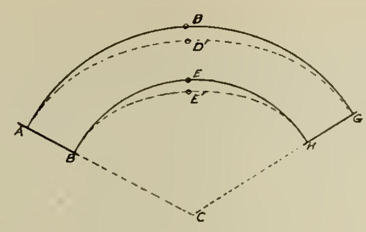

Figure No. 2.

crown, and the segment will be deformed to some such curves as *GD'A* and *BE'H*. This change involves bending moments which will be of one sign at the springing line and of the contrary sign at the crown. When these moments are combined with the tangential thrust, the resulting condition of stress will be as shown in figure No. 3. At the abutments, the stress varies from a maximum at the intrados to a minimum at the extrados; at the crown, from a maximum at the extrados to a minimum at the intrados. At or near the quarter points, the stress is uniform over the section, but the masonry is nowhere used to its maximum advantage. The condition shown in figure No. 3 is more favourable than is usual in an arched dam. As a general rule, tension will be found on the minimum side for some distance either way from the crown and almost always for some distance inwards from the abutments. If the stresses are to be made uniform throughout the arch, it is necessary to introduce by mechanical means stresses of opposite sign to those set up by the deformation under the water load.

Consider for the moment that the arch is constrained only at the abutments and free at all other points. Assume that a very thin radial slice, perpendicular to the plane of the paper, were cut out of the arch at the crown, *DE*, and that an infinite number of very small jacks were inserted in the cut, so arranged that they would either force the sides apart or pull them together. Let each jack exert the same force as existed previously in the uncut arch, the stresses in the masonry adjoining the cut would be the same as before the cut was made and we would have the condition shown in figure No. 4, where each jack is represented by an arrow, and the force which it exerts is measured by the length of the arrow, positive or compression when drawn to the right, and negative or tension when drawn to the left. Now assume that to the force exerted by each jack there be added an equal positive increment, we should have the condition represented in figure No. 5, where U represents the amount of the increment. The effect is to change previously existing tension to compression, but it also results in increasing the compression at the opposite edge where, by hypothesis, it was already at the allowed maximum. Clearly, nothing much has been gained by this operation.

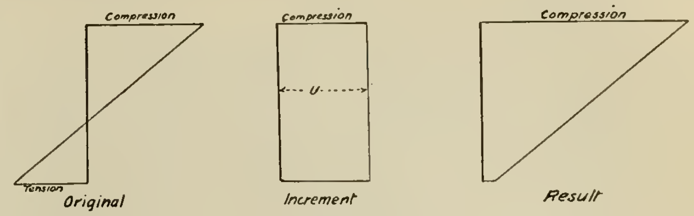

Figure No. 5.

Instead of applying an equal increment to all the jacks, assume that the increment is graduated so that it is negative where the initial stress is positive and positive where the initial stress is negative. In this way we could get the result shown in figure No. 6, with the stress uniform across the section. For mechanical reasons, it probably would not be possible to introduce negative increments in this way, the best we could do would be to graduate the increment from zero at the positive edge to a maximum at the negative edge with the result shown in figure No. 7, where the stress is still uniform but higher than in figure No. 6. We have assumed an infinite number of very small jacks. In practice we should have to use some finite number and, for many reasons, we should limit this to two or, at most, three, and we should have the condition shown in figure No. 8, where G_1, G_2, G_3 are the increments of the forces which each jack must exert. Actually, of course, the line of the resulting stress would not be stepped as shown but would be smoothed off as indicated by the dotted line.

Hitherto, it has been assumed that the compensating forces were applied after the dam was deformed by the water load. Obviously, it will make small difference in the ultimate result if we apply them first and the load afterwards. In that case we should deform the dam in the opposite direction and in opposite amounts to the deformation which will afterward occur under the water load. In the case of a bridge arch, the live load (and, possibly, part of the dead load) is still to come on, and it makes no difference which we do first, though, for practical reasons, the compensating forces are more easily applied while the bridge is on its centres. In the case of a dam, we must apply the compensating forces before the water load comes on, otherwise the dam would be subject to the very conditions which we wish to avoid.

The method of using jacks to compensate for the deformation stresses due to dead load and shrinkage has been used, principally in Europe, with success in the case of long span bridges. The operation is carried out while the arch is on its centres and, after jacking is completed, the wedge-shaped cuts are filled with concrete. The operation is a delicate one and the apparatus expensive. Consequently, the method has been confined to long spans where the possible saving in concrete can pay for the labour and plant involved. Even in a small bridge, the total forces required are very great, but not out of reach of hydraulic jacks. In even a very small dam, the forces are enormous and quite beyond the possibilities of any system of hydraulic jacking. Something cheaper is needed.

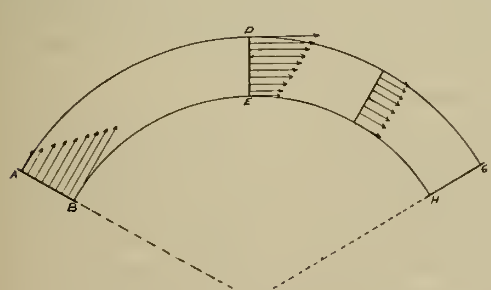

Figure No. 3.

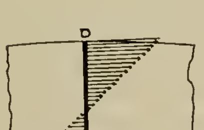

Figure No. 4.

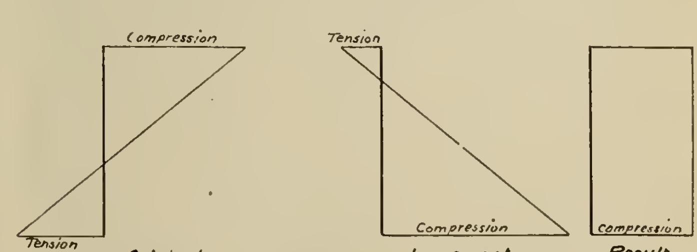

Figure No. 6.

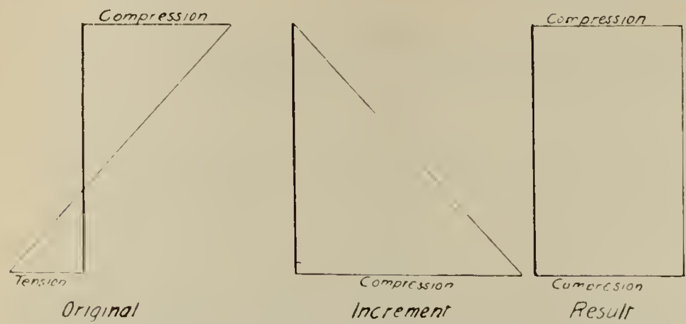

Figure No. 7.

cannot begin until either the joints or cracks are closed, or all the tension has been changed to compression. In other words, the dam must first deflect enough to compensate for all the shortening due to shrinkage, and during this primary deflection the dam is not an arch at all but a system of cantilevers. This effect can be avoided if construction joints are provided and filled up solid, *but only if this is done after all the shrinkage has taken place.* In a thick dam, this may not occur till after the lapse of months, or, even years. It is one of the advantages of Dr. Vogt's method that the shrinking process can be very much accelerated and the time materially reduced.

Method of Differential Pressure Grouting

The method now to be described was developed primarily for use with arch dams, but it is perfectly general and can be used even with quite small bridges and shows a saving where the use of mechanical jacking would be quite out of the question by reason of cost. The method requires no expensive apparatus unusual on small jobs, a small pump and a grout mixer being all that is needed. The process is the invention of Dr. Fredrik Vogt, a noted Norwegian engineer, formerly retained by the United States Bureau of Reclamation as consultant in the design of the proposed Boulder canyon dam on the Colorado river.

Shrinkage and Arch Dams

Any dam is bound to be subjected to stress arising from the shrinkage of the concrete in setting. If it were free in space, this shrinkage would amount to something in the neighbourhood of three-quarters of an inch in 100 feet; but, since it is not free, the shrinkage must result in setting up stress in the concrete and the dam will probably crack across at intervals. If it were a straight dam, these cracks would come at intervals between 30 feet and 60 feet apart. In a curved dam, some of the stress can show up by shortening the versed sine of the arc, that is, by pulling the arch downstream, and the cracks may be much further apart. The consequence is that ugly stresses of very uncertain magnitude may be set up. In order to avoid these, it is now common practice to divide the arch into sections or voussoirs by construction joints from 30 feet to 60 feet apart along the arc. These joints are generally formed with steps or off-sets so that half the area is available to take any shear which may develop and also to prevent leakage.

It must be noted that these joints do not prevent the shrinkage; shrinkage takes place, joints or no joints. Their function is to prevent the concrete from cracking across at undesirable, unexpected and unpredictable places and to ensure that the structure will be, at least, relatively free from utterly incalculable stresses. If joints are provided in an arch dam, shrinkage opens them up; if no joints are provided, the dam either cracks across or the concrete is subject to very high tension. In any event, arch action

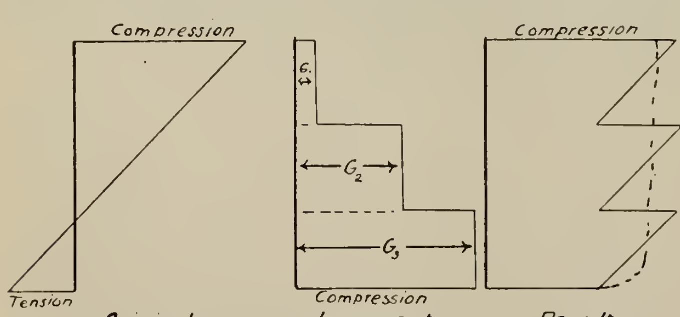

Figure No. 8.

Description of the Vogt Method

The Vogt method does not avoid the use of construction joints, in fact they are an essential feature in its operation. Figure No. 9 is a horizontal section across one of these joints as designed for use in the Vogt process. Positive water stops are provided as shown at two or more points dividing the joint into vertical compartments, usually two or three. These compartments are closed top and bottom by other stops, as shown in figure No. 10, which is a vertical section across the same joint. They are also subdivided into sub-compartments by other horizontal stops. Suppose one of these sub-compartments were filled with fluid grout and that, before it could set, the grout were subjected to

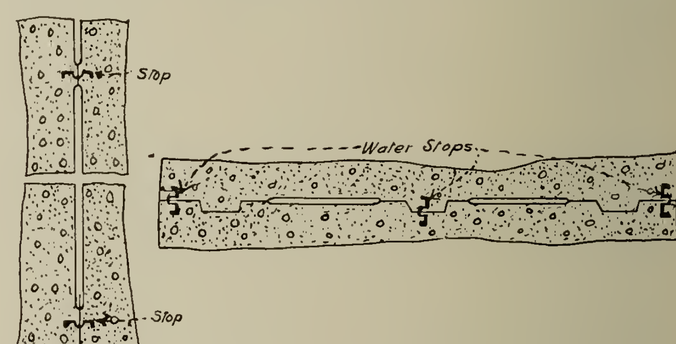

Figure No. 9. Figure No. 10.

the proper hydraulic pressure. The result would evidently be to force the sides of the compartment apart, just as the jacks would do in the previous illustration; in fact, the compartments are jacks of high efficiency on a very large scale. If this pressure were maintained until the grout had set hard, the condition of figure No. 8 would exist thereafter. Freed of detail, this is the method patented by Dr. Vogt.

Analysis of Arch Dams

An arched dam may be conceived as made up of a system of elementary horizontal arches superimposed one on another. Since the lowest arch of the system is constrained by the foundations and each of the rest is more or less constrained by its neighbours as well as at the abutments, these elementary arches cannot deform independently according to the load which each might be supposed to carry. In addition to this, the spans of the elementary arches all differ and so may their radii. As a result of all these and many other factors, the real condition of stress in an arch dam is so complex that an exact mathematical analysis is impossible. If any analysis at all is to be attempted, some simplifying assumptions must be made.

Simple Cylinder Hypothesis

In the earliest practice, it was assumed that each of the elementary arches carried its share of the load to the abutments as if it were a *complete cylinder*, free from constraint by its neighbours and able to deform in its own way; that is, the stresses due to deformation were ignored or assumed to be zero. This very convenient hypothesis is generally known as "the simple cylinder hypothesis" and it results in a very simple and easily applied formula. It was early realized that it gave a far from exact picture of the actual condition of things, and the unit stresses were always assumed at a very low value in order to compensate for the unknown factors. While very high unit cylinder stresses are found in some early examples, 940 pounds per square inch in one case, it is worth notice that, in over 100 dams, only eight show cylinder stress over 400 pounds per square inch, and in but three of these is the cylinder stress over 600 pounds. In these latter cases, the dams are thin and of long radius, conditions which are favourable to the simple cylinder hypothesis. The theory is still used to get the preliminary design for analysis by more exact processes.

The Modern Hypothesis

In the more modern dams, the analysis is based on a much more complex theory. The dam is assumed to be made up of a system of elementary horizontal arches superimposed on a system of intersecting elementary vertical cantilevers, and the water load is assumed to be divided between the two systems in such proportions that the deflection of any point, considered as a point on an elementary arch, will be the same as its deflection, considered as a point on the intersecting cantilever, when each element carries its proper share of the load. The tests of the experimental dam at Stevenson creek have shown that this hypothesis gives results which are sufficiently close to the truth for practical purposes of design. Any errors there may be are of a lower order of importance than the inevitable errors in choosing the elastic co-efficients and other constants involved. Analyzed on this hypothesis, the arch loads are generally found to be far from uniform around the arc. Moreover, there are shearing stresses, both radial and tangential, between the arches. For these reasons, among others, it is not possible to compensate for the deformation stresses at the crowns of the arches only, as we can do with a bridge arch. It is necessary to vary the compensation stresses at several points along the arch and also at several points on the cantilevers. For the ideal 100 per cent efficiency, it would of course, be necessary to have an infinite number of joints and an infinite number of compartments in each, and to apply different pressures in each compartment. This is, of course, impossible. For practical purposes, it is sufficient to divide the dam by the usual number of joints; to divide each joint into one or more vertical compartments, and each compartment into one or more sub-compartments. In this way, it is possible to get results within 60 per cent to 80 per cent of the ideal.

Cantilever Stresses

This process of forcing grout into the construction joints has the effect of lengthening the neutral axes of the arches and, hence, of forcing the arches upstream. This, in turn, forces the cantilevers to bend upstream. As the effect of the water load is to bend them downstream, the two effects are opposed, and the result is that the cantilevers are relieved of some of their load and the cantilever stresses are reduced.

Lamé Effect

It will be remembered that, when figure No. 1 was considered, it was stipulated that the walls of the cylinder must be thin relative to the external diameter. The stresses in the walls of a cylinder are never uniform under any circumstances. However, if the thickness does not exceed about one-fortieth of the diameter, they are so nearly uniform that the departure may be neglected. As the ratio increases, the departure also increases until, when it reaches one-quarter, the stress in the intrados may be about three times that at the extrados. This is known as "the Lamé effect" and is the same phenomenon which makes it necessary to build up a big gun by shrinking the outer hoops onto the inner tube. In a high dam of short radius, the thickness of the lower arches may be so great that they cannot be treated as thin cylinders and the arch stresses, quite apart from the stresses due to deformations, will be very far from uniform over the section. Dr. Vogt's system can compensate for this inequality in the same way as it compensates for the stresses due to deformation under load.

The Merits of the System

Summing up, the merits of the system described may be set out as follows:—

(1) It acts to equalize the arch stresses by correcting for the distortion caused by the water loads;

(2) It acts to equalize the, so-called, cantilever stresses and eliminate tension in the cantilever elements;

(3) It compensates for shrinkage and can, if necessary, accelerate the shrinking process;

(4) It compensates for the Lamé effect in thick arches.

If all the above actions were 100 per cent efficient, it would be possible to design by the simple cylinder formula with the assurance that the assumed cylinder stress would not be exceeded and that, so-called, cantilever stresses would not exist. In actual practice, the efficiency can be brought up to better than 80 per cent and the dam can be designed as a free cylinder on the basis of a unit stress 80 per cent of the maximum with the assurance that the prescribed stress will not be exceeded and that cantilever stresses will be of no importance, and certainly not show tension.

Examples of Practice

It may be said that all the above is very fine in theory, but what can the system accomplish in practice? The following examples may answer the question. Neither represents a structure which has actually been built, but they do show in a measure what results can be obtained.

Figure No. 11 shows plan, elevation and section of a dam designed by Dr. Vogt with the use of his method an essential factor in construction. The dam is 350 feet high with a span of 700 feet. It is of the variable radius type and its dimensions were determined by the simple cylinder formula using a unit stress of 420 pounds per square inch as a basis. The construction joints are spaced about 40 feet apart and are divided into compartments as indicated by the dotted lines on the cross-section. The design was then analyzed by the more exact hypothesis. Table No. 1, case No. I, gives the stresses so found. It is assumed that the construction joints have been filled up *after all the shrinkage has occurred*. In case No. II, the various compartments have been grouted, each with the proper pressure, varying from 380 pounds per square inch downward. Note that, in case No. I, both arch and cantilever stresses show tension of sufficient magnitude to crack the concrete, while in case No. II, there is no tension at all, not even in the cantilever elements where we should expect to find it in a dam of this sort. The high tension in the cantilever elements is an undesirable by-product of the variable radius and vertical downstream face. At the same time, the use of a variable radius makes for an enormous saving in masonry over a dam for the same site with constant radius. Without the use of the compensating process this dam could not be designed with variable radius and this saving could not have been effected. For this site, had a dam with constant radius been designed, the subtended angle of the lower arches would have been so small that arch action there would have been doubtful, to say the least. However, assuming that arch action would exist, the lower arches would have been so thick that the Lamé effect would govern for dimensions and the resulting dam would have approached the gravity section. It will be seen, therefore, that the differential grouting process effected a double saving, in that, it allowed the use of the variable radius, and the maximum stresses are very near the average. The maximum arch stress in case No. II is 490 pounds per square inch while the stress by the simple cylinder formula is 420 pounds. Thus, the efficiency is rather better than 80 per cent. The maximum cantilever stress is below 600 pounds per square inch. As good concrete will safely stand at least 800 pounds per square inch, the dam might have been made with a smaller section even than shown. If designed for a maximum of 800 pounds per square inch instead of 600 pounds per square inch, the saving in masonry would have been about 20 per cent.

The dam as designed is about 96 feet thick at the base, and half-way up it is still about 60 feet thick. Without artificial aid, it might require from five to nine years for all the chemical heat to dissipate. If the construction joints were filled up before this lapse of time, the remaining shrinkage would, at least, reduce the arch action and thus throw additional load on the cantilever elements, with horizontal cracks in the upstream face as a probable consequence. If the dam is designed for differential pressure grouting, the shrinkage can be much accelerated. Without artificial aid, all the chemical heat must be dissipated by conduction through the only available surfaces, i.e. the two faces of the dam; also the temperature gradient is fixed by the atmospheric temperature at these two faces. If cold water were circulated through the

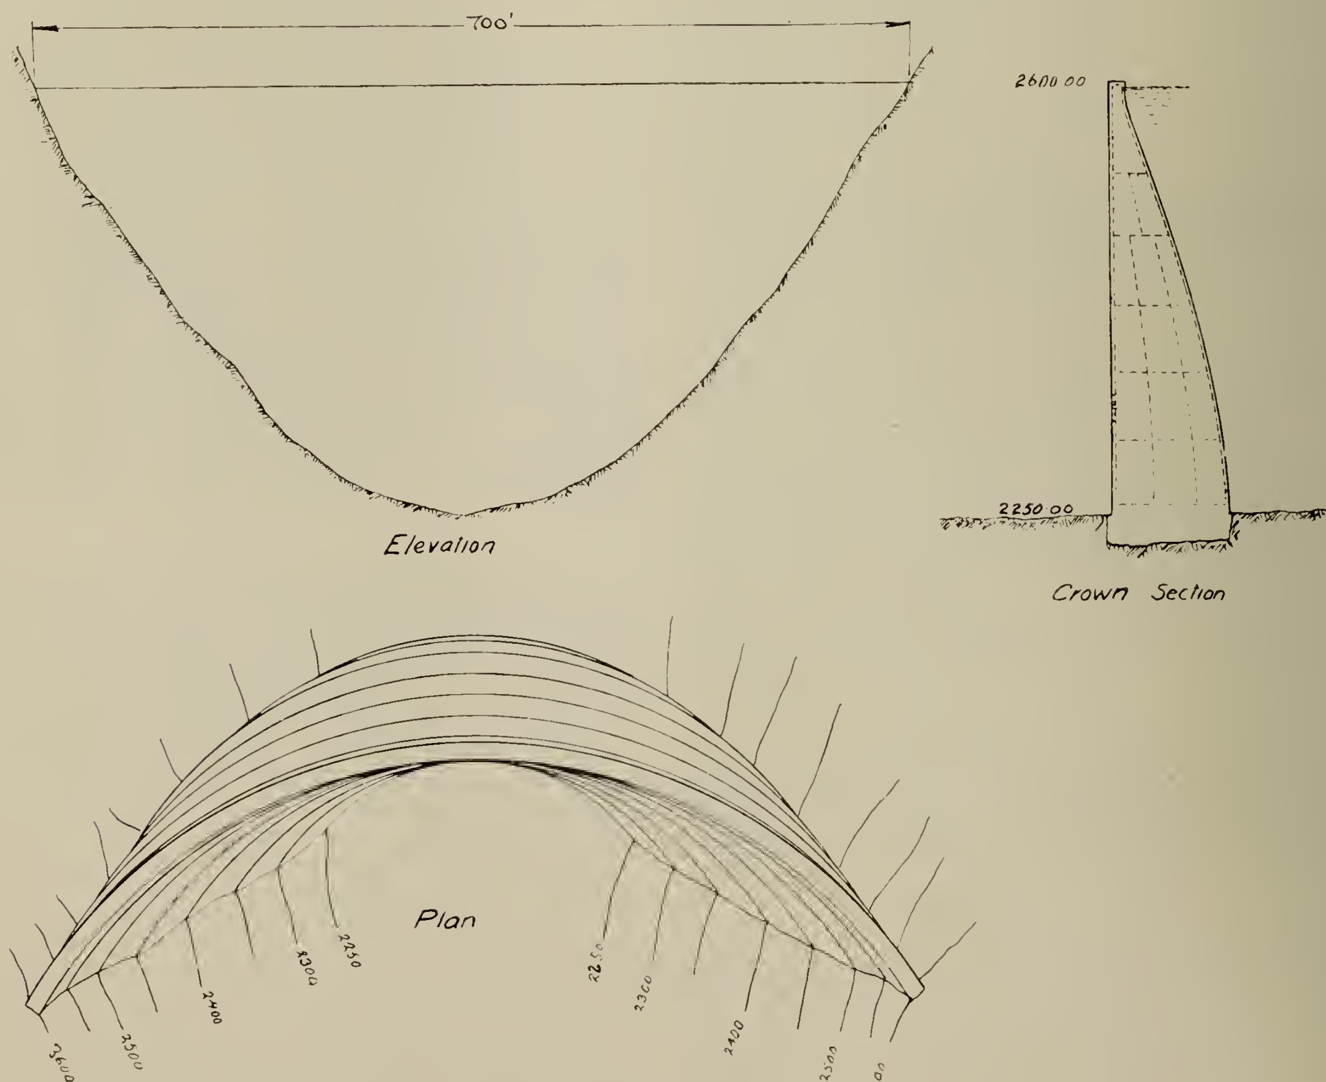

Figure No. 11.

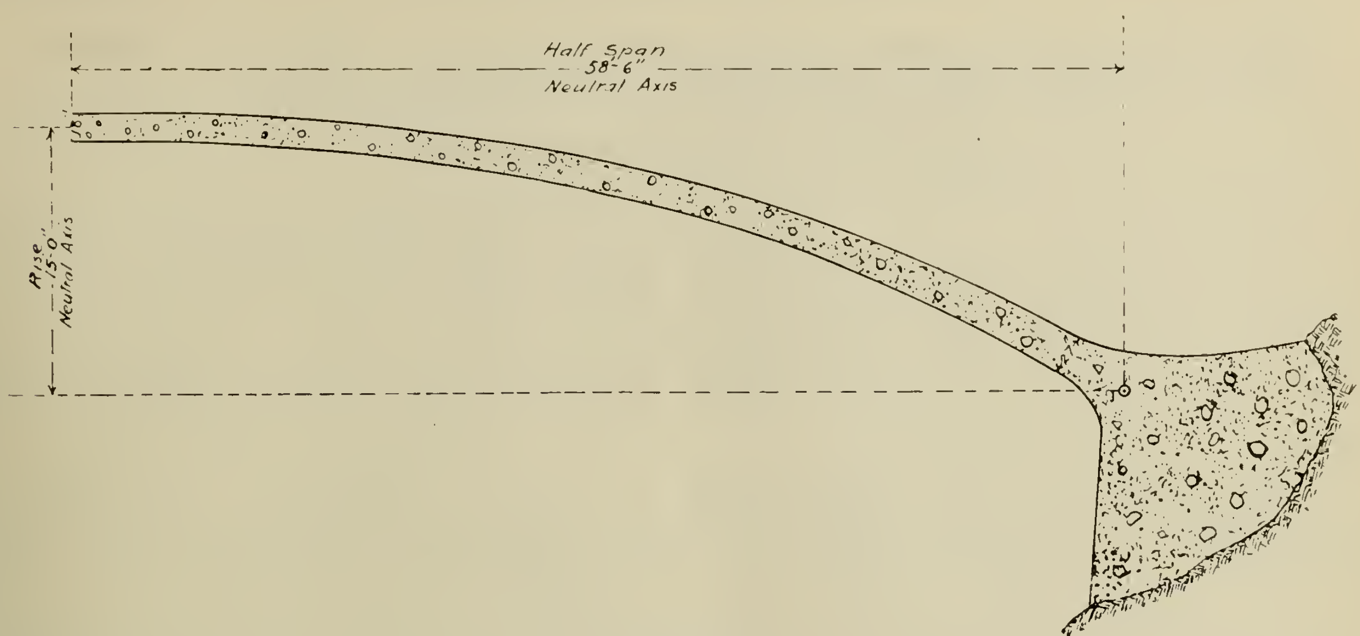

Figure No. 12.

grouting compartments, the available radiating surface would be about doubled and the temperature gradient increased about eight times. As a result, 90 per cent of the chemical heat could be dissipated in about one-tenth of the time otherwise necessary. To compensate for the whole of the shrinkage by pressure alone would require pressures in the order of 1,200 pounds per square inch while the remaining ten per cent would only need about 120 pounds per square inch.

Application to a Bridge Arch

As an example of this method of compensating for the deformation stresses as employed for a bridge arch, figure No. 12 is presented. The arch shown is one of a series of three for a highway bridge designed by the writer. It is a spandrel-filled arch with a span of the neutral axis of 117 feet and a rise of 15 feet. In a flat arch of this ratio, the stresses due to rib shortening and shrinkage reach very large proportions. In the particular example shown, they are so great that the arch would not be stable without reinforcement to the extent of one per cent of steel in each face. If these stresses could be neutralized, the arch would be stable with rather less than one-quarter per cent in each face. In order to do this, a grouting compartment is formed at the crown, eleven inches wide with its centre one inch below the neutral axis, and grouted at a pressure of 260 pounds per square inch. Table No. II shows the results. The stresses shown are calculated for the plain concrete rib without reinforcement and include dead and live load, rib shortening, shrinkage and temperature stresses. The residual tension at the springing line is due to temperature and might have been avoided by a slight increase in thickness. However, a small amount of steel is a wise precaution in a flat arch for reasons other than the possible stresses and it did not seem worth while to make the change. The saving in the weight of steel in the three arches amounts in money to about $9,500.00.

This arch ring is 30 feet wide and the total compensating force is, therefore, about 520 tons. To apply this force by jacks would require, say, 29 jacks, each of 18 tons capacity. On account of the limited room available, ordinary commercial patterns could not very well be used and they would have to be specially made in consequence. As the salvage, if any, would be small, the cost may be imagined. With the grouting method, there is no special plant to speak of, a small pump being all that is needed, so that cost would not be great.

As a further example, applied to a small arch dam designed by the writer, the grouting process worked a saving of about 900 cubic yards of concrete in a total of 4,000 cubic yards, which in money is worth about $16,000.00. Even if half this sum were needed for the grouting process, an impossible assumption, the remaining saving is by no means negligible.

Table No. I

350 feet variable radius arch dam, 700 feet span

		Stresses—lbs. per sq. in. tension minus: Maximum	Minimum
Case No. I	Uncompensated, Cantilever stresses	+ 940	− 160
	Arch stresses	+ 650	− 90
Case No. II	Compensated, Cantilever stresses	+ 590	+ 80
	Arch stresses	+ 490	+ 280

Table No. II

117 feet spandrel-filled arch bridge 15 feet rise

	Stresses—lbs. per sq. in. tension minus: Extrados	Intrados
Crown stresses:		
Compensated	+ 725	+ 113
Uncompensated	+ 908	− 92
Springing line:		
Compensated	− 116	+ 724
Uncompensated	− 409	+ 1,043

Acknowledgments

The writer is indebted to Dr. Vogt, patentee of the process, for the calculation of the first example, and to him and Mr. B. F. Jakobsen of Los Angeles for reviewing the paper and for much valuable advice in its preparation.

Discussion on "A Method of Equalizing Stresses in Masonry Arches with Particular Reference to Arched Dams"

Paper by H. B. Muckleston, M.E.I.C.[1]

C. R. Young, M.E.I.C.[2]

In the first paragraph there is too broad a statement with respect to the possibility of designing a rib in such a manner as to give uniform intensity of stress for every radial section. Obviously this would not be possible for any moving load such as might be realized on a bridge or roof arch. The author probably had the arched dam in mind when writing this paragraph and perhaps it would be well for him to make the limitation clear.

While entirely favourable to the publication of this paper, Professor Young is not sure that certain difficulties in practical carrying out of the method might not be encountered and that it might prove less satisfactory than a theoretical discussion would indicate. Concrete is notoriously porous, and the discussor wonders whether it would be possible to maintain a sufficient water-tightness by means of water stops, particularly at the corners of the open spaces, to make the development of large hydraulic pressures through a grouting machine possible. If the author knows of any actual tests of high pressure grouting, it might be useful to add some mention of it to the paper.

H. B. Muckleston, M.E.I.C.[3]

The author notes Professor Young's remarks concerning the porosity of concrete, and the possibility of maintaining sufficient water-tightness to make the development of large hydraulic pressure possible. It would, no doubt, be difficult if the operating fluid were water, but, even then, some fairly large water pressures have been retained in concrete cylinders. With a highly viscous fluid, such as fairly stiff grout, there should be no practical difficulty in holding the pressure for twenty-four hours, which is all that is necessary with high alumina cements. It is, of course, necessary to provide against the possibility of the stops being blown out. This is a mechanical problem. In the case of the bridge arch illustrated, it was proposed to make the grouting pocket a completely enclosed box of thin copper well tied across by wire to prevent bursting out at the ends.

The system is now being used on a dam designed by the writer for the water supply of Nanaimo, B.C. This dam is about 90 feet high with a crest span of 180 feet. The subtended angles vary from 120 degrees at the crest to 104 degrees near the bottom and the radius of the extrados from 97.5 at the crest to 70.7 at the bottom. At the centre of the crest, the dam overhangs the base about 27 feet and is only 7 feet thick at the base. It will be grouted at a maximum pressure of 110 pounds per square inch. It is hoped that this work will be the subject of a further paper, probably by a University of British Columbia student working on the job, who has commandeered the writing of it as a thesis for his final examination for registration with the Association of Professional Engineers of British Columbia.

The Annual General Meeting at Montreal, 1931

The Forty-fifth Annual General Meeting of The Engineering Institute of Canada is scheduled to convene at Headquarters, 2050 Mansfield street, Montreal, on January 22nd 1931, at 8.00 o'clock p.m., for the reading of the minutes of the last Annual General Meeting and the appointment of scrutineers and auditors, after which the meeting will be adjourned and reconvened on Wednesday, Thursday and Friday, February 4th, 5th and 6th, 1931.

The reconvened meeting and other functions will be held at the Windsor hotel, and arrangements have been made to accommodate a large number of out-of-town guests as well as the Montreal Branch members.

The programme of the functions is now being arranged and a most interesting three days are in prospect.

The tentative programme for the technical sessions indicates papers on many diversified subjects that should cover the various fields wherein members of The Institute practise their profession. For example, there will be a number of papers on interesting construction points of the Chute-à-Caron and other water power developments; a detailed paper on the fabrication of the lock gates of the Welland ship canal, and a complete set of papers on the Sun Life building, covering architectural details, construction problems and the design and installation of heating and ventilating systems and mechanical equipment, as well as numerous others. A number of inspection trips will be made to points of interest, including the Sun Life building and engineering developments under way in the vicinity of Montreal.

A committee has been appointed to take care of the ladies' activities, and it is hoped that a large number will attend, as they are sure to find the time well taken up.

The Montreal Branch has always done remarkably well in the manner in which they have staged the annual meetings held in their city, and they are sure to equal their enviable record, if not better it, in 1931.

The "Buy Canadian Products" Campaign

It is difficult to choose between the various prescriptions offered to us by doctors of economics as remedies for our present feeling of industrial and commercial ill-health. These physicians, indeed, do not agree on any one diagnosis of our trouble. Some would have it that we are merely victims of a state of mind and that all that is needed to promote prosperity is an outburst of enthusiasm to be generated by a high pressure campaign of publicity and maintained by suitable super-salesmanship. Others point to the mechanization of the age. They note such things as a crowd of unemployed watching a steam shovel moving more material than could be handled by hundreds of men, and they attribute our trouble to unemployment, caused by the substitution of machine for hand labour. Another expert, perhaps bewildered by the output statistics of our automobile or radio factories, blames mass production. His neighbour believes that all immigration should be stopped. On the other hand, another adviser would encourage immigration, and points to our slow increase in population as the root of the evil. The ideas of too much government interference with industry, or the apathy of the government towards industry, are in turn brought forward, and such topics as the dumping of Russian and Argentine wheat in Europe, the recurrence of business cycles, and many others are discussed without much regard as to whether they are causes or effects.

The fact remains that, for some reason or other, commercial and industrial activity has slackened in Canada and elsewhere. Employment is less active; people do not spend money as they did; there is a reduction in car loadings on our railways, the country's revenue has diminished, and, strangest of all, fewer automobiles are being built.

For some time there has been a growing sentiment in Canada that apart from all the theories as to the causes of industrial depression and unemployment, there is one remedy, possibly not a complete one, but easy to apply and reasonably certain in its results. Elsewhere in this issue will be found an announcement from the Minister of Trade and Commerce, pointing out that a large proportion of the goods imported into Canada are such as could have been produced by our own mines, farms or factories. When allowance is made for those commodities, such as cotton or rubber, which cannot be grown or produced in this country, it is surprising to learn that each individual in Canada consumes annually some eighty dollars worth of goods made or produced elsewhere, which could have afforded employment in Canada to our own people.

It is of course true that unless payment for our exports is made in gold or its equivalent, goods must be imported in return, but the suggested replacement of a large proportion of our present imports by Canadian products would eventually enable us to increase our consumption of those imported commodities which cannot be produced here.

The appeals sent out by Mr. Stevens should be heeded by all true Canadians, and will be backed by all who have at heart the welfare of their country and the prosperity of its people. If actively carried out, the policy of buying Canadian products will do much to promote a feeling of industrial independence and, by aiding the Canadian manufacturer and industrialist, will help those depending on him for employment. Canadian industry will have larger opportunities for demonstrating that its products compare favourably in quality and price with those with which they compete, a matter which has not always received the attention it deserves.

Canadian citizens will undoubtedly receive the minister's suggestion with approval and will be prepared to do their part in carrying it out, but it is little use advocating the purchase of Canadian products if the buyer, willing to pay an equal or even slightly higher price for domestic goods, finds that they are less satisfactory than those produced elsewhere, which he is asked to refuse.

A further responsibility is placed upon the leaders in Canadian industry and those charged with directing expenditure on large enterprises or public works, who should see to it that when scientific, technical or professional advice is required, foreign engineers, architects, chemists or technically trained men are called in only when no properly qualified Canadians are available for the work desired. In the past there have been cases where legitimate criticism on these points has been heard, and the success of the movement now initiated will only be insured if industry does its part as well as the general public.

List of Nominees for Officers

EXTRACT FROM BY-LAWS

Section 68—Not later than the seventh day of November, the Secretary shall mail to each corporate member of The Institute the list of nominees for officers, as prepared by the Nominating committee and the Council.

Additional nominations for the list of nominees for officers signed by ten or more corporate members and accompanied by written acceptances of those nominated, if received by the Secretary on or before the first day of December, shall be accepted by the Council and shall be placed on the officers' ballot. The words "Special Nomination" shall be printed conspicuously near such names, and the names of the members making such nominations shall be printed on some part of the officers' ballot.

Section 74—Notices shall be deemed to have been mailed to members as prescribed by the By-laws if such notices are printed in The Journal of The Institute and mailed by the dates prescribed in the By-laws.

Nominations

The report of the Nominating committee was presented to and approved by Council at the meeting held on September twenty-third, nineteen hundred and thirty. The following is a list of the nominees as prepared by the Nominating committee and now published for the information of all corporate members, as provided by Sections 68 and 74 of the By-laws:—

President:	S. G. Porter, M.E.I.C.	Calgary.
Vice-Presidents:		
*Zone "A"	H. B. Muckleston, M.E.I.C.	Vancouver.
	P. Philip, M.E.I.C.	Victoria.
*Zone "C"	O. O. Lefebvre, M.E.I.C.	Montreal.
Councillors:		
‡Halifax Branch	W. P. Copp, M.E.I.C.	Halifax.
	C. A. Fowler, M.E.I.C.	Halifax.
†Cape Breton Branch	A. L. Hay, M.E.I.C.	Glace Bay.
‡Saint John Branch	A. R. Crookshank, M.E.I.C.	Saint John.
	E. J. Owens, A.M.E.I.C.	Saint John.
†Moncton Branch	M. J. Murphy, A.M.E.I.C.	Moncton.
	G. C. Torrens, A.M.E.I.C.	Moncton.
‡Saguenay Branch	G. E. LaMothe, A.M.E.I.C.	Chicoutimi.
†Quebec Branch	Hector Cimon, A.M.E.I.C.	Quebec.
‡St. Maurice Valley Branch	B. Grandmont, A.M.E.I.C.	Three Rivers.
††Montreal Branch	C. V. Christie, M.E.I.C.	Montreal.
	A. R. Ketterson, A.M.E.I.C.	Montreal.
	E. A. Ryan, M.E.I.C.	Montreal.
	D. C. Tennant, M.E.I.C.	Montreal.
‡Ottawa Branch	John McLeish, M.E.I.C.	Ottawa.
	F. H. Peters, M.E.I.C.	Ottawa.
†Peterborough Branch	R. L. Dobbin, M.E.I.C.	Peterborough.
‡Kingston Branch	D. M. Jemmett, A.M.E.I.C.	Kingston.
‡‡Toronto Branch	Thomas Taylor, M.E.I.C.	Toronto.
†Hamilton Branch	E. H. Darling, M.E.I.C.	Hamilton.
‡London Branch	W. P. Near, M.E.I.C.	London.
	J. A. Vance, A.M.E.I.C.	Woodstock.
†Niagara Peninsula Branch	E. G. Cameron, A.M.E.I.C.	St. Catherines.
‡Border Cities Branch	A. E. West, A.M.E.I.C.	Walkerville.
†Sault Ste. Marie Branch	A. E. Pickering, M.E.I.C.	Sault Ste. Marie.
‡Lakehead Branch	C. H. Burbidge, M.E.I.C.	Port Arthur.
†Winnipeg Branch	N. M. Hall, M.E.I.C.	Winnipeg.
‡Saskatchewan Branch	R. W. E. Loucks, A.M.E.I.C.	Regina.
†Lethbridge Branch	G. N. Houston, M.E.I.C.	Lethbridge.
‡Edmonton Branch	A. W. Haddow, A.M.E.I.C.	Edmonton.
	R. W. Ross, A.M.E.I.C.	Edmonton.
†Calgary Branch	F. J. Robertson, A.M.E.I.C.	Calgary.
	R. S. Trowsdale, A.M.E.I.C.	Calgary.
‡Vancouver Branch	P. H. Buchan, A.M.E.I.C.	Vancouver.
	A. D. Creer, M.E.I.C.	Vancouver.
†Victoria Branch	H. F. Bourne, A.M.E.I.C.	Victoria.
	K. M. Chadwick, M.E.I.C.	Victoria.

*One Vice-President to be elected for two years.
†One Councillor to be elected for one year.
††Two Councillors to be elected for three years each.
‡One Councillor to be elected for two years.
‡‡One Councillor to be elected for three years.

Attention is drawn to the recent change in Section 13 of the By-laws, making the term of office for councillor two years instead of one year. To give effect to this arrangement council has decided that at the forthcoming election in 1931 one-half of the branches entitled to one councillor will elect their councillor for a one-year term, the remainder electing for two years. Accordingly, in 1931, the following branches will elect their councillor for one year, and in 1932 will elect for two years: Cape Breton, Moncton, Quebec, Peterborough, Hamilton, Niagara Peninsula, Sault Ste Marie, Winnipeg, Lethbridge, Calgary and Victoria. The following branches in 1931 will elect their councillor for two years, and will not elect a councillor in 1932: Halifax, Saint John, Saguenay, St. Maurice Valley, Kingston, London, Border Cities, Lakehead, Saskatchewan, Edmonton and Vancouver.

In 1932 and thereafter, all elections of councillors for such branches, will be for a two-year term, thus carrying out the intent of the amendment to the By-law, namely, to insure a measure of continuity in council membership.

Prizes and Medals of The Institute

Attention is drawn to the various prizes and medals to be awarded by The Engineering Institute of Canada at the end of the prize year, July 1st, 1930, to June 30th, 1931. The competitions for these distinctions are open to those belonging to The Institute and the regulations governing them will be found below.

The principal object of these prizes is to encourage a larger proportion of our members to contribute papers of merit, passing on the results of their experience for the benefit of others. But it should be remembered that the acceptance and publication of a good paper enhances the writer's professional status, and the discussion of his own, and his participation in the discussion of others' papers, make his name better known to his fellow-engineers. Also, the standing of The Engineering Institute of Canada among other engineering societies depends largely on the character of the papers contained in our publications, which is governed by the extent to which our members are prepared to put their experience and information on record.

The Council of The Institute would, therefore, ask members' consideration of the following:

Rules Governing the Award of the Prizes and Medals of The Institute

The Past-President's Prize

In recognition of the fund establish in 1923 by the then living past-presidents and contributed to by subsequent past-presidents, a prize, to be called "The Past-Presidents' Prize," may be awarded annually according to the following rules:—

1. The prize shall be awarded for the best contribution submitted to the council of The Institute by a member of The Institute of any grade on a subject to be selected and announced by the council at the beginning of the prize year, which shall be July first to June thirtieth.

2. In deciding on the subject to be specified, the council shall confer with the branches, and use its discretion, with the object of selecting a subject which may appear desirable in order to facilitate the acquirement and the interchange of professional knowledge among the members of The Institute.

3. The papers entered for the competition shall be judged by a committee of five, to be called the Past-Presidents' Prize committee, which shall be appointed by the Council as soon after the annual meeting of The Institute as practicable. Members and honorary members only shall be eligible to act on this committee.

It shall be within the discretion of the committee to refuse an award if they consider no paper of sufficient merit.

4. The prize shall consist of a cash donation of the amount of one hundred dollars, or the winner may select books or instruments of no more than that value when suitably bound and printed, or engraved, as the case may be.

5. All papers eligible for the competition must be bona fide work of the contributors and must not have been made public before submission to The Institute.

6. All papers to be entered for the competition must be received during the prize year by the General Secretary of The Institute, either direct from the author or through a local branch.

7. The award shall be announced in The Engineering Journal at the annual meeting, and, if possible, the presentation shall take place at that meeting.

Prizes to Students and Juniors

1. Five prizes may be awarded annually for the best papers presented by Students or Juniors of The Institute in the vice-presidential zones of The Institute, as follows:—

The H. N. Ruttan Prize,—in Zone A—The four western provinces.

The John Galbraith Prize,—in Zone B—The province of Ontario.

The Phelps Johnson Prize,—for an English Student or Junior in Zone C—The province of Quebec.

The Ernest Marceau Prize,—for a French Student or Junior in Zone C—The province of Quebec.

The Martin Murphy Prize,—in Zone D—The Maritime provinces.

2. Awards shall only be made if, in the opinion of the examiners for a zone, a paper of sufficient merit has been presented to a branch in that particular zone.

3. The winner of a prize shall be required to specify such technical books or instruments as he may desire to the total value of approximately twenty-five dollars when suitably bound and printed or engraved, as the case may be.

4. The award of prizes shall be for the year ending June thirtieth. On that date, each branch secretary shall forward to the examiners for his particular zone all papers presented to his branch by Students and Juniors during the prize year, regardless of whether they have been read before the branch or not.

5. The prizes shall be awarded only to those who are in good standing as Students or Juniors of The Institute on June thirtieth following the presentation of the paper.

6. The papers must be the bona fide production of those contributing them and must not have been previously made public or contributed to any other society in whole or in part. It is to be understood, however, that a paper which has won or been considered for a branch prize is nevertheless eligible for The Institute Prize. No paper shall be considered for more than one of the five prizes.

7. The examiners for each zone shall consist of the vice-president of that zone and two councillors resident in the zone, appointed by council. In the case of Zone C, two groups of examiners shall be appointed under the two vice-presidents, one for the English award and one for the French award. The awards shall be reported to the annual meeting of The Institute next following the prize year, and the prizes presented as soon thereafter as is reasonably possible.

The Gzowski Medal

A gold medal, to be called the Gzowski Medal, shall be struck each year and paid for from the annual proceeds of the fund provided for that purpose by Col. Sir Casimir Gzowski, A.D.C., K.C.M.G., late past-president of The Institute, which medal shall be awarded according to the following rules for papers presented to The Institute.

1. Competition for the medal shall be open only to those who belong to The Institute.

2. The award of medals shall not be made oftener than once a year, the medal year shall be the year ended June last previous to the annual meeting at which the award is to be made.

3. The papers entered for competition shall be judged by a committee of five, to be called the Gzowski Medal committee, which shall be appointed by the council as soon after the annual meeting of The Institute as practicable. Members and Honorary Members only shall be eligible to act on this committee.

4. Papers to be eligible for competition must be bona fide productions of those who contribute them, and must not have been previously made public, nor contributed to any other society in whole or in part.

5. The medal shall be awarded for the best paper of the medal year, provided such paper shall be adjudged of sufficient merit as a contribution to the literature of the profession of civil engineering, but not otherwise.

6. In the event of the committee not considering a paper in any one year of sufficient merit, no award shall be made; but in the following year or years, it shall be in the power of the committee to award the accumulated medals to the authors of different papers which may be deemed of sufficient merit.

7. The medal shall be suitably engraved by The Institute, and shall be handed to the successful authors at the annual meeting, or be given to them as soon afterwards as possible.

The Leonard Medal

A gold medal, called the Leonard Medal, shall be struck each year and paid for from the annual proceeds of the fund provided for that purpose by Lieut.-Col. R. W. Leonard, which medal shall be awarded in accordance with the following rules for papers on mining subjects presented either to The Canadian Institute of Mining and Metallurgy or to The Engineering Institute of Canada.

1. Competition for the medal shall be open to those who belong to The Canadian Institute of Mining and Metallurgy or to The Engineering Institute of Canada.

2. Award shall be made not oftener than once a year, and the medal year shall be the year ended June last previous to the year in which the award is made.

3. The medal shall be presented at annual meetings of The Engineering Institute of Canada.

4. A committee of five shall judge the papers entered for competition, all of whom shall be members both of The Canadian Institute of Mining and Metallurgy and The Engineering Institute of Canada, this committee to be appointed by the council of The Engineering Institute of Canada.

5. All papers presented shall be the work of the author or authors and must not have previously been made public, except as part of the literature of The Canadian Institute of Mining and Metallurgy or The Engineering Institute of Canada.

6. Should the committee not consider the papers presented in any one year of sufficient merit, no award shall be made, but in the following year, or years, the committee shall have power to award the accumulated medals or to award a second prize in the nature of a silver medal, or a third prize of books to be selected by the committee.

7. The medal shall be suitably engraved, containing the name of The Engineering Institute of Canada, and the words, "The Leonard Medal" together with the adopted design, and on the reverse side the name of the recipient, the date and any other inscription that may be decided upon by the committee.

The Plummer Medal

A gold medal, to be called The Plummer Medal, shall be struck each year and paid for from the annual proceeds of the fund provided for that purpose by Mr. J. H. Plummer, D.C.L., which medal shall be awarded according to the following rules for papers on chemical and metallurgical subjects presented to The Institute.

1. Competition for the medal shall be open to those who belong to The Engineering Institute of Canada, and to non-members if their papers have been contributed to The Institute and presented at an Institute or Branch meeting.

2. Award shall be made not oftener than once a year, and the medal year shall be the year ended June last previous to the year in which the award is made.

3. The medal shall be presented at annual meetings of The Engineering Institute of Canada.

4. A committee of five shall judge the papers entered for competition, all of whom shall be members of The Engineering Institute of Canada, and shall be appointed by the council of The Institute.

5. All papers presented shall be the work of the author or authors and must not have previously been made public, except as part of the literature of The Engineering Institute of Canada.

6. Should the committee not consider the papers presented in any one year of sufficient merit, no award shall be made, but in the following year, or years, the committee shall have the power to award the accumulated medals or to award a second prize in the nature of a silver medal, or a third prize of books to be selected by the committee.

7. The medal shall be suitably engraved, containing the name of The Engineering Institute of Canada, and the words, "The Plummer Medal," together with the adopted design, and on the reverse side the name of the recipient, the date and any other inscription that may be decided upon by the committee.

The Fourth Plenary Meeting of Council

The Fourth Plenary Meeting of the Council of The Institute was held on Monday, Tuesday and Wednesday, September 22nd, 23rd and 24th, 1930, the following members being present:

President A. J. Grant, M.E.I.C., in the chair; Past-Presidents A. R. Decary, D.A.SC., M.E.I.C., C. H. Mitchell, C.B., C.M.G., D.Eng., M.E.I.C., and H. H. Vaughan, M.E.I.C.; Vice-Presidents F. R. Faulkner, M.E.I.C., (Maritime Provinces), C. J. Mackenzie, M.E.I.C., (Western Provinces), George R. MacLeod, M.E.I.C., (Province of Quebec), and W. G. Mitchell, M.E.I.C., (Province of Quebec); Councillors L. M. Allan, A.M.E.I.C., (Border Cities), V. C. Blackett, A.M.E.I.C., (Moncton), H. F. Bennett, A.M.E.I.C., (Halifax), J. L. Busfield, M.E.I.C., (Montreal), H. Cimon, A.M.E.I.C., (Quebec), F. A. Combe, M.E.I.C., (Montreal), E. H. Darling, M.E.I.C., (Hamilton), R. L. Dobbin, M.E.I.C., (Peterborough), B. Grandmont, A.M.E.I.C., (St. Maurice Valley), G. N. Houston, M.E.I.C., (Lethbridge), W. J. Johnston, A.M.E.I.C., (Saint John), O. O. Lefebvre, M.E.I.C., (Montreal), T. Lees, M.E.I.C., (Calgary), W. L. Malcolm, M.E.I.C., (Kingston), D. A. R. McCannel, M.E.I.C., (Saskatchewan), P. B. Motley, M.E.I.C., (Montreal), W. P. Near, M.E.I.C., (London), C. H. Scheman, M.E.I.C., (Niagara Peninsula), E. Stansfield, M.E.I.C., (Edmonton), J. G. R. Wainwright, A.M.E.I.C., (Toronto), H. R. Wake, A.M.E.I.C., (Saguenay), L. W. Wynne-Roberts, A.M.E.I.C., (Toronto), R. B. Young, M.E.I.C., (Toronto), and Treasurer F. P. Shearwood, M.E.I.C., (Montreal). Mr. W. C. Adams, M.E.I.C., and Mr. A. C. Tagge, M.E.I.C., members of the Special Committee on the Publications of The Institute, were also present at the request of Council.

Expressions of regret at being unable to attend the meeting were received from Past-Presidents G. H. Duggan, D.Sc., M.E.I.C., J. M. R. Fairbairn, D.Sc., M.E.I.C., J. G. Sullivan, M.E.I.C., and George A. Walkem, M.E.I.C., and Councillors Sydney C. Mifflen, M.E.I.C., (Cape Breton), and A. E. Pickering, M.E.I.C., (Sault Ste Marie).

Monday, September 22nd

After a welcome to the visiting councillors from the President and the confirmation of the minutes of the last meeting, routine business arising from previous meetings was taken up.

On receiving the news of the death of George F. Porter, LL.D., M.E.I.C., a distinguished engineer and former member of Council, a resolution of regret and condolence was unanimously passed, and the Secretary was directed to communicate it to Mr. Porter's family.

Recommendations from the Finance committee were received and adopted, and the financial statement to August 31st, 1930, was submitted and approved.

A communication was presented from Councillor W. J. Johnston, A.M.E.I.C., drawing attention to the fact that competition for the prizes and medals of The Institute has not been so active as might be desired, and suggesting the consideration of certain changes in the method of awarding prizes for students. After considerable discussion, during which the importance of this matter was fully recognized, it was decided to appoint a small committee* to bring in a report at a later session of the meeting, and action was taken accordingly.

The President having asked J. L. Busfield, M.E.I.C., chairman of the Committee on Classification and Remuneration, to make a statement regarding the work of that committee, Mr. Busfield reported that in order to secure information regarding present day conditions with respect to the remuneration of the engineering profession, the committee had sent out a questionnaire to all corporate members and Juniors of The Institute. About eleven hundred replies had been received, the information thus secured had been summarized, and he presented a brief report for the confidential information of Council. He remarked that there seemed to be great diversity of opinion amongst engineers themselves as to the correct classification of engineers and their work, and asked for an expression of opinion from councillors present to assist him in preparing his final report.

During the discussion which followed, attention was drawn to the difficulty of drawing up for the purposes of such a report any system of classification of engineers which would be sufficiently flexible to include the many branches of engineering work existing to-day. Members present agreed that such a classification would be very useful for employers in considering engineers' remuneration, but that classification of engineers after they have reached positions of an executive nature would be almost impossible, either on the basis of years of experience or professional responsibility. It was felt that the information now before Council, being of a preliminary nature, should be treated as confidential until the completion of the committee's work, and it was hoped that it would be possible to have a report ready for presentation to Council prior to the next annual meeting.

In connection with the Forty-fourth Annual General and General Professional Meeting of The Institute, to be held in Montreal in February next, it was resolved, following the recommendation of the Finance committee, that an accountable advance of $500.00 be made to the Montreal Branch.

Considerable discussion followed as to the arrangements desirable for the programme and the annual dinner of The Institute, and a tentative programme was approved.

Applications for admission and transfer were next considered, and the following elections and transfers were effected:

Elections		*Transfers*	
Members	1	Junior to Assoc. Member	8
Assoc. Members	6	Student to Assoc. Member	3
Juniors	6	Student to Junior	4

At the beginning of the afternoon session attention was drawn to the desirability of improvement in the arrangements for securing technical papers for professional and branch meetings, and particularly in promoting good discussions, and members present were in agreement as to the importance of this matter. It was pointed out that many of the branches of The Institute have experienced increasing difficulty in obtaining speakers and papers of merit for their meetings, and, on the suggestion of Mr. Busfield, general approval was expressed of a proposal to appoint Institute or branch committees from time to time to make definite technical reports on certain subjects or projects. In the opinion of many, the apparent reluctance of members to prepare technical papers was largely due to the trend of the times, and particularly to the remarkable growth of technical periodicals in recent years. After further discussion the matter was referred to the Papers committee, with the request that they take it up with all the branches and report to Council before the end of the year.

Tuesday, September 23rd

The Secretary reported the receipt of information from Professor E. A. Allcut, M.E.I.C., to the effect that the Institution of Mechanical Engineers may possibly come to Canada for the purpose of holding their summer meeting in 1932. Mr. Calvin Rice, the Secretary of the American Society of Mechanical Engineers, had also stated that the American Society of Mechanical Engineers is making arrangements for a Summer Meeting in 1932 in Ontario. It was unanimously resolved that the Secretary be instructed to write to the Institution of Mechanical Engineers and the American Society of Mechanical Engineers offering the co-operation of The Engineering Institute of Canada in connection with their meetings if held in Canada in 1932.

The President asked Mr. W. C. Adams to present the Report of the Special Committee on the Publications of The Institute,† which was accordingly done. The report first discussed the general problem of the publications of The Institute, stressing their importance to the welfare of The Institute. The committee was convinced of the desirability of making The Institute's papers available in a permanent and convenient form, namely, in the shape of Transactions. The committee was also of the opinion that while the Journal in its present form was in many respects an excellent paper, a number of improvements could be suggested. The committee's report covered first, those points on which it was prepared to make definite recommendations to Council, and, secondly, a number of suggestions as to matters which might with advantage be dealt with at a later period and when the finances of The Institute would permit.

The recommendations for immediate action included an increase in the advertising rates; the discontinuance of the publication of the Engineering Index in The Journal; the issue of Transactions; the appointment of a whole-time editor at Headquarters for work on the publications of The Institute; proposals for obtaining a better supply of technical papers; the continuation of the E-I-C News, and the annual publication of the Year Book.

Suggestions made for action at a later time included the holding of a professional meeting each year in each zone; arrangements for taking stenographic reports of discussions at branch meetings; the appointment of an assistant secretary for each province, with a suitable honorarium, his duties being to co-operate with the General Secretary and branch secretaries; the appointment of selected committees to prepare reviews of engineering development in Canada and abroad; the appointment of a member of the Headquarters' staff to prepare abstracts of engineering articles and other publications; and, when Transactions are available, the publication of technical papers in The Journal only in abstract form, these papers, with their discussions, to be published in full in the Transactions.

Prolonged discussion followed the presentation of this report, after which the following decisions were reached in connection with the committee's definite recommendations. The Secretary was directed to increase the advertising rates in The Journal approximately twenty-five per cent. He was also directed to discontinue the publication of the Engineering Index at the end of the present volume of

A. C. Tagge, M.E.I.C.

The Journal. The publication of Transactions was decided upon, paper covered volumes to be issued free to members, with an extra charge for binding.

These decisions having been reached, Mr. Adams drew attention to the representations which had been made for some time by the Niagara Peninsula Branch as to the desirability of reducing the size of The Journal, and pointed out that his committee, while giving expression to its own opinion on this matter, had purposely refrained from making a definite recommendation as to the size of The Journal.

Mr. Scheman presented, for the consideration of Council, a specially prepared dummy of a Journal in the 6 by 9 size, and pointed out the advantages which, in the opinion of the Niagara Peninsula Branch Executive committee, would result from the adoption of this make-up for The Journal, and Mr. Scheman hoped that this proposition, and the arguments for it, would be placed before all the branches of The Institute. Mr. Adams gave the results of his committee's investigations on the question of size, which indicated that while there would be little difference either way in the cost of publishing The Journal in the 6 by 9 size as compared with the 9 by 12, their inquiries had indicated that the 9 by 12 size was more advantageous in other respects, his committee's reasons for this view having been given in an appendix to the committee's report.

General Mitchell reminded the Council that this matter had been thoroughly discussed at the last Plenary Meeting of Council, and had already been brought to the attention of the branches in various ways, and he felt sure that if there were any widespread desire on the part of members for a reduction in the size of The Journal the Council would have been informed of it. He complimented the Niagara Peninsula Branch on the thorough way in which they had gone into the question, but felt that the opinion reached by Mr. Adam's committee, after consultation with many experts, was convincing.

After further discussion it was unanimously decided that the committee's recommendation providing for the publishing of Transactions in the size 8⅝ by 11¼ be adopted, and that the question of the size of The Journal be closed forthwith.

Discussion followed on the other definite recommendations of the committee, and while Council was entirely in accord with the recommendation that an editor of The Journal should give his undivided attention to The Journal and the E-I-C News, it was felt impossible to take action on this as the means are not available at the present time. The Treasurer was asked to bring in a report on this matter for consideration at the annual meeting. The committee's recommendations as regards the obtaining of technical papers, the continuation of the E-I-C News, the publication of by-laws, and the annual publication of the Year Book, were unanimously adopted.

The further suggestions made by Mr. Adams' committee, but not covered by their definite recommendations, were then considered, and Mr. Adams stated that his committee was particularly anxious that these should be put into effect as soon as conditions would permit, but thought that it was perhaps somewhat premature to discuss them in detail at this meeting. It was accordingly unanimously resolved that the suggestions for improvement, not covered by definite recommendations, be referred to the committees concerned and to Council for further consideration, and the thanks of the Council were extended to Mr. Adams' committee for their services, and to the Niagara Peninsula Branch for their efforts in this matter. The Special Committee on the Publications of The Institute was then discharged.

General Mitchell reported that the committee appointed to study the question of The Institute prizes had met and reviewed the whole situation, and after considerable discussion had come to the conclusion that the five existing prizes of twenty-five dollars awarded to Students and Juniors should remain as at present. They considered it very desirable that these should be continued.

The committee further recommended that a new group of prizes be instituted to be known as "The Engineering Institute of Canada Prizes," and to be offered annually for competition among the registered students in the year prior to the graduating year in the engineering schools and applied science faculties of the following institutions:

University of Alberta
University of British Columbia
Ecole Polytechnique, Montreal
University of Manitoba
McGill University
University of New Brunswick
Nova Scotia Technical College
Queen's University
Royal Military College
University of Saskatchewan
University of Toronto

Each prize should consist of twenty-five dollars, and should be awarded by the university authorities to the student who had proved himself most deserving as disclosed by the examination results of the year in combination with his activities in the students' engineering organization, or in the local branch of a recognized engineering society. The committee's suggestion met with general approval, and the recommendation was unanimously adopted, the Secretary being directed to communicate as soon as possible with the various universities concerned.

The list of nominees for officers for 1931, prepared by the Nominating committee, was presented, and approved by Council. This list will be found elsewhere in this issue of The Journal.

Attention was drawn to the recent change in Section 13 of the By-laws, which becomes effective at the elections of 1931, making the term of office for councillor two years instead of one year. In order to carry out this arrangement it was decided that at the 1931 election one half of the branches entitled to one councillor should elect a councillor for two years, the other half electing their councillor for a one year term. In 1932 the only branches entitled to one councillor which would hold an election would be those electing a councillor for one year only in 1931. In 1932 and thereafter all elections for such branches would be for a two-year term, so that about half the membership of Council would change each year. The Secretary's suggestion that the two and one year terms for 1931 be allocated alternately to the branches across the country was unanimously approved.

Following this action, Mr. Busfield drew attention to the fact that, with the present organization of the Nominating committee, and the recent change in Section 67 of the By-laws providing that the list of nominees for officers shall "contain the names of one or more nominees for each office to be filled," it appeared possible for a single member of the Nominating committee, without consultation with any other person, to submit one name to the Nominating committee for any particular vacancy for councillor or vice-president. This would probably result in the election of the person so named. Council was of the opinion that this matter should be considered, and the president appointed a small committee* to study the matter and bring in recommendations at a later period of the meeting.

*J. L. Busfield, M.E.I.C., Chairman.

T. Lees, M.E.I.C.
W. G. Mitchell, M.E.I.C.
R. B. Young, M.E.I.C.

A report was presented from the committee* appointed by Council on May 30th, 1930, to consider recommendations contained in a report to Council from the Ottawa Branch regarding the formation of professional sections, and the affiliation of these sections with engineering societies in other countries. The work of this committee had special reference to the desirability of making provision for the formation of professional sections dealing with aeronautical and radio work. The report recommended the acceptance by Council of the main recommendations received from the Ottawa Branch in May last, but was of the opinion that instead of amending The Institute's by-laws so as to provide for professional sections of The Institute, it would be more advantageous to conform to the existing structure of The Institute by providing for affiliation of technical sections of branches with other engineering societies. The committee recommended the favourable consideration of the arrangements outlined in a draft agreement prepared by the Secretary of The Institute and the Secretary of the Royal Aeronautical Society, which was ready for submission to Council.

The Secretary reported that while Mr. McCrory's report was being prepared, he had, in accordance with Council's instructions, discussed the matter with Group-Captain E. W. Stedman, M.E.I.C., and J. L. Pritchard, the Secretary of the Royal Aeronautical Society, who had visited Canada with a view of ascertaining the possibilities of forming a Canadian section of the Royal Aeronautical Society. As a result of several conferences with Mr. Pritchard, a draft agreement between the Councils of The Engineering Institute of Canada and the Royal Aeronautical Society had been drawn up, copies of which had been submitted to all members of Council for their consideration, and which would be placed before the Council of the Royal Aeronautical Society at their September meeting.

The Secretary pointed out that it had been possible to draw up this proposed agreement in its present form, because the branch organization of the Royal Aeronautical Society was somewhat similar to that of The Engineering Institute. The Society was one of the leading aeronautical engineering societies in the world, and had recently united with the Institution of Aeronautical Engineers; the membership at the present time consisted of members and fellows, the original members of the Institution of Aeronautical Engineers being called members, and the original members of the Aeronautical Society being called fellows. The corporate or technical membership thus included fellows, associate fellows, members and associate members. In addition there were in the local branches many local branch members, not necessarily qualified engineers, who corresponded to our branch affiliates in being members of the branches, but not members of the Society itself.

The Secretary read the draft agreement as submitted to the members of Council, and expressed the hope that the Council would give very careful consideration to this proposal, as the adoption of the policy involved would not only afford an opportunity of affiliation with the Royal Aeronautical Society, but would offer the possibility of similar arrangements with organizations in other specialized branches of engineering. The question of radio engineers had already come up, and a copy of the proposed agreement had been sent to the Secretary of the Institution of Electrical Engineers with a view of ascertaining whether the Council of that Institution would be willing to consider such a proposal in connection with their Wireless section. Professor Malcolm understood that very shortly a communication might be received by the Council of The Institute from the Military Engineers' Institute of Canada with a similar request for co-operation.

Council then proceeded to the consideration of the draft agreement with the Council of the Royal Aeronautical Society, the provisions of which met with general approval, with the exception of section 4, dealing with the officers of an Aeronautical section of a branch of The Institute, which was amended so as to provide that as far as possible an equal number of corporate members of The Engineering Institute of Canada and technical members of the Royal Aeronautical Society should be included.

After further discussion the general principle of forming professional sections of branches rather than professional sections of The Institute, and the advisability of affiliating such professional sections with other engineering societies of high standing and dealing with specialized branches of engineering, was approved, and on the motion of Mr. Busfield, seconded by Mr. Wynne-Roberts, it was unanimously resolved that the report of Mr. McCrory's committee be accepted, and that the proposed draft agreement between The Engineering Institute of Canada and the Royal Aeronautical Society, with section 4 amended as above, be approved. The Secretary was directed to notify the Royal Aeronautical Society of Council's decision in this matter, and it was decided that should proposals be received from other societies for affiliation or co-operation, each application would be considered by Council on its own merits.

George R. MacLeod, M.E.I.C., chairman of the Finance committee, in reviewing the financial situation, pointed out that this year the expenditure and income had been substantially in accordance with the budget, and drew attention to the fact that Council's proposal for an increase in annual fees had been defeated two years in succession. Mr. MacLeod did not believe that The Institute could carry on efficiently its present activities, much less improve the service to members, without additional revenue.

In Mr. Shearwood's opinion the Council should go to the membership again with the same proposal for an increase in the annual fees. The annual fees of other national engineering societies were much higher than those of The Engineering Institute of Canada.

Council was reminded that in December last a resolution had been received from the Hamilton Branch suggesting amendments to certain sections of the By-laws involving changes in members' annual fees, and in the rebate system, with a view to obtaining additional revenue for The Institute. In view of the proposal for an increase in fees being put before the annual meeting by the Council, the Hamilton Branch, at Council's request, had then withdrawn their proposal.

A further communication under date of September 19th, 1930, had now been received from the Hamilton Branch, in which it was stated that in view of the fact that Council's proposals had been lost, the Hamilton Branch now presented, over the signature of twenty-one corporate members, certain amendments to the By-laws intended to give about the same increase as Council's proposals. According to these proposals non-resident fees would be done away with, and Associate Members, after ten years in that class, would be required to pay the same fees as Members, whether or not they transferred to the higher class.

Mr. Darling stated that the proposed amendments now submitted by the Hamilton Branch were the result of very extensive study, particularly on the part of W. F. McLaren, M.E.I.C., past-secretary and past-councillor of the branch, and he hoped that they would receive the careful consideration of Council.

*J. A. McCrory, M.E.I.C., Chairman.
J. E. N. Cauchon, A.M.E.I.C.
P. L. Pratley, M.E.I.C.
L. W. Wynne-Roberts, A.M.E.I.C.

Prolonged discussion took place, and it was the feeling of the meeting that Branch non-residents would strongly object to being required to pay the same fees as those to whom the advantages of Branch membership are available; that it was only fair that Montreal resident members should pay a higher fee than those members who cannot make use, to the same extent, of the facilities of the headquarters' building; and that many Associate Members of over ten years standing might not be eligible for transfer to the class of Member, and could hardly be expected to pay the same fee as Members. The Council was in accord with the proposal increasing the rebates to smaller branches, but as this would involve additional expenditure, it could only be considered after additional funds had become available.

After further discussion, on the motion of Mr. MacLeod, seconded by Mr. Lefebvre, it was unanimously resolved that Council's proposal of last year to amend Section 34 so as to provide for an increase in the annual fees of $3.00 for Members, $2.00 for Associate Members, and $1.00 for Juniors, be submitted for the consideration of the next annual meeting.

The Secretary was directed to convey to the Executive committee of the Hamilton Branch Council's appreciation of the work they had done in connection with the proposals submitted; to give Council's reasons for not being able to agree with their suggestions, and to ask the members signing them if they would be good enough, in view of the fact that Council has decided that the proposals of last year should again be placed before the membership, to withdraw the proposals conveyed in their letter of September 19th, 1930.

Wednesday, September 24th

On the assembly of the Council on Wednesday morning, the president welcomed Past-President H.H. Vaughan, M.E.I.C., and asked him if he would present the report of the sub-committee* of the Committee on the Relations of The Institute with the Provincial Associations of Professional Engineers, of which he was chairman.

Mr. Vaughan explained that the sub-committee had not been able to accomplish very much during the summer months, as Dr. Lefebvre had been away attending the World Power Conference, and he himself had been extremely busy. A meeting of the sub-committee had been held however, and a report had been prepared for the consideration of Council, in the hope that a course of action could be decided upon and proceeded with.

The duty of the sub-committee was "To approach the Provincial Associations and in conjunction with them devise a detailed proposal to bring about a co-ordination of interests and activities of the various professional associations and The Engineering Institute of Canada." This purpose, of course, could only be achieved by co-operation with committees appointed by the several Provincial Associations.

Mr. Vaughan presented the report and explained the views of his sub-committee as embodied therein. They were of opinion that a study of the possibilities in this matter should be made by a committee of members nominated by all of the Provincial Associations and The Engineering Institute, and suggested that this committee should be known as "The National committee." It was felt also that until this National committee could be organized, The Engineering Institute's sub-committee might be permitted to act in making the necessary preliminary arrangements for the mutual interchange of views and suggestions. Members of the National committee had already been nominated by the Provincial Associations of Nova Scotia, New Brunswick, Ontario, Quebec and Manitoba, and he would suggest that the associations which had not already nominated members should be asked to do so. When this had been done, the report proposed that the preparation of an analysis and comparison of the various provincial acts and requirements for admission to membership should be undertaken in so far as they might affect the subject under consideration, and this work, it was thought, could be best done by one man having suitable training, at a cost which they did not think would exceed $500 00. This analysis having been prepared, it was suggested that three members should be selected by the National committee from among its members, representing respectively the Maritime provinces, Ontario and Quebec, and the provinces west of Ontario, these three members to meet and prepare a draft set of by-laws and requirements for membership that could apply to all the Provincial Associations and to The Engineering Institute of Canada. His committee, further, was of the opinion that when this draft had been prepared it should be communicated to all members of the National committee for their criticisms, and when reasonable agreement had been obtained by correspondence, a meeting of the National committee should be held. It was hoped that this meeting might agree on a definite set of draft requirements, which could then be submitted to the Councils of the Provincial Associations and The Engineering Institute of Canada. Several of the Councils of the Professional Associations had already undertaken to contribute towards the cost of all this work.

Discussion followed, during which Dean Mackenzie outlined the principal features of the new Saskatchewan Act, and Professor Faulkner drew attention to the fact that a clause regarding the requirements for admission to the Nova Scotia Association is embodied in the Act itself, and any amendment in this connection would have to go before the Legislature.

After further discussion, the recommendations of the report were unanimously adopted, and the Secretary was directed to forward a copy of the report to the Councils of the various Associations with a covering letter asking for their co-operation along the lines suggested.

The report of the committee appointed to investigate the procedure with regard to the nomination and election of officers was next presented by Mr. Busfield. This report recommended that Council propose an amendment to Section 66 of the By-laws to provide for the following:

1. The appointment each year by Council of a Nominating committee of five members consisting of one member from each of the vice-presidential zones, together with a chairman. The Honorary Councillors shall be ex-officio members of the Nominating committee.
2. The requirement: that the Nominating committee shall obtain recommendations from Branch Executive committees for nominees to the vacancies on the Council, and shall in turn submit to Council the list of nominees for office as under present procedure.
3. That no changes be made regarding such points as members of the Nominating committee not being officers of The Institute, the acceptance of nomination by the nominees, term of office of councillors, provision for independent nominations, method of ballot and so forth.

*J. M. R. Fairbairn, M.E.I.C., Honorary Chairman.
H. H. Vaughan, M.E.I.C., Chairman.
A. R. Decary, M.E.I.C.
O. O. Lefebvre, M.E.I.C.
A. D. LePan, A.M.E.I.C.
George R. MacLeod, M.E.I.C.

Discussion took place as to the difficulty which might arise in connection with the appointment of the zone representatives on the Nominating committee, and Mr. Young considered that it would be better if the members of the last year's Nominating committee were made ineligible for re-appointment to that committee.

After further consideration, it was unanimously resolved that the report of the committee be adopted, provided that the third recommendation be amended by the insertion of the words "nor members of last year's Nominating committee" after the word "Institute." The Secretary was directed to refer this report to the Legislation committee with the request that they prepare the necessary proposal for the amendment of section 66 of the By-laws.

The next subject to be dealt with was that of the membership of The Institute, attention being drawn to a communication addressed to Council last year by W. C. Adams, M.E.I.C., pointing out that an active policy for enrolling new members was being carried out by the American Institute of Electrical Engineers and other similar bodies, and suggesting the advisability of the adoption of similar methods by The Engineering Institute of Canada. The subject had been held over for consideration by the Plenary Meeting.

Prolonged discussion followed, during which it was remarked that this matter had already been brought up at many Council meetings. It was felt that the efforts being made at the universities to induce the student body to join The Institute had not been so effective as might be desired, and that the work and objects of The Institute were not being brought to the attention of the growing number of industrial engineers in the way that they should be.

Mr. Shearwood observed that a great many of the men who were doing engineering work in the industrial organizations throughout the Dominion were not members of The Institute. In most large industrial organizations a great deal of the detailed engineering work, such as designing of details in connection with bridge or structural work, etc., was being done by men who are not college graduates. He thought that more of these positions should be filled by graduate engineers, and believed that in the near future practically all superintendents, chief inspectors, etc., would be college graduates.

Mr. Busfield remarked that the principal object of The Institute was to facilitate the acquirement and interchange of professional knowledge amongst its members. To-day the tendency seemed rather towards making the profession a closed one by making it increasingly difficult for the man who was not a college graduate to get into The Institute. In his opinion, if we wished to facilitate the acquirement and interchange of professional knowledge, we ought to be helping non-graduates to get in, so that thereby we could help them to develop professionally. These were the men who were not in The Engineering Institute to whom Mr. Shearwood had drawn attention. The Institute should be definitely looked upon as an educational body, carrying its members on from the day that they left college.

In working out a scheme of co-ordination with the Professional Associations it might perhaps be arranged to have one class of members of The Engineering Institute confined to men who are licensed to practise, and another class (say of Associate Members) to take care of the men of a less purely professional status whom we should also have in The Institute. The Institute could then be something very much larger and more progressive than at present.

Mr. Lefebvre thought the present meeting afforded an excellent opportunity to obtain expressions of opinion from the different branches which were represented. In his opinion the solution of the membership problem lay in the plan of federation with the Professional Associations, and he was opposed to the admission to The Institute of specialists in certain limited fields who were not fully trained as engineers. He did not think it fair that such men, although experts in their own particular duties, should be admitted to The Institute as corporate members.

Professor Faulkner wondered how many members of The Institute, in interviewing applicants for positions, asked what their standing was in The Engineering Institute of Canada. He thought this practice might bring in additional members.

Mr. Houston thought that the men we should try to get in The Institute were the large number of men who occupy responsible positions, and who are recognized by the public as occupying such positions, and yet who do not belong to The Engineering Institute of Canada. If these men joined The Institute he felt sure that the rank and file would want to come in. There should not be restrictions which keep those men out on account of their education if they have reached a position of responsibility in the profession.

Mr. Bennett felt that the present situation was largely due to a lack of enthusiasm and organized effort on the part of the members of The Institute generally. As in all societies, continuous work was required to maintain and increase the membership of The Institute, and a great deal of this effort must necessarily fall upon the branches. Members of Council could do much to awaken interest in this matter in their branches. He would endeavour to do this, and on his return to Halifax he also intended to propose to the branch executive committee a determined effort to get more students to join.

Mr. MacLeod thought that after this discussion a committee should study the question, and on the motion of Mr. MacLeod, seconded by W. G. Mitchell, M.E.I.C., it was unanimously resolved that a committee be appointed to study the whole question of membership, and bring in a report to Council in time for presentation to the Annual Meeting of The Institute.

The President appointed the following committee: Brig.-Gen. C. H. Mitchell, M.E.I.C., chairman; Messrs. W. C. Adams, M.E.I.C., H. F. Bennett, A.M.E.I.C., C. J. Mackenzie, M.E.I.C., and D. C. Tennant, M.E.I.C., with power to add to their number.

Mr. Bennett drew attention to the fact that it had been the policy of The Institute to have the General Secretary visit as many of the branches as possible each year, and he suggested as a possible alternative that the Council consider the desirability of having each vice-president visit the branches in his zone, the expenses in connection with such visits to be paid by The Institute.

Discussion of this suggestion followed, and it was unanimously resolved that this Council go on record as endorsing the policy of the vice-presidents visiting the branches in their several zones, the Council, if possible, to meet the expenses of such visits.

Attention was drawn to the fact that Professor W. F. McKnight, A.M.E.I.C., who had attended the last Plenary Meeting of Council as the representative of the Halifax Branch, had passed away during the summer, and on the motion of Professor Faulkner, seconded by Mr. Bennett, it was unanimously resolved that this meeting go on record as expressing appreciation of his work in the interest of the profession and deeply regretting the loss sustained by The Institute. The Secretary was directed to send a copy of the resolution to his widow.

On the motion of Dr. Lefebvre, seconded by Mr. MacLeod, it was unanimously resolved that a hearty vote of thanks be extended to the President for the able and dignified manner in which he had presided at all the sessions of this Plenary Meeting.

The meeting then adjourned.

Members of Council at Plenary Meeting.

12. F. R. Faulkner, M.E.I.C.
13. V. C. Blackett, A.M.E.I.C.
14. H. F. Bennett, A.M.E.I.C.
15. T. Lees, M.E.I.C.
16. W. J. Johnston, A.M.E.I.C.
17. J. L. Busfield, M.E.I.C.
18. R. B. Young, M.E.I.C.
19. J. M. H. Cimon, A.M.E.I.C.
20. O. O. Lefebvre, M.E.I.C.
21. J. G. R. Wainwright, A.M.E.I.C.
22. R. J. Durley, M.E.I.C.
23. B. Grandmont, A.M.E.I.C.
24. G. N. Houston, M.E.I.C.
25. J. F. Plow, A.M.E.I.C.

Members of Council present at the Plenary Meeting, but not included in the photograph are:

A. R. Decary, M.E.I.C.
H. H. Vaughan, M.E.I.C.
George R. MacLeod, M.E.I.C.
W. G. Mitchell, M.E.I.C.
F. A. Combe, M.E.I.C.
P. B. Motley, M.E.I.C.
E. Stansfield, M.E.I.C.
H. R. Wake, A.M.E.I.C.
L. W. Wynne-Roberts, A.M.E.I.C.

Meeting of Council

A meeting of Council was held on Friday, October 17th, 1930, at eight o'clock P.M., with Vice-President George R. MacLeod in the chair, and six other members of Council present.

With regard to the publication of Transactions it was noted that the last volume, issued in 1927, had included twelve of the outstanding papers presented during the years 1923, 1924 and 1925. It was decided that the Publication committee of The Institute be asked to review the papers published during the years 1926 to 1930 inclusive, and make a recommendation to Council as to their inclusion in the new volume or volumes of Transactions and as to the arrangements necessary for their publication.

The chairman of the Legislation committee presented a draft of the proposed amendments to Sections 66 and 67 of the By-laws, putting into effect the recommendations approved at the Plenary Meeting of Council regarding the membership of the Nominating committee. These amendments were approved for communication to the membership, and for presentation at the Annual Meeting.

The membership of the Leonard Medal committee, as submitted by the chairman, was approved as follows:

F. W. Gray, M.E.I.C., Chairman
F. D. Adams, Hon. M.E.I.C.
L. H. Cole, M.E.I.C.
S. C. Mifflen, M.E.I.C.
W. S. Wilson, A.M.E.I.C.

The resignation of Professor T. R. Loudon, M.E.I.C., as chairman of the Papers committee of The Institute, was accepted with regret, and it was unanimously resolved that R. B. Young, M.E.I.C., be appointed chairman of this committee, and asked if he would be good enough to carry out the programme which had been suggested at the Plenary Meeting regarding the preparation of papers.

The request of the Executive committee of the Montreal Branch that the dates of the Annual General and General Professional Meeting be changed from Thursday, Friday and Saturday, February 5th, 6th and 7th, 1931, to Wednesday, Thursday and Friday, February 4th, 5th and 6th, 1931, was considered, and it was unanimously resolved that this change in dates be approved. The tentative programme as submitted by the Secretary was approved.

Arrangements were made for the appointment of representatives from The Institute on the Council of the International Federation for Housing and Town Planning.

One resignation was accepted; two reinstatements were effected, and one Life Membership was granted.

A number of applications for admission and transfer were considered, and the following elections and transfers were effected:

Elections		*Transfers*	
Assoc. Members	7	Assoc. Member to Member	2
Juniors	5	Junior to Assoc. Member	8
Students admitted	4	Student to Assoc. Member	3
		Student to Junior	5
		Student to Affiliate	1

The Council rose at ten forty-five P.M.

OBITUARIES

Henry Martyn MacKay, M.E.I.C.

It is with deep regret that we record the death, on October 25th, 1930, of Henry Martyn MacKay, M.E.I.C., Dean of the Faculty of Applied Science and William Scott Professor of Civil Engineering in McGill University, Montreal. Born in Nova Scotia in 1868, he was educated at the Pictou Academy; Dalhousie University, where he graduated in Arts with Honours in 1888, and at McGill University, where he gained the Governor-General's Medal in 1894. Among his other distinctions may be noted the Honorary Degree of LL.D., which he received from Dalhousie University in 1929. On the completion of his university course, he served from 1894 to 1897 as assistant engineer of tidal surveys with Dr. W. Bell Dawson, M.E.I.C., in the Department of Marine and Fisheries, and then spent two years as mathematical master at his old school at Pictou. In 1899 he took up the branch of engineering with which he was to be chiefly identified during

H. M. MacKAY, M.E.I.C.

his professional career, and joined the staff of Waddell and Hedrick, consulting engineers of Kansas City, Missouri. For six years he was engaged in the design and field construction of a large number of important railway and other bridges and railway shops in the United States and Mexico, having charge, also, of many extensive investigations and reports. In 1905 he was invited to return to his old university as assistant professor of civil engineering, becoming associate professor in 1907, and professor in 1908. On the retirement of Dean F. D. Adams, Hon.M.E.I.C., in 1924, he was appointed Dean of the Faculty of Applied Science of McGill University, and all who knew him felt that a worthy successor has been found to that distinguished man of science.

Dr. MacKay joined the Canadian Society of Civil Engineers as a Student in 1894, became Associate Member in 1906, and was transferred to the class of Member in 1913. He served on Council from 1914 to 1916, and while, in later years, pressure of other duties prevented him from taking a very prominent part in the affairs of The Engineering Institute of Canada, he was a frequent contributor to the meetings and discussions. In 1915, jointly with Professor Ernest Brown, M.E.I.C., and C. M. Morssen, M.E.I.C., he was awarded the Gzowski medal for a paper on tests on the shearing resistance of reinforced concrete beams. His other contributions to the publications of The Institute included a report on the Strength of Steel I-beams Haunched with Concrete, based on extensive investigations carried out jointly with the late Professors Peter Gillespie and C. C. Leluau, and published in volume XXXV of the Transactions; a paper on Some Secondary and Impact Effects in Pony Truss Railway Bridges, presented before the Montreal Branch in February 1924 and based on investigations made for the Canadian National Railways, and an illuminating paper on Engineering Education, presented at the Annual General Professional Meeting in Montreal in January 1925.

Dr. MacKay was elected a member of the American Society of Civil Engineers in 1907; he was also a prominent member of the Society for the Promotion of Engineering Education, and the American Society for Testing Materials. He belonged to the Sigma Xi Society, and was president of the Graduates Society of McGill University from 1926 to 1928.

While carrying on his academic duties he found time for a considerable amount of important engineering work, largely in the nature of research. From 1913 to 1918, jointly with Professor E. Brown, M.E.I.C., and J. E. Howard of the United States Bureau of Standards, he directed important laboratory tests made in connection with the construction of the Quebec bridge, comprising investigations on the strengths of large columns and eye-bars, and on the distribution of stress in wide flat plates. His work for the Canadian National Railways, on the determination of secondary stresses in rivetted trusses, was of a remarkable character, and involved difficult experimental work on bridges under actual traffic conditions. In the civil engineering laboratories at McGill University, under his direction, much important work has been done on the strength of rivetted joints, and at the time of his death he was engaged on an investigation on welded joints and the internal stresses in structural members arising from welding. His services on the Board of Advisory Engineers on the Montreal Harbour bridge from 1924 to 1929 will be recalled by all who have had to do with that important structure.

During his term of services as Dean, he undertook an interesting and important inquiry as to the careers of the engineering graduates from the university, the results of which were communicated to the Society for the Promotion of Engineering Education, in the work of which body Dr. MacKay took a very active interest. His professional attainments as a mathematician, structural engineer, and investigator of engineering problems were outstanding. His reputation as an authority on engineering education was equally distinguished. Eminent as a teacher, it was a matter of great regret to past-graduates and to the undergraduate body that, when he became Dean, Dr. MacKay had no longer the same opportunity of taking part in the actual teaching work of the faculty. His loss will be keenly felt, not only by his colleagues and the student body at his university, but also by the many engineers now in active work who were formerly his students, and who owe so much to his teaching, influence and guidance. All who came in contact with him were attracted by his kindly personality, his modesty, his fairness and wisdom as an administrator, and his thorough grasp of his profession, and few who have been at the head of great engineering schools leave behind them a more enduring monument in the affection and memories of their old students.

William Robert Warren, A.M.E.I.C.

Members of The Institute will learn with regret of the death of William Robert Warren, A.M.E.I.C., of Regina, Sask., which occurred at Vancouver, B.C. on September 12th, 1930.

Mr. Warren was born at Taunton, England, on March 25th, 1876, and received a general school education and private tuition in electrical engineering. At the time of his death, Mr. Warren was deputy minister and chief engineer for the Saskatchewan Department of Telephones. His connection with the provincial telephone system of Saskatchewan dates back to August 1908, when he was appointed engineer of the system. In 1912 Mr. Warren was promoted to chief engineer and in this capacity was in charge of construction, maintenance and operation until 1927, when he was appointed deputy minister and chief engineer. Prior to going to Saskatchewan, Mr. Warren was local superintendent in charge of construction, maintenance and operation of the telephone system in Winnipeg, Man. He was an Associate Member of the Institution of Electrical Engineers.

Mr. Warren became an Associate Member of The Institute on May 21st, 1918, and took a keen interest in Institute affairs, acting as Chairman of the Saskatchewan Branch in 1921.

Arthur Lees Mellor, A.M.E.I.C.

Regret is expressed in recording the death of Arthur Lees Mellor, A.M.E.I.C., which occurred in September, 1930, at Montreal, Que.

Mr. Mellor was born at Stalybridge, Cheshire, England, on October 24th, 1877, and received his education at Rossall School, Fleetwood, Lancs. From 1899 to 1926, Mr. Mellor was in the employ of Messrs. G. H. Hill and Sons, at Manchester, England, first as a pupil, and later as assistant on their staff. From 1920 to 1926 he was resident engineer for the company on the construction of an impounding reservoir with a capacity of 210,000,000 gallons with subsidiary works for the Stalybridge and Dukinfield (District) Joint Water Board. In 1927 Mr. Mellor came to Canada and was for a time engaged by the Milton Hersey Company, Ltd., Montreal, on the construction of the Montreal Harbour bridge.

Mr. Mellor joined The Institute as an Associate Member on May 18th, 1928.

Percy Edward Hart, M.E.I.C.

Deep regret is expressed in recording the death of Percy Edward Hart, M.E.I.C., which occurred at Toronto, Ont., on September 12th, 1930. Mr. Hart was born at Turnchapel, near Plymouth, England, on January 9th, 1870, and received his early education in the School of Science, Cardiff, Wales.

He came to Canada in 1888, and in 1889 took charge of the plant of the Brandon Electric Light Company, Brandon, Man. In 1891 Mr. Hart joined the Edison General Electric Company, later the Canadian General Electric Company, and from 1893 to 1895 was superintendent of construction for the Maritime Provinces for this company, with headquarters at Halifax, N.S. In 1895 he was appointed special expert on heavy installations for the same company, and in 1901 he was transferred to the head office of the Canadian General Electric Company, where he was in charge of contracts and later chief estimating engineer in the contract and sales department. In 1913 Mr. Hart joined the staff of the Toronto Hydro-Electric System as electrical engineer, he was later appointed managing engineer and finally, chief engineer, the position he occupied at the time of his death.

Mr. Hart was a Fellow of the American Institute of Electrical Engineers, and a registered professional engineer of Ontario. He was also a member of the Engineers' Club of Toronto.

He joined The Institute as a Member on October 22nd, 1918.

PERSONALS

Percy G. Delgado, A.M.E.I.C., for the past sixteen years assistant city engineer of the city of Westmount, Que., has been appointed city engineer of that municipality.

Ross White, M.E.I.C., formerly superintendent of the Alcoa Power Company, Ltd., Kenogami, Que., is now with the Dominion Construction Company, Ltd., at Fraserdale, Ont..

Hugh C. Ritchie, A.M.E.I.C., has been appointed city engineer of Moose Jaw, Sask. Mr. Ritchie, who was formerly city engineer of Medicine Hat, Alta., is a graduate of the School of Practical Science, University of Toronto, of the year 1910.

T. V. McCarthy, A.M.E.I.C., is now with the Dominion Construction Company, Ltd., at Abitibi Canyon, Ont. Mr. McCarthy who was formerly with H. G. Acres and Company Ltd., was at one time assistant laboratory engineer with the Hydro-Electric Power Commission of Ontario.

J. B. Barnum, A.M.E.I.C., has joined the staff of the Beauharnois Power Corporation, Beauharnois, Que. as field engineer. Mr. Barnum was formerly with the Gatineau Power Company, Ottawa. He has at various times been connected with the Foundation Company of Canada and the Riordon Pulp Corporation.

Gordon Mitchell, A.M.E.I.C., formerly superintendent of construction with the Hydro-Electric Power Commission of Ontario, at Nipigon, Ont., is at present with the Dominion Construction Company at Fraserdale, Ont. Mr. Mitchell was at one time resident engineer for the Spruce Falls Power and Paper Company at Smokey Falls, Ont.

C. W. Justice, Jr.E.I.C., is at present engaged as electrical demonstrator at the University of Manitoba, Winnipeg, Man. Mr. Justice graduated from the University of Manitoba, with the degree of B.Sc., in 1926, following which he took a test course with the Canadian General Electric Company. Prior to accepting his present appointment, Mr. Justice was in the engineering department of the Canadian General Electric Company at Peterborough, Ont.

C. S. MacLean, A.M.E.I.C., is employed in teaching technical subjects by the school board of the city of Calgary, Alta. Mr. MacLean, who is a graduate of the University of New Brunswick of the year 1913, was formerly engaged on general mechanical engineering in connection with the design and manufacture of valves and specialties and sulphite pulp mill apparatus, with T. McAvity and Sons, Ltd., Saint John, N.B.

F. Gordon Green, A.M.E.I.C., is now assistant to the chemical director of International Combustion Tar and Chemical Corporation, New York. Following graduation from McGill University in 1921 with the degree of B.Sc., Mr. Green was with the D'Arcy Exploration Company, Wallace process oil shale plant (experimental) at Rosevale, N.B., first as chief chemist and later as plant superintendent. In 1922 he became connected with the N-Y-U Company, at Santa Maria, California, as superintendent on standardizing operation of twenty-ton experimental plant (oil shales) construction and operation of forty ton unit.

P. E. Jarman, A.M.E.I.C., has been appointed general manager of the city of Westmount, Que. Mr. Jarman, who is of English birth, came to this country as a youth, and from 1904 to 1906 was inspector of structural steel work for the Dominion Bridge Company. From 1906 to 1908 he was assistant town engineer of the town of Outremont, Que. In 1908 Mr. Jarman joined the staff of the city of Westmount as assistant city engineer, being appointed city engineer in June 1913.

A. N. Ball, A.M.E.I.C., has accepted a position with the McIntyre Porcupine Mines, at Timmins, Ont. Mr. Ball, who was formerly in the engineering department of Fraser Companies Ltd., at Edmundston, N.B., is a graduate of Queen's University of the year 1914. In 1919 he was engineer and surveyor with the Parson Engineering Company, in 1926 he was with the St. Lawrence Paper Mills Ltd. at Three Rivers, Que., and in 1927 Mr. Ball was connected with Morrow and Beatty at Kapuskasing, Ont.

D. Simpkin, Jr.E.I.C. has returned to Tocopilla, Chile, as construction foreman with the Anglo-Chilean Consolidated Nitrate Corporation. Following his graduation from the University of Alberta in 1922 with the degree of B.Sc., Mr. Simpkin became a steel detailer with the Bethlehem Steel Company at Buffalo, N.Y. and in 1923 held the same position with the McClintic Marshall Construction Company in Pittsburgh, Pa. In June 1923 he went to Chile as structural draughtsman with the Braden Company, and in 1925 he joined the staff of the Anglo-Chilean Consolidated Nitrate Corporation at Tocopilla, Chile, as steel and concrete designer. In 1929 Mr. Simpkin returned to Canada and joined the staff of the Horne Copper Corporation at Noranda, Que.

S. E. McColl, A.M.E.I.C., of McColl Brothers, Winnipeg, Man., has been appointed Director of Surveys by the Manitoba government. Mr. McColl will head a new engineering division operating under the Department of Mines and Natural Resources of the Dominion. Among the important matters to be undertaken by Mr. McColl are the construction of the town of Churchill, Man., the setting aside of mining areas in the north and areas destined to be public shooting reserves and the handling of fur-ranching territory. Mr. McColl is a graduate of the University of Manitoba of the year 1907. He secured his commission as a Manitoba Land Surveyor in 1909, and that as Dominion Land Surveyor in 1911. He has been a member of the firm of McColl Brothers, surveyors and engineers, since 1912.

L. L. Bolton, M.E.I.C., assistant deputy minister of the Department of Mines, Ottawa, Ont., has been appointed as acting chairman of the Dominion Fuel Board. Following his graduation from Queen's University in 1906 with the degree of B.Sc., Mr. Bolton was student assistant with Dr. R. W. Brock, M.E.I.C., engaged in studying for the Geological Survey the economic geology of Rossland mining camp. From 1907 to 1914 he was employed by the mines department of the Lake Superior Corporation as geologist and utility engineer, and from 1915 to the present time Mr. Bolton has been in the service of the Federal Department of Mines. In 1915 he was assistant mining engineer in the division of Mineral Resources and Statistics, Mines Branch, and there assisted in the compilation of "Iron Ore Occurrences of Canada." In 1916 Mr. Bolton was transferred to the office of the Deputy Minister as private secretary, the work of the office growing to such an extent that in 1919 his position was designated as secretary, Department of Mines. In April 1925 he was appointed assistant deputy minister.

F. S. B. Heward, M.E.I.C., forms New Company

F. S. B. Heward, M.E.I.C., recently resigned his position as president and general manager of Affiliated Engineering

F. S. B. HEWARD, M.E.I.C.

Companies, Ltd., Montreal, and has formed F. S. B. Heward and Company, Ltd., Montreal, for the purpose of carrying on in Canada the sale, service and installation of engineering products. Mr. Heward graduated from McGill University in 1912, with the degree of B.Sc., and subsequently became manager in the United States and Canada of James Howden and Company Ltd., manufacturers of steam turbines, condensing plant, high-speed engines, etc. In 1918 he became director and works manager of James Howden and Company of America, Inc., and later was also director of Combustion Engineering Corporation, Ltd.

W. H. Greene, M.E.I.C., formerly with the Canada Creosoting Company at Edmonton, Alta. is at present with the Alberta Wood Preserving Company, and is located at Calgary, Alta. Mr. Greene was for a number of years assistant city engineer of Moose Jaw, Sask. He is a graduate of the University of Toronto, having received his degree in 1909, following which he joined the staff of the Teton County Co-operative Irrigation Company as district engineer on irrigation construction in Montana, U.S.A. In 1910 he was appointed by the Department of the Interior as engineer-in-charge of a party investigating the Moose Jaw river as a source of water supply for the city of Moose Jaw, and in the following year carried out, for the same department, an investigation of stream-flow under ice cover in southern Alberta. In 1912 Mr. Greene received his appointment as assistant city engineer of Moose Jaw, and in 1921 was made superintendent of waterworks and building inspector in addition to his duties as assistant city engineer.

The Dunham-built Dwyer unit heater made in Canada by C. A. Dunham Company, Ltd. is gaining wide acceptance in industrial heating. This type of heater is manufactured in four sizes with normal heat output capacities ranging from 50,000 to 272,000 b.t.u.'s per hour. A large air delivery, two-speed motor, and replaceable tube construction are features.

Frick Company, Incorporated. Waynesboro, Pa. announce the publication of bulletin No. 198-A, entitled "Ice and Frost," which describes and illustrates modern indoor ice-skating rinks. Copies of this bulletin are obtainable from the offices of the company upon request.

ELECTIONS AND TRANSFERS

At the meeting of Council held on September 22nd, 1930, the following elections and transfers were effected:

Member

STAIRS, Denis, B.E., (Dalhousie Univ.), chief engr., Montreal Engineering Company, 244 St. James Street, Montreal, Que.

Associate Members

ANDERSON, Yngve Ragnald, B.E., (Univ. of Sask.), ceramic engr. and plant manager, International Clay Products, Ltd., Prince Albert, Sask.

ASHFORD, Arthur George, bridge dept., C.P.R., Montreal.

ELLIS, Norman Thomas, Major, M.C., res. engr., Thomsen & Clark Timber Co., Bowser P.O., Vancouver Island, B.C.

FYFE, Robert John, (Univ. of Sask.), managing director, R. J. Fyfe Ltd., 200 Broder Building, Regina, Sask.

VICKERS, Harold, (Liverpool Univ.), dftsman., Consolidated Mining & Smelting Company, Trail, B.C.

WALLACE, David Gemmell, B.Sc., (Glasgow Univ.), designing engr., Dominion Bridge Company, Limited, Montreal, Que.

Juniors

ANDREWES, William Edward, B.Sc., (McGill Univ.), Lieut., Royal Canadian Engineers, Halifax, N.S.

DURNIN, Edward James, B.Sc., (Univ. of Man.), Saskatchewan Power Commission, Regina, Sask.

MacCARTHY, Henry Blair, B.Sc., (McGill Univ.), 110 Lisgar Street, Ottawa, Ont.

MACLEOD, Ernest M., B.Sc., (N.S. Tech. Coll.), control wireman, Shawinigan Engineering Company, Grand Mere, Que.

PYLE, John (Grad., Inst.M.E.), works manager, Thornycroft (Canada) Limited, Montreal, Que.

RAMSTAD, Ivar Asbjoern, C.E., (Tech. Univ. Norway), dftsman., Shawinigan Engineering Company, St. Michel des Saints, Que.

Transferred from the class of Junior to that of Associate Member

BISSELL, Harold Rudolph, B.Sc., M.Sc., (McGill Univ.), manager, Stirling Mines Ltd., c/o The British Metal Corporation, Stirling, N.S.

CHISHOLM, Joseph Donald, B.Sc., (McGill Univ.), Sales engr., Harland Engineering Company, Ltd., Montreal, Que.

HUGHES, Chester Arthur, B.A.Sc., M.A.Sc., (Univ. of Toronto), asst. prof. of structural engrg., University of Minnesota, Minneapolis, Minn.

JOHNSTON, Clifford Milton, B.Sc., (Queen's Univ.), vice-pres. and sec.-treas., Welch & Johnston Ltd., Ottawa, Ont.

McMULKIN, A. Frank, (Mt. Allison Univ.), asst. engr., Montreal Terminal Development, C.N.R., Montreal, Que.

RICHARDSON, Roderick McDougald, B.Sc., (McGill Univ.), divn. constrn. supt., Eastern Ontario Divn., Bell Telephone Company of Canada, Ottawa, Ont.

STILES, Raymond Donald, B.Sc., (N.S. Tech. Coll.), asst. engr., transformer section, General Electric Company, Lynn, Mass.

WELCH, Henry R., B.Sc., (Queen's Univ.), pres., Welch & Johnston Ltd., Ottawa, Ont.

Transferred from the class of Student to that of Associate Member

BASTABLE, Ross Waller, B.Sc., (McGill Univ.), supervisor of bldgs., eastern area, Bell Telephone Company of Canada, Montreal, Que.

BOWN, William Edmund, B.Sc., (McGill Univ.), asst. supt., coke oven dept., Dominion Iron & Steel Company, Ltd., Sydney, N.S.

McINTOSH, James Harrington, B.A.Sc., (Univ. of Toronto), asst. works mgr., British Columbia Cement Co. Ltd., Bamberton, Tod Inlet, B.C.

Transferred from the class of Student to that of Junior

GILMOUR, William Alexander Turner, B.Sc. (Mech.), B.Sc. (Elec.), (McGill Univ.), chief dftsman and engr., The Smart Turner Machine Company, Ltd., Hamilton, Ont.

LYONS, Gerald Stanley, B.Sc., (Queen's Univ.), toll cable engr., Quebec Divn. Plant, Bell Telephone Company of Canada, Montreal, Que.

POUND, William Thomas, B.Sc., (Queen's Univ.), Ontario Paper Company, Thorold, Ont.

ROCHESTER, Bertram Cole, B.Sc., (McGill Univ.), head of eastern sales, McCarthy & Robinson, 821 Castle Building, Montreal, Que.

At the meeting of Council held on October 17th, 1930, the following elections and transfers were effected:

Associate Members

ARVESEN, Ragner Woll, (Grad., Porsgrund Tech. Coll.), designer, Abitibi Power & Paper Co., Sault Ste Marie, Ont.

BARTLETT, Oswald Willoughby, B.Sc., (Univ. of London), A.C.G.I., asst. elect'l. engr., Fraser Brace Engineering Co. Ltd., Montreal, Que.

BERLYN, Martin John, M.A. (Hons. Mech. Sci. Tripos), (Cambridge Univ.), on technical staff, hydraulic dept., Dominion Engineering Works, Lachine, Que.

DELGADO, Percy George, asst. city engr., City of Westmount, Que.

FEETHAM, Luke Bernard, B.Sc., (N.S. Tech. Coll.), asst. engr., Halifax Harbour Commission, Halifax, N.S.

MATHEWS, Henry Mends, (Diploma, Faraday House Elect'l. Engrg. Coll.), Canadian representative, Messrs. Merz & Partners, Montreal, Que.

PORTER, William Thompson, asst. mech'l. engr., Welland Ship Canal, St. Catharines, Ont.

Juniors

ANDERSON, William Galloway Macdonald, engrg. dept., Price Bros. & Co. Ltd., Quebec, Que.

de CHAZAL, Philippe, instr'man., Shawinigan Engineering Company, Montreal, Que.

MOULD, John, B.E., (Univ. of Sask.), res. engr., Dept. of Highways, Prince Albert, Sask.

SIMMONS, William Raymond, B.A.Sc., (Univ. of Toronto), elect'l. engrg. dept., Montreal Tramways Company, Montreal.

STENDAL, Lars, C.E., (Tech. Inst. of Norway), reinforced concrete and structural steel designing dftsman., Power Engineering Company, Montreal, Que.

Transferred from the class of Associate Member to that of Member

KNIGHT, James A., B.A.Sc., (Univ. of Toronto), designing engr., Beauharnois Construction Company, Beauharnois, Que.

WEST, Arthur Elemere, operating manager, Canadian Bridge Co. Ltd., Walkerville, Ont.

Transferred from the class of Junior to that of Associate Member

BUDDEN, Arthur Napier, B.Sc. (Mech.), B.Sc. (Elec.), (McGill Univ.), supt., Laurentide power house, Shawinigan Water & Power Company, Grand Mere, Que.

COOIL, Thomas Reginald, B.Sc., (Univ. of Sask.), city engr., North Battleford, Sask.

DeLONG, Robert Keys, division engr's. office, C.N.R., Moncton, N.B.

DICK, Victor William, B.Sc., (Univ. of Man.), elect'l. designer, Northwestern Power Co. Ltd., Winnipeg, Man.

MAXWELL, Edward Gerrard, B.Sc., (McGill Univ.), plant efficiency engr., Pittsburgh Plate Glass Co., Creighton, Pa.

OAKS, Harold Anthony, B.A.Sc., (Univ. of Toronto), director of aerial operations and asst. gen. mgr., Northern Aerial Minerals Exploration Ltd., Toronto, Ont.

POOLE, John Maurice, dfting. and outside engrg. work, Halifax Harbour Commission, Halifax, N.S.

ROSS, Malcolm Vaughan, B.Sc., (McGill Univ.), asst., elect'l. dept., Brown Corporation pulp mill at LaTuque, Que.

Transferred from the class of Student to that of Associate Member

CHADWICK, Austin Ralph, B.A.Sc., (Univ. of Toronto), manager and director, Construction Equipment Co. Ltd., Montreal, Que.

CHAMPION, Cecil Hugh, B.Sc., (McGill Univ.), i/c mech'l. dept., Price Bros. & Co. Ltd., Kenogami, Que.

MUELLER, Emil Karl, B.A.Sc., (Univ. of Toronto), district plant engr., central northern divn., Bell Telephone Company of Canada, Toronto, Ont.

Transferred from the class of Student to that of Junior

DAVIS, George Roland, B.Sc., (Queen's Univ.), asst. dist. meter and relay engr., H.E.P.C. of Ontario, Smiths Falls, Ont.

FOX, John H., B.A.Sc., (Univ. of Toronto), asst. engr., C. A. Dunham Co. Ltd., Toronto, Ont.

KYLE, John Sheridan, B.Sc., (Univ. of Alta.), elect'l engr., C.N.R., Toronto, Ont.

McKILLOP, Douglas Bruce, B.Sc., (Queen's Univ.), res. engr., bridge engr's. dept., C.N.R., Carnduff, Sask.

McMILLAN, Ralph Edwin, B.Sc., (McGill Univ.), elect'l. designer, Fraser Brace Engineering Co. Ltd., Montreal, Que.

Transferred from the class of Student to that of Affiliate

THOMPSON, Frank Blashford, manager, technical and trade papers divn., Ronalds Advertising Agency, Ltd., Montreal, Que.

Students Admitted

BURNS, Edward Thompson, B.A.Sc., (Univ. of Toronto), student test course, Canadian General Electric Co. Ltd., Peterborough, Ont.

GROSSMAN, Ralph, electrician, Angus shops, C.P.R., Montreal, Que.

LANCTOT, Guy, (Undergrad., Ecole Polytech.), 1908 Van Horne Ave., Montreal, Que.

SWARTZMAN, Lewis, (Undergrad., Univ. of Man.), 381 Selkirk Ave., Winnipeg, Man.

Reinforced Concrete Bridge at Plougastel, France

Figure No. 1.—Condition of bridge nearly completed, in June 1930.

Figure No. 2.—The timber centring, originally built on shore, having been used for the first arch, has been lowered on to barges and is being moved to the site of the centre arch. In the background can be seen the pre-cast pier tops to which the centring will be secured.

The Plougastel Bridge

This remarkable reinforced concrete arch bridge is situated six kilometres east of Brest and has recently been completed. It carries a 26-foot roadway on the upper deck, with a single track railway on a lower deck, and crosses the estuary of the River Elorn, where the tidal range is 26 feet. It consists of three arches, each 610 feet centre to centre of piers; the vertical clearance is 118 feet, and the bridge has a total length of 2,887 feet. These are the largest concrete arches yet undertaken, and their construction involved many novel and ingenious features.

The arch section consists of an upper and lower slab 31.1 feet wide, connected by four vertical walls, the maximum thickness of which at the abutments is about three feet. Internal tension resulting from permanent shortening was relieved by the use of jacks placed in a niche in the arch crown. A small amount of steel reinforcement was used to take care of secondary stresses. The arches were designed for a total maximum stress of 1,000 lbs. per square inch, and were built by the use of a timber centring with reinforced concrete ends, which was floated into place, lifted into position by jacks on the piers, and secured to the pier tops, being afterwards removed and used for the next arch.

The two land abutments were constructed in circular reinforced concrete cofferdams. The two river piers were built by the use of a concrete caisson, employed as a diving bell for founding the first pier in shallow water, and then floated off and used as a pneumatic caisson for the second pier. The pier tops, forming the lower parts of the arches, were precast on shore, floated out, and attached to the pier shafts. Where the piers are exposed to tidal range, alumina cement was employed.

For handling materials to the arches and for unloading barges, etc., two cableways were used, each 250 feet above low water, and 2,260 feet span, suspended from timber towers.

The accompanying photographs are reproduced through the courtesy of "L'Illustration."

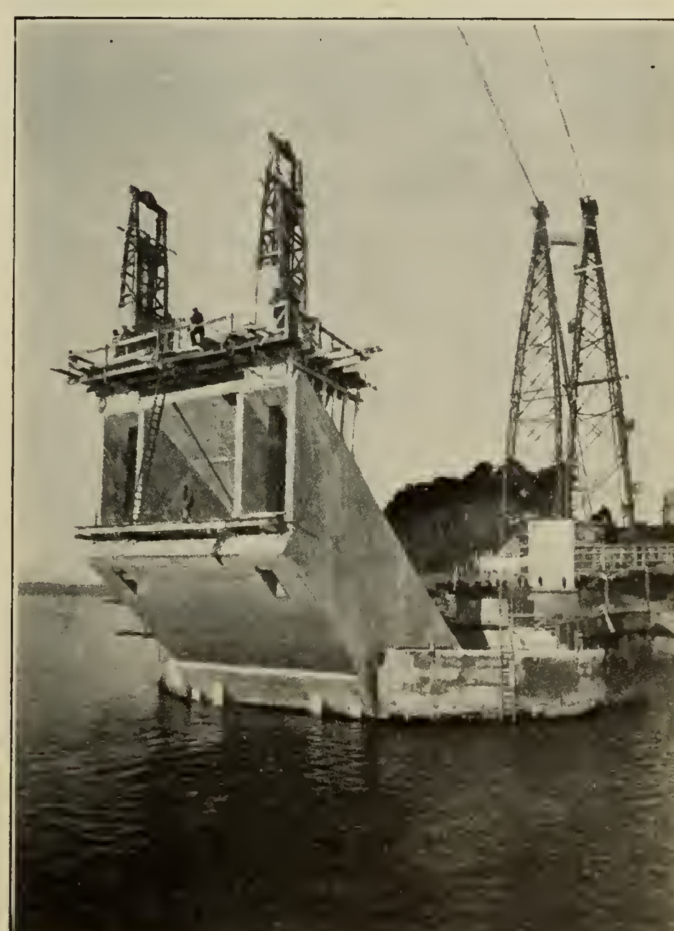

Figure No. 3.—Brest abutment ready to receive the centring and showing cross section of arch.

BOOK REVIEW

Bearing Metals and Bearings

(American Chemical Society Monograph Series.)

By W. M. Corse. Chemical Catalog Company, Inc., New York, 1930, cloth, 6 x 9 in., 383 pp., tables, $7.00.

The book is divided into four parts, viz., part I, History; part II, Bibliography, with Literature References from 1900 to 1928, inclusive; part III, Abstracts of Selected Papers; and part IV, Tables Showing Properties of Bearing Metals.

Part I, dealing with history, is clearly written and gives in a condensed form an excellent idea of the subject of bearing metals and bearings.

The bibliography contained in part II is very complete and is written in a manner that makes it a matter of easy reference.

The abstracts of selected papers, forming part III of the book, comprise perhaps its most valuable section. These have evidently been written by a man well versed in the science, who is, therefore, able to give the essential features of the papers, so that they are really of practical value to the reader without necessitating his securing the paper itself. Further, this also means that one has sufficient knowledge of the paper to avoid the necessity of searching out a number of papers only to find that they do not contain the details expected.

Part IV, giving tables showing properties of bearing metals, brings together within the limits of a few pages a mass of valuable data, much of which have not been previously available in any one publication.

From personal knowledge, covering an experience of some twenty-five years, the reviewer realizes that the book is up to date, and takes into consideration the most recent bearing metal alloys.

The author index and subject index are adequate and of practical value.

If there were more monographs of this nature they would be much appreciated, particularly by technologists in the various metal plants of the world.

Harold J. Roast, *General Manager,*
National Bronze Company, Limited, Montreal.

CORRESPONDENCE

Engineering Education

October 1, 1930.

To the Editor of The Engineering Journal.

Dear Sir:

In your September issue I have read with deep interest your "Abstracts of the Seven Papers Submitted for the Past-Presidents' Prize of 1929," on the subject of "Engineering Education"; and beg to register respectfully my approval of not only the action of the past-presidents in establishing such an annual competition, but also in the choice of the topic for last year.

For nearly half a century I have been writing periodically on technical education; and for several years past I have served (and am still serving) as the chairman of the committee on Engineering Education for the American Association of Engineers. For these reasons I am taking the liberty of sending you this letter, and discussing therein some of the opinions of the aforesaid seven writers on certain salient points in technical education. With most of these opinions I heartily agree; but there are some to which I shall have to take exception.

My discourse will be divided into the following headings:

A. Chief weaknesses in engineering education.
B. Teachers of technical students.
C. Preliminary training and entrance requirements.
D. Scholarships and loan-funds.
E. Layout of the curriculum.
F. Teaching methods.
G. Post-graduate study.

Before beginning my dissertation, it might be well for me to state why I feel qualified to pass judgment on matters of technical education. My reasons are these:

First. When I was a young man, I taught engineering for six years, all told, two at Rensselaer, my alma mater, as assistant in "Rational and Technical Mechanics," and four in the Imperial University of Japan at Tokyo, where I occupied the chair of Civil Engineering.

Second. I am a charter member of the Society for the Promotion of Engineering Education; and, ever since its inauguration, I have taken part in its functioning.

Third. Last year at Shanghai, when acting as Technical Advisor to the National Government of China, one of my numerous duties was laying out and inaugurating for Nanyang University, the principal technical school of the republic, a new, practical course in civil engineering—also the supervision for a few months of its running with the aid of two young men imported specially for the purpose from my New York office.

Chief Weaknesses in Engineering Education

In February, 1926, I delivered an address to a joint meeting of the departments of Civil Engineering of Lafayette College and Lehigh University and the Lehigh section of the American Society of Civil Engineers, entitled "In What and Why Does Engineering Education Fail to Attain Its Greatest Possibilities?";* and in it I listed the principal shortcomings, as follows:

A. Graduating many men who are lacking in breadth or vision, or, in slang parlance, who are narrow-gauge—also some who are absolutely unfit for engineering practice.
B. Failure to train students adequately in the use of their mother tongue—in both writing and speaking.
C. Neglecting to inculcate in the young men the principles of neatness, accuracy, and system.
D. Omitting to provide adequate instruction in economic subjects, especially engineering economics.
E. Allowing men to graduate who are incapable of doing satisfactory drafting, lettering or tracing.
F. Turning out graduates who are utterly ignorant of the first principles of business, accounting and auditing.
G. Omission of instruction in the elements of architecture and in esthetics of design.
H. Ignoring the necessity of teaching students how to make freehand drawings approximately to scale and how to do field sketching—as it is taught to army engineers.
I. Neglecting to instruct students concerning engineering as a profession, the ground it covers, its history, its importance to humanity, its ethics and the names and lives of its great leaders.
J. Permitting the wasting of too much of the students' valuable time on outside activities.

Concerning this matter of shortcomings, the author of paper No. 2 says:

"The chief weakness of engineering education is the lack of relation in the student's mind of things read or heard, or supposedly learned, to practical work.

"There is a lack of connection between school studies and the daily life and work of the engineer. Some engineering executives, who have achieved great material success, have become almost obsessed with the unpracticability of college education."

Teachers of Technical Students

To the preceding reasons for weaknesses in engineering education might be added the employment of young, inexperienced, and inefficient teachers, mainly because of the low salaries they are willing to accept, and the retention, through either misplaced sympathy or sheer force of habit, of old, fossilized instructors. Such men, through their lazy habits, inefficiency and indifference, do an untold amount of injury to the young minds entrusted to them for training. If such men were allowed to work without any salary whatsoever, they would by no means be an economic asset to the institution; because the harm they do by their bad example to the students much more than offsets the apparent value of their labour as instructors.

In general, it may be stated that a good teacher is born—not made, and that unless a man has in him the faculty of communicating his knowledge to others, *and really loves to do so*, he should not attempt teaching as a career or even as a means of tiding over a spell of bad times.

If the salaries of all the really good technical teachers of North America were doubled, and if all the poor ones there were discharged, a strikingly great advance in engineering education would result; but, to secure the maximum of benefit, this policy should be applied also to the instructors in the preparatory schools.

The author of paper No. 1 very tersely remarks that:

"The greatest difficulty in organizing engineering education is in providing teachers who will command respect, enforce discipline, inspire a love of study, and train the students to be seekers after knowledge."

This statement condenses the matter into a nutshell.

The same author says:

"If the teachers in our technical schools spend part of their lives in outside work, it will enable them to be more independent, to command higher salaries, and be worth more in particular as educators."

This is certainly true, and the doing of outside practice by engineering teachers should be made obligatory; but the amount of time spent thereon should have a reasonable limit, for otherwise their scholastic work would be neglected. Some years ago I was consulted by an eminent engineering professor as to how much time should be devoted to outside practice. My reply was "Either one-quarter of the scholastic year plus all vacations, or, preferably, one-third of the scholastic year plus two-thirds of the total vacation time."

*Reproduced in "Memoirs and Addresses of Two Decades," a book edited lately by Frank W. Skinner, consulting engineer, and published by The Mack Printing Company of Easton, Pa.

The author of paper No. 4 says:

"Too many teachers are graduates of the institution they serve, with limited knowledge and experience. No one should be permitted to teach in a school from which he has graduated, until he has spent an apprenticeship in teaching elsewhere. No one should be allowed to serve as an engineering teacher who has not had some years of practical experience. The Scottish practice, whereby assistant professors have greater chances of advancement by transferring to other colleges, is recommended."

This is truly-sound doctrine; and I have been advocating it both orally and in print for nearly half a century. The practice of taking into the faculty members of the graduating class, which custom is far too common, is most reprehensible. In my opinion, no one who has not had at the very least three years of practical experience in office and field should be allowed to teach, even in a minor capacity, in any engineering school; and the professors should have at the very least five full years of such practical experience. The young instructors can secure thereof about three months per annum by doing outside practical work during vacation time.

It is the opinion of many deep-thinking persons that inbreeding in the faculties of schools is just as pernicious in its results as it is among both humans and animals. For all of fifty years I have vigorously opposed such inbreeding in our technical institutions of learning.

There is a winked-at custom that I desire again to condemn, viz., that of professors utilizing the services of their students to aid them in doing their outside engineering work—on the plea that such experience is valuable to the young men. It certainly has some value, but not by any means enough to compensate for the time thus taken from their scholastic work. This restriction applies also to research work done by the professors; for, while the making of scientific and industrial investigations is good for both the professors and the school, and also indirectly for the undergraduates, in that they can see it going on and are told of its value by the faculty, it is only post-graduate students who should be called upon for assistance therein. There are two sound reasons for this—the undergraduates cannot spare the time, and they are not skillful enough, while the post-graduates have the requisite leisure and are more highly educated and better trained in practical matters.

The author of paper No. 7 says:

"Engineering professors should attend engineering-society annual meetings as the representatives of their university, the expenses to be provided for annually in the budget of the university."

This statement I most heartily endorse, and specially in respect to the meetings of the Society for the Promotion of Engineering Education.

Technical institutes should encourage their young professors to attend the "Summer School for Engineering Teachers," established a few years ago by the Society for the Promotion of Engineering Education; and, in the case of impecunious young men, should aid in defraying the expenses involved—at least to the extent of caring for tuition and railroad fares. That school, if well managed, should accomplish a vast amount of good in the development of technical teaching, and consequently should greatly benefit the entire engineering profession. On this matter I can speak with some authority; for last July, at Yale University, I lectured on "Bridge Economics" to the said school.

Preliminary Training and Entrance Requirements

The author of paper No. 1 says:

"It is desirable to weed out of the technical school and university the unfitted, the uninterested and the indifferent students."

If this could be done, it would be a god-send to all concerned; because the slow students usually set the pace for the entire class, thus holding back the brilliant ones and lowering the grade of the graduating output. Again, much money is wasted in the endeavour to train the unfit, which money could be spent to advantage on the better instruction of high-class students. Another good reason for rejecting unfit applicants for admission is that flunk-outs, during their entire lives, are apt to be overshadowed by the depressing sense of failure, and, in consequence, are discouraged from putting forth their best efforts. Some of such rejects might have proved quite successful in other lines of endeavour, or even in some of the minor lines of engineering, if they had had a good course in a trade-school or some similar institution of practical technics.

The author of paper No. 4 says:

"A suggestion is made that a psychological or intelligence test and a personal interview might be useful in determining whether or not a prospective student should take an engineering course."

The suggestion is valid; and the said test should be universally applied. Some claim that it is unfair to a young man to prevent him from trying to obtain an education for which he is willing to pay; but such a view of the matter is most decidedly wrong; because it is not the welfare of the individual that is to be considered, but that of the entire class and of the engineering profession—moreover, the young man would be paying for only a small portion of his education, the remainder being the gift of the institution. The sooner this psychology test is universally established, the better will it be for technical education, for the advancement of the engineering profession, and for the general welfare of the world, because the material progress of mankind is dependent primarily upon the engineers.

The author of paper No. 5 says:

"More attention should be given to the student during school and high-school days with departments or agencies to advise with parents and children regarding suitable careers for the young student."

This remark is directly in line with the policy of the American Association of Engineers, which, two or three years ago, started, through its "Engineering Education committee," the preparation of a book on "Vocational Guidance in Engineering Lines," to be written by a number of high technical authorities and edited by that committee. Some work was done by myself as chairman thereof, but the rest of the committee failed to function; and late in 1928 I was called to China for a year's service, hence the matter was temporarily dropped, but I am now trying to make arrangements for its resumption under better conditions. The object in view is to issue a very low-priced book on the subject for distribution among young men who contemplate entering the engineering profession, so as to show them and their parents all the pros and cons and to indicate what kinds of youths will constitute suitable material for our profession and its various specialties.

The Society for the Promotion of Engineering Education is also investigating the subject of "Vocational Guidance"; and I intend to try to co-operate with that organization in my committee work.

The last-mentioned author says also:

"After high-school graduation, a year in some industrial plant as a labourer or mechanic is suggested, with one or two evenings per week at pre-university studies."

This scheme might work well in exceptional cases; but its general adoption would require too great an expenditure of the young men's time, and, therefore, would result in an economic waste.

The same author says:

"Requirements for matriculation should be more scientific and less academic."

This statement is correct. I do not believe in the altogether-too-common practice of accepting candidates for admission to the freshman class in engineering schools solely on high-school diplomas, because the selection of the high-school studies adopted may have been entirely inappropriate. It might be practicable to recognize such diplomas, if the high-school course had been selected specially for engineering requirements; but it must be confessed that high-school education in general is sadly lacking in thoroughness and efficiency. For this reason it has been, and still is, necessary to teach elementary mathematics in engineering courses.

In my opinion, the entering freshman should be well grounded in the English language (including especially spelling), arithmetic, algebra, geometry, plane trigonometry, general world-history, the history of his country, and the history of engineering. He should also have an elementary or general knowledge of the sciences. I include plane trigonometry, so that he can at once begin to study the theory and practice of surveying.

Unless reliable evidence be offered that the applicant has received proper instruction in all of these subjects, the entrance examination should not be waived.

Rigid requirements for entrance tend to good progress in classwork, especially during the freshman year.

The author of paper No. 6 says:

"The value of an arts course before the engineering course may be over-rated, unless there is a definite programme of study and objective throughout the courses."

This statement is correct; for time and money are often wasted by taking an arts course preparatory to studying engineering. If the arts course be properly selected with a view to entrance into the sophomore class in engineering, the method would be a good one for those young men who have an ample amount of money to spend on their technical education; but, as a matter of economics, it will usually be found wanting.

The last-mentioned author says also:

"Adaptability to engineering is an inherent trait, and the college cannot create it, but only develop it.

"The intelligence or psychology or other tests should be applied to students wishing to enter college.

"There should be a point in the intelligence scale (obtained by comparison of school achievement and intelligence tests) below which students should be discouraged from entering a university."

These dicta are absolutely sound, but I would modify the last sentence by substituting for "discouraged" the word "prevented."

Scholarships and Loan-Funds

The author of paper No. 1 says:

"It is desirable to encourage by scholarships and loan-funds those who are anxious to learn but who have no one to pay their way. It is most unwise to allow students to spend more money than is actually required by the necessities of their college life."

There is no finer use for a rich person's surplus money than enabling worthy and capable young men and women to obtain the education they truly desire but are otherwise unable to secure—nor does one have to be rich in order to be of service in this manner. On several occasions during my long professional career, I have taken such an interest in certain young men as to lend them money to go through college—and in each case the loans made have eventually been repaid. The method I have adopted is simple, just to all concerned (including the lender's family and heirs), and fairly safe as an investment. It consists in having the young man insure his life for an amount somewhat in excess of the estimate of total cash required, turn the insurance certificate over to the lender as security, borrow money from him in small amounts when needed, give a note at the current rate of interest for each loan, pay the debt after graduation as soon as feasible, and receive back the insurance policy (which should then have a cash value) when the total indebtedness is removed. A debt of honour of this kind is not really a hardship for a young person, but will serve as an incentive to effective effort in his professional career. Moreover, he will not be burdened with the thought that he has been made an object of charity, as might be the case if he had taken the money as a gift.

Scholarships may rightfully be considered as public prizes for unusual ability and energy; and the recipient of one need not deem himself an object of charity because of its acceptance; nevertheless I believe that loan-funds are preferable to scholarships, in that they put the users on their mettle both to utilize economically and advantageously and to repay the money borrowed. Moreover, loan-funds need not call for competition in their award, while scholarships generally do. For that reason the former are of wider applicability and greater usefulness. Again, a much smaller sum is required for a loan-fund than for a scholarship; and the money invested therein does greater effective duty through serving more people. By careful ruling and handling, a loan-fund may be made not only perpetual but of steadily increasing value. Some twenty years ago I established one in the University of Nebraska by the deposit of one thousand dollars. It has been in constant use ever since, and its value has more than doubled, which indicates that there have been few, if any, losses; because the individual loans bear only simple interest.

Layout of the Curriculum

Concerning the actual make-up of engineering curricula, the authors represented in your compendium speak as follows:

The author of paper No. 1 says:

"It is thought that the technical student should be drilled in the use of clear, forcible English, when speaking as well as when writing."

Author No. 3 says:

"A study of the Latin and Greek languages, as languages, is not necessary for an engineer; and cannot the cultural tradition desired be obtained from translation? The ability to write and speak both English and French is necessary in Canada.

"It is not possible for the engineer to know too much of mathematics (including accounting), and of natural science.

"The dead languages, psychology, political economy, and English literature should not be included in an engineering curriculum.

"Training for executive positions is outside the scope of educational institutions."

Author No. 5 says:

"Mathematics, physics and mechanics should have first consideration in an engineering course.

"During college course, basic or elementary principles should be given throughout the course: from two-thirds to three-quarters of the entire time of college work is suggested in studying basic principles."

It is quite evident from the preceding quotations that there is a decided difference of opinion as to the content of an engineering curriculum. This must be deemed unavoidable if one recognizes the correctness of the old saw "Mony men o' mony minds, etc."; but there is still another valid reason, viz., different technical schools have different objects for attainment—for instance, high-grade engineering schools and trade-schools, the former being suited for the instruction of future engineers of importance, and the latter for the rank-and-file, the "hewers of wood and drawers of water." Again, there is a vast difference between the curricula of the usual high-grade technical institutions and of post-graduate schools of engineering. Finally, a curriculum appropriate to North America might not be at all suitable for some foreign land—for instance, the before-mentioned course in civil engineering that I laid out last year for Nanyang University in China.

As I explained in my report to the National government, the fundamental principle that guided me in my recommendations was diametrically opposite to what I have been advocating during the last three or four decades for the engineering schools of America. For the latter I have counseled the inclusion of numerous cultural courses and the reduction, to a proper minimum, of instruction in engineering practice; while for the former I recommended cutting down the cultural studies to a legitimate minimum and the inclusion of as much instruction as possible in engineering practice. My reason for this policy is that practical experience in any line of technical work is readily obtainable in America, while in China it is always difficult, and in some cases impossible, to secure.

Concerning my opinion about the curricula of vocational schools, high-grade professional schools, and post-graduate schools of engineering, I would refer those interested therein to pages 281 to 284, inclusive, of "Memoirs and Addresses of Two Decades."

In respect to the study of English by engineering students, I have been striving constantly for over four decades, both orally and in print, to inaugurate fundamental innovations in the technical schools of America; for I contend that a thorough knowledge of his native tongue is the most important asset that an engineer can have, because he can hire assistants to do his mathematical work, make his designs, and attend to his business matters, but he cannot employ anyone to do his talking for him, or even to express effectively in writing his individual ideas.

For years I have held the belief that a special kind of instruction in the English language is requisite for engineers, covering the reading, writing and speaking of correct modern English, but omitting consideration of the history of the language and ignoring all reference to antiquated writing and diction. The students, however, should not only be taught polished English; but, if it be possible, they should be compelled to use it in their daily lives.

There are certain high-class books on English for engineers; and these should be used for both text and reference. Among others, I would recommend the following:

"A Course in English for Engineers" by Naether & Richardson, published by Ginn & Company, in two volumes.

"English for Engineers" by Harbarger, published by McGraw, Hill & Company.

"English and Engineering" by Ayedelotte, published by McGraw, Hill & Company.

Besides these special books for engineers, I can recommend the following treatises that are of a more general nature:

"Workmanship in Words" by Kelley, published by Little, Brown & Company.

"Public Speaking for Business Men" by Hoffman, published by McGraw, Hill & Company.

"The King's English" by Fowler & Fowler, published by the Clarendon Press, Oxford.

"Good Engineering Literature" by Harwood Frost, published by the Chicago Book Company.

"Technical Writing" by Rickard, published by John Wiley & Sons.

"Composition of Technical Papers" by Wait & McDonald, published by McGraw, Hill & Company.

If any technical man will faithfully read, study and endeavour to apply the teachings of these various books, he will be almost sure to obtain a fine, useful knowledge of the English language, and make himself a master of its diction.

As for foreign languages, I am unalterably opposed to wasting time on the study of Latin and Greek; but I concede that for a man to be a real master of his native tongue it is necessary for him to struggle with and master the intricacies of at least one foreign language. For the United States I advocate Spanish, because of the proximity of the Latin American countries, and for Canada the French language, because it is the standard in the province of Quebec. In my opinion, either of these two modern languages will give the student as good mental and linguistic training as can any dead language; and, in addition, it has an important economic advantage.

The author of paper No. 3 asks whether the desired cultural tradition of Latin and Greek can be obtained from translations. In reply I would ask another question, "What is there in the writing of some two thousand years ago that would be really useful to modern engineers?" Our profession looks forward and not backward. It is concerned with questions of the present time and not with those of past ages. I would wipe out absolutely the compulsory study by engineering students of Latin and Greek and of translations therefrom.

The same author says: "it is not possible for the engineer to know too much of mathematics and of natural science"; but the study of pure mathematics is almost endless, and could occupy all of a student's time. In my opinion, class-room work in mathematics should end with the usual amounts of differential and integral calculus that are given in the leading American and Canadian technical schools.

At the International Mathematical Congress, held in Toronto, in the summer of 1924, which I attended as representative of the Royal Academy of Sciences and Arts of Spain, I presented a paper entitled "Mathematics from a Consulting Engineer's Viewpoint." In it I indicated that, while a thorough study of mathematics, both pure and applied, is essential for technical students and young engineers, the longer an engineer lives the less does he have to employ them in his personal work—also that mathematics is merely a useful tool and not, as many mathematicians seem to think, a god for man to fall down and worship. The article referred to is reproduced in "Memoirs and Addresses of Two Decades."

In respect to what is said in paper No. 3 concerning a thorough study of natural sciences I heartily agree, but I must take issue concerning the suggested exclusion of psychology, political economy, and English literature from engineering curricula. Any man who is not posted on the principles of psychology is very likely to be worsted in business matters; and, without some knowledge of political economy, one cannot be a man of the world, take his place among the best elements of society, or converse intelligently on many live topics of importance.

As for English literature, an engineer should be well versed in modern English book-lore, but not necessarily in that of ancient days. It is modern English that we employ in our every-day lives; and an engineer of high standing should be unusually well versed in it, a thorough master of its principles, and so conversant with its correct usage as not to have to think at all about the correctness of his speech and writing.

I disagree, also, with author No. 3 when he says "training for executive positions is outside the scope of educational institutions"—surely, he would not deny it a place in post-graduate instruction! If there were time available, it should be covered in the undergraduate curriculum.

While conceding to author No. 5 that "mathematics, physics and mechanics should have first consideration in any engineering course," a thorough training in "humanities" (using the modern acceptation of that term) is equally essential, and a certain amount of time should be devoted to practical technics. He is quite right, however, in his claim for instruction in elementary principles and the proportion of time to be devoted thereto.

It is strange that the question of including "engineering economics" in the curriculum has not been treated by any of the seven authors. It is true that author No. 1 says it is essential "to point out in all courses that successful application rests on good business methods, good ethics, and sound economics"; that author No. 4 says "English and economics are generally included in an engineering course"; and that author No. 5 states that a certain national board in answer to its questionnaire re the pulp and paper industry received replies to the effect that "subjects requiring more attention in college courses were economics, business administration, accounting, public speaking and psychology."

These three side-issue references are the only indication that economics is a proper subject for an engineering curriculum, when, in truth, it is the very acme of importance in all engineering work. For some two decades past, practising engineers have been earnestly urging the engineering teachers of North America to pay more attention in their curricula to "engineering economics," but, until quite lately, with very little effect. I have been one of the prime movers in this matter, hence I know whereof I speak. There are two probable fundamental reasons why the said engineering teachers refuse, viz., the lack of time in the present four-year courses for any additional studies, and the ignorance of many of the instructors themselves concerning even the first principles of the subject—to say nothing of the details.

It will not be well for me, however, to get started on a dissertation upon this matter, for I should not know when to stop; but I might state that I shall keep on pounding away until something worth while has been accomplished in respect to this important *desideratum*.

I might mention again, that last July, I gave to the Summer School of Engineering Teachers, held this year at Yale University, two long lectures on "Bridge Economics." The manuscript thereof contains some twenty-five thousand words; and, on account of the expense that would be involved in its publication, it may never see the light of day, which would be regrettable, as in it I endeavoured to cover, either directly or by reference to standard works, everything of any importance that is known today concerning the subject.

After finishing my discourse, I requested my audience to give me their individual opinions concerning its suitability, if put into book form, for engineering classes, and whether, if thus published, they would utilize it; and a few days thereafter I repeated the question in a circular letter. Without exception, although they are unanimous in stating that they would like to have the suggested book for reference and would put it into the school library, they state they could not use it as a text-book. This is a clear indication of the unwillingness of engineering teachers to instruct their students in practical technical economics. However, I firmly believe that the day is not far distant when the influence of practising engineers will force the professors to change their mistaken policy and teach thoroughly "engineering economics."

Teaching Methods

The author of paper No. 4 says:

"The quality of those entering our schools is probably better than formerly; our teaching is improving; industry and the schools are co-operating more closely than formerly; and the engineering profession is taking more interest than formerly in educational matters."

The author of paper No. 3 says:

"The future of education for engineering lies with engineers, whose judgment in any educational matters should prevail over that of professional educationalists."

While the statement of author No. 4 is strictly correct, there still exists much room for improvement in all lines of technical education; and, as indicated by author No. 3, it is the practising engineers, not the teachers of engineering, to whom the profession must look to effect the desired advancement. The reason for this is that the practising engineers are in a position to judge concerning the efficiency of the teachers' products, while the said teachers are not. It may be somewhat difficult to convince the latter of the correctness of this claim, and they may continue their ancient resentment against certain practising engineers for alleged interference with scholastic functioning. Some teachers used to be quite bitter in their remarks about such interference; but of late I have noticed a decided change in their general attitude towards this question.

Author No. 5 says:

"The conference method in class is advisable rather than the set-lecture method."

In this I certainly agree with him—in fact, as far as I can learn, I was the first engineering professor to inaugurate the conference method for class-room instruction. This I did in the Imperial University of Japan during the latter half of 1882. It was eminently successful—possibly because of the unusual ability, energy and ambition of my Japanese students.

As for the lecture system, I have been opposing for a full half-century its wholesale adoption. In my opinion, the only lectures suitable for any practical engineering course are one at its inception, so as to indicate the ground to be covered and how to study it, and another at its close to serve as a résumé. Of course, pertinent lectures by practising engineers of prominence are always valuable to engineering students, notwithstanding the fact that they are discouraged by the faculties of many technical schools, on the plea that they interfere too much with the routine of class-work. In my opinion, such lectures have an exceedingly beneficial influence on the young men, and should be encouraged instead of discouraged.

The author of paper No. 5 strikes a keynote when he says:

"Special provision should be made for brilliant pupils in selected classes, rather than mass instruction for students of different abilities."

One of the chief hold-backs in technical education today is that the curriculum is adjusted to the capacity of the average student and not to that of the upper half or, preferably, upper third of the class. Every inducement should be offered to brilliant students to take post-graduate studies; and it is for that purpose that the scholarships should mainly be employed. They would serve as well-earned rewards for extra effort and lofty purpose.

Author No. 4 says:

"Small classes where something approaching individual teaching is given are preferred to large classes."

This statement is axiomatic, yet the principle involved is too often violated. For instance, I knew of a case in a high school where a single teacher attended to eighty boys in eighty minutes! How much teaching of any real value could he perform under such conditions? If it were left to me to decide, there would never be more than twenty students at a time handled by one instructor. An even smaller number would be better for efficiency.

Author No. 5 says:

"The graduate who is trained how to think normally, rather than what to think, is the more useful in his profession, and the more capable of expansion and personal success."

This is eminently true; but the teaching of "how to think" should be started in the preparatory school, or, if possible, still earlier in life, rather than be left to the technical institute or university. There is a very good little book by Dr. Geo. F. Swain, published by McGraw, Hill & Company, entitled "How to Study." This should be read and re-read by school boys until its atmosphere has been absorbed. There is another book by the same gifted author entitled "The Young Man and Civil Engineering," published by the Macmillan Company, that should be read and closely studied by every young man who contemplates becoming a civil engineer. Author No. 6 quoted some good advice from the book.

Post-Graduate Study

The engineering alumnus who, soon after graduation, parts with or sets aside his school-books, with the idea that he will have no use for them in his practice, makes the grand mistake of his life; for not only will he have to refer often to his old text-books, but also he will have to buy and read many new books. To be a truly successful and prominent engineer, one has to study hard and read technical literature all his life, not merely in order to do his work properly, but so as to keep abreast of the times and posted concerning all important general technical innovations and discoveries. His reading should cover not only technics, but the sciences, current events, and good literature in general. The man who fails to read is the man who will make a failure in professional life.

Author No. 3 says:

"The education of an engineer is incomplete when he leaves college, and he is only commencing its more practical phase.

"Engineering students for continuance of their education should attend engineering society meetings, where papers on engineering subjects are read and discussed."

Author No. 5 says:

"The young graduate should take an active interest in an engineering society; and such societies should make co-operation with him a definite part of their activities.

"Post-graduate occupation should be regarded for at least five years as a part of training and education."

For nearly half a century I have been urgently advocating both *viva voce* and in print that every engineering graduate immediately after commencement day should join one of the four national founder engineering societies and take as prominent a part as practicable in its activities and functions. For instance, my elder son received his Rensselaer diploma at Troy one night; and the next forenoon at New York city I delivered in person his application for admission to the American Society of Civil Engineers, and secured quick action thereon. Without any exaggeration, I can claim to have influenced considerably more than one hundred young men to join that society.

Author No. 4 says:

"The 'settling-down' period of a graduate, extending over from perhaps one to five years, should be carefully checked up by the engineering school, and any necessary assistance given, the graduate meanwhile to keep the school informed of his whereabouts and circumstances."

This idea of extending the influence of the technical school over its alumni for at least a few years after graduation is an excellent one and ought to be adopted, notwithstanding the extra labour that it would involve for the faculty. One always can find leisure for doing some extra work of special importance, hence technical teachers should not hesitate to undertake any task that will militate for the benefit of the alumni of their school. While it is granted that professors are often overworked, nevertheless, on the whole, they do not have to labour as hard as do engineers in practice.

Recent alumni should make a point of consulting with practical engineers of eminence concerning a course of technical reading and study to be followed, so as to utilize all of their spare time to best advantage. Contact alone with such men will always prove to be a valuable asset in one's professional career; and the wider the young alumnus's technical acquaintance the better will it be for his advancement—to say nothing of the pleasure and satisfaction involved.

Concerning civic duties for engineers, author No. 6 says:

"In recent years modern society has come to realise that men with a solid foundation in science and engineering must be capable of taking a leading part in matters of policy and government."

On this subject author No. 7 says:

"With improved personnel in the engineering profession, a higher standard of appreciation from the public would be created and more remuneration obtained.

"There should be insistence of a more intensive infiltration of engineering into all positions—in parliament, on commissions, in executive positions generally, in industry, in city-manager and town-planning positions, etc."

These three remarks cannot be gainsaid; and they indicate the necessity for engineers to take a much more active part than is now customary in civic, state and national affairs, if our profession is to occupy in general society the high position to which it is entitled because of its fundamental worth and importance.

These seven competitive papers that your periodical has in part reproduced would well serve for a much wider dissertation than I have herein written; but probably, I have already occupied too much of your valuable space.

Respectfully submitted,
J. A. L. WADDELL, M.E.I.C.,
Consulting Engineer.

The Savery Engine

Editor, The Engineering Journal,
Dear Sir:

In The Engineering Journal for October 1930, I was interested to see in a paper on coal mining by T. L. McCall, M.E.I.C., a brief discussion of the history of the steam engine.

The reference to Savery's engine, however, is open to criticism. It is stated in the paper that "this pump acted on much the same principle as the present day pulsometer, with the exception that, steam pressure being absent, the pump acted as a suction pump only."

This statement is hardly true, as it is well known that although his successors, Newcomen and Watt, made no use of steam pressure, Savery was well in advance of his time and used both the pressure and suction principles. This point was well established by an eminent English engineer, David Brownlie, who wrote in "The Power House" as follows:

"The exact pressure Savery employed is not known with certainty, but it is generally estimated to have been 40-60 pounds per square inch, although it may have been much higher.

"This pump was worked for a considerable time, and in one installation water was pumped 80 feet high continuously, and Savery mentions that to pump water 60 feet high required a 3-inch pipe, and the firebox for the boiler was only 20 inches deep and 14-18 inches wide."

The fact that water was pumped to a height of 80 feet is a direct proof that a considerable amount of steam pressure was employed.

Yours faithfully,
E. A. ALLCUT, M.E.I.C.,
Associate Professor of Mechanical Engineering,
University of Toronto.

BRANCH NEWS

Cape Breton Branch

S. C. Mifflen, M.E.I.C., Secretary-Treasurer.
Louis Frost, Branch Affiliate, Branch News Editor.

The modernity and progressively aggressive policy of the Bethlehem Steel Company, the second largest steel operators in the world, was adequately illustrated by Geo. A. Richardson, technical lecturer of that organisation, during the course of an illustrated address to a large audience of ladies and gentlemen, at the central schools, Sydney, on Friday, October 17th, given under the auspices of the Cape Breton Branch of The Engineering Institute of Canada.

The speaker, who was introduced by acting-chairman A. P. Theuerkauf, M.E.I.C., paid tribute to the local steel plant and during the course of his lecture pointed out how the selective fabrication of a wide variety of steel products can only be achieved by highly modernized organizations, backed by adequate capital.

Motion pictures were shown, which illustrated in detail the fabrication of steel, from the landing of the ore from boats, to the different finished products. A panoramic view of the plant at Lackawanna, Pa. and of the blast furnaces at Johnstown, proved of great interest, as showing the mammoth operations of this company. Of peculiar interest to the steel men present, were the close-ups, showing the various phases of steel manufacture and the machinery used in the production of the fabricated units.

A bolt and nut making machine shown in operation, has a capacity of a million and a half pieces per day, other phases illustrated a 52-inch plate mill in operation and the manufacture of 36-inch steel girders, weighing 300 pounds per foot.

A distinctive feature of the plant at Lackawanna, were the time-saving methods employed to bring the plant up to a hundred per cent operating capacity. One of these operations showed the changing of rolls by moving the whole unit weighing 275 tons by a crane, the tremendous proportions of which will be readily recognized by the fact that the motor employed in this operation is rated at 8,500 h.p.

The films concluded with aerial views of the Delaware bridge and the new bridge across the Hudson at New Jersey, for which the Bethlehem Steel Company is supplying the steel. The latter bridge has a span of 1,750 feet with towers 600 feet in height.

At the conclusion of the meeting a vote of thanks to the speaker was moved by K. H. Marsh, M.E.I.C., chief engineer of the Dominion Steel and Coal Company, and seconded by J. H. Frazer.

Saint John Branch

A. A. Turnbull, A.M.E.I.C., Secretary-Treasurer.

Members of the Branch motored to the plant of the Canada Lock Joint Pipe Company, East Saint John, on Saturday, June 21st, and spent an interesting two hours viewing the manufacture of the large steel reinforced concrete pipe being laid for the new water main from the Marsh bridge to Little river.

Accompanying the members over the plant were R. Hugh Bruce, representative of the Canada Lock Joint Pipe Company, W. W. Trickey, superintendent of construction, and the Hon. R. W. Wigmore, commissioner of the Water and Sewerage Department, under whose direction the large programme of work is being carried out in the Water department of the city of Saint John.

The tour of inspection covered all the various stages in the manufacture and laying of the pipe. Large steel plates were cut and punched, then rolled to form one-third of the shape of a cylinder. Three of these rolled sheets were then welded to form a cylinder. Circular iron collars or ends were then welded to these cylinders after which the whole cylinder was tested for leaks in the welded joints by being subject to heavy air pressure. Upon passing the test for air-tight joints, the cylinders were next enclosed in a sort of steel cage consisting of steel bars and rings which were wired into place to form additional reinforcing when the cylinder is encased in concrete. The completed steel cylinder with steel reinforcing cage, is placed on end and the inside and outside moulds fitted to it. The concrete is then poured and worked down by means of long rods. It is allowed to set, after which the forms are removed and the pipes thus formed are allowed to stand until the concrete has sufficiently hardened. Each pipe weighs approximately 6,800 pounds. When laid in the excavated trench, the caulking of the sections of pipe is done from the inside and by means of a special lead caulk which is wedge-shaped and has a tightly compressed cotton core. This lead caulk is driven tightly for a considerable depth. About 30 of the large joints were being manufactured each day. The actual laying of the pipe was then inspected on Rothesay avenue.

Members were also treated to an additional feature in the form of a brief visit to the nearby Duntile plant of the Eastern Cement

Products and were shown through this plant by John N. Flood, A.M.E.I.C., president of the company. Mr. Flood explained the manufacture of the Duntile blocks and told of the growth in business which warranted new machinery, as the first unit could not cope with the heavy demand for the product.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

"The Manufacture of Structural Steel Shapes and Related Products" was the subject of an address delivered before the Branch on October 14th by G. A. Richardson, technical lecturer of the Bethlehem Steel Corporation, Bethlehem, Pa. The meeting was held in the city hall and was open to the public, upwards of two hundred being in attendance. A. S. Gunn, A.M.E.I.C., presided.

The address was illustrated throughout by motion pictures. Mr. Richardson brought with him not only the films but the entire projection equipment, and he was accompanied by a special operator. The pictures were much superior to any shown at previous Branch meetings and received very favourable comment from those present.

The speaker's remarks were not confined to the manufacture of structural shapes but covered the general field of operations of one of the largest steel corporations in the world. In connection with the handling of raw materials, the mammoth cargo unloaders excited particular interest. Each of these giant machines has a clam shell capacity of 17 cubic yards, and is controlled by one man, yet with a delicacy of movement that is amazing. A noteworthy time saving procedure has developed in the rolling mill. Formerly a change of section to be rolled meant a delay of twenty-four hours in changing the rolls. Now, the rolls are not touched, but instead the entire housing is lifted out and another substituted, an operation that may be performed in twenty minutes. The fabricating shop contains a somewhat novel machine called the piano-player punch, which does exactly what its name indicates, by punching steel plates in accordance with the perforations in a paper template fed into it. Not the least interesting was a description of the nut and bolt machines—almost human in their movements and considerably more than human in their speed and accuracy. Mr. Richardson's address brought out very forcibly the modern tendency towards time and labour saving devices and the mechanization of industry.

A hearty vote of thanks was tendered the speaker on motion of C. S. G. Rogers, A.M.E.I.C., seconded by Professor H. W. McKiel, M.E.I.C.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

On October 2nd, 1930, J. O. Bason presented a very interesting paper on "The Phenomena of Oil Circuit Breaker Interruption." Mr. Bason commenced by giving a brief description of the physical phenomena occurring during the rupture of an arc under oil. This was followed by several reels of moving pictures taken at ultra-high speeds, showing the actual operations of an oil circuit breaker. These pictures had been secured by the use of a special circuit breaker, the sides of which were constructed of plate glass and which was filled with a special transparent oil. This is the first occasion on which pictures of this kind have been shown, and the initial flash on breaking the metallic contact, the formation of the gas bubble, the rising of this bubble to the surface of the oil and the final extinction of the arc were shown with great clearness. Additional pictures showing the effects of electrode damage due to heavy arcing with various types of contacts were presented.

F. Newell, M.E.I.C., occupied the chair.

On October 9th H. R. Bartell, engineer of The General Steel Castings Corporation, Granite City, Ill, addressed the members of the Montreal Branch on the design, development and manufacture of special steel castings in locomotive and railway car construction.

Mr. Bartell attributed the major portion of present-day improvement and efficiency in railroad operation to the creation of sturdy and substantial foundations for locomotives, tenders, passenger and freight cars through steel castings. A careful study over a period of years indicated that most of the difficulties encountered either in the manufacture of steel castings or that developed later in service could be eliminated by changes in design. If not, modifications to the manufacturing processes could prevent all but a small percentage of the remainder of these difficulties.

In the opinion of some, too great an emphasis has been laid on metallurgical practices and methods but the speaker stated that in his experience, engineering design and manufacturing practice offered the greatest avenues for improvement in the quality of steel castings. Mr. Bartell further pointed out that, while the earlier designs of steel castings followed in general outline the appearance of the fabricated structures which they displaced, it was not long before designing engineers recognized that lightness and strength could be combined with good appearance, so that to-day much attention is given to producing castings that not only possess utility but that are also pleasing to the eye.

Steel castings originated with the development of the crucible furnace by Benjamin Huntsman, a clockmaker of Sheffield, England, in 1740. At this time, however, on account of the necessarily small size of the crucible, the production of large castings was very difficult. Henry Bessemer's invention in 1855 of the converter for transforming iron into steel, removed the limitation in size imposed on the crucible. Then the later development of the open-hearth furnace by the Siemens brothers of Germany and the French metallurgists, P. and E. Martin, blazed the way for much of the modern steel foundry practice of to-day.

The first steel castings used in locomotives were driving wheel centres built in 1895. At the same time when the movement towards larger and heavier locomotives began, it was found that cast steel engines were of great advantage. Mr. Bartell stressed the remarkable advancement in the art of steel casting during the past decade and predicted that even greater progress might be expected in the future.

F. Newell, M.E.I.C., occupied the chair.

Peterborough Branch

F. G. A. Tarr, S.E.I.C., Secretary-Treasurer.
B. Ottewell, A.M.E.I.C., Branch News Editor.

The Peterborough Branch of The Institute commenced the season's activities on September 13th, 1930, by a trip to the nearby village of Lakefield, where an inspection of the Canada Cement Company's plant was made. Mr. F. W. Bailey, the manager of the plant, and his staff of guides were indefatigable in making the tour interesting and educational. Several improvements in the plant had lately taken place, notably the addition of a 300-foot concrete chimney, replacing a number of steel stacks.

Following the inspection trip, the members indulged in a programme of sports, consisting mainly of vocal encouragement given to the visitors' softball team in a battle with the cement mixers, with the satisfactory result of a win for the former.

The day's events wound up with an excellent dinner served on the lawn of "Reydon Manor," Lakefield. About 70 members and friends took part in this trip.

A meeting of the Peterborough Branch of The Institute was held on October 9th, 1930, in the canteen of the Western Clock Company, under the chairmanship of A. B. Gates, A.M.E.I.C., after which a tour of the plant was undertaken, proving of keen interest, affording as it did an insight into the many intricate details of operation which contribute to the Westclox alarms and watches.

"We cannot conceive of a clock without knowing something of the thing we are dealing with—time," stated Mr. J. H. Vernor, general manager of the company, "and we cannot get down to practical things, leaving the realm of the speculative until we know what we intend to do." The speaker then dealt with the various means of time division which have been employed throughout the ages, adding, the calendar has varied considerably during the past six thousand years. The Western Clock Company was one of the first, if not the first, firms to adopt a newer and better calendar of thirteen months. "Our accounting periods" said Mr. Vernor, "are all divided into twenty-eight days, because it standardizes the entire plant and makes accurate comparisons possible. If the year itself is inaccurate, how can we make a timepiece which is accurate—and make it at a price where the public can be reached?" A mechanical device such as a clock is designed to perform certain functions accurately. The train of gears will revolve a given number of times per day. Therefore since the day itself is not evenly divisable by any set train of teeth in the gears, the timepiece cannot be perfect. The best the most accurate timepiece can do is to run at a given rate. The closer this rate, the better the timepiece. It is the practice of the Western Clock Company in the manufacture of alarm clocks which must sell to the wholesale trade for less than $1.00, to regulate them to within two minutes per day. They can be more accurately regulated, but this has to be done by the purchaser who may run them under different temperature conditions than is done at the plant.

A tour through the plant which followed the conclusion of Mr. Vernor's address, was proof that the preparation for the manufacture of a clock takes in many divisions of the engineering. Special attention was called to some double-acting draw presses on which the brass and steel shells for certain of the cases are drawn, while it was also pointed out that many of the smaller machines were designed and built in the plant, and have no counterpart elsewhere. One of the machines in particular, which performs the operation of making the bevel on the front of watch cases, was displayed with justifiable pride, having been fashioned and designed in the company's own tool room from parts taken off the junk pile. It has a special safety feed, which is a feature of all the machines in the Westclox plant, and which makes it almost impossible for the operator to get trapped.

The wheels used in all the clocks and watches are blanked, even the teeth in the watch wheels are not cut, and it is necessary that they be blanked without a burr. One of the dies was set up for the inspection of the visitors and another operation, that of piercing holes in a watch plate, was followed with interest. The operator of the piercing machine is able to produce approximately fifteen thousand parts daily, piercing a hole .021 inches in diameter through stock .054 inches in thickness. None of the holes on Westclox watch and clock plates are drilled; they are all pierced on power presses.

In the assembly department an operator was observed, deftly putting in the wheels that go between the plates of an alarm clock mechanism. One operator is capable of assembling 210 such parts per day. The wheels for the dial movement are put in by a separate operation. Nominally 2,000 clocks are assembled daily.

Mainspring casings for alarm clocks were also seen in the process of manufacture, and the machine performing the operation of punching the anchor hole in the barrel is stated to have a capacity of 2,200 per hour.

At the end of the assembly room is situated the regulating room wherein thousands of clocks, carefully guarded from dust, undergo a rigid test, running at 100 per cent for a period of three to five days. The clocks are all run in three positions before receiving the O.K. of the inspection staff. Maintaining a perfect silence, the visitors were able to hear these thousands of timepieces, their concerted action sounding like gently falling rain.

Hamilton Branch

John R. Dunbar, A.M.E.I.C., Secretary-Treasurer.
J. A. M. Galilee, Affiliate E.I.C., Branch News Editor.

Meeting in Toronto, October 10th

The members of the Hamilton Branch were invited by the Ontario section of the American Society of Mechanical Engineers to attend their opening meeting. This was arranged as a joint meeting of the Toronto section American Institute of Electrical Engineers, the Ontario section American Society of Mechanical Engineers, and the Toronto Branch of The Engineering Institute of Canada. Several members of the Hamilton Branch availed themselves of the invitation. The afternoon was given up to an inspection of the Royal York hotel mechanical and electrical equipment, the Toronto Terminal Railway steam plant, and the mechanical and electrical equipment of the new Canadian Bank of Commerce building.

At the dinner, which was held at the Royal York hotel, those present were glad to hear R. J. Durley M.E.I.C., General-Secretary, bring greetings from the Council of The Institute.

The speakers were Messrs. J. B. Andrews and L. P. Rundle, the subject being "Mechanical and Electrical Features of the Welland Ship Canal." Attendance—113 at dinner and 175 at the meeting.

Executive Committee Meeting, October 13th

A luncheon meeting of the Executive committee was held on Monday, October 13th, at the Wentworth Arms hotel.

The secretary reported that the proposed joint meeting with the Ontario section, American Society of Mechanical Engineers, could not be arranged in October but that an attempt was being made to arrange for a joint meeting in March or April.

Discussion took place regarding Council's action in requesting that the amendments to the constitution which had been submitted to Council and which had been discussed at the Branch meeting on September 11th be withdrawn. The following resolution was carried unanimously:

> "The Executive committee is still of the opinion that the original resolution as suggested by the Hamilton Branch members contains many features which if adopted would be of great assistance to The Institute at large. However, in view of the request from headquarters, they recommend to those who signed the amendments, that the resolution be withdrawn in its entirety, leaving it to the discretion of Council whether to use any of the material or not.
>
> "The Executive committee wish to express their appreciation of the courteous way in which the resolution was received by Council, and the attention which was given to it."

Discussion took place regarding the details of the Branch meeting to be held on October 21st. It was decided to extend an invitation to the ladies to attend the meeting.

Action was taken on one resignation as Branch Affiliate and on two applications for admission to The Institute.

The list of meetings as submitted by E. M. Coles, A.M.E.I.C., chairman of the Papers committee, was approved. The arrangement of the details of the meetings was left to the Papers and the Entertainment committees, together with the chairman and secretary.

Branch Meeting, Oct. 21st, 1930

(Reported by J. A. M. Galilee, Affiliate E.I.C., and J. R. Hutton, S.E.I.C.)

A meeting of the Branch was held in the grill room of the Royal Connaught hotel, at 8 o'clock p.m., Tuesday, October 21st, 1930. In the absence of the chairman and the vice-chairman, H. A. Lumsden, M.E.I.C., immediate past-chairman, occupied the chair.

Mr. Lumsden called upon G. F. Foot, assistant manager of sales, Canadian Westinghouse Company, Branch Affiliate, for his address on "Illumination of the Endless Caverns of Virginia," which was illustrated by coloured lantern slides. Mr. Foot took his hearers through the caverns and described the various formations of flow stone and drip stone, whose natural beauty is greatly enhanced by well-designed illumination.

The Illumination of the Endless Caverns of Virginia

The Endless Caverns of Virginia are located just off the famous Lee highway, 12 miles south east of New Market, Virginia. They have been called "endless" because explorers have worked for a long time seeking terminals to the winding channels and vast underground chambers.

"Skyland," for example is a combination of stalactites hanging down from the ceiling and stalagmites built up from the floor with the ceiling in many spots of virgin blue-gray limestone which lends itself almost perfectly to illumination from daylight lamps, and the production of a scene in which darker clouds seem to float in the afternoon sky. All the lights are concealed behind formations and broken rocks on the floor.

Caves are formed in two ways: by an upheaval of the earth which opens large seams and cracks within it suddenly, or by the slow unceasing action of acidulated waters seeping here and there through microscopic cracks in the original limestone. Ever so gradually these cracks widen. The acidulated waters are helped by silt and gravel-bearing waters and the process of solution is hastened by the action of erosion. Every erosion cave in its youth and early maturity is being enlarged by this action. Gradually however, as the water level of the surrounding country recedes, that is as the master streams eat their way further and further toward the level of the sea, the underground stream does likewise, and leaves behind its former channels. At the same time, or almost before this stream has begun to recede, the same acid-bearing waters which have played their part in the forming of the cave commence to fill it up again.

A section of a stalactite was shown and it was noted that there was a hole through the centre, extending from end to end. During the formation of the stalactites, mineral-bearing waters flowing through that hole gradually permeate through the formation, evaporate and build it larger and longer. Some perhaps have noticed that active stalactites almost invariably have a drop of water upon the tips. When the mineral-bearing waters are passing through the stalactite at a rate greater than the evaporation from the stalactite itself, the surplus drops from the tip of the stalactite to the floor of the cave beneath. There, more of it is evaporated, gradually building up a mound of material similar in composition to the stalactite but not similar in the mechanics of its construction because, here, the growth is in the form of successive layers formed upon the outside gradually building up a more or less conical structure. The stalagmite, therefore, is solid and consists of a number of rings of material, one encasing the other. Through the thousands of years in which one of these stalagmites is forming, the salts which the water contains in solution may change in composition over and over again. There are, therefore, layers of different materials making up the stalagmites, and these were clearly shown in the slide.

One of the interesting features brought out by the speaker was the fact that, although the visitor must retrace his steps, the illuminating engineer has so designed the illumination that the visitor is not conscious of having made the return journey by the same way as he came in.

Some of the caverns have romantic names given to them, names which their character suggests, such as "Weeping Willow Falls," "Hawaiian Village," "Gateway to Fairyland." The colours of the lantern slides brought out the attractive features of each.

Floodlighting and its Applications

The second speaker of the evening was G. F. Mudgett, manager of the Illumination Division of the Canadian Westinghouse Company. His subject was "Floodlighting and its Applications" and proved to be very interesting and much enjoyed by the members and guests. Floodlighting is a term which is becoming rapidly familiar to every one, including as it does the lighting of building façades and athletic fields.

A few applications of floodlighting are: buildings, railway yards, athletic fields, airports. These applications have entirely different conditions and requirements and the degree of illumination varies over an extremely wide range. The amount of light required depends upon the activities which are to be carried out. Due to the value of contrast effects, the colour and reflecting qualities of the surfaces to be lighted are very important factors. A dark-surfaced building in a brightly lighted district may require an intensity of 75- or 100-foot candles, whereas a light-surfaced building in dark surroundings may require but 8-foot candles.

Railway yards require a relatively low degree of illumination to produce the desired contast. A maximum intensity of .25-foot candles is used and for general yard lighting .05-foot candles or about twice full moonlight will surface. Because of the great length of most yards, lamps as large as 2,500 watts are sometimes used and to avoid glare, the projectors must be mounted as high as 100 feet.

The use of athletic fields at night is rapidly gaining in popularity. Well lighted fields have shown a great increase in attendance over daytime attendance. Baseball parks and football fields represent different conditions. The difference in size of the balls, their speed in play and height to which they rise require entirely different treatments.

Football lighting is accomplished by mounting projectors behind the stands at a height of 75 to 90 feet. The intensity may be as low as 2-foot candles and the energy required about 37 kw. Practically, however, intensities of 8- or 10-foot candles are used and it is believed that 200 kw. will be soon considered a minimum for this type of lighting.

Baseball fields should have an intensity of 15-foot candles on the infield and 8- to 10-foot candles in the outfield. Much light must be projected high in the air and as much energy as 30 kw. is expended in lighting the air. The total energy required is at least 175 kw. Glare is eliminated by mounting the projectors at a height of at least 100 feet and great care is necessary to ensure uniformity of illumination.

Airports require to be floodlighted at night to permit safe landings and take-offs. The Department of National Defence specifies that the minimum intensity of illumination must be .15-foot candles and as many fields are one-half mile or greater in length and width, the equipment must be very efficient and economical in operation.

The most efficient units use the Fresnel dioptric lens system, which is one of the oldest known and yet one of the most efficient. These lenses are in the form of half cylinders of 1,000 or 500 mm. diameter and mounted in suitable housings.

A 1,000 mm. unit with a 150-ampere, 100-volt high intensity arc as the light source, produces a beam candle power of 4,000,000 and a vertical divergence of 1¾ degrees. This will cover a field 3,800 feet by 3,800 feet with a minimum intensity of .15-foot candles.

The 500 mm. unit uses a 3,000-watt, 32-volt incandescent lamp as a light source, and produces 245,000 beam candle power. This beam has a spread of 180 degrees horizontally and 2½ degrees vertically. Four of these units, with a maximum candle power of 980,000, will completely cover a field 2,500 feet by 2,500 feet with light of minimum intensity of .15-foot candles.

These floodlight projectors are mounted with a slight downward tilt and with their small vertical beam divergence admit of little possibility of glare to a pilot and still permit uniform illumination of such large areas economically.

E. H. Darling, M.E.I.C., moved a hearty vote of thanks, which was carried with applause.

Mr. Lumsden announced the coming meetings and expressed his appreciation of the work of the chairman of the papers committee in arranging for such an excellent programme so early in the season.

After the meeting was adjourned, coffee and sandwiches were served.

Attendance 60, including 10 ladies.

Sault Ste. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting of the Sault Ste. Marie Branch of The Institute was held in the Old Stone House, Sault Ste. Marie, on September 26th, 1930, at 8 o'clock p.m., following a dinner.

C. H. E. Rounthwaite, A.M.E.I.C., chairman, called the meeting to order and the minutes of the last meeting were read and adopted.

On the motion of F. H. Barnes, A.M.E.I.C., and W. S. Wilson, A.M.E.I.C., the meeting adjourned to enable those present to visit the Algoma Central Railway car shops.

The party was conducted through the store, roundhouse and machine shop of the Algoma Central Railway by I. W. Boyd, A.M.E.I.C., who pointed out the interesting points about the shops; engines 50 and 51, and especially their cabs, attracted much attention. In all, a most profitable two hours was spent in examining the railway's plant and equipment and rebuilding engines, cars and all the various things that keep a railroad fit and in good running order.

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.

The Lethbridge Branch got away with a flying start for the coming season when over 60 members and their wives and friends gathered in the private dining room of the Marquis hotel on October 4th.

The excellent dinner provided by Lethbridge's ambitious and successful community hotel prepared those present for the boisterous round of singing which followed. The entertainment committee under J. Haimes, A.M.E.I.C., has brought out a revised and enlarged song sheet, through the mazes of which the diners were ably led by R. S. Lawrence, A.M.E.I.C., who also rendered a vocal solo.

The speaker of the evening was B. L. Thorne, M.E.I.C. of the Department of Natural Resources, Canadian Pacific Railway Company, and his subject was "The Oilfields of Europe and Africa." Mr. Thorne outlined the various oil producing regions of these parts of the world, giving their production figures and details of the varied drilling methods employed. Following this, motion pictures were shown illustrating the life and industrial activity of the oil regions previously described.

Following the address an informal dance was enjoyed till midnight, music being supplied through the courtesy of Mr. Brown's orchestra.

Mass Production of Homes

With increasing force, there is being brought to public realization the fact that the industry of providing houses or "shelter" is lagging far behind other basic industries. From the viewpoint of modern mass production, house building is still in the dark ages. During the War perhaps this fact first became generally evident. Since then, it has been given continually increasing attention in governmental, engineering and architectural thought and action in both the professional and the popular press......

Recent years have produced many new building materials, processes and finishes, but thus far they have been built in or superimposed upon the old traditional structure. Among these products are light fibrous and aerated mineral materials for insulation and for sound deadening; also a great variety of metallic and synthetic roofings and exterior finish and numberless interior finishes in the form of plasters, wall boards, tiles paints etc. ... It is interesting to note that although there is a vast amount of experimental and research work being done on building materials and quite a little on structural elements or details, there are very few minds at work on new structural systems or methods as applied to minor buildings.

For the past five or ten years, a graduate of the Massachusetts Institute of Technology in civil engineering has studied as his avocation the problems outlined above. Through a Massachusetts corporation organized for manufacturing and building purposes, he has carried on extensive research in housing structure and materials, and tried out in actual building many new ideas, probably more novel structural methods than any one else working in the same line. As a result, several structural types have been evolved. All of them are based upon an abstract conception of building structure, the conception of a relatively small cube as a module or unit of measure by which the proportions of other parts are regulated. The final structure may be imagined as made almost entirely from such small cubes, all of one standard size and shape; practically all lengths, widths and thicknesses are exact multiples of the dimensions of this cubical module.

The cube is used first in the analytical process and then in the synthetical. It is primarily a *structural module*, and architectural standards develop from it. Usually hitherto, the modular method of design has been employed in two dimensions (surfaces) only. Modular methods like those of Ernest Flagg have been primarily architectural and the structural considerations have been subordinated to the architectural. But the new methods explained herein, though not in detail, are primarily structural, and will, it is expected, fulfil the requirements of modern industry, engineering efficiency, mass production, speedy assembly and will also open new fields to invention, design and the creation of domestic and civic beauty.

In the first place, the method makes possible the mass production of framing parts (of steel, aluminum, etc.) Relatively few cross sections are involved, few lengths, because modularized, and few connections. With similar simplicity the supplementary elements (blocks, panels and slabs) including finish "grounds" may be manufactured. In many different materials, but all modularized, these are cut and finished and shipped, all ready for swift assembly on site.

Secondly, the structure thus assembled in the field is perfectly adapted for the ready and almost automatic application of finish to its modularized surface. The use of a relatively small structural module of the order of 2, 3 or 4 inches means that all existing and prospective finishes, exterior and interior, can be conveniently designed and manufactured in form and size suitable for such application; and through general use of modularized openings, doors, windows and, perhaps, stairs could be made more economically than at present and without substantial limitation of architectural design.

Thirdly, in this new modularized structure the installation of heating, plumbing, lighting and other services can be provided without interference with either structure or finish. Eventually some of such accessories may be integrally included in the structure.

The methods thus outlined, while at first thought open to the accusation of "machine made," "standardized," do not in reality impose upon the architect harmful restrictions either in the laying out of plans or in architectural design. ... The architect can plan freely. At the same time the householder gets the benefit in the lower cost of mass production. As soon as a good number of the building materials industries recognize and adopt these modular methods, all that they now offer in the way of finish—panelling, tiling, fire-proof and sound-proof linings, and many new possible forms—can be used not only in the new structures but on those of the traditional type, with enormously greater ease, flexibility, range of effect and lower cost. Standardized modular design opens the way to the greatest possible development of materials, it takes away nothing from what we already have and it offers a more efficient structure from the viewpoints of cost, utility and beauty.

—*Industrial Bulletin of Arthur D. Little, Inc.*

Canada Wire and Cable Company, Ltd., Toronto, Ont., have recently published catalogue No. 30, on wire rope and fittings. This catalogue, which is illustrated, also contains a short article giving general information regarding wire rope.

Preliminary Notice

of Applications for Admission and for Transfer

October, 23rd, 1930

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in December 1930.

R. J. Durley, *Secretary.*

* The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BICKLE—WARNER PENTLAND, of Winnipeg, Man., Born at Gladstone, Man., Apr. 26th, 1903; Educ., B.A., 1923, B.Sc., 1924, Univ. of Man.; 1918-22 (summers, and winter of 1919-20), chainman, rodman, etc., Man. Good Roads Board; 1923-29, with Man. Good Roads Board as follows: 1923-25, instr'man., 1925-26, asst. engr., District No. 5; 1927-29, asst. dist. engr. (Civil Service Appointment), Brandon District; 1929 to date, supt., paving dept., Carter-Halls Aldinger Co. Ltd., Winnipeg, Man., i/c of bituminous treatment work for western Canada, and partial supervision paving work.

ROSS—DAN, of 921 St. Clair Ave., Toronto, Ont., Born at Glasgow, Scotland, May 7th, 1902; Educ., 1920-24, Royal Tech. College, Glasgow; 1919-23, workshops, 1923-26, dftsman., Barr & Stroud Ltd., Engrs., Glasgow and London; 1926-27, asst. to chief dftsman., William Beardmore & Co. Ltd., Parkhead Steelworks; 1927 to date, plant layout engr. i/c of design and install'n. of equipment and all constrn. work, Willys Overland Ltd., West Toronto, Ont.
References: C. S. L. Hertzberg, A. H. Harkness, J. J. Spence, L. A. Badgley, C. J. Madgett.

SHUTTLEWORTH—WILBUR IRVIN, of 192 James Street, Ottawa, Ont., Born at Ottawa, Ont., Oct. 4th, 1901; Educ., 1916-20, Ottawa Collegiate. Private tuition; 1917 (4 mos.), rodman and dftsman with city engr., Ottawa; 1922 (6 mos.), recorder on precise levelling party, Geod. Survey, Ottawa; 1924 to 1927 (6 mos. each year), instr'man. and asst. engr., Geod. Survey, Ottawa; Sept. 1927 to Aug. 1928, instr'man., Gatineau Power Co., Ottawa; 1929 (Apr.-Sept.), engr. on three tunnels, Foundation Company of Canada, Montreal; Sept. 1929 to Feb. 1930, engr. on pulp mill extension, etc., MacLaren Lumber Co., Buckingham, Que.; 1930 (Mar.-July), engr. on Log Lodge Hotel, and Aug. 1930 to date, engr. in water dept., Lucerne in Quebec.
References: R. DeL. French, C. B. Breed, M. D. Stewart, W. Griesbach. C. O. Whitman, F. E. Holland.

TRACY—EDGAR HERBERT, of 525 Bolivar St., Peterborough, Ont., Born at Harvey Stn., N.B., July 22nd, 1900; Educ., B.Sc. (E.E.), Univ. of N.B., 1930; 1916-25, ran a steam plant for the C.P.R. (pumping water); 3 mos., elect'l. dept., C.P.R., Union Depot, Toronto; June 1930 to date, student test course, Canadian General Electric Company, Peterborough, Ont.

TURTON—EDWARD PURCELL, of Montreal, Que., Born at Leeds, Yorks., England, May 11th, 1905; Educ., 1918-23, The Central School, Leeds, Matric.; Post-Matric. course for apprentices at Leeds Polytechnic; 1923-24, engr's ap'tice, Green & Son, Leeds; 1925 to date, with the Northern Electric Co. Ltd., Montreal, 2 years, circuit dfting., 3½ years, dial system equipment engrg., and at present, engr., Technical Publications Dept.
References: N. L. Morgan, W. B. Cartmel, N. L. Dann, A. J. Lawrence, H. J. Vennes.

WRIGLEY—TOM, of 1729 Gouin Blvd. West, Cartierville, Que., Born at Oldham, Lancashire, England, Oct. 22nd, 1896; Educ., 1909-14, Oldham Technical Institute. Intensive home study on mech. design and mfg. methods; 1909-14, ap'tice, works and dfting office, Messrs. Haighs Ltd., Oldham; 1914-16, jig and tool dftsman., Rolls Royce Ltd., Derby, England; 1916-18, designer of jigs, tools, special machine tools, Crossley Motors, Manchester, England; 1918 (Feb.-Dec.), designer and checker, jigs and tools, Avro Aircraft, Manchester; Dec. 1918 to Feb. 1921, designer and checker, jigs and tools, Henry Ford & Co., Cork, Irish Free State; 1921-28, designer and consultant, Messrs. Platt Bros. & Co. Ltd., Oldham; Sept. 1928 to Mar. 1929, designer and checker, General Motors Corpn., Oshawa, Ont.; Mar. 1929 to Apr. 1930, jig designer, Curtiss Reid Aircraft, St. Laurent, Montreal; Apr. 1930 to date, dftsman., Dominion Rubber Co. Ltd., Montreal.

FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

CIMON—HECTOR, of 87 Park Avenue, Quebec, Que., Born at Riviere du Loup, (en bas), Que., April 28th, 1893; Educ., B.A., 1912, B.A.Sc. in C.E., 1916, Ecole Polytechnique, Montreal; 1912-13-14 (summers), with Dept. P.W. of Canada; 1916 to date, with Price Bros. & Co. Ltd., as follows: 1916-19, in charge of surveys for several water power developments and storage reservoirs, meterings of stream flow, preparation of plans and estimates for dams, mills bldgs., etc., inspections and investigations; 1919-23, design and direct supervision of constrn. of various engrg. works including substructure and approaches of steel highway bridge over Saguenay River, three-mile log flume, timber and concrete dams, waterworks and filtration plant, etc.; 1923-30, in charge of engrg. works for the South Shore Divn. of the company, including design, constrn. and mtce.
References: W. G. Mitchell, A. R. Decary, O. O. Lefebvre, A. B. Normandin, A. Lariviere, A. Frigon.

FOR TRANSFER FROM THE CLASS OF JUNIOR TO A HIGHER CLASS

FRASER—JOHN DOUGLAS, of 29 Larch Street, Halifax, N.S., Born at Halifax, Apr. 7th, 1902; Educ., B.Sc., Dalhousie Univ., 1923. B.Sc. (M.E.), McGill Univ., 1925; 1925-26, student engr., General Electric Company, Lynn, Mass.; 1926-27, air compressor test engr., with same company; 1927 (Mar.-Aug.), asst. supt., Electric Washing Machine Divn., Lauders, Frary & Clark, New Britain, Conn., in charge of inspection, planning factory layout, research, and designing, and general operating under supt. (asst. in charge of 150 men, including 6 foremen); Sept. 1927 to Dec. 1928, asst. plant engr., and Dec. 1928 to date, plant engr., Moirs Ltd., Manufacturing Confectioners, bakery products, wood boxes and paper boxes. In charge of mtce., constrn., installn., power, etc., and service dept. consisting of 8 supts. and 65 men.
References: J. H. Winfield, C. H. Wright, W. P. Copp, H. F. Bennett, K. L. Dawson.

TISON—MAURICE, of 2619 Leclaire Avenue, Montreal, Que., Born at Montreal, Apr. 25th, 1895; Educ., 3½ years, McGill Univ., 1915-16-19-20; 1912-14 (summers), asst. on engrg. staff, City of Maisonneuve; 1916 (summer), munition inspr., Canada Cement Co.; 1917 (summer), cable elect'l. testing, Northern Electric Co. Ltd.; 1915 (summer), asst. to supt'g. engr., Paving & Constrn. Co. of Canada; 1917-19, overseas, Lieut., R.A.F.; 1919 (summer), appraisal work, Ottawa Tramway Co.; 1920-23, elect'l. engr., on design of elect'l. structures, control boards, switchboards, etc., for low level pumping station, Montreal Water Board; 1923 to date, elect'l. engr. in charge of mtce., Electrical Commission of Montreal.
References: C. V. Christie, G. E. Templeman, C. J. Desbaillets, J. F. Brett, L. L. O'Sullivan.

FOR TRANSFER FROM THE CLASS OF STUDENT TO A HIGHER CLASS

BUTLER—ERNEST W. R., of Winnipeg, Man., Born at Ashton, Ont., March 16th, 1903; Educ., B.Sc. (Mech.), McGill Univ., 1924; 1924-29, sales-service engr., Bailey Meter Company, Ltd., work as supervisor and constrn. and mtce. engr. on equipment in the field which included making efficiency tests and combustion tests in boiler plants all through Canada, and at present in charge of the Western Canada office of the same company, management, sales, service, and testing of boiler plant equipment from Port Arthur to the Pacific Coast.
References: A. R. Roberts, A. R. Greig, J. W. Sanger, C. A. Robb, W. H. Stuart, N. M. Hall.

GEALE—CHARLES NORMAN, of Port Colborne, Ont., Born at Montreal, Que., March 31st, 1891; Educ., B.A.Sc., Univ. of Toronto, 1915; 1915-20, overseas, R.A.F. and R.N.A.S.; 1911, general survey work, Peterborough; 1912, township outline survey, Sudbury Dist.; 1913, colonization roads, Cochrane Dist.; 1920-21, instrument work, etc., on canal lock and dam constrn. at Bobcaygeon, Ont., Trent Canal; 1921-23, asst. to engr. in charge on constrn. of dam and power house substructure at Nassau, Trent Canal; 1923-24, gen. canal constrn., etc., head office, Trent Canal, Peterborough; 1924-27, asst. to engr. in charge on constrn. of canal, including breakwalls, bridge abutments; 1927-30, highways and general canal constrn. and office work, Welland Ship Canal.
References: A. J. Grant, E. G. Cameron, E. P. Murphy, R. L. Dobbin, G. Kydd.

HENDERSON—GORDON R., of Montreal, Que., Born at London, Ont., Mar. 6th, 1900; Educ., B.Sc., Queen's Univ. 1925; 1925-27, student ap'tice course, H.E.P.C. of Ontario; 1927-28, designer and water wheel work, Dominion Engineering Works, Ltd.; Sept. 1928 to date, constrn. and gen. engrg. with Power Corporation of Canada, Ltd., Montreal.
References: W. P. Wilgar, J. N. Stanley, H. S. Van Patter, J. S. H. Wurtele, F. R. Leadley.

JOHNS—CHARLES FREDERICK, of Sackville, N.B., Born at Portsmouth, England, Nov. 24th, 1903; Educ., B.Sc., Mount Allison Univ., 1928. 1919-24, ap'ticeship in elect'l. engrg. dept., His Majesty's Dockyard, Portsmouth, last two years in charge of party; 1926-28, attached to Royal Can. Corps of Signals for summer courses; Qualified for commission R.C.C.S., June 1928; Qualified for position as asst. prof. of aeronautics, at Univ. of Oklahoma, July 1930; instructor in physics, Mount Allison Univ., 1925-28, Mount Allison Ladies College, 1926-28; 1928 to date, in charge of engrg. dept., Enterprise Foundry Co. Ltd., Sackville, N.B., design of equipment and planning of install'ns. for domestic and industrial heating, also elect'l. equipment.
References: H. W. McKiel, F. L. West, C. S. G. Rogers, F. R. Faulkner, A. A. MacDiarmid.

LEMAIRE—WILLIAM ALFRED, of 4539 Bordeaux Street, Montreal, Que., Born at Montreal, Dec. 1st, 1902; Educ., 3-year day course, Montreal Technical School, received Prov. Govt. Diploma, May 1927; 1 year private tuition, engrg. maths.; 1 year, struct'l. engrg. course, Dominion Bridge Company; 1916-18, ap'tice on engrg. staff, Spartan Machine Co. Ltd.; 1918-20, ap'tice on mtce. staff, Crane Ltd.; 1927 to date, struct'l. steel detailer, Dominion Bridge Company, Montreal.
References: N. Cageorge, R. M. Robertson, A. Peden, D. C. Tennant, G. G. Clarke.

NOTMAN—JAMES GEOFFREY, of 771 Roslyn Avenue, Westmount, Que., Born at Westmount, May 6th, 1901; Educ., B.Sc., McGill Univ., 1922; 1919 (summer), tracing, Canada Cement Co.; 1922 to date, with Dominion Engineering Works, Ltd., as follows: 1922-23, foundry engr.; 1923-24, i/c pump design, paper dept.; 1924-26, production engr.; 1926 to date, asst. to general manager, and 1928 to date, also works manager, Chas. Walmsley & Co. (Canada), Ltd.
References: G. H. Duggan, J. C. Smith, F. P. Shearwood, D. C. Tennant, A. Peden, H. G. Welsford, H. S. Van Patter, F. Newell.

ROSS—HUGH GORDON, of Pittsburgh, Pa., Born at Ottawa, Ont., May 4th, 1903; Educ., B.Sc., McGill Univ., 1925; 1925 to date, with Westinghouse Electric & Mfg. Co., Pittsburgh, as follows: 1925-26, graduate student course; 1926 to date, design and development engr., supply engrg. dept., 1926-27, development and design work on power capacitors of oil type and on wax capacitors for various applications such as radio, ignition, lightning arresters, etc., 1927-28, responsible for design of all radio capacitors used in Radiola 16, 17 and 105, and also numerous experimental capacitors for amplifiers and talking movies; 1928-30, responsible for design of further wax capacitors for radiolas and also numerous experimental capacitors for phototone, television, etc.; Jan. 1930 to date, in charge of group responsible for development and design of all wax capacitors, radio capacitors, neon obstacle markers, airway signal devices using capacitors, etc., etc.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

INDUSTRIAL ENGINEER, qualified to reorganize a factory employing 500 to 1,000 operators, manufacturing electrical and radio apparatus in a modern, efficient manner and to direct its activities for most economical results; who possesses initiative and the ability to direct employees. Application must state complete qualifications, including history, education, and salary expected. Apply to Box No. 620-V.

CHEMICAL ENGINEER. A pulp and paper mill in the province of Quebec has an opening for an assistant chemical engineer. Must be a graduate and have some experience in pulp and paper mill work. Good opening for right party. Apply to Box No. 623-V.

DESIGNING DRAUGHTSMAN, with good technical or university education, preferably in mechanical or civil engineering, and at least two years of practical experience, for engineering department of an up-to-date pulp and paper mill. This offers a good opportunity in an expanding organization. In first letter state nationality, citizenship, education, experience, whether married or single, number of dependents, salary desired and when you could report. Apply to Box No. 632-V.

DRAUGHTSMAN. A company in Northern Ontario has an opening for a junior draughtsman and first-class tracer. Samples of work should be forwarded with application. Apply to Box No. 638-V.

DESIGNING ENGINEER. First-class designing engineer and draughtsman with extensive experience in metallurgical plants, such as cyanide, flotation and crushing plants. Only those with the required experience need apply. Apply to Box No. 639-V.

RECENT GRADUATE, in mechanical engineering, of one or two years, for sales work in connection with heating and ventilating equipment. Apply to Box No. 640-V.

Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., married, desires employment with manufacturer of industrial products, selling to industrial and other markets. His experience includes engineering and building construction, administration and operation of utilities, municipal works, etc. Record of integrity; moderate salary; location immaterial. Apply to Box No. 14-W.

ELECTRICAL ENGINEER, B.Sc. (McGill '26), Can. Gen. Elec. Co. test course, with experience in testing and maintenance. Apply to Box No. 39-W.

ELECTRICAL ENGINEER seeks connection with Montreal engineer or architect for part time work involving the design and specification for industrial and public buildings. Experienced and capable of complete responsibility. Apply to Box No. 40-W.

Situations Wanted

CIVIL AND MECHANICAL ENGINEER; aggressive, practical engineer, with background of experience in design, construction, maintenance and operation of pulp and paper mills. Especially qualified to reduce mill costs. Apply to Box No. 53-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), fifteen years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Apply to Box No. 107-W.

ELECTRICAL ENGINEER, B.Sc., age 30. Experienced in power distribution and electrical communication, including design of carrier current systems. Apply to Box No. 110-W.

ELECTRICAL ENGINEER, graduate '27, fifteen months students' test course; fifteen months switchboard layouts and substation design. Before graduation experience consisted of machine shop practice and electrical construction. Apply to Box No. 132-W.

COLLEGE GRADUATE, age 34, with over ten years experience in power developments and pulp and paper mill construction and maintenance, largely in direct charge of design or construction; desires new connection as chief or assistant engineer or construction superintendent. Apply to Box No. 167-W.

CIVIL ENGINEER, B.Sc. (McGill), M.E.I.C., P.E.Q. and B.C., with broad experience in hydro-electric power investigations, studies and exploration of forest lands, including design and construction driving and storage dams, wharves, flumes, piers and booms and loading plants, as well as general engineering and contracting, is open for engagement. Location immaterial. Now engaged but available on short notice as projects are nearing completion. Speaks French fluently, physically fit, active and energetic, and can get results. References can be furnished if required. Apply to Box No. 177-W.

CIVIL ENGINEER, A.M.E.I.C., Canadian, 21 years experience, railways, highways, water-power and conservation, concrete structures, electric transmission lines, etc.; field surveys, office engineering and construction. Working knowledge of French and Spanish. Available about October 1st. Now employed in Mexico. Prefer Canada, but willing to go anywhere. Apply to Box No. 327-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., R.P.E., Ont., with twenty-four years experience embracing dams, wharves, grain elevators, foundations, pile driving, highways, municipal engineering, water power surveys, road locations, inspections and estimating is open for engagement as engineer or superintendent in construction, operation or maintenance. Location immaterial. Apply to Box No. 358-W.

CIVIL ENGINEER, A.M.E.I.C., university graduate, O.L.S., married, twenty years experience city surveys, calculations for curved surveys, design, layout and supervision, sidewalks, pavements, sewers and water systems. Acted in capacity of chief engineer for large engineering and surveying firm for five years. Best of references. Available on short notice. Apply to Box No. 413-W.

ELECTRICAL AND MECHANICAL ENGINEER, S.E.I.C., educated Oundle and Manchester, age 24. Student course, Brit.-Westinghouse. Three years design, production, advertising, sales and control of sales force on mechanical and electrical goods. One year outside plant engineering leading public utility company. Desires work in sales, production or engineering capacity. Available immediately. Location immaterial. Apply to Box No. 415-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), graduate. Eighteen years experience in survey and construction, railway, hydro-electric and buildings. Experience comprises both office and outside work. Desires responsible position. Would consider position with commercial or manufacturing firm. Available immediately. Apply to Box No. 425-W.

CIVIL ENGINEER, S.E.I.C., 1930 graduate of Nova Scotia Tech. with experience as plane table topographer, instrumentman and draughtsman and particularly interested in hydro-electric power development and reinforced concrete design, desires position. Willing to go to foreign fields. Available at a few weeks notice. Apply to Box No. 431-W.

SALES ENGINEER, B.Sc. (McGill, 1914), A.M.E.I.C., 37, married, presently employed in position of responsibility, desires to communicate with a prominent railway equipment supply house, with a view to becoming its Pacific Coast representative. Has a complete knowledge of railway locomotive equipment particularly. Excellent references can be furnished. Apply to Box No. 444-W.

CONSULTING ENGINEER. A member of The Institute with many years experience in general engineering is open for an engagement in consulting, advisory or inspecting capacity. Would like to meet corporation or large contracting firm to whom such qualifications may be useful. Apply to Box No. 445-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc. (McGill Univ., '27), age 26. Fifteen months outside plant engineering with large public utility. Twenty months sales engineering experience with electrical manufacturing company. Available on reasonable notice. Apply to Box No. 463-W.

ELECTRICAL ENGINEER, B.Sc. (McGill), Jr.E.I.C., age 28, graduate Canadian General Electric Company test course, with two years experience in the design of induction motors and direct current machines. Previous experience includes electrical installation in large paper mill, and assistant to engineer in charge of small utilities company. Married. Location immaterial. Apply to Box No. 466-W.

CIVIL ENGINEER, experienced in road construction, mine surveying, transmission line survey and construction; paper mill construction; age 27. Available on short notice. Apply to Box No. 468-W.

CIVIL ENGINEER, A.M.E.I.C., age 39, with wide experience on design and construction of reinforced concrete structures, desires position. Apply to Box No. 475-W.

PLANT ENGINEER, A.M.E.I.C., age 37. Experienced in layout and maintenance of plant equipment. Special study in plant efficiency using Bedaux system and setting of standard rates and bonus payments. Apply to Box No. 485-W.

Two-Fluid Cycles for Power Plants

If water served no other purpose, one might almost suppose that it was specially provided by nature to lead mankind to the invention of steam engines. The high latent heat of its vapour and the useful pressures obtainable at very moderate temperatures combined to make steam an almost ideal working fluid for such engines as could at first be constructed. But while the art of engine building has advanced, the properties of water have remained stationary. Its cheapness and innocuousness are as valuable as ever, but the very fact that it provides a fairly high pressure at a comparatively low temperature involves the corresponding disadvantage that the pressure becomes higher than is generally desirable before the boiler temperature can be raised to the point which the designer would like. Any steam temperature required can, of course, be obtained by superheating, but the greater the amount of superheat, the further the conditions recede from the thermodynamic ideal of putting the whole of the heat into the working fluid at the highest temperature of the cycle. The falling off of the latent heat as the pressure is increased is, for the same reason, a further disadvantage from the thermodynamic point of view. The physical properties of water therefore at the upper temperature of a modern steam cycle leave much to be desired. We are, indeed, very close now to the limits of steam engineering as regards efficiency, unless something can be done to improve the conditions of the heat-receiving portion of the cycle. As to the low-temperature portion, nothing seems likely to have greater merits than steam as a working fluid, so that the only course open for progress would appear to be in the direction of some two-fluid cycle. According to this scheme, one fluid would receive heat in the boiler, and after doing its allotted work, would reject its unused heat to a heat exchanger, in which steam would be generated for the production of further useful work.

The idea of a two-fluid cycle is by no means new. The trouble is to find some suitable substance for the high-temperature work. The only thing which nature seems to have given us more or less ready-made is mercury. This has both good and bad properties. In its favour is the fact that the pressure of mercury vapour, even at a temperature of 1,000 degress F., is only about 180 pounds per square inch, so that its use would render practicable an upper temperature for the heat cycle far higher than is possible with steam alone. The poisonous nature of mercury vapour is, however, one obvious drawback, and its very small heat capacity is another. Nevertheless, a mercury-steam cycle on a commercial scale has been in operation for some years in a power station at Hartford, Conn., though whether Mr. Emmet's enterprise in this direction will ever be largely followed is doubtful, if only for the fact that there is not enough mercury in the world to enable it to be used on any considerable scale for power production. If, then, we have to dismiss mercury as an auxiliary working fluid, the only alternative appears to be the use of some synthetic product. This possibility, moreover, opens up quite new avenues for exploration, both by chemists and engineers. The former are required to find some reasonably cheap material possessing the useful characteristics required, and as harmless as possible, both to man and metal. The greater the measure of their success, the less will be the difficulties of the engineer, though the latter in any case will have to devise means of dealing with liquids and vapours having properties very different from those of water and steam. Ammonia has long been employed as refrigerating medium, so that if it should prove the most practical substance for the high temperature part of a two-fluid cycle, the problems may be less serious. The possibilities of ammonia were discussed in considerable detail by Dr. E. Koenemann in a paper presented by him at the recent World Power Conference in Berlin.

An overall thermal efficiency from fuel to shaft horse-power of 32.4 per cent would be realized according to the calculations given, and even this figure would be improved on with a higher steam pressure for the second portion of the cycle. The chemicals, moreover, are cheap and non-corrosive, and there is no reason why the plant should be expensive in first cost. Under experimental conditions, the ammonia salts have given no trouble, the boiler pipe work and pump metal being unattacked by them. Nor has there been any difficulty with leakage at the flanges. The design of effective turbine glands to prevent the escape of ammonia vapour and stuffing-boxes on the pumps to retain hot ammoniates are obviously matters incidental to the proper functioning of a plant on the lines proposed by Dr. Koenemann, but a lot can be done with the incentive of an overall thermodynamic efficiency of well over 30 per cent. The realization of such efficiencies with turbine machinery and boilers would still further weaken the position of the internal combustion engine, hard pressed as it now is by steam, and relegate to some unknown future the day so often confidently predicted when explosion engines would be the universal source of thermal power.

—*The Engineer.*

SEALED TENDERS addressed to the undersigned, and endorsed "Tender for Wharf Extension, Father Point, P.Q.," will be received until **12 o'clock noon, Thursday, November 20, 1930,** for the construction of an extension to the wharf, at Father Point, County of Rimouski, P.Q.

Plans and form of contract can be seen and specification and forms of tender obtained at this Department, at the offices of the District Engineer, St. Lawrence Power Building, Rimouski, P.Q., L'Association des Constructeurs de Québec, 267 St. Paul Street, Quebec, P.Q., and at the Post Office, Father Point, P.Q.

Tenders will not be considered unless made on printed forms supplied by the Department and in accordance with conditions contained therein.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Minister of Public Works, equal to 10 per cent of the amount of the tender. Bonds of the Dominion of Canada or bonds of the Canadian National Railway Company will also be accepted as security, or bonds and a cheque if required to make up an odd amount.

Note.—Blue prints can be obtained at this Department by depositing an accepted cheque for the sum of $20.00, payable to the order of the Minister of Public Works, which will be returned if the intending bidder submit a regular bid.

By order,

N. DESJARDINS,
Secretary.

Department of Public Works,
Ottawa, October 30, 1930.

The Construction of the Steel Lock Gates of the Welland Ship Canal

E. S. Mattice, M.E.I.C.,
Vice-President, National Bridge Company of Canada, Ltd., Montreal.
Late Manager and Engineer, Steel Gates Company, Ltd.

Paper to be presented before the Annual General and General Professional Meeting of The Engineering Institute of Canada at Montreal, February 4th, 5th and 6th, 1931.

SUMMARY—The fabrication and erection of the Welland ship canal gates presented several shop and field problems which were of great interest, and some of which appeared to be entirely outside of previous Canadian experience. It, therefore, seemed that a description of some of these might be of interest to the members of The Engineering Institute of Canada.

In the original design of the gates, and in the original measures adopted by the contractor and sub-contractors to ensure a good and thoroughly efficient structure, some precautions to ensure accuracy and watertightness were taken, which afterwards either proved, or appeared, to be unnecessary; while on the other hand, certain refinements might have been made which would have in the end reduced the cost of the work.

Examples of the first condition were: the punching of all field holes one-eighth inch smaller than the diameter of the rivet was found to be quite unnecessary due to the use of modern spacing tables and multiple punches. The construction of the 82-foot gate endposts in one length in the shop does not seem to have been necessary, and certainly added very greatly to the difficulty and cost of the work.

As an example of the second condition, the frames may be cited; it was specified that these be fabricated by ordinary structural practice. However the apparently unavoidable toeing in of the connection angles rendered the securing of a watertight job very expensive. It would have been much better had the ends of the frames been milled to a true plane surface.

The particularly interesting points in connection with the contract were:—

1. The method adopted to secure a uniform length for all girders, and the accurate machining of their ends, at the same time locating the holes for attaching the diaphragms.
2. The shop fabrication and erection of the endposts.
3. The adjustment of the end bearing plates to a practically true line, and the measuring for and machining of the shims to attain this end.
4. The erection of the spare leaves vertically in lock No. 2, and then the procedure of placing them in a horizontal position, and floating them to the gate yard.

The contract for the construction of the steel lock gates for the Welland ship canal was awarded in the spring of 1926 to the Steel Gates Company, Ltd., of Montreal, of which Mr. William Lyall was president and the author manager and chief engineer.

In this paper it is the author's intention to deal with some of the problems encountered in the actual construction of these gates and the means taken to solve them. It will be assumed that all are familiar with their design, as this has been thoroughly dealt with by F. E. Sterns, M.E.I.C., in his paper presented at the Annual Meeting of The Institute in 1928, and therefore only those details of design which are necessary to the understanding of this paper will be touched upon.

The frame of a leaf consists of a series of horizontal plate girders, placed at from 4- to 5-foot centres, and supported one upon the other by end diaphragms, frames, and intercostals. The end diaphragms are designed to transfer the end thrusts, due to water pressure, when the leaves are mitred together, into the girders. The frames and intercostals are designed to transfer the water pressure from the skin plates to the girders, the former also being designed to keep the girders vertically over each other. The girders are also held in their proper position by heavy continuous endposts running from top to bottom of the leaf, these posts being in effect vertical girders. The frame, when thus assembled, is covered both on the upstream and downstream side by sheathing plates running between the endposts and joined together along the centre line of the flange of each girder; and lastly, doubling plates about 48 inches wide, running vertically from top to bottom of the leaf, are placed at each end of the up and downstream faces, passing outside the sheathing plates and under the flange of the endposts.

To this steel framework were attached the various castings and forgings, which were necessary for the support and operation of the leaf, such as anchorage eyebars and pin, pintle casting, sheaves, end bearing castings and end bearing plates, the two latter items running from top to bottom of the leaf at the quoin and mitre ends, and attached to the endposts by 2-inch turned bolts, their purpose being to transfer the thrusts to the frame, and to seal the joints between the mating leaves, and between each leaf and its corresponding quoin bearing. The general arrangement described above is shown in figures Nos. 1 and 4.

The two main points to be considered in planning the shop work were: the ultimate watertightness of each leaf, and the extreme accuracy in the length of girders, so that any leaves of the same height would be interchangeable. In addition to these, the best method of ensuring a satisfactory assembly of the endposts, girders, skin plates and doubling plates at the quoin and mitre ends of each leaf had to be studied.

The endposts are of constant section, and had to be shop fabricated into one piece the total height of a leaf. The sections of the endposts of an 82-foot leaf are shown in figure No. 1.

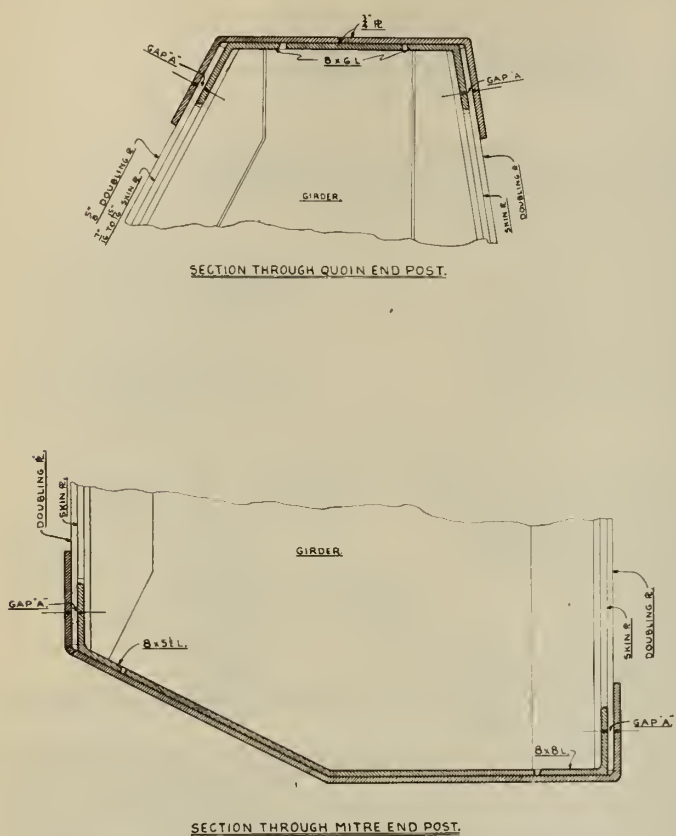

Figure No. 1.—Sections of End Posts—82-foot Leaves.

The girders enter between the 8-inch by 4-inch angles and their ends are faced to bear on the endpost web. The up and downstream doubling plates, which are of constant thickness, enter between the backs of the 8-inch angles and the flanges of the endpost plates, while the skin plates assemble between the girder flanges and the doubling plates. These skin plates vary in thickness from 15/16 to 7/16 of an inch and had the original design of constant depth girders been adhered to, the gap "A" between the 8-inch angle and the endpost flange would have had to be slightly over 15/16 of an inch, and a series of thin wedge-shaped shims used with all thinner skin plates. It was, therefore, suggested to the engineer in charge that the outside face of all skin plates be kept flush with the back of the 8-inch endpost angles, varying the depth of the girders to secure this condition. When the skin plates were under ¾ of an inch thick the ends of the girder flange angles were crimped, and when over, shims were used between the girder flanges and the skin plates.

As to clearances, the in-to-in of endpost angles was made 1/32 of an inch greater than the back-to-back of girder angles, and the space of entry of the 5/8-inch doubling plate was made 21/32 of an inch at the root and 11/16 of an inch at the outside edge. On the whole, these clearances were found satisfactory, though in some cases considerable trouble was experienced in entering the doubling plates.

The endpost plate as originally designed was in one piece, bent and flanged to the proper shape for the ends of the leaf. The practicability of flanging ¾-inch plates approximately 80 feet long to the required tolerances for clearance and straightness was taken up with several of the largest firms on the continent, and the conclusion was reached that a variation of at least ¼ of an inch must be expected, which was entirely too much. Welding was finally adopted as the solution and the endpost plate was built up by welding all longitudinal seams, and, for the 82-foot posts, making the plates in three lengths with two horizontal welds; the welds in the flanges breaking joint with those in the web.

A great deal of trouble was naturally experienced in developing an efficient shop practice for the manufacture of these posts. Heavy steel forms set in concrete pedestals and carefully lined and leveled were set up at from 4- to 5-foot centres, corresponding to the centres of the girders in the finished leaf, and to these the plates were bolted for welding. The first plates assembled were subpunched throughout. After welding, a total shrinkage in length of nearly ¾ of an inch was discovered, and it was necessary to scrap these plates. Thereafter the endposts were drilled from the solid after welding and after the inside filler plate had been assembled. The holes in the 8-inch leg of the post angles were drilled after assembling and riveting to the posts, at the same time as the holes in the flanges of the endpost plate. All drill burrs on the inside of the flanges were carefully scraped off to allow the doubling plate to be freely entered. The holes in the doubling plate were similarly scraped.

The endposts of the smaller gates were made in the same manner, but with a great deal less trouble, there being little difficulty experienced in securing accurate work on the 35-foot posts. Therefore should it be necessary to build other high gates of a similar design, it might be better to have the endposts shipped to the field in two or three lengths and connected up after assembly in the leaf, with efficient riveted or welded splices.

To ensure proper transmission of horizontal thrust into the girders and to keep the girder ends properly aligned the vertical end diaphragms were specified to be planed on the top and bottom and on the vertical face bearing on the endposts so that top and bottom faces should be truly parallel and at right angles to the vertical face. In fabrication, the web plates of the diaphragms were planed before the connection angles were assembled and riveted to them, and the outstanding legs of these angles were not punched. When assembled and riveted the angles on the three sides were planed down to the planed edges of the web plate, and the field holes were drilled in them to steel templates (all

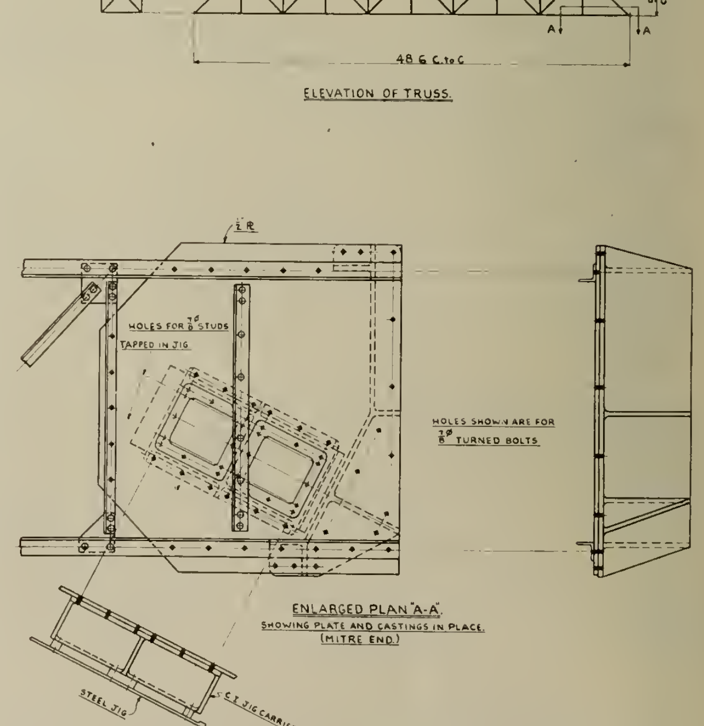

Figure No. 2.—Jigs for Girders—82-foot Leaves.

templates having case-hardened bushed holes) which had been drilled to match similar templates used for drilling the corresponding field holes in the girder webs.

The vertical frames, which with the intercostals transmit the water pressure from the skin plates to the girders, while not specified to require the same accuracy as the diaphragms, proved, with the exception of the endposts, the most troublesome pieces to deal with. To secure watertight rivets they had to be practically truly rectangular, and the outstanding legs of the flange angles practically at right angles to the web.

The former condition was taken care of at first by assembling and riveting all frames in rectangular jigs. Unfortunately these jigs were not made stiff enough, and when the fabrication was about two-thirds finished, several of the jigs became more or less distorted, and had to be abandoned. Thereafter a very careful hand squaring of the frames was resorted to.

The fact that a large proportion of the angles supplied by the mills toed in between 1/8 and 3/16 of an inch led to great trouble in the field, which will be discussed when describing the erection.

Jigs were also made and used at first for the assembly of the intercostals, but it was found that sufficient accuracy could be obtained by careful assembly, and the jigs were abandoned.

In the girder assembly care had to be taken to ensure an accurate and constant width at the ends between flange angles to ensure a neat fit between the endpost angles. To secure this, two heavy U-shaped castings were made to fit over the girder ends, and to these the girder flange angles were bolted. These castings each had two accurately located reference points marked on them, and they were carefully set for distance and square by tape measurement, which gave sufficient accuracy of assembly for everything except the end diaphragm holes and the machined length. The actual overall length of girders, within a normal tolerance, was not important, but it was most important that all girders should be the same length. To obtain this result, a lattice truss bridge was made 48½ feet long, 5 feet wide and 5 feet 4 inches deep. Castings similar to those used for squaring the girders, and having large steel plates bolted to their top flange, were attached to the first girder built. The bridge was then placed on these plates, 7/8-inch holes were drilled through the bottom chords of the bridge, and the plates were carefully bolted to it with 7/8-inch turned bolts. The castings were then detached from the girder and the bridge lifted, taking with it the plates and castings, thus forming a jig, which was used in finishing all the other girders. Cast iron jig carriers, carefully set in relation to the end castings, were also bolted to the bridge plates. The proper jigs for drilling the holes in a girder to match the diaphragm connecting to it were fastened to the carriers by stud bolts, and the bridge was then placed on each partly finished girder and connected to it through the end castings. (Figure No. 2.) A few holes were drilled in the girder web through the jigs; the jigs bolted to the girder; the studs removed and the bridge taken away, leaving the jigs attached to the girder, which was then drilled and end planed from them.

All the steel and iron castings, the forgings and bronze work were sublet to one firm, who supplied them to us finished ready for assembly in the work, and the only point to be touched on in this connection is, that 8-inch by 3½-inch and 12-inch by 3½-inch wrought steel bearing plates were supplied as slabs by the Algoma Steel Company of such excellent quality that they met the tests of the American Society of Testing Materials specifications for steel forgings, class E, without forging being necessary, and so far as is known, with no rejections after planing.
