Fabrication and Erection of the Superstructure of the Montreal-South Shore Bridge

L. R. Wilson, M.E.I.C.,
Vice-President in Charge of Operations, Dominion Bridge Company Limited, Montreal.

Paper to be presented before the Annual General and General Professional Meeting of The Engineering Institute of Canada at Ottawa, February 12th, 13th, and 14th, 1930

Introduction

The new South Shore bridge at Montreal is the outcome of an insistent demand for a more adequate connection between that city and the numerous important highways south of the St. Lawrence river which have hitherto converged on the well-known Victoria bridge where the roadway accommodation is extremely limited. This demand was reinforced by increasing pressure on the part of the rapidly developing communities on the south shore and public sentiment unanimously supported the Hon. Dr. W. L. McDougald, president of the Montreal Board of Harbour Commissioners, when with courage and foresight he undertook the solution of the problem.

In January, 1925, Messrs. Monsarrat and Pratley, consulting engineers of Montreal, were appointed designing and supervising engineers for the proposed bridge, with J. B. Strauss of Chicago as associate. At the same time an Advisory Board of Engineers was created, representative of the various interests affected, to collaborate in the selection of a site and in the preparation of the plans and specifications. The Advisory Board consisted of Mr. T. W. Harvie, M.E.I.C., general manager of the Montreal Harbour, chairman; Mr. G. H. Duggan, D.Sc., M.E.I.C., president of the Dominion Bridge Company Limited; Dr. H. M. MacKay, M.E.I.C., dean of the Faculty of Engineering, McGill University; Mr. S. A. Baulne, consulting engineer, Montreal; Mr. H. A. Terreault, M.E.I.C., director of public works, City of Montreal; and Mr. Ivan E. Vallee, A.M.E.I.C., chief engineer, Department of Public Works, Quebec. Tenders were called in due course and in October, 1925, the contract for the entire steel superstructure was awarded to the Dominion Bridge Company Limited, of Montreal.

The contract stipulated that the bridge was to be built to plans and specifications as prepared by the engineers and approved by the Advisory Board. The contractor was, however, required to assume the entire responsibility for the construction of the superstructure and reserved the right to submit alternative proposals as regards the design if deemed advisable. In case of disagreement with the engineers, such proposals were to be referred to the Advisory Board whose decision was to be final. It is worthy of note that complete agreement was reached in every instance between the engineers and the contractor.

The general characteristics of the bridge are illustrated by figures Nos. 1 to 5. Figure No. 1 shows its location in relation to the vicinity, the storage yards and the railway connections for transportation of materials. Figure No. 2 is an elevation diagram showing the component parts, principal dimensions and distribution of weight. Figures Nos. 3, 4 and 5 show typical cross-sections illustrating the arrangement of the roadway, tramway tracks, and sidewalks. For convenient reference, the structure was subdivided by the engineers into section 1—south approach; section 2—main span, and section 3—north approach. The steelwork of the pavilion was awarded as a separate contract but will be considered as part of section 1 for present purposes.

The design drawings for the south approach were practically complete at the time the contract was awarded, thus enabling detail drawings to be proceeded with at once. The design of the main span was, however, in an embryonic condition owing to the lack of time previously for proper investigation and it was obvious that considerable time would be required to develop the details, estimate the weights, and complete the calculations. After a number of changes in the general proportions of the main span had been discussed with the engineers and agreement reached, the contractor undertook to fully develop the design of this section of the superstructure, all calculations and details to be checked and approved by the engineers. At this period the alignment of the north approach was unsettled. Difficulties regarding property expropriations finally led to a radical alteration in the original arrangement with the result that it was impossible to complete the design of this section until the spring of 1928.

The methods to be employed in the erection were left for the contractor to determine with the single stipulation

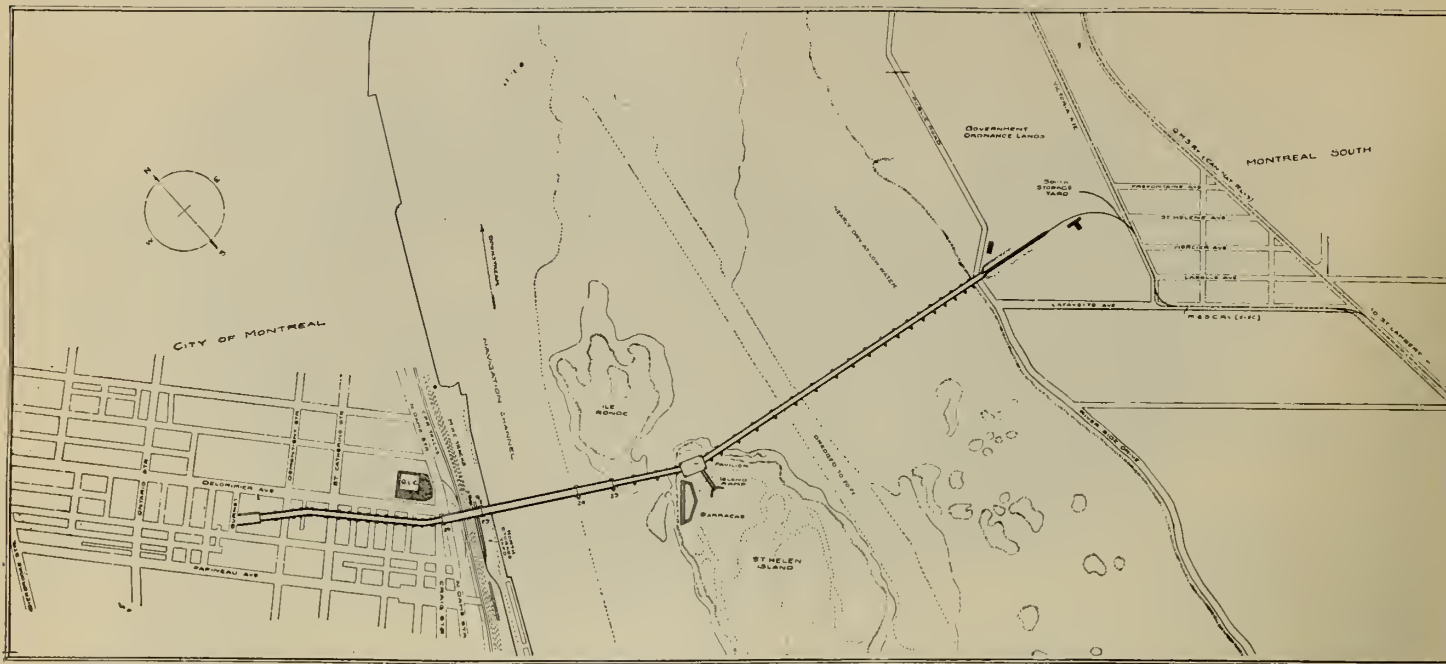

Figure No. 1.—Plan of Bridge and Vicinity.

that the navigation channel must at all times be kept clear of obstruction to shipping. It was therefore requisite that each half of the channel span be erected by cantilevering to the centre of the span, at which point the final connection would be made.

In a project of such magnitude the erection of the superstructure is a problem of outstanding importance and has a pronounced influence on the design and on the entire programme of construction. The order of operations is determined partly by the nature of the structure itself and partly by other controlling factors such as the construction programme to be followed on the substructure and the time necessary to complete final designs and drawings, to obtain the materials from the various mills, and to fabricate the steelwork. Before the designs can be completed erection methods must be decided on, and these in turn

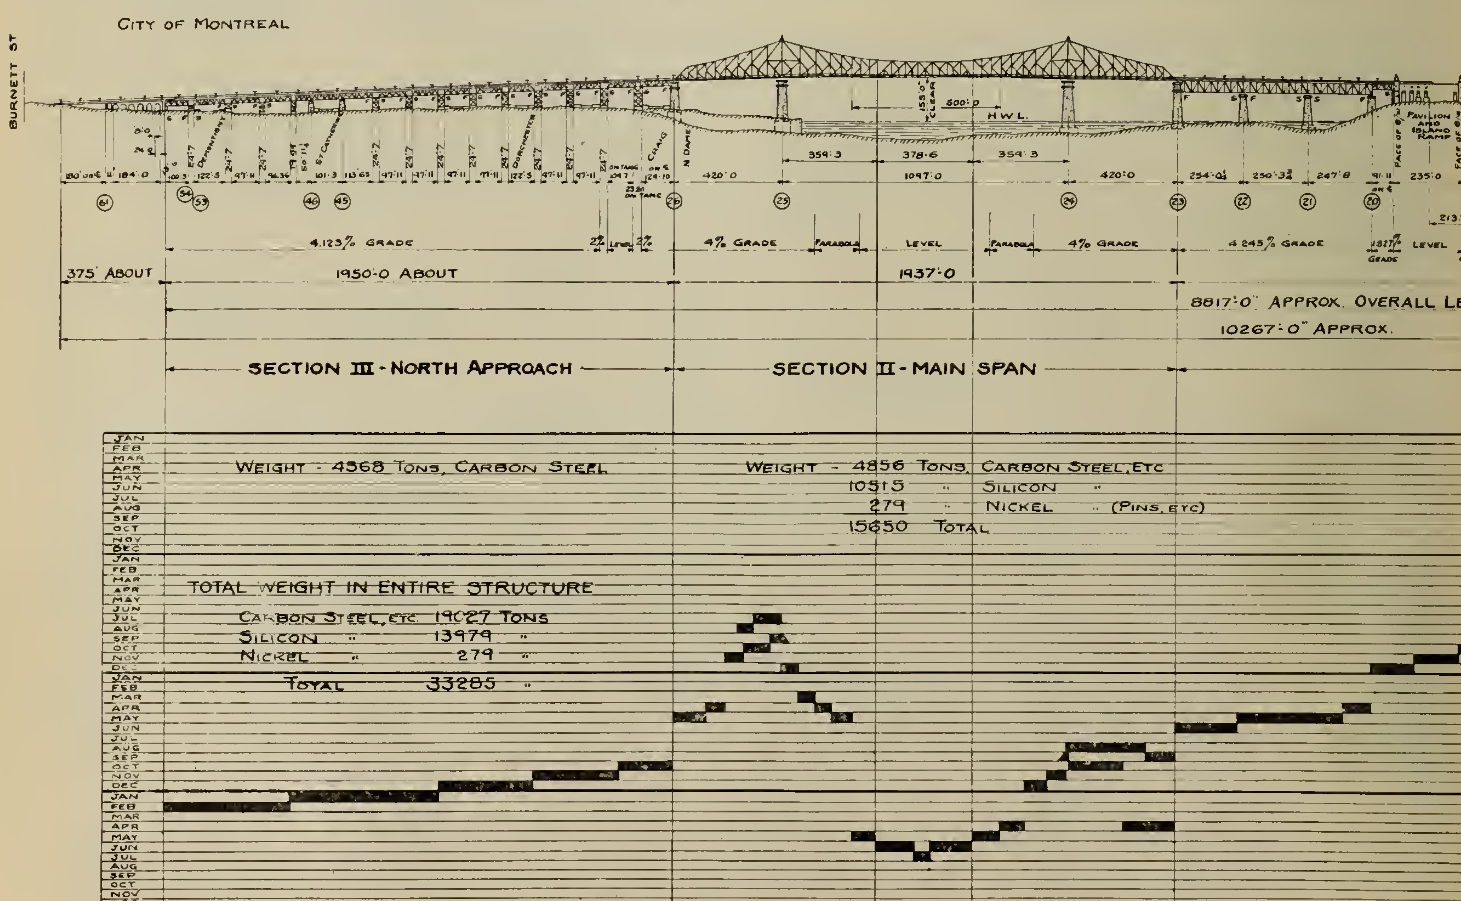

Figure No. 2.—Profile of Bridge

are governed largely by the problems of transportation and handling of materials. Where heavy erection equipment is required the weights must be determined and provision made for them in the design of the structure.

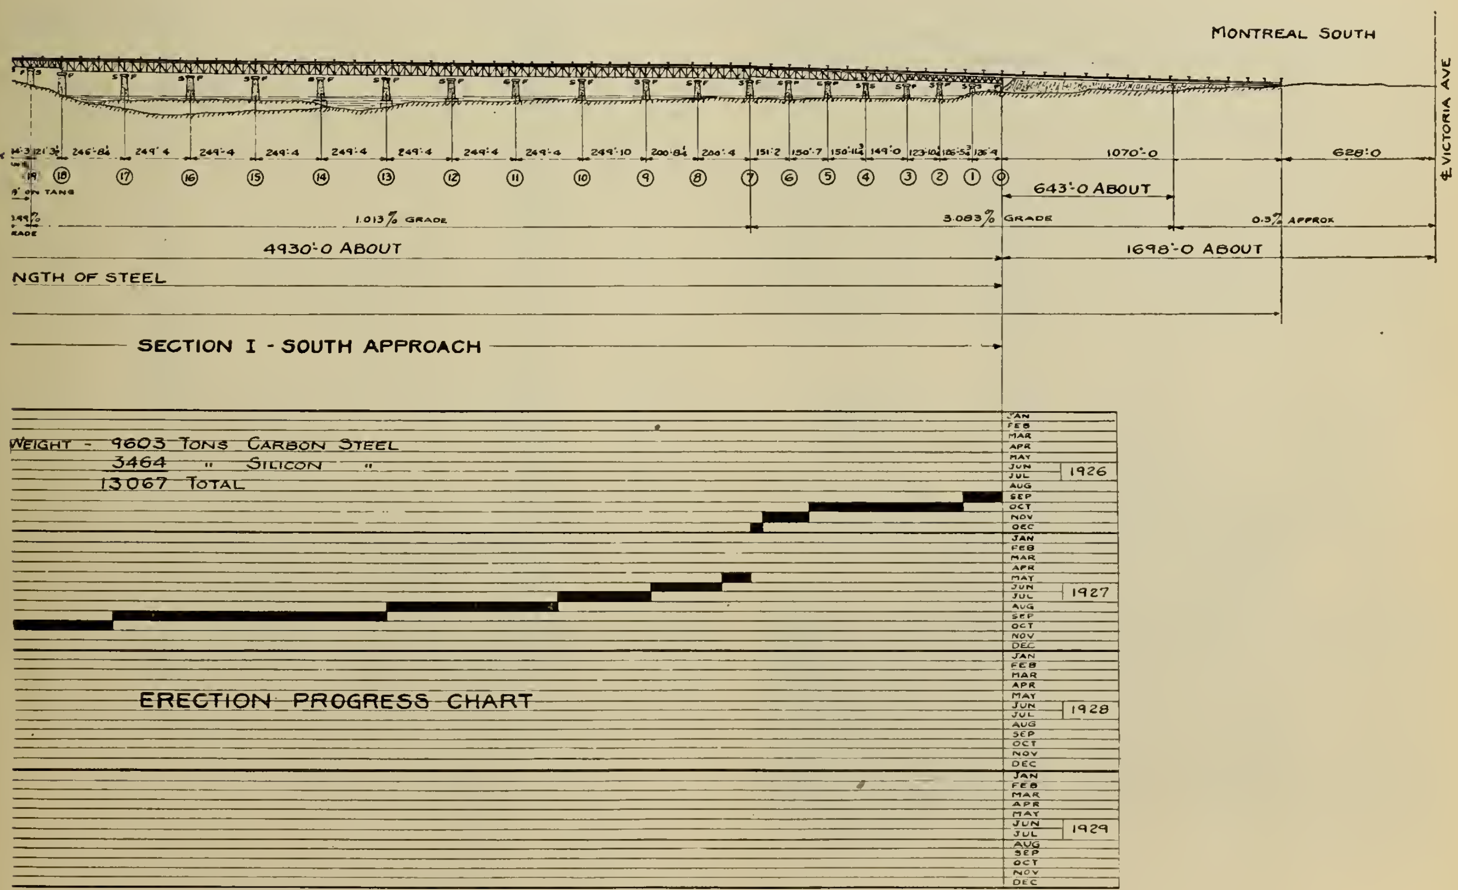
The bridge is designed to carry highway, tramway, and pedestrian traffic only. The floor system was consequently of insufficient strength to permit the use of the derrick cars and locomotive cranes so common on railway bridge erection and it was necessary to develop special equipment. The safe capacity of the floor system and other practical considerations limited the weight of individual members to about 40 tons.

The transportation of materials to the site and to their final location in the structure was one of the first problems attacked. Road transportation was out of the question for the greater proportion of the materials. Water transportation was considered carefully but was abandoned after it was established that satisfactory railway connections could be obtained which would ensure more economical and more flexible handling. On the south shore, a storage yard was established at the lower end of the approach fill leading to the bridge and rail connections made with the Canadian National Railway over the electric lines of the Montreal and Southern Counties Railway. This permitted the cars of material being delivered directly from the shops to sidings installed in the storage yard. On the north shore, it was impossible to make direct rail connections with the floor of the bridge. The harbour tracks however pass under the north anchor arm and the storage yard was established at this point with railway sidings connecting to the harbour tracks.

It is evident that the dividing line of erection was the centre of the channel span. The superstructure to the south had as its base of operations the south storage yard where materials were received, unloaded for storage, and re-handled as required to the bridge over the connecting service tracks. It was necessary that erection be commenced at the south abutment and be carried on in sequence to St. Helen's island and thence to the main span. The superstructure north of the dividing line had as its base of operations the north storage yard under the north anchor arm. Materials were received here at ground level, hoisted to the floor of the bridge as required, and distributed to their destination. Erection naturally commenced on the anchor arm, the north approach being inaccessible until after completion to the anchor pier.

The storage yards were equipped with offices and stores, repair shops and other necessary facilities in addition to the railway sidings. Materials were handled in the yards by locomotive cranes of 30 to 40 tons capacity. On the south side, the motive equipment consisted of a 40-ton standard gauge saddle-tank locomotive and a number of standard gauge 40-ton capacity flat cars; several of the latter were also supplied for use on the north side. It was decided to provide for two standard gauge service tracks throughout the structure on the lines of the future tramway tracks, consisting of 56-lb. rails on 8- by 10-inch B.C. fir bridge ties 10 feet long, every alternate tie being secured by hook bolts to the flanges of the track stringers. The length of haulage and the steep gradient in certain sections made every precaution necessary to avoid delay to the erecting crews.

After every factor affecting erection had been carefully reviewed in collaboration with the engineers, a working programme was adopted which required the erection of the south approach to be commenced at the south abutment in the fall of 1926 or spring of 1927, depending on progress on the substructure; of the north half of the main span in the early summer of 1927; of the south half of this section during the summer of 1928; and of the north approach



and Erection Progress Chart.

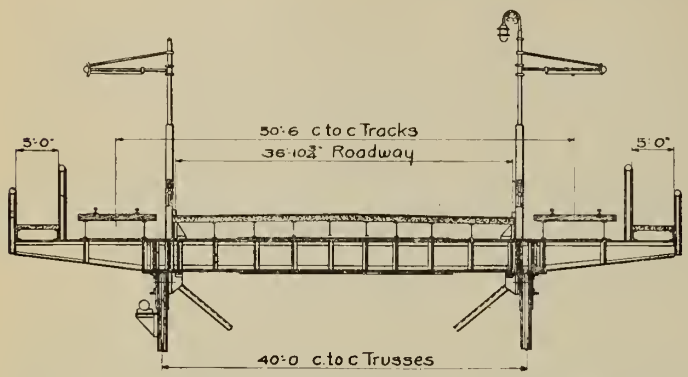


Figure No. 3.—Typical Cross-section of Floor on Approach Spans.

during the fall of 1928. The date stipulated in the contract for completion, exclusive of the field painting was July 1st, 1930. The actual progress of erection is illustrated graphically in figure No. 2 and will be referred to in detail later.

Mention may also be made of the fact that tenders had been invited based on concurrent erection of both halves of the main span, the object in mind being a possible saving in time of construction. However, the greatly increased cost owing to duplication of equipment and other factors led to this scheme not being adopted, particularly as any actual saving in time was somewhat hypothetical.

South Approach and Pavilion — Section 1

The south approach extends in a straight line from the south abutment to the pavilion on St. Helen's island, a distance of approximately 4,000 feet. Changing alignment at this point, it continues to the south end of the main span, a further 900 feet. A ramp 250 feet in length leads from the pavilion to road level on St. Helen's island. The total length is therefore approximately 4,900 feet from south abutment to main span, or slightly less than one mile, including the ramp.

The approach consists principally of a series of deck truss spans carried on masonry and concrete piers, and graduated in length from 122 feet 6 inches to 245 feet, the arrangement being illustrated in figure No. 2. The floor rises on a 3.083 per cent grade for about 1,000 feet, flattens to 1.013 per cent to St. Helen's island, and after a level section over the pavilion, rises sharply on a 4.245 per cent grade to the end of the main span.

The trusses are of conventional Warren type, are spaced at 40-foot centres and vary in depth with the span. The floor system is carried above the trusses by floorbeams which rest on and cantilever over the top chords, as shown in cross-section in figure No. 3. The lateral and bracing systems are of liberal proportions. Short skew spans were necessary at each end of the pavilion to suit the arrangement at that point and the ramp is also somewhat different in design to the main approach. The steelwork of the pavilion is of simple design, the floor of the bridge being carried on the roof of the pavilion by means of heavy girder construction. Throughout the main portion of the approach the floor panels are 24 feet 6 inches in length; this uniformity proving a great advantage during erection.

The steelwork of the approach is of special carbon steel except in the trusses of the 245-foot spans where silicon steel is used with a limiting thickness of ¾ inch. For further particulars on the characteristics of these materials, see Section 2—Main Span.

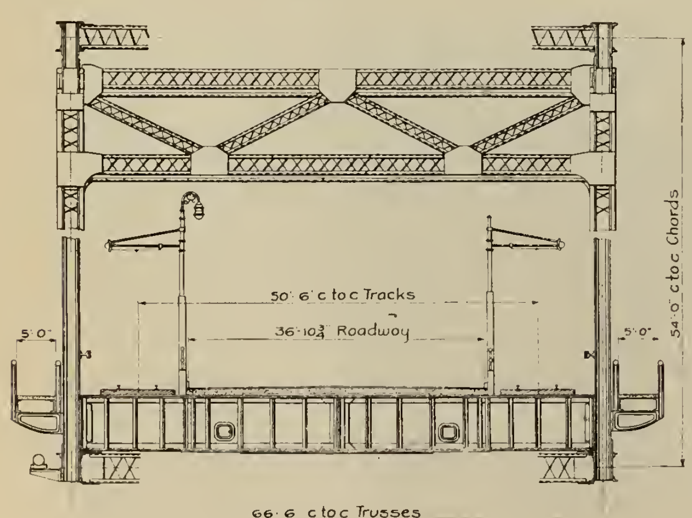

Figure No. 5.—Cross-section of Main Span at Centre.

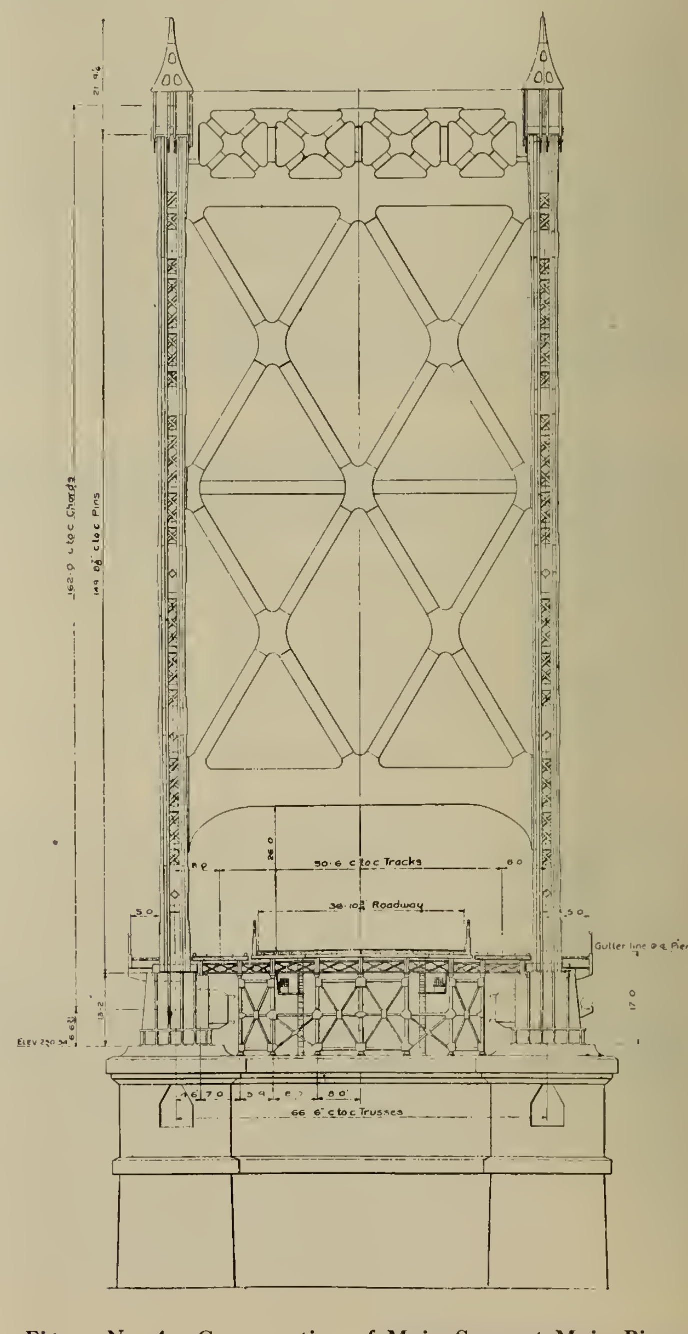

Figure No. 4.—Cross-section of Main Span at Main Piers.

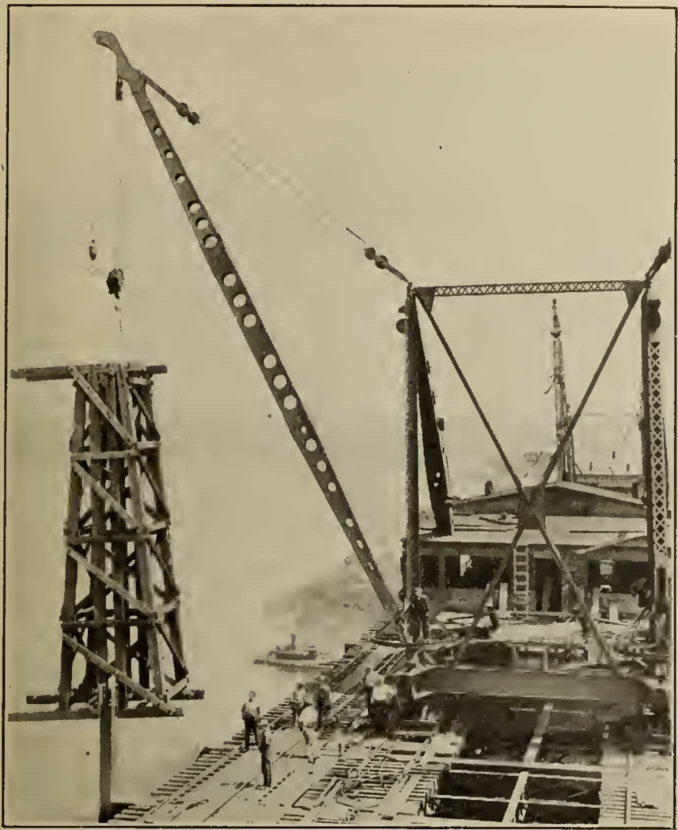

Figure No. 6.—South Approach—Front View of Traveller No. 1 handling Timber Falsework.

Fabrication followed well established practice and presented no unusual difficulties. The main gusset plates were rivetted to the chords, the field connections for the web members being drilled full size to template in the gussets before assembly. The chords were in general spliced in two-panel length of about 50 feet, the splices being arranged for continuous erection of each span from the south end. The chord splices were faced and reamed to template, without assembly of the adjoining members, Lateral, swaybracing and floor connections were punched fullsize. Owing to pressure of work, the fabrication of the roadway and tramway stringers and roadway curbs was sublet to Canadian Vickers Limited of Montreal.

Erection was commenced at the south abutment during September, 1926, and seven spans were completed in that season. Operations were resumed during April, 1927, and the structure was completed during that season to pier 20, one span beyond the pavilion. The remaining spans were erected early in the season of 1928. It had been planned to complete the south approach by the end of 1927, but operations were retarded throughout by the progress on the piers and pavilion substructure with the result that winter ice conditions made it impracticable to proceed further than the point noted.

The superstructure was erected by means of travellers operating on the deck of the bridge, the materials being delivered alongside on either service track as required. The service tracks being 50 feet 6 inches centres, it was necessary to restrict the overall width of the travellers to about 40 feet. The changes in the floor gradient had also to be provided for in the traveller construction.

The principal erection was carried out by the specially designed traveller No. 1, the base of which consisted of a steel frame 25 feet wide by 50 feet long, mounted on four 4-wheel trucks travelling on two tracks of 4 feet 2 inches gauge spaced 25 feet centres. On this base were mounted two steel derricks with masts over the forward trucks and booms 70 feet long, each boom being equipped with main falls of 20 tons capacity and an auxiliary line of 5 tons capacity.

The hoisting lines were of ¾ inch diameter 6-19 special wire rope, using six parts in the main falls and thirteen parts in the boom falls. Power was supplied by two standard 3-drum 8- by 12-inch steam hoisting engines. The masts were fitted with 9-foot diameter bull wheels for swinging purposes operated from independent single-drum swinging engines. An auxiliary derrick was mounted at the centre of the rear end with a 50-foot boom of 5 tons capacity. Somewhat elaborate details were developed to facilitate the movement of the traveller and provide positive anchorage against movement or uplift in the working positions, the convenience of these features amply repaying their expense. The weight of the traveller in full working order was 120 tons. It was designed to permit the safe handling of a weight of 16 tons on either or both booms, at 60-foot forward radius and 40-foot side or rear radius, the capacity increasing at lesser radius to a maximum of 20 tons. The general arrangement of traveller No. 1 is illustrated in figure No. 6.

It was the intention to use this traveller on the erection of the north approach also which would require its operation on a downward 4 per cent grade. The base was therefore so arranged that by altering the blocking on the rear trucks it could be kept level on any floor gradient from 4.25 per cent upward to 4 per cent downward, thus maintaining the derrick masts in proper working position at all times.

The roadway stringers, 20-inch, 65-lb. I-sections, were inadequate to carry the weight of the traveller while being moved. Doubling-up of the stringers under the traveller tracks was first considered but the amount of blocking for stability on such a length of floor led to the decision to provide special track girders for the traveller. Each unit

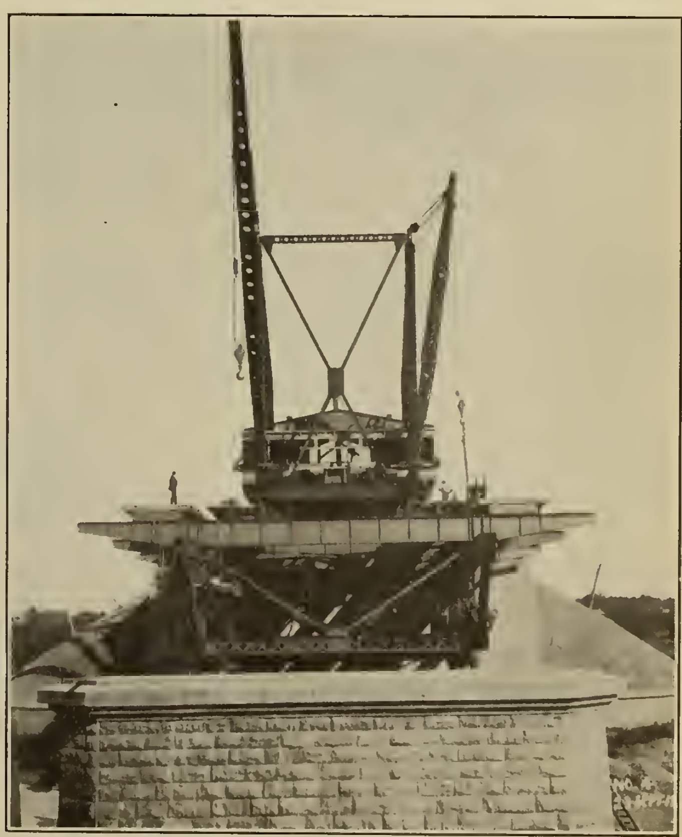

Figure No. 7.—South Approach—Front View of Traveller No. 1 showing Arrangement of Deck.

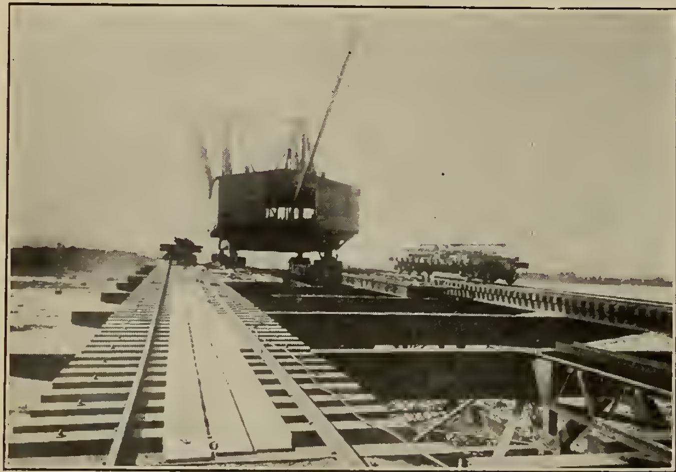

Figure No. 8.—South Approach—Rear View of Traveller No. 1 and Deck.

Figure No. 9.—South Approach—Timber Falsework under Short Spans.

consisted of two 24-inch, 106-lb. I-sections, 24 feet 6 inches long, rigidly braced and stiffened, and with brackets on the outer side. The track rails were clamped directly to the top flanges of the beams and the entire deck of the unit planked over. The track girders were of sufficient strength to carry the truck reactions of the traveller in the working positions, the maximum reaction being 86 tons. Sufficient girders were provided for four panels of floor. As the traveller was moved forward the girders behind were lifted as released by the rear boom, placed on the flat cars and moved forward for use in the next panels. At such few points where the panels were not of standard length special blocking and temporary grouping of the stringers proved sufficient. The general arrangement on the deck is shown in figures Nos. 7 and 8, which show the service tracks with material cars, traveller No. 1 and the temporary track girders.

An auxiliary traveller, No. 2, was also provided, the base of which was of simple timber construction mounted on special double-flanged truck wheels rolling directly on the flanges of the roadway stringers. On this base were placed two standard stiff-leg derricks with 70-foot booms of 12 tons capacity, operated from steam hoisting engines. This traveller was used to place the floor steel behind traveller No. 1, remove falsework, and perform other handling operations as required.

At a later date a third traveller was used to place the fences, curbs, lamp poles and other sundry steelwork of the deck. This traveller consisted of a light Jinniwink derrick mounted on a standard flat car and operated from the service tracks.

The south approach is shown in profile in figure No. 2, the method of erecting the various spans being partly on timber falsework and partly by cantilevering. The use of falsework throughout this section had serious drawbacks as a study of the profile will suggest. In the first place, winter ice conditions prohibited falsework in the river from about December 15th until the following May. Secondly, the river bottom between the south shore and St. Helen's island consists for the most part of irregular shale rock which entirely precluded the driving of piles. Although the water is very shallow throughout the greater part of the season, the depth is sufficient when coupled with the current to render very laborious the fitting of falsework to a good bearing on the bottom. Thirdly, the changes in grade and in the depths of the spans resulted in a constantly changing distance from the underside of the steel to the river bottom necessitating alterations in the height of the

Figure No. 10.—South Approach—Timber Falsework under Span No. 10 (245-foot).

Figure No. 11.—South Approach—Timber Falsework under Span No. 22 (245-foot).

falsework at every panel. Fourthly, the very considerable height of steel above river bottom, particularly beyond St. Helen's island, was unfavourable to the use of falsework on account of the quantity involved and the time required for setting up and dismantling. These various factors led to the decision to erect by cantilevering wherever practicable as being both more economical and more expeditious. In all, three of the four 147-foot spans and ten of the twelve 245-foot spans were erected in this manner.

The falsework, where used, consisted of timber towers framed in the yard of specially imported B.C. fir and shipped forward to the erecting crews as required, the units being as large as handling conditions permitted. Each tower consisted of two bents 8 feet centre to centre; the posts, caps and sills being of 12 by 12 inches, and the bracing 4 by 8 inches with steel scabs at the joints. The towers were erected on previously prepared cribwork footings and were braced together and to the piers sufficiently to ensure stability. The spans were supported on the towers by an arrangement of blocking which permitted jacking when necessary. Typical details of the falsework and the arrangement during erection are shown in figures Nos. 9 and 10. A special arrangement of falsework was necessary under the first 245-foot span beyond the pavilion owing to the ground contours at that point and the depth of water. As illustrated in figure No. 11, a three-bent tower was used near the centre of the span in view of the heavy reaction while cantilevering the forward half of the span.

The erection of the spans on falsework requires no special comment. Sufficient towers had been provided to avoid delay to traveller No. 1 and as each span was completed and jacked on to the piers, the falsework was removed by traveller No. 2 and moved forward for further use as required.

The three forward 147-foot spans were cantilevered, the span immediately behind being used in each instance as an anchor span. The trusses were of sufficient depth that reinforcement for erection stresses was unnecessary. The end top chord sections of the adjoining spans were fabricated as continuous members to avoid heavy temporary connections over the piers while cantilevering beyond. Special temporary shoes were placed between the faced ends of the adjacent bottom chord sections. The span having been erected as a cantilever, was jacked at the forward end to relieve the stresses at the rear. The continuous top chords were then cut by burning, the temporary shoes removed and the span lowered to permanent position on its pier members.

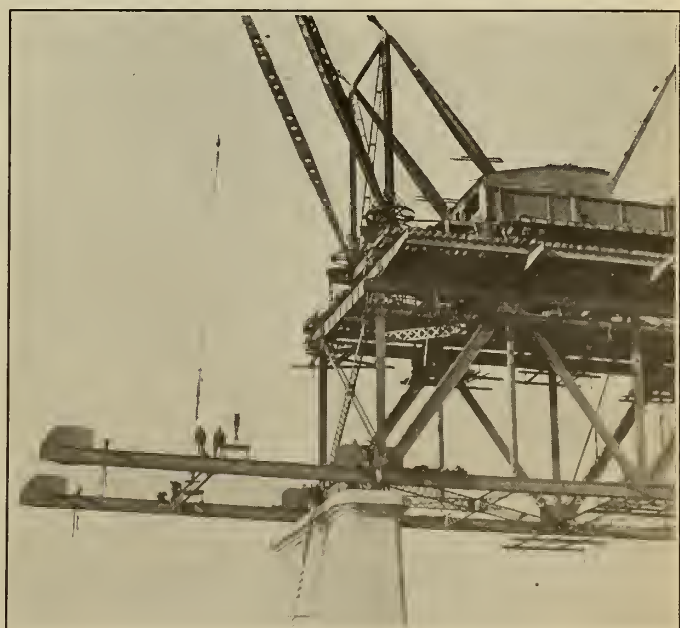

Figure No. 12.—South Approach—Cantilever Erection of 245-foot Span—First Stage.

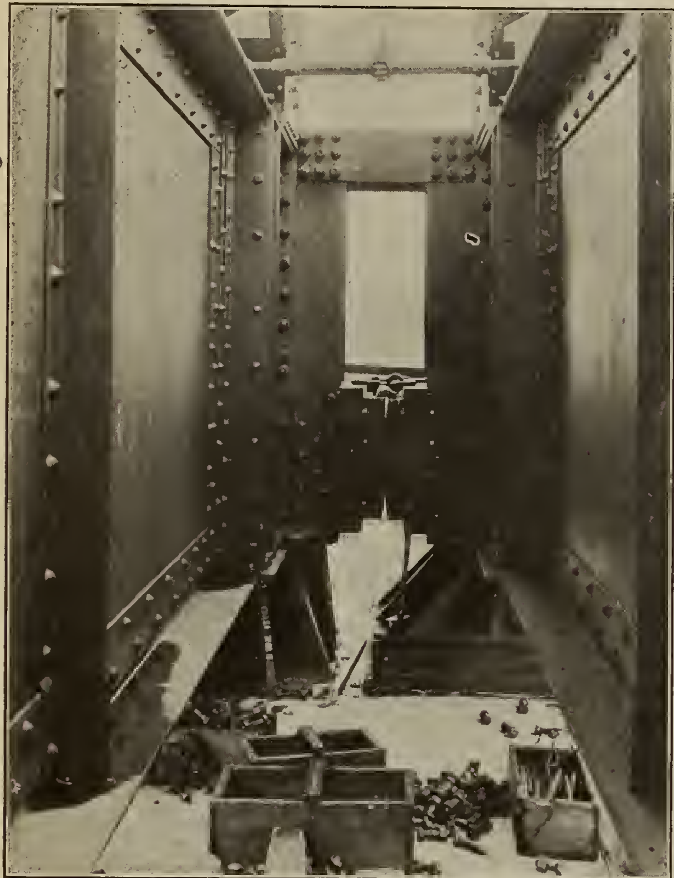

Figure No. 13.—South Approach—Cantilever Erection of 245-foot Span—Special Shoe Details.

Eight of the nine 245-foot spans south of St. Helen's island and two of the three similar spans north were also erected as cantilevers. Special treatment of them was necessary to avoid an excessive amount of erection reinforcement in the chords adjacent to the loaded pier. An overhead harness was specially developed which increased the effective depth of the trusses at the pier from 35 to 70 feet, and reduced the reinforcement required to a small addition in the end bottom chord sections. The general arrangement of the harness is shown in figure No. 18. The tension members consisted of medium heat-treated eyebars having a yield point of 50,000 lbs., and an ultimate strength of 80,000 lbs. per square inch. Silicon steel was used in the posts and the 10 ½-inch pins were of forged nickel steel. The necessary top chord sections of the spans were specially bored in the shops, the pinholes being liberally reinforced. Particular attention was given to all details to ensure ease of handling during the successive use of the harness.

The first operation in the erection of a typical 245-foot span was the placing of the bottom chord sections at the pier. (See figure No. 12.) Temporary shoes were placed between the faced ends of the adjacent chords and connections made at the top of the main gusset plates to sustain the weight of the chords. (See figure No. 13.) Three panels of the span were then cantilevered with temporary connections to the rear span, in the line of the top chord, the temporary bottom chord gusset connections being removed on the completion of the first panel. (See figure No. 14.) This portion of the span was erected with a slight inclination to facilitate the connection of the harness, which was now set up omitting the bracing between the posts for the time being to permit the passage of traveller No. 1. By means of the booms of traveller No. 1, the harness was toggled upwards at the midpoint over the pier to release the temporary top chord connections which were removed, the harness being then slacked off. The general arrange-

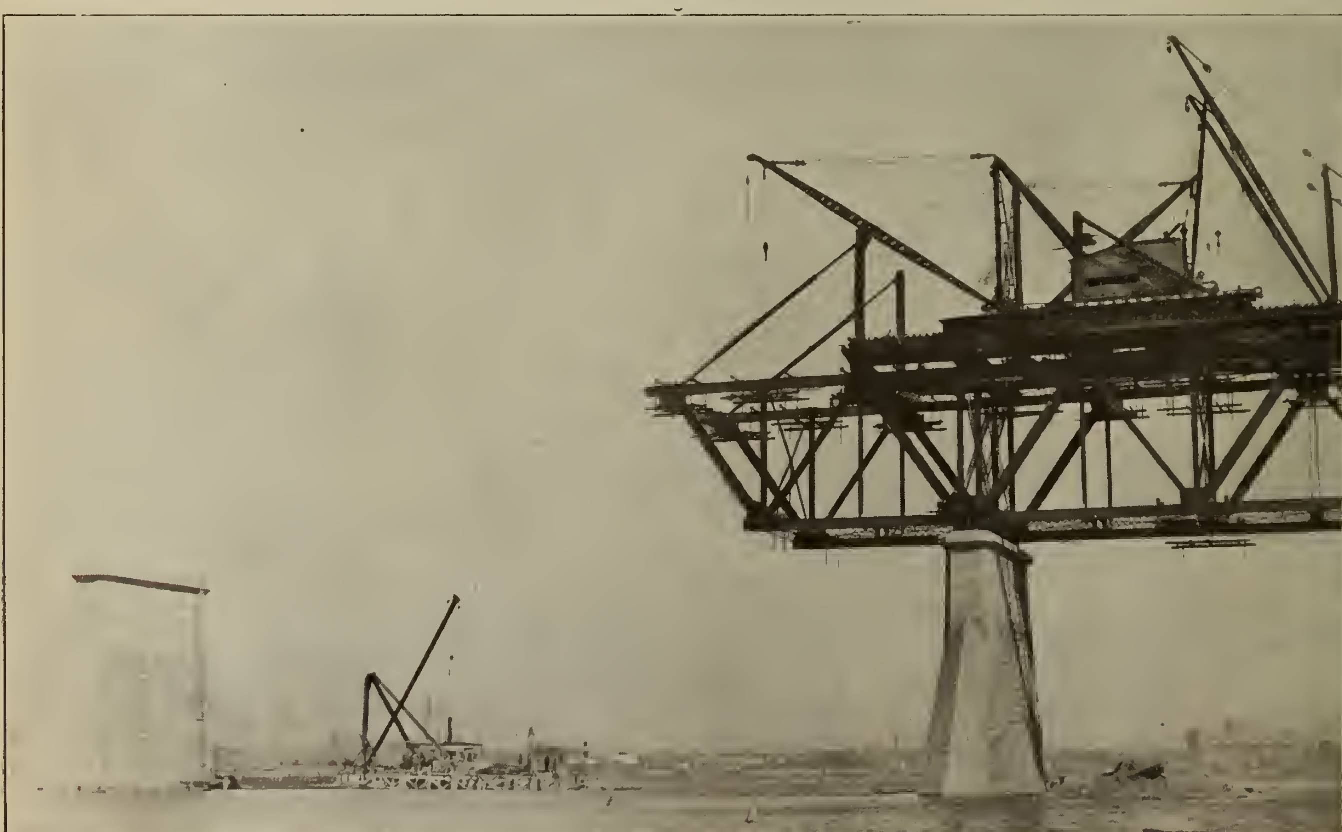

Figure No. 14.—South Approach—Cantilever Erection of 245-foot Spans—Second Stage.

ment during this stage is illustrated by figure No. 15, which shows the harness in its toggled condition. Traveller No. 1, having been moved forward, proceeded with the erection of the span after placing the front harness bracing, while traveller No. 2 placed the rear harness bracing, (see figure No. 16), being afterwards moved to the back end of the rear span as additional anchorage. At this point temporary vertical and lateral connections were also made to the span behind to ensure stability under all conditions. Conditions on the deck at this stage with further details of the harness are shown in figure No. 17. On the completion of the span to the forward pier, (see figure No. 18), the bottom chords were blocked after jacking a small amount, the remaining material being then erected. (See figure No. 19.) Hydraulic jacks of 190 tons capacity having been placed under each end of the jacking girder, the end of the span was raised to release the harness and permit its disconnection. The bottom chord shoes were also removed and the span then lowered by jacking on to the permanent pier members.

The amount of jacking was determined in advance by accurate calculations of the deflections during erection, actual results corresponding closely with the calculated. The length of the harness members was made such as to ensure ample room for the jacks under the jacking girders at the forward pier when cantilevered to that point. The amount of upward jacking to relieve the sag in the cantilevered span and release the harness was about 22 inches, it being necessary to lower the end approximately the same amount while landing on the shoes. The ratio of width to length in the spans resulted in exceptional stiffness even when fully cantilevered, there being virtually no vibration in the structure from either wind or the traveller.

The temporary shoes between the abutting bottom chords at the loaded pier were developed with some care.

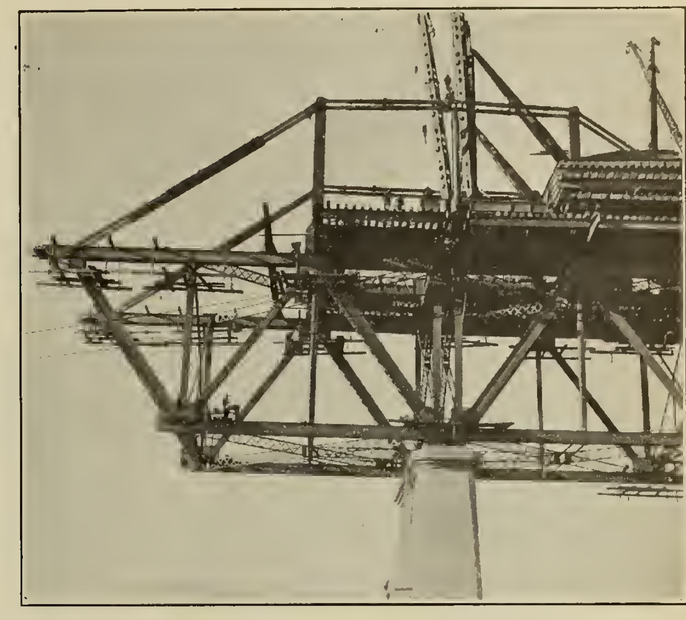

Figure No. 15.—South Approach—Cantilever Erection of 245-foot Spans—Third Stage.

The change in angle of the end chords due to the span deflections was sufficient to produce a definite vertical movement at the contact faces of the shoes. The bearing face of one shoe at each point was, therefore, made convex, (see figure No. 13), to prevent bearing on the edges and facilitate vertical adjustment by sliding during the earlier stages before the load was sufficient to make the shoes seize. The approximate secondary bending stresses in the end chords were calculated and provision made for them by

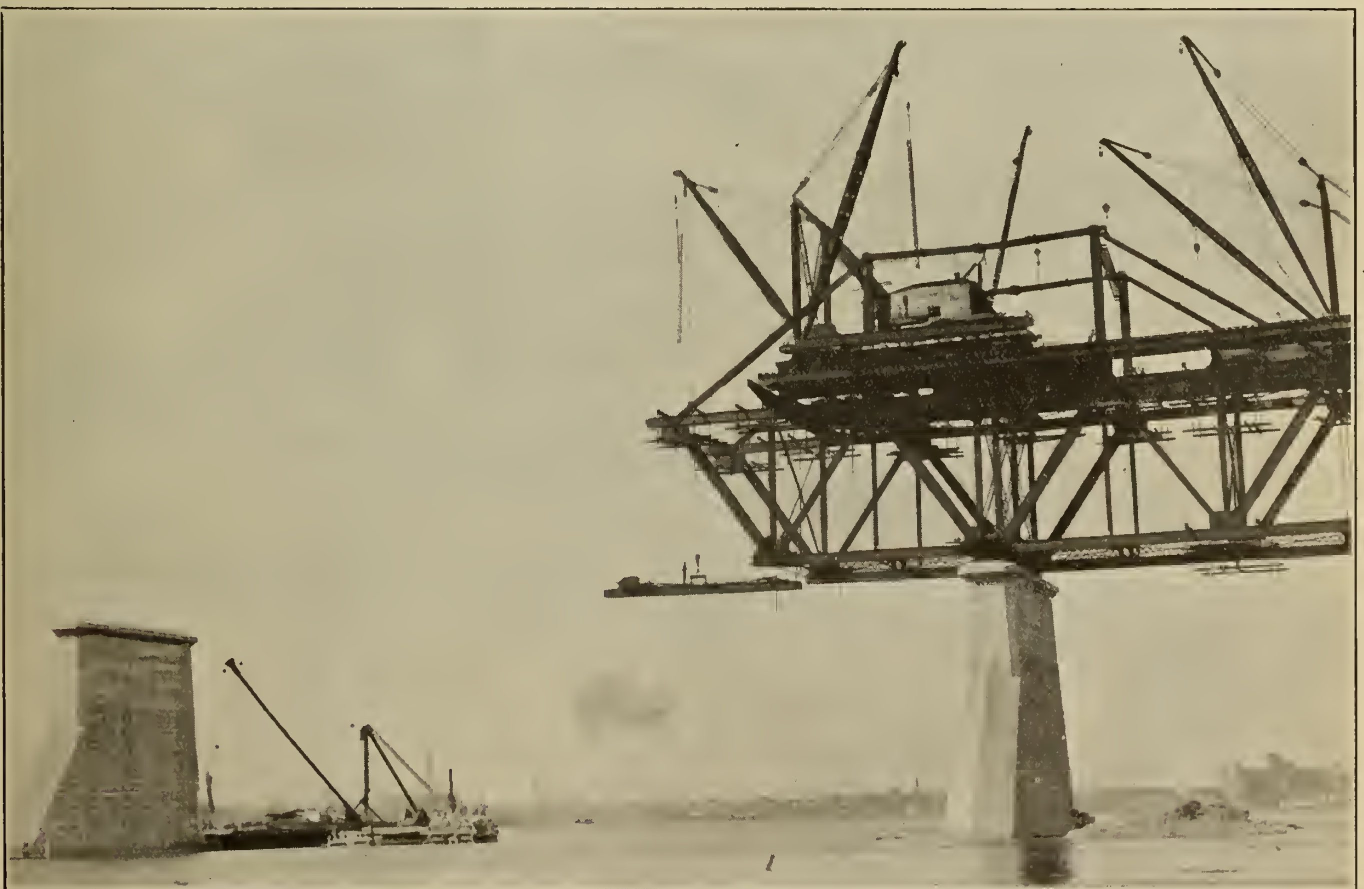

Figure No. 16.—South Approach—Cantilever Erection of 245-foot Spans—Fourth Stage.

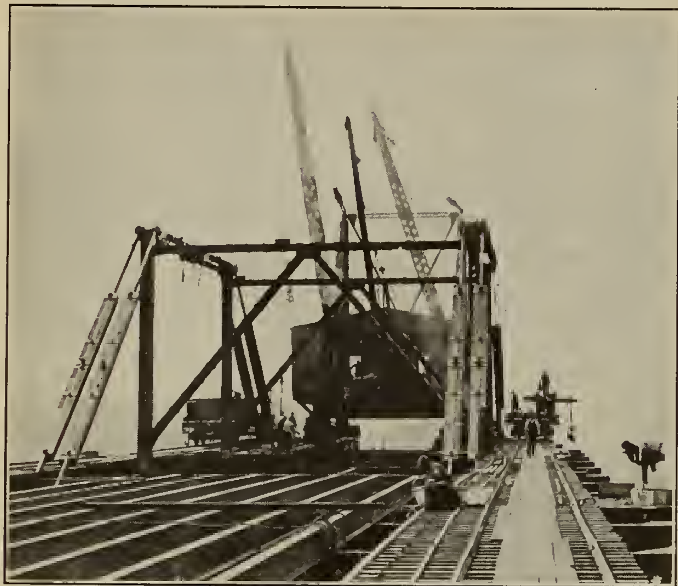

Figure No. 17.—South Approach—Cantilever Erection of 245-foot Spans—Details of Harness.

local reinforcing. The removal of the shoes was simplified by erecting each span slightly behind its ultimate position. As the forward end was lowered on to the disc-like tops of the fixed shoes, the span mechanically centered itself on these shoes by moving forward as a whole, releasing the temporary erection shoes and making their removal easy.

Throughout the approach, the work of traveller No. 1 was restricted to the erection of the main framework thus greatly accelerating its rate of progress. The remaining floor steel was placed by traveller No. 2 as it advanced behind traveller No. 1, the miscellaneous material such as fences, curbs, etc., being left for later erection.

The steelwork of the pavilion was erected with traveller No. 1, the type of construction being illustrated by figure No. 20. The ramp leading from the pavilion to St. Helen's island was erected during the summer of 1928 with auxiliary equipment.

That the equipment devised for the erection of the approach superstructure was well suited to the purpose is best illustrated by the fact that during September, 1927, four 245-foot spans were completely erected, representing a length of 980 feet, and a weight of approximately 2,260 tons. Had it been possible to accelerate sufficiently the progress on the substructure the entire steelwork of the south approach could have been erected during the season of 1927, and no advantage resulted from the commencement of work in 1926. Fortunately it was found possible to so co-ordinate operations on the south half of the main span as greatly to offset the delay on the south approach.

North Approach — Section 3

At the Montreal end, the approach to the main span consists of a viaduct approximately 2,300 feet in length commencing at ground level some distance north of St. Catherine street east, and rising on a 4.123 per cent gradient to near its junction with the main span. Of the total length, 1,950 feet is of steel construction and consists of a series of short deck truss spans supported on steel towers except for masonry piers at St. Catherine street. The original layout involved a viaduct of straight alignment parallel to Delorimier avenue; this was later modified by introducing a reverse curvature, the ultimate arrangement being illustrated by figure No. 21, which shows a view of the deck looking north from the main span.

The viaduct crosses a number of important thoroughfares of which Craig street and St. Catherine street carry tramway traffic. The spans are arranged to suit the street crossings and are for the most part 98 feet and 122 feet 6 inches in length with special construction where necessary, as illustrated in figure No. 2. The floor construction is similar to that of the south approach. The spans are also of similar design to the short spans of the south approach, the trusses being spaced at 40 feet centres as on the south side. The tower bases are 40 feet in width by 24 feet 6 inches in length except where skew construction was necessary,

Figure No. 18.—South Approach—Cantilever Erection of 245-foot Spans—Fifth Stage.

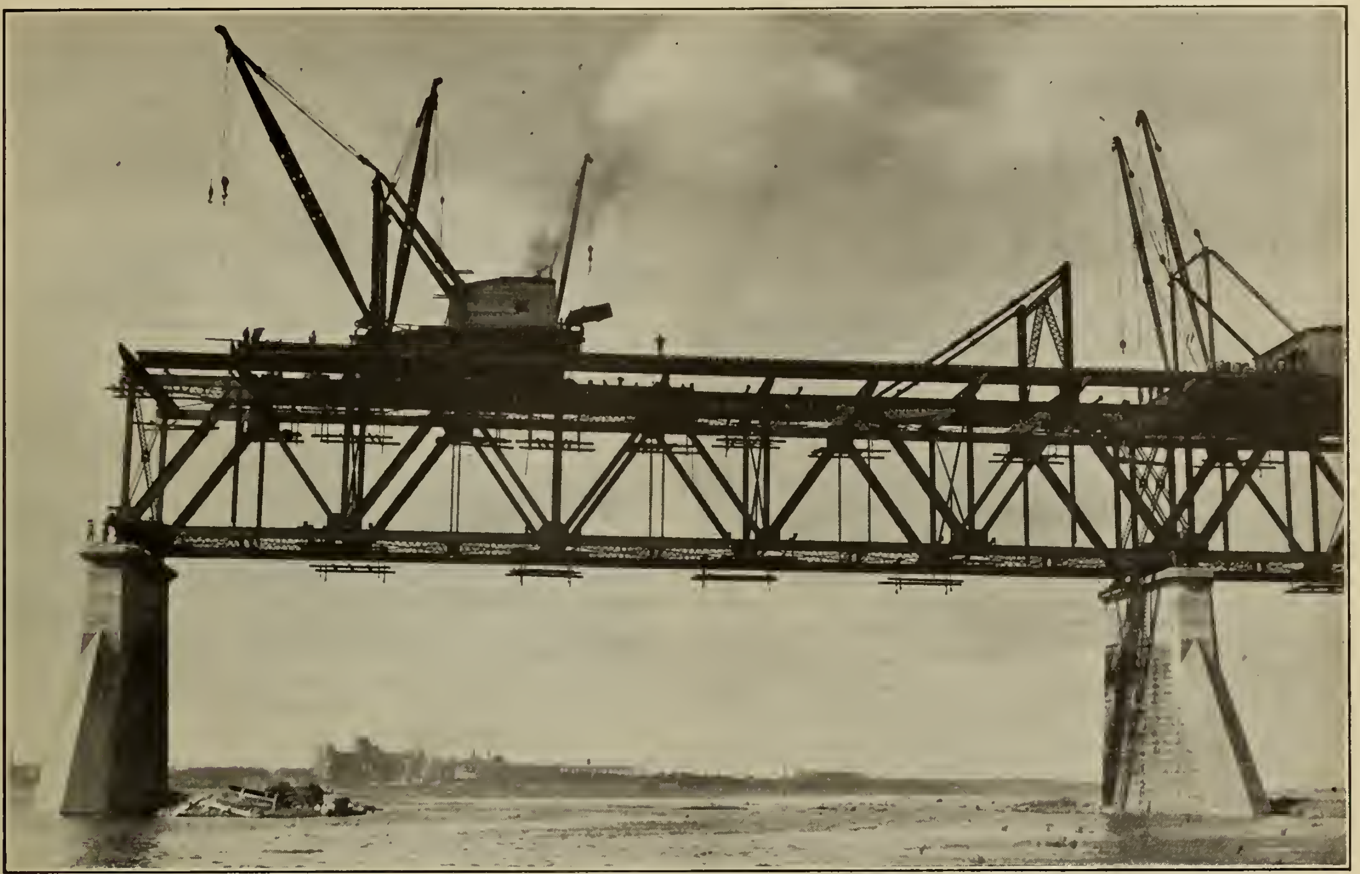

Figure No. 19.—South Approach—Cantilever Erection of 245-foot Spans—Sixth Stage.

the towers themselves consisting of four vertical steel posts with suitable bracing.

Erection commenced at the end adjacent to the main span during October, 1928, and was completed in February, 1929. Traffic was diverted by the authorities at the various streets in turn while construction proceeded overhead, with the exception of St. Catherine street where heavy tramway traffic throughout the day prohibited interference. The materials were received in the north storage yard by rail, hoisted to the floor of the bridge and distributed by flat cars on the service tracks to the point required. These cars were operated by cables leading to steam winches on the deck near the north main pier.

The first span of the approach crosses Craig street. It was erected by traveller No. 3 which had been used on the erection of the north anchor arm earlier in the season and a description of which is given elsewhere. The span was supported near its midpoint by a timber tower of similar construction to those used in the south approach falsework. (See figure No. 22.) With the traveller standing at this point, it was possible to erect the near bent of the steel tower which was sufficiently rigid to permit the span being blocked thereon. (See figure No. 23.) The traveller, having been moved forward, completed the erection of the tower after which the span was jacked clear of the falsework and landed on the tower. A portion of the next span was then erected and traveller No. 1, previously used on the south approach, was set up for the erection of the remaining spans. With the exception of the span over St. Catherine street, the remainder of the structure was erected in the manner outlined above, the timber towers being shortened progressively to suit the grade. Special arrangement of the floor was necessary temporarily where the alignment changed; elsewhere the traveller was carried on the same track girders used on the south side.

At St. Catherine street the method of erection was modified owing to the impracticability of placing falsework in the middle of the street. This span, 98 feet in length, was erected as a cantilever using a simplified harness similar in principle to that used on the erection of the 245-foot spans of the south approach and made up of some of its parts. (See figure No. 24.) In this manner, the span was erected quickly without interference with the tramway traffic below.

Traveller No. 1 placed the roadway stringers and curbs during the erection of each span; it also removed the falsework tower as soon as released. This dispensed with any need for an auxiliary traveller on the north approach; for convenience however, the fences, etc., were placed later by equipment similar to that employed on the south approach.

Main Span—Section 2

General Design

The main span of the bridge is a symmetrical cantilever having an overall length of 1,937 feet. (See figure No. 2.) The centre span is 1,097 feet centre to centre of main piers which provides a clear navigation channel of 1,000 feet, the pier on the north wharf being set back about 50 feet from the face of the dock wall. The north anchor pier is located near the intersection of Craig and Notre Dame streets and clears each thoroughfare, the resultant length of the anchor arms, which were made alike, being 420 feet. The navigation clearance in the channel is 155 feet at mean high water level on a central length of 500 feet as stipulated by the authorities. The roadway is level on this section and descends each way on a gradient of 4 per cent, the arrangement of the deck being illustrated by figures Nos. 4 and 5.

The trusses of the anchor and cantilever arms are of the K-design so successfully introduced in the Quebec bridge

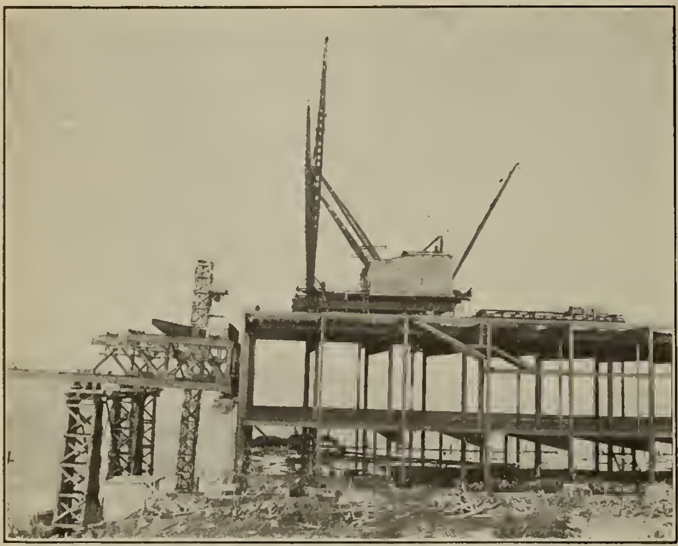

Figure No. 20.—Pavilion on St. Helen's Island.

and are spaced at 66 feet 6 inches centres to suit the floor requirements. They are 162 feet in depth at the main piers, reducing to 50 feet at the end of the anchor arm, and to 54 feet at the centre of the span. Special pains were taken to obtain the most pleasing outline consistent with economical proportions, the top chord curvatures being carried through into the suspended span for the sake of appearance. To permit a harmonious treatment of the web members, a varying length of panel was adopted for the main arms, the longer panels being subdivided for the sake of economical construction. A tapering effect was introduced in the top and bottom chords of the main arms, and the bracing at the main posts and end portals laid out with special regard to appearance.

The tender plans called for a suspended span 312 feet in length as lending itself to ease of erection. In the interest of economy and appearance, however, the contractor suggested and undertook the erection of a longer span, the length finally adopted being 378 feet 6 inches. The ultimate arrangement of the members in this portion of the span was governed largely by erection considerations.

The present description of the design and details of the span must of necessity be limited to sufficient for an understanding of the problems of fabrication and erection. The trusses are in parallel planes throughout and are of rivetted construction, with pin connections at points where free articulation is desirable. The truss members consist for the most part of two built-up webs in planes parallel to the axis of the bridge, connected by suitable lacing systems and squared-up by transverse diaphragms at intervals. The distance between webs is 42½ inches in the anchor and cantilever arms except in the case of the main post where it is 47½ inches, and is 26 inches in the suspended span. The gusset plates of the upper and lower connections are built into the top and bottom chords respectively; those at the midpoints into the lower diagonals.

Figure No. 21.—North Approach from Top of Main Span.

Figure No. 22.—North Approach—Typical Method of Erection—First Stage.

The trusses are supported at the main piers on shoes of special design, consisting in each case of a cast-steel base in three sections on which is mounted a structural member built up of four massive webs with inter-connecting diaphragms. (See figures Nos. 44 and 69.) The base rests on a bush-hammered surface on the pier concrete, layers of heavy canvas being laid on this surface and coated with red lead just prior to the placing of the castings in position. The base is connected to the pier by anchor bolts which were set in advance to template, and to the upper shoe section by rivets and turned bolts. All truss members converging on the shoes are pin-connected, important advantages being facility of erection and easement of secondary bending stress by rotation on the pins. The bottom chord and shoe connections consist of 20-inch diameter pins in split bushings of 30 inches external diameter. For the main post, the pins are 24 inches and the split bushings 36 inches diameter; for the diagonals, the pins are 16 inches diameter, no bushings being required. All bored holes are semi-circular; single plates were, however, extended on the bottom chords and on the inner webs of the shoes to fully engage the pin bushings, thus providing a positive connection during the early stages of erection. The base castings of the shoes weighed 17 tons each; the upper sections were divided longitudinally in halves for shipment, each unit weighing about 39 tons.

Each main post consists of six sections, the location of the splices being determined by weights and to suit the members connecting to the posts. The sections are built up of two webs 84 inches wide and 47½ inches apart, with a continuous middle diaphragm and a plane of lacing on either flange. (See figure No. 25.) The upper post sections which support the links are provided with wing plates on either side, bored to engage the pins which connect the upper diagonals to the links. (See figure No. 26.) The weight of each post section was approximately 40 tons.

In order to avoid heavy secondary bending stresses at the top of the main post during erection and in the completed structure, links are provided similar in principle to those used in the Quebec bridge. (See figures Nos. 27 and 28.) Each link is built up of four massive webs with inter-connecting diaphragms, and is carried on top of the main post on a pin with split bushings of the same size and type as at the base of the post. The converging truss members are pin-connected, the size of the pins being 21 inches for the top chords and 13 inches for the upper diagonals. The wing plates on the upper post sections provide interlocking connections with the links which ensure stability under all conditions, any unbalanced loading being readily compensated by the bending resistance of the posts. The construction also proved most convenient during erection. The links are surmounted by ornamental finials of simple plate construction with cast iron caps. The links were divided longitudinally in halves for shipment, each unit weighing about 25 tons.

The bottom chords of the anchor and cantilever arms are spliced at all main panel points, and at the mid-panel point where necessary on account of weight. The sections are built up of two webs 42½ inches apart and tapering in depth from 60 inches at the shoes to 39 inches at the anchor pier and 42 inches at *CLO* on the cantilever arm. (See figure No. 37.) In the heavier members the webs are connected by continuous coverplates on the top flanges and lacing on the bottom; elsewhere, by lacing on both flanges. (See figure No. 29.) The main gusset plates are spliced into the webs, the chord joints being located in each case at the edge of the gusset plates. All joints are of the butt-type but spliced in addition for practically the full value of the material. The various sections varied in weight up to a maximum of about 40 tons.

The top chords are spliced at all main panel points and were also divided longitudinally in halves for shipment where necessary on account of weight. The sections are built up of two webs 42½ inches apart and vary in depth from 62 inches at the main post to 40 inches at the ends of the arms. The depth is constant throughout each panel, but is made to reduce about 3 inches in each successive

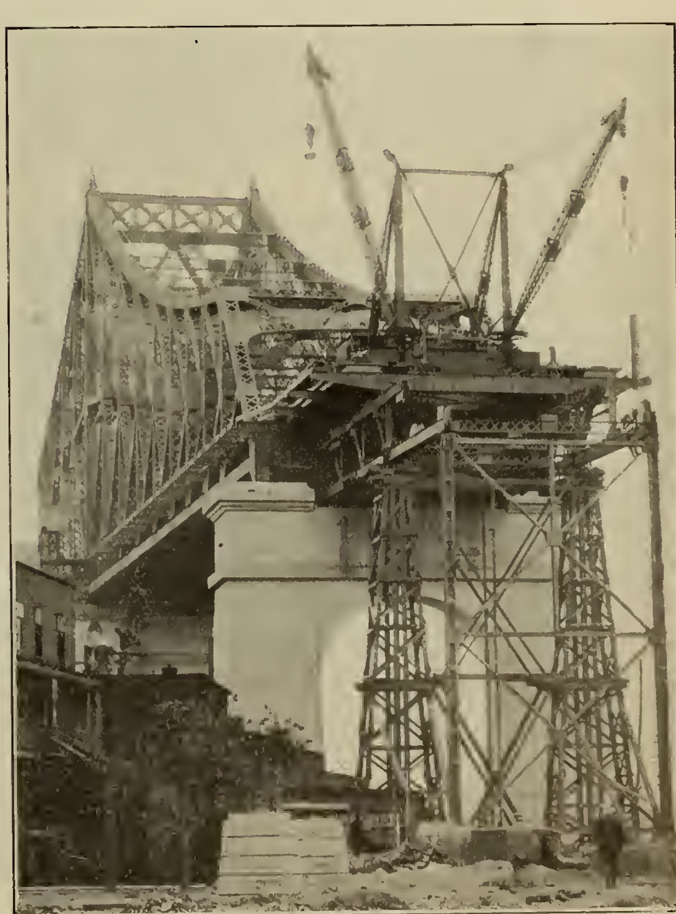

Figure No. 23.—North Approach—Typical Method of Erection—Second Stage.

panel by a novel treatment at the main gusset plates which are spliced into the webs. The webs are connected by lacing on each flange. The splices are of the lap-type and are located immediately beyond the gusset plates. (See figure No. 30.) The various sections varied in weight, those adjoining the main post being about 84 feet long and weighing 45 tons per web.

The order of erection naturally led to all chord splices in the main arms being located a short distance beyond the respective panel points on the side remote from the main pier.

The web members of the trusses are of simple design with splices in the longer diagonals. The gusset plates at the mid-points were rivetted to the lower diagonals and required somewhat careful treatment in design on account of their size. Secondary members are introduced over the main pier, that on the anchor arm side bracing the main post and carrying load from the floor sub-panel concentrations while that on the cantilever arm side is redundant and for appearance only, with a sliding connection at one end.

The anchor arms are connected at the anchor piers to anchorage grillages built into the body of each pier. Each grillage consists of a 4-web structural detail engaging the mass of the pier. The connection is by means of structural members 50 feet long, pin connected at either end to the anchor arm and anchorage grillage respectively, the pinholes being bushed for pins 12 inches in diameter. The members are of rigid construction as it is theoretically possible that a small reversal of the uplift reaction may occur under certain extreme conditions of loading. They were, also, designed to support the anchor arms during erection until that stage was reached where a permanent uplift resulted from the weight in the channel span.

The suspended span swings from the ends of the cantilever arm on structural hangers about 60 feet long, pin connected at either end, the pinholes being bushed for pins 17 inches in diameter. This span was of conventional design except for some special features referred to in the section dealing with the erection of the suspended span.

The bracing of the suspended span consists of top and bottom laterals in the plane of the chords, and swaybracing on the main diagonals above the roadway clearance line. Transverse forces are delivered at each end to the main bottom lateral systems which extend throughout the cantilever and anchor arms in the plane of the bottom chords and are connected to anchorages in the anchor piers. At the latter points and at one end of the suspended span the lateral connections are specially designed to permit the longitudinal movements which result from temperature changes and varying deflections. Top laterals are omitted in the cantilever and anchor arms, the upper structure being braced by planes of swaybracing as deep as permitted by the roadway clearance requirements. In general this bracing extends between the upper verticals, following the lower diagonals below the midpoint. The swaybracing between the main posts is of massive proportions, being designed both for rigidity and appearance.

The floor system is raised above the plane of the bottom chords and laterals and is carried on floorbeams 6 feet 8 inches in depth which frame into the lower verticals immediately above the bottom chords or into the sub-verticals at the mid-panel points. The tramway tracks are supported on built stringers, rigidly braced under each track. The roadway slab rests on 10-inch I-beams about 4 feet apart, laid transversely on five lines of built stringers which are braced together at intervals by cross frames. These longitudinal tramway and roadway stringers frame into the floorbeams, being connected to the stiffeners, with special brackets at expansion points. The sidewalk stringers are outside the trusses and are carried on brackets.

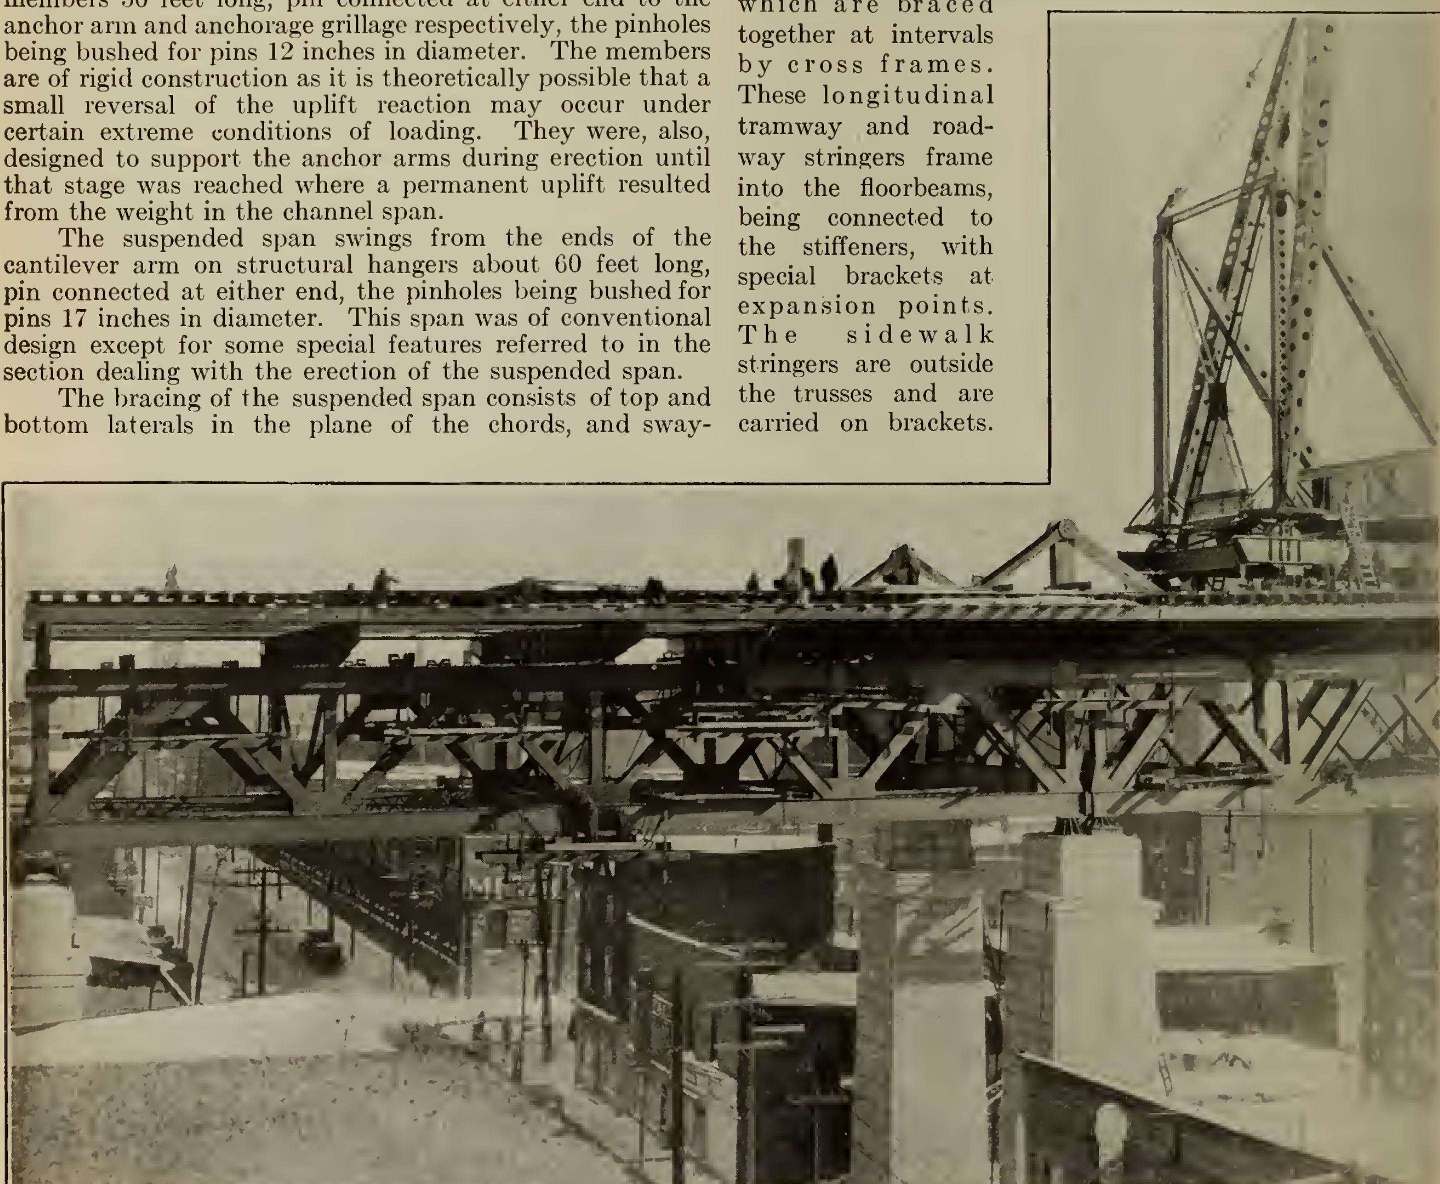

Figure No. 24.—North Approach—Cantilever Erection of Span over St. Catherine Street.

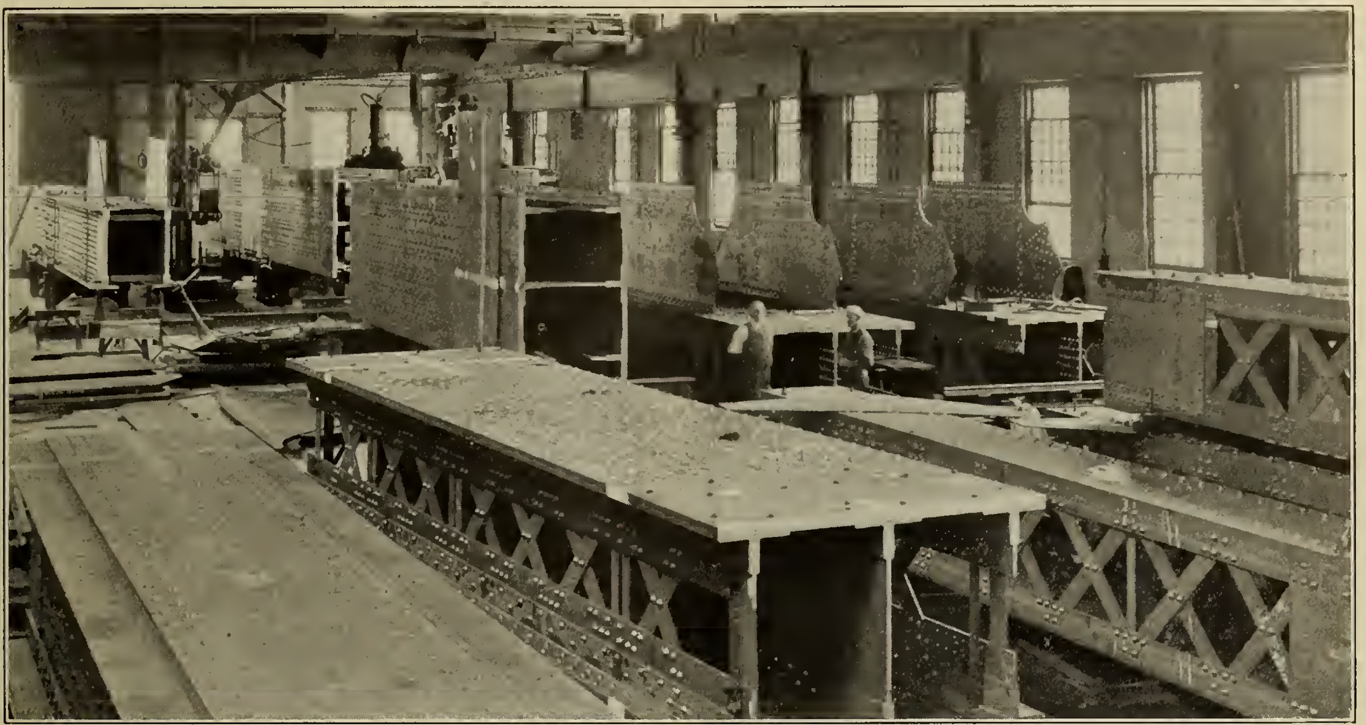

Figure No. 25.—Fabrication of Main Span—Main Post, Intermediate Sections.

The floorbeams at the ends of the anchor arms are of special double-web construction, flush on the underside with the bottom chords and with the stringers resting on their upper flanges. The bottom lateral systems frame into these floorbeams which connect to the transverse anchorages with provision for longitudinal movement. Special provision was made in these floorbeams for jacking loads during erection. The floor system is carried at the main piers on steel trestles of simple construction. At the junction of the cantilever arms and suspended span the construction consists of a pair of floorbeams 7 feet apart at *CLO* and *SLO* respectively. (See figure No. 37.) These floorbeams are flush on the underside with the bottom chords and support the stringers on their top flanges. The bottom lateral systems frame into these floorbeams and between them are inserted the special details which constitute the connections between the lateral systems, with provision for longitudinal movement at one end of the suspended span.

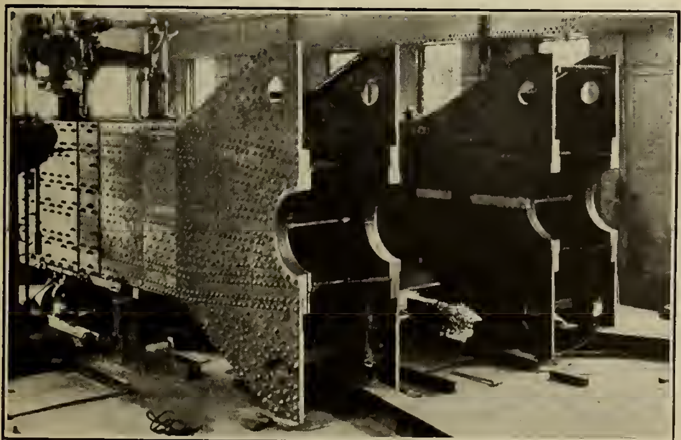

Figure No. 26.—Fabrication of Main Span—Main Post, Top Sections.

The double floorbeam construction at the junction of the cantilever arm and suspended span was dictated by the method adopted for the erection of the latter, which made it necessary to brace very securely the ends of the cantilever arm bottom chords immediately adjacent to the suspended span. The independent floorbeam at *CLO*, (see figure No. 37), being connected to the bottom lateral systems, provided the requisite support in the horizontal plane, that in the vertical plane being provided by the introduction of subdiagonals between *CMI* and *CLO*.

Figure No. 27.—Assembly at Top of Main Post.

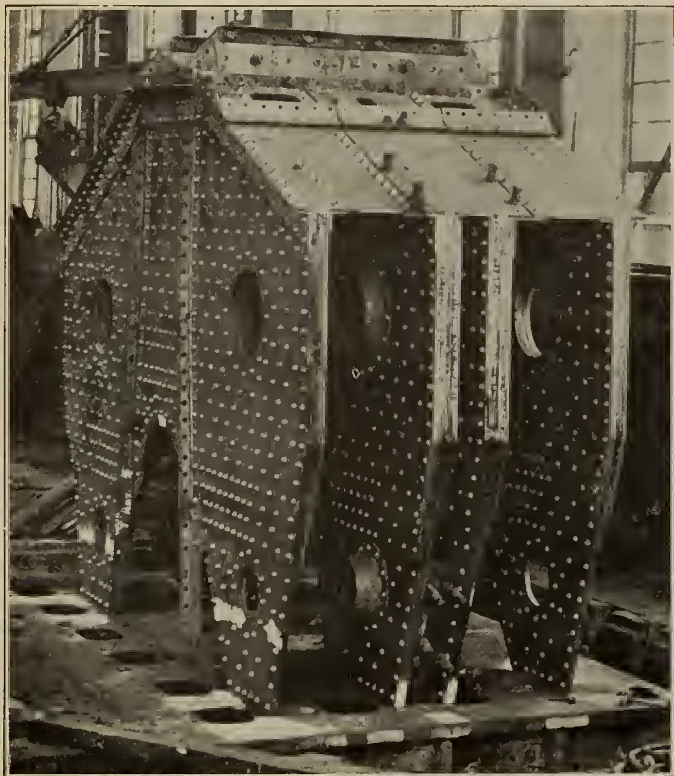

Figure No. 28.—Fabrication of Main Span—Main Post Link.

Silicon steel is used in all the main truss members; in the flanges of the floorbeams and of a number of the longitudinal stringers; and in the main material of most of the bottom lateral system. Elsewhere the structural material is of special carbon steel. The pins and bushings are of forged nickel steel, bronze liners being used in the bushing at points where pronounced movement occurs.

All material used in the superstructure was in accordance with the "Specification for Steel Superstructure" prepared by the engineers and attached to the contract. The material was subjected to mill inspection at the point of manufacture by the engineers and no shipments were permitted before such inspection and acceptance. The

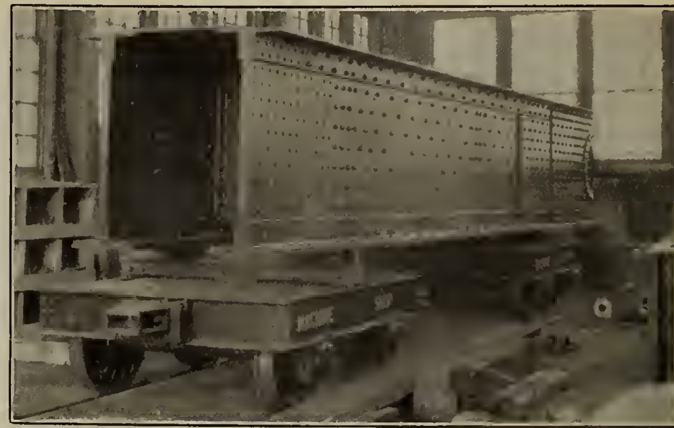

Figure No. 29.—Fabrication of Main Span—Main Bottom Chord Section—Boring of Member.

principal physical requirements for the structural steels were as follows:—

	Special Carbon Steel lbs. per sq. in.	Silicon Steel lbs. per sq. in.	Rivet Steel lbs. per sq. in.
Ultimate tensile strength..	60,000-70,000	80,000-95,000	48,000-56,000
Minimum yield point.....	36,000	45,000	28,000
Minimum elongation in 8 ins.............		1,500,000 ÷ ultimate	
Minimum reduction in area..............	42 per cent	35 per cent	50 per cent

The permissible normal unit stresses used in the design of the superstructure were as follows:—

	Special Carbon Steel lbs. per sq. in.	Silicon Steel lbs. per sq. in.
Tension on net section........	18,000	23,500
Compression on gross section..	$17,000 - 70\frac{L}{R}$	$22,000 - 100\frac{L}{R}$
with maximum..	15,000	19,000
Shear on webs...............	11,000	13,000
Pin bearing..................	20,000	26,000

Rivets, shop driven......shear 12,000, bearing 24,000
Rivets, field driven......shear 11,000, bearing 22,000
Pins, nickel steel..............bending 35,000
Steel castings..................bending 16,000

An increase of 25 per cent was permitted in the above normal unit stresses during erection, for the combined effect of the weight of the structure, the weight of erection

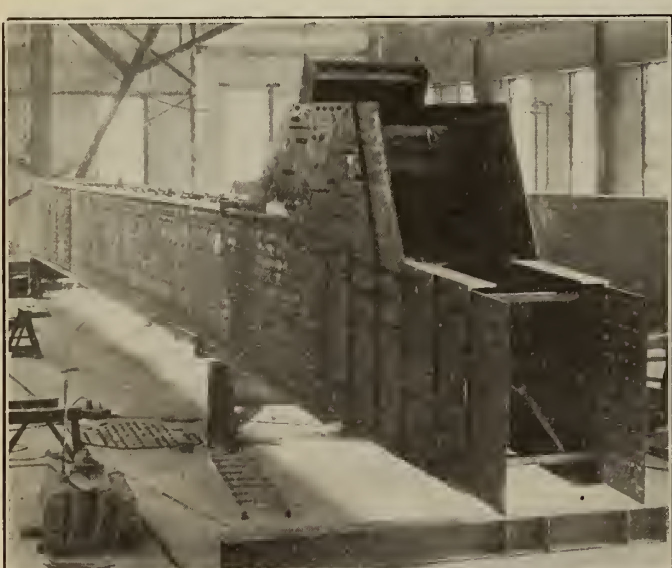

Figure No. 30.—Fabrication of Main Span—Main Top Chord Section—Assembled in Inverted Position for Reaming of Detail.

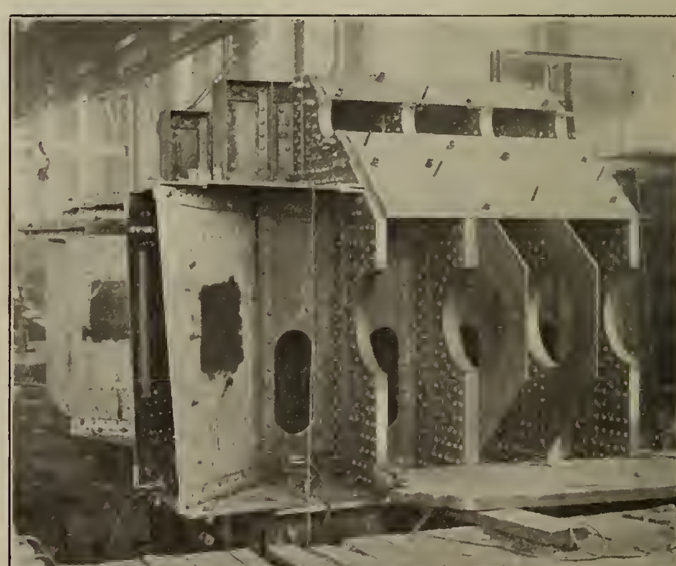

Figure No. 31.—Fabrication of Main Span—Main Shoe during Assembly.

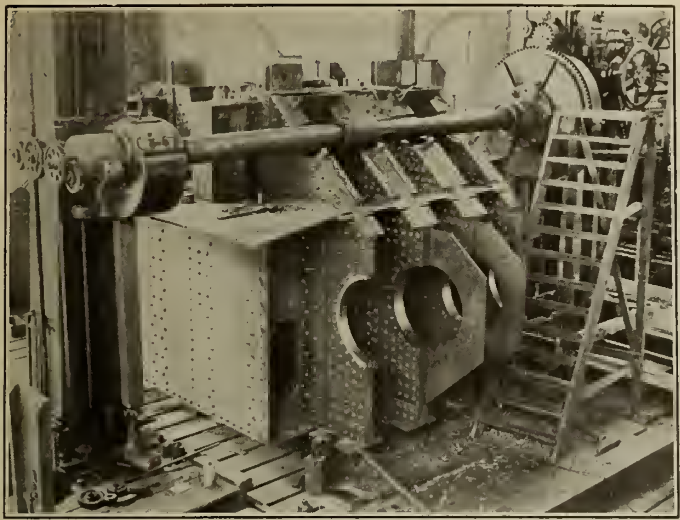

Figure No. 32.—Fabrication of Main Span—Main Shoe during Boring of Pinholes.

travellers and other equipment, and a wind load of 30 lbs. per square foot on exposed surfaces. In general the erection stresses were kept considerably under the above permissible limit, both in the superstructure and in the erection travellers and falsework.

Thickness of material was limited in general to ¾ inch particularly in tension members and main gusset connections, multiple thicknesses being used where necessitated by the area of material required.

The design of the various members was the result of prolonged study, every effort being made to obtain the best proportions and disposition of material for efficiency and economy.

Fabrication

The base castings of the shoes, which were supplied by Canadian Steel Foundries, Limited, were planed top and bottom, and on the adjoining faces; the outstanding lugs on these faces were also drilled for the turned bolts with which they were connected. The individual webs of the upper shoe sections were first assembled and rivetted as units, and the lower edges planed to provide perfect bearing on the base castings. Each entire shoe was then assembled complete with bottom lateral connection plates in place on a specially prepared base, the connections between the webs reamed, and the rivetting completed except in the field connections. (See figure No. 31.) The connections to the base castings were marked from the upper sections and drilled after their removal. Owing to their size, it was necessary to have the upper sections bored at the plant of the Dominion Engineering Works, Limited, on equipment previously used for the Quebec bridge. Each upper shoe was completely re-assembled on the table of the boring machine and the five holes bored, after which the shoe was taken apart for shipment. (See figure No. 32.)

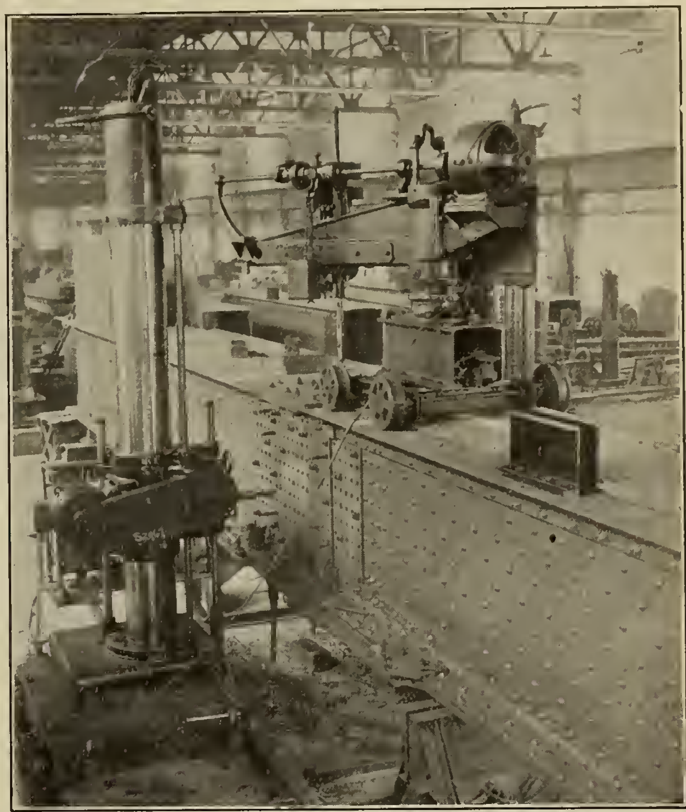

Figure No. 34.—Fabrication of Main Span—Bottom Chord Sections—Assembly of Field Splice.

The links were fabricated in the same general manner as the shoes and were bored on the same machine.

The tapered web-plates of the bottom chords were received from the mills as rectangular plates and their edges planed to the required taper in the shops. The material for the various sections was sub-drilled or subpunched depending on the thickness, after which each web was assembled as a unit, reamed and rivetted. In the case

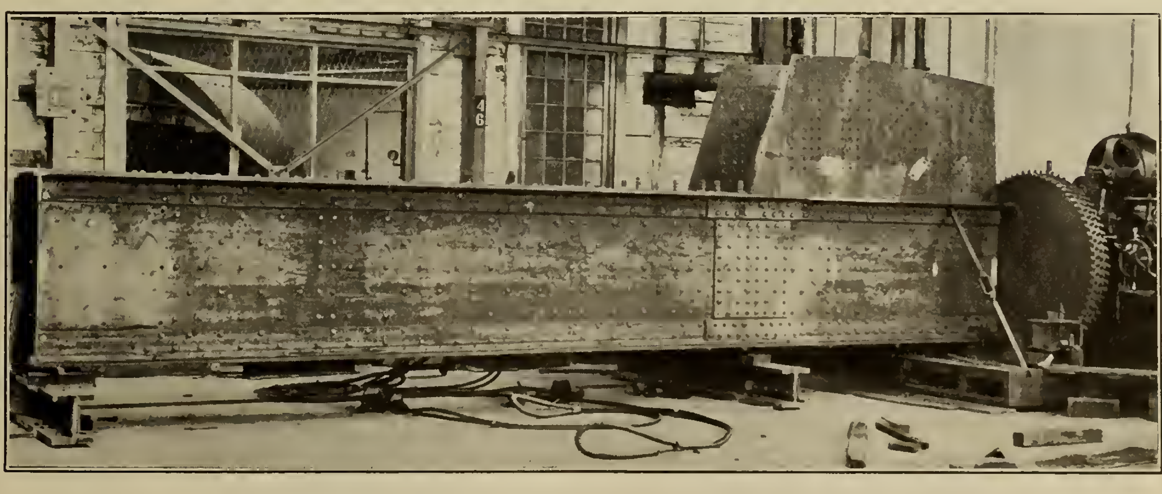

Figure No. 33.—Fabrication of Main Span—Bottom Chord Section—Facing End on Rotary Planer.

of the main gusset plates, the connections for the adjoining truss members were drilled full size before their assembly in the chord sections. The two webs comprising a section were next assembled with their intervening coverplates, lacing and diaphragms which were rivetted after the necessary reaming. The ends of the section were then planed on a rotary planer. (See figure No. 33.) The section was now assembled with the section adjoining at the end towards the shoe. The faces were drawn to close contact and, with the splice material in place, the joint was fully drilled and matchmarked. (See figure No. 34.) The contact at the joints was carefully inspected with feelers before placing the splice plates and a joint was not accepted until 90 per cent of the face was in contact and the remainder would not admit a feeler over four thousandths inch thick. In the drilling, the exterior splice material, in which the holes were drilled full size, before assembly, was used as a template, the ends of the member and the other splice material being left blank except for occasional holes provided for bolting purposes. The successive chord sections were treated in similar manner.

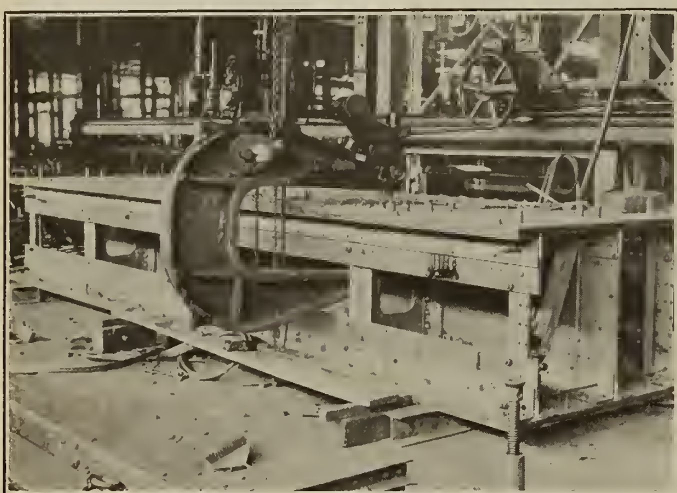

Figure No. 35.—Fabrication of Main Span—Main Post Section—Assembly and Rivetting.

The main post sections were fabricated by the same general methods as employed on the bottom chords, all adjoining sections being assembled in pairs for drilling and matchmarking. (See figure No. 35.)

The top chords, as previously mentioned, were fabricated partly as complete sections and partly as single webs, two of which were required for the ultimate members. In the former case the treatment was similar to that for the bottom chords except for the omission of the end facing. In the latter case the individual webs were assembled, reamed and rivetted. The flange angles were formed in easy curves at the panel points to suit the change in the chord depth and inclination in the adjacent panels, and special arrangement of the other material was also necessary at these points to ensure adequate strength at all planes. The two webs of a section were next assembled on the skids with the intervening detail in place, all of which was reamed, matchmarked, and removed. (See figure No. 30.) Each web was then assembled with the corresponding web of the section adjoining at the end towards the main post, the alignment and length being carefully checked. After all splice material had been placed, the joint was drilled and matchmarked. (See figure No. 36.)

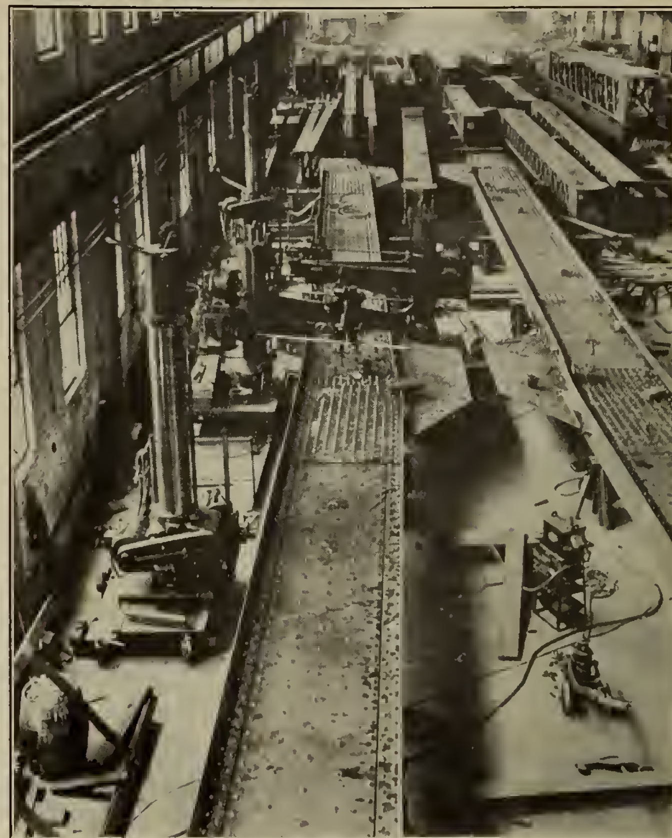

Figure No. 36.—Fabrication of Main Span—Top Chord Webs—Assembly of Field Splice.

The fabrication of the web members was simple in nature, the end connections being, in general, reamed or drilled full size to template. The lateral and swaybracing connections were also reamed to template.

The shop lengths of the members were derived from the camber requirements as laid down in the specifications, all measurements being made with standardized steel tape supported at close intervals.

Prefix "*S*" denotes South Side, thus—*SAL7*, etc.

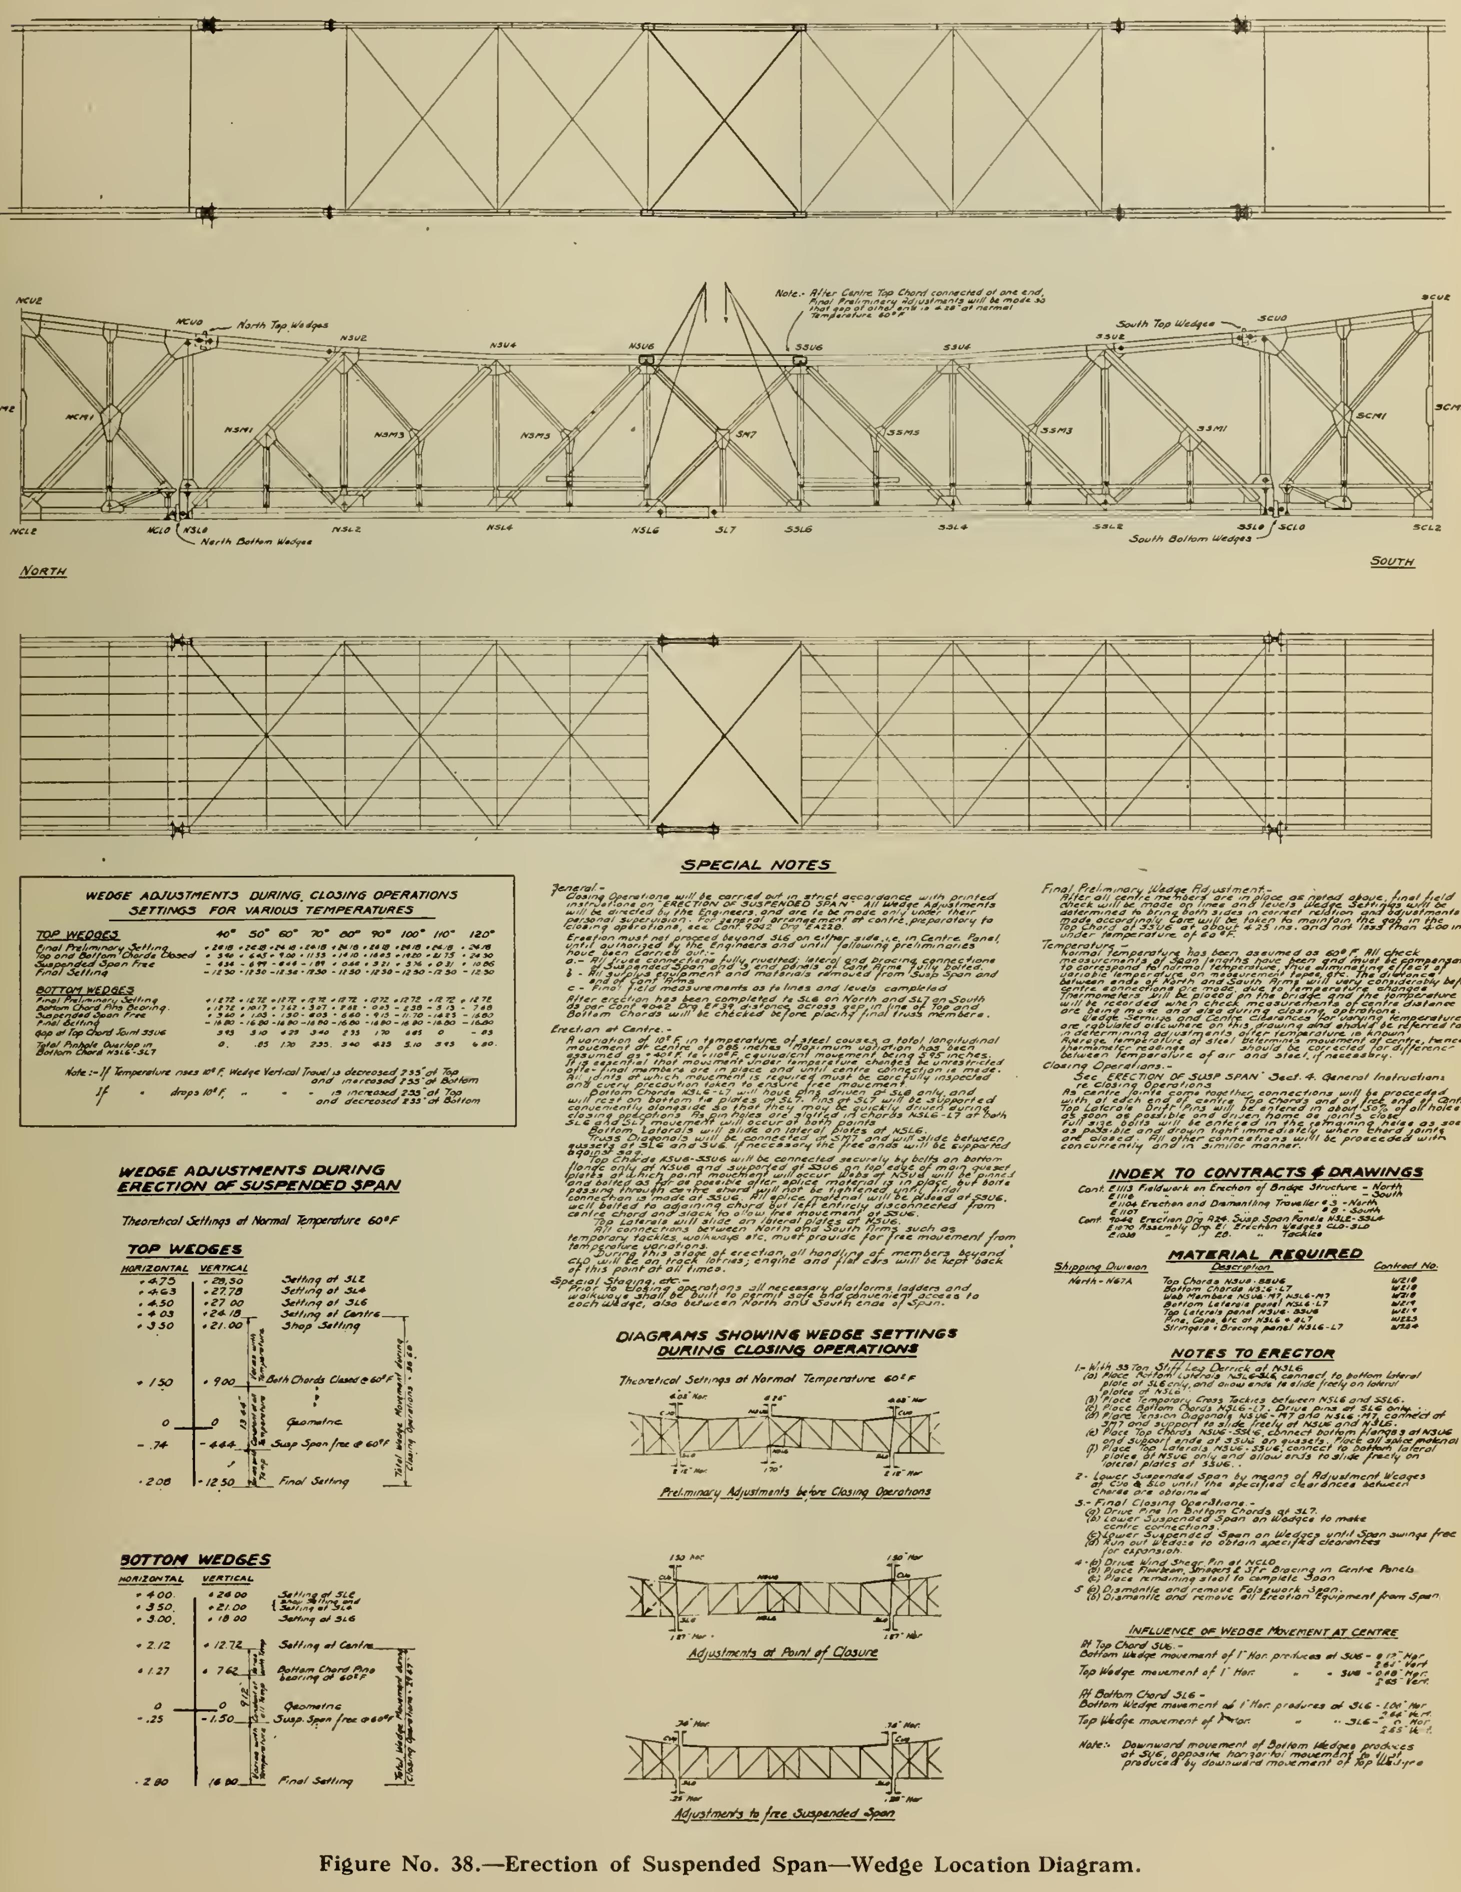

Figure No. 38.—Erection of Suspended Span—Wedge Location Diagram.

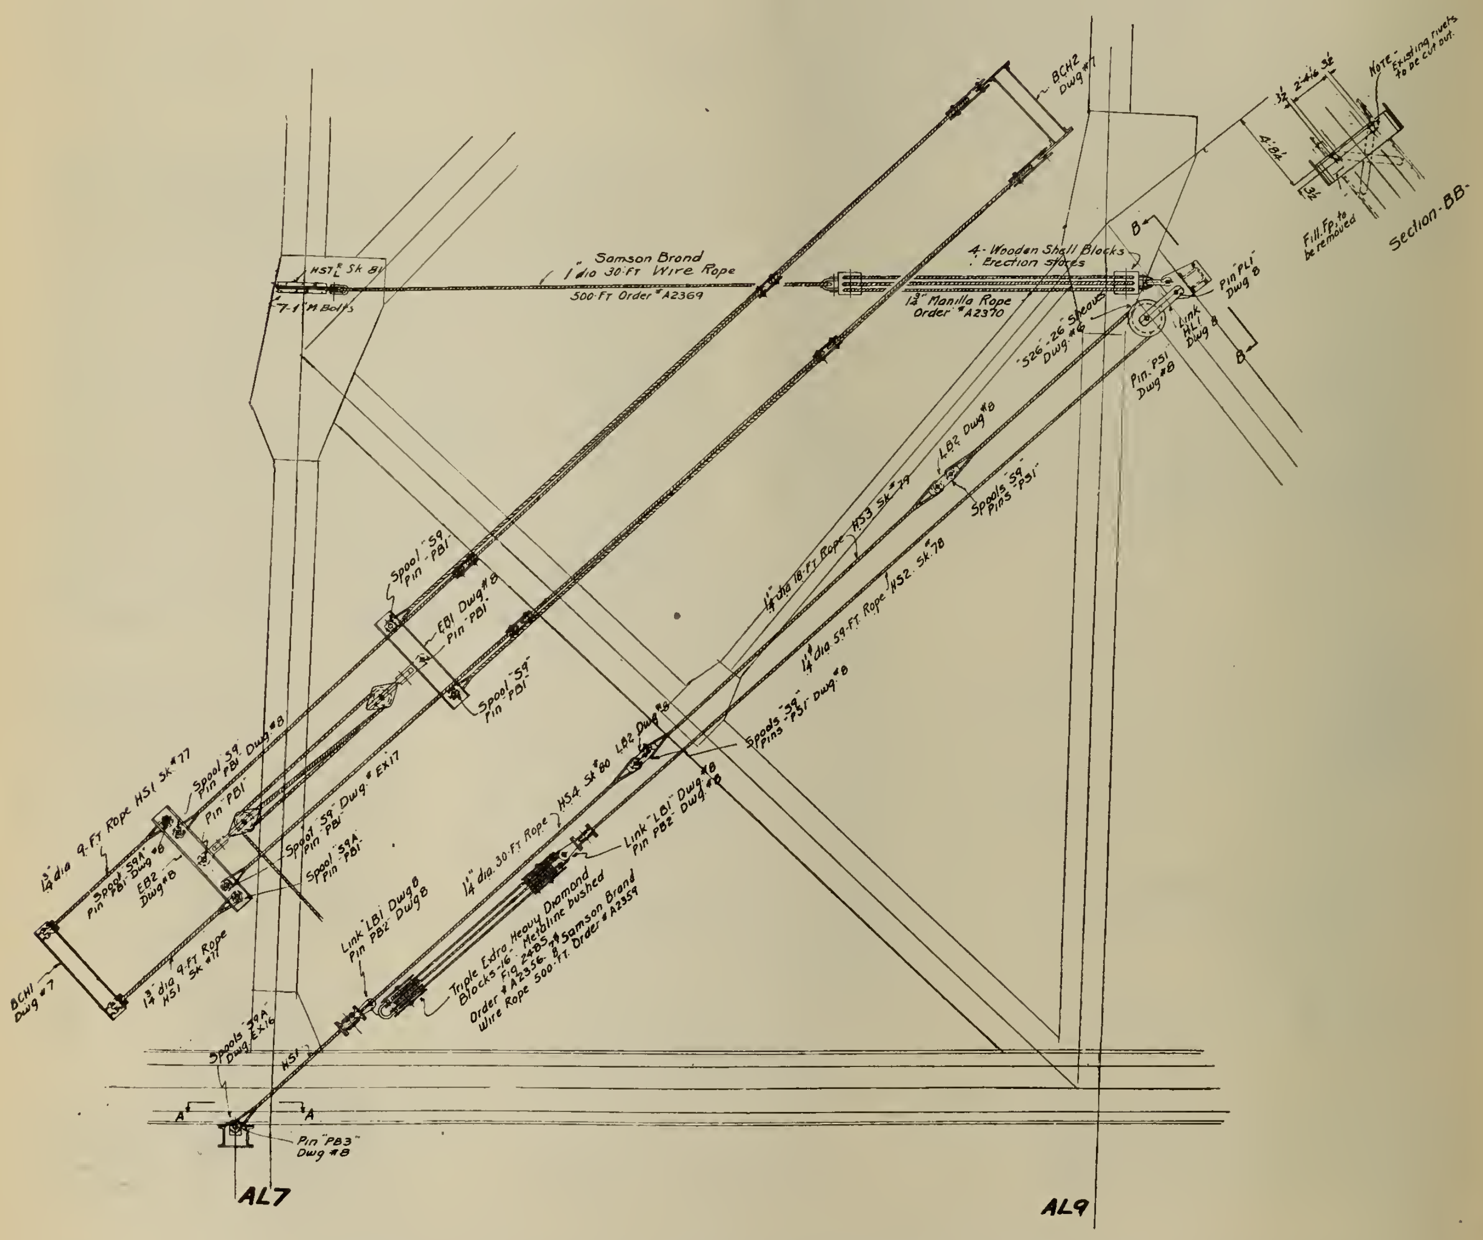

Figure No. 39.—Adjustable Tackles used during Erection of Main Span.

The forgings for the pins and bushings were supplied in a semi-finished state by Canada Foundries and Forgings, Limited, and finish-machined in the shops of the contractor.

The standard of workmanship was in accordance with established practice on construction of such importance. Sheared edges of material over ⅝ inch in thickness were planed to remove incipient cracks, this including virtually all silicon steel. Punching was permitted in silicon steel up to ⅝ inch and in carbon steel up to ¾ inch in thickness, material over these limits being drilled. In general, the individual pieces were sub-punched or sub-drilled ⅛ to ¼ inch small and reamed to size after the assembly of the members. The rivets varied in size up to 1⅛ inch diameter, according to the thickness of the material in contact. The

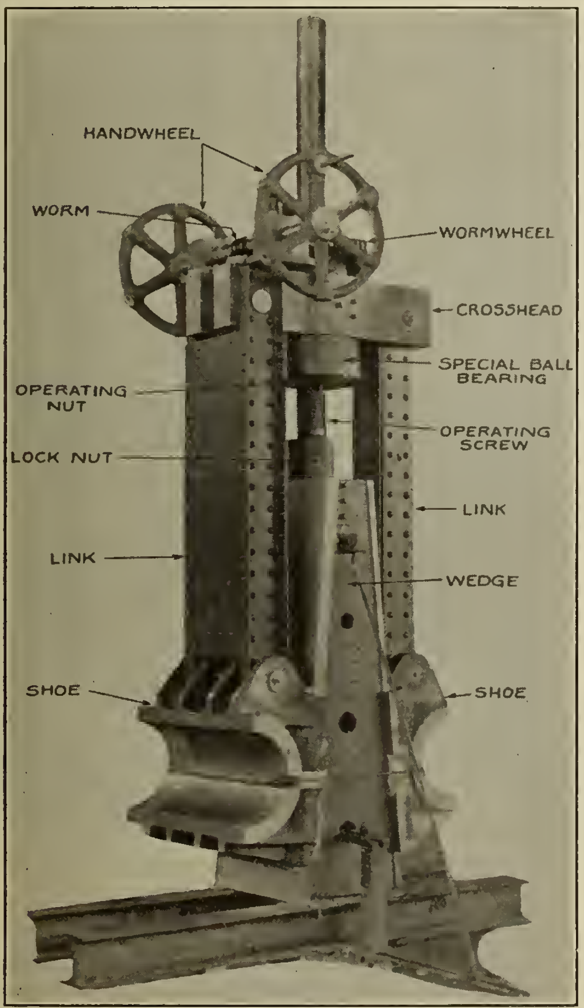

Figure No. 40.—Wedge Mechanisms used in Erection of Suspended Span.

minimum size for the important truss members was, however, 1 inch diameter to permit the use of ¾-inch bolts in the unreamed holes during assembly. Bolts of "Mayari" steel were used during the assembly of the heavier members, to facilitate the drawing together of the material.

It is fitting to note that the field experience proved the quality of the fabrication to have been of the highest order, reflecting most creditably on those associated with the preparation of the detail drawings and with actual fabrication in the shops.

The special carbon steel did not differ sufficiently from the commonly used grades of structural steel to create special problems in fabrication beyond slightly greater

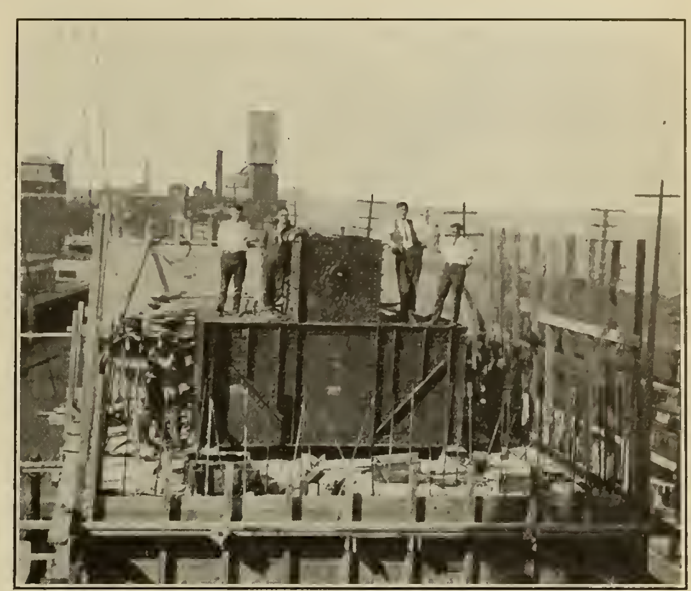

Figure No. 41.—Main Span, North Side—Setting of Anchorage Grillage at Anchor Pier.

demands on the machines and some increase in genera wear and tear.

In the case of the silicon steel, however, quite different characteristics appear, as a comparison of its strength with that of medium structural steel will at once suggest. Particular care is necessary at the mills during manufacture, there being a pronounced tendency towards segregation in

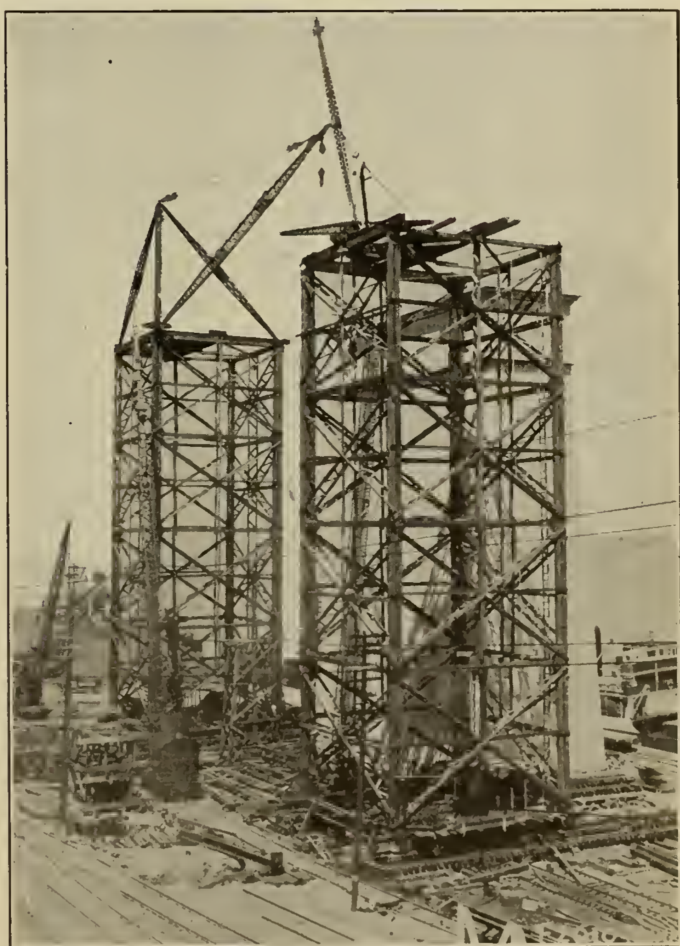

Figure No. 42.—Main Span, North Side—Travellers Nos. 5 and 6 during Assembly.

Figure No. 43.—Main Span, North Side—Setting Main Shoe Castings on Main Pier.

the ingots which requires careful and extensive cropping. Experience proves the importance of extremely thorough inspection at the mills as a much larger percentage of rejections may be expected than in the ordinary grades of steel. Fortunately, in this instance the mill inspection was exceptionally rigid and thorough. Rigid inspection was maintained at all stages of fabrication, the proportion of material rejected at the fabricators plant for native defects being comparatively small.

The most common defects appearing during fabrication were in the form of occasional hard spots and pipes, the latter being revealed during the punching, shearing or facing of the material.

As may be inferred from the relative strength of silicon steel, its fabrication demands heavy and powerful equipment, particularly as the thickness increases. In shearing and punching, the metal literally breaks with a sharp report quite different to the similar operation with ordinary grades and with a much more crystalline fracture. To obtain satisfactory results, operations must be slowed up, cutting and punching tools carefully selected, and the settings of shear blades and punches regulated in the light of actual experience. Wear and tear on tools and equipment is, of course, greatly increased. With proper precautions and an expert organization, however, the material is quite workable.

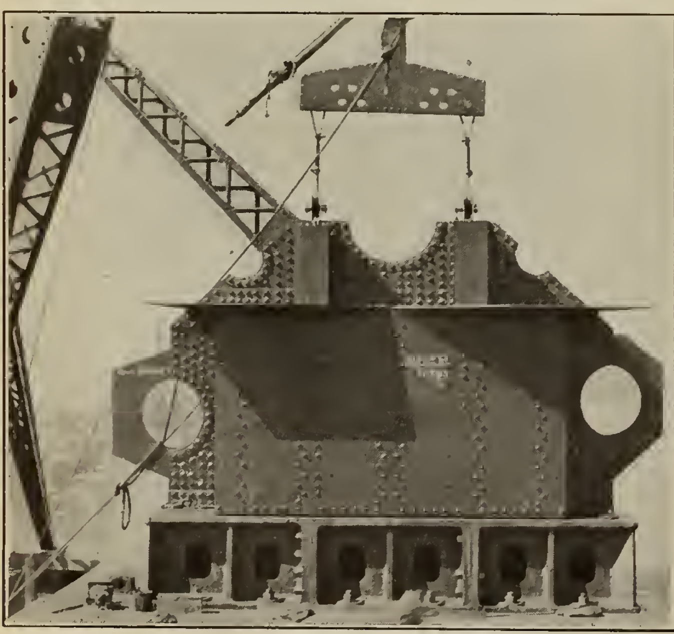

Figure No. 44.—Main Span, North Side—Setting Main Shoe on Main Pier.

Based on experience, the unit fabricating cost for silicon steel is from 25 to 35 per cent greater than for ordinary structural steel, depending on the nature of the work, any advantage from lighter material being offset by the added cost of the operations as outlined above.

All material which could be supplied by Canadian mills was obtained from them, the balance being obtained from United States mills. The silicon steel was manufactured by the United States Steel Corporation with the exception of a quantity of the lighter sections manufactured by the Algoma Steel Corporation Limited.

Erection

The problems connected with the erection of the main span were unique, differing considerably on the north and south sides of the channel. Tentative erection plans were developed during the preparation of the tender but, after the award of the contract, were subjected to prolonged study. The methods finally adopted adhered closely to the preliminary plans, greater confidence being naturally felt after the comparison with alternative methods.

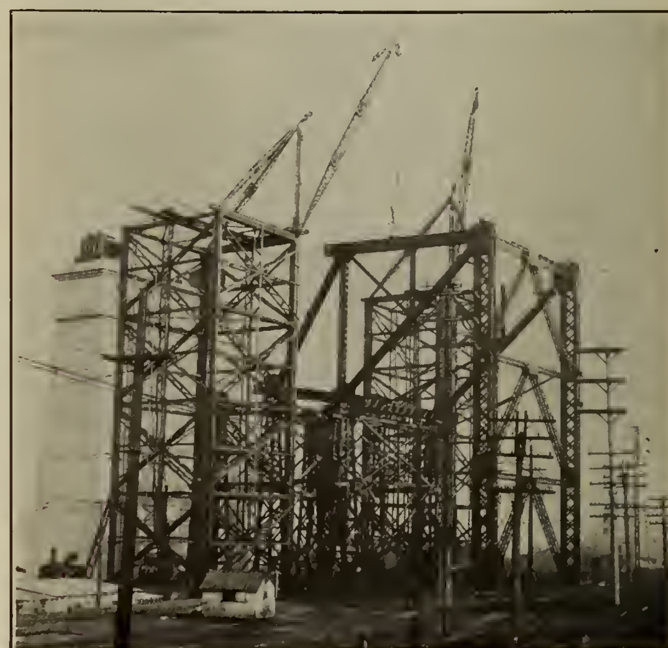

Figure No. 45.—Main Span, North Side—Erection of Falsework Span and Tower—First Stage.

As previously stressed, the erection of the south half of the main span was dependent on the completion of the south approach. The adopted programme required operations to commence on the north half early in 1927 and on the south half during 1928, after the transfer to this side of considerable equipment to be used in the first instance on the north side.

Method of Erection for Anchor Arms

The first outstanding problem was the method of erection to be employed on the respective anchor arms, ground conditions being entirely different in the two cases. The north anchor arm spans the main railway tracks of the harbour and Canadian Pacific Railway; a large building used at that time as a brewery warehouse; and Notre

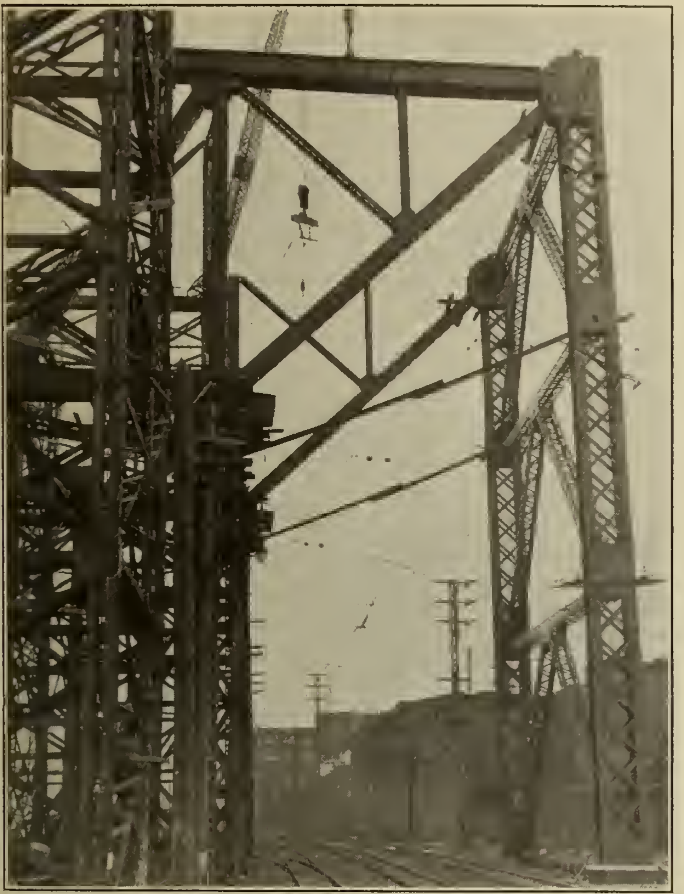

Figure No. 46.—Main Span, North Side—Arrangement of Falsework Tower.

Dame street, a busy thoroughfare with tramway tracks. The only ground available for construction purposes was a strip about 100 feet wide between the main pier and the railway tracks. The existing conditions entirely prohibited the use of falsework under the greater portion of the anchor arm.

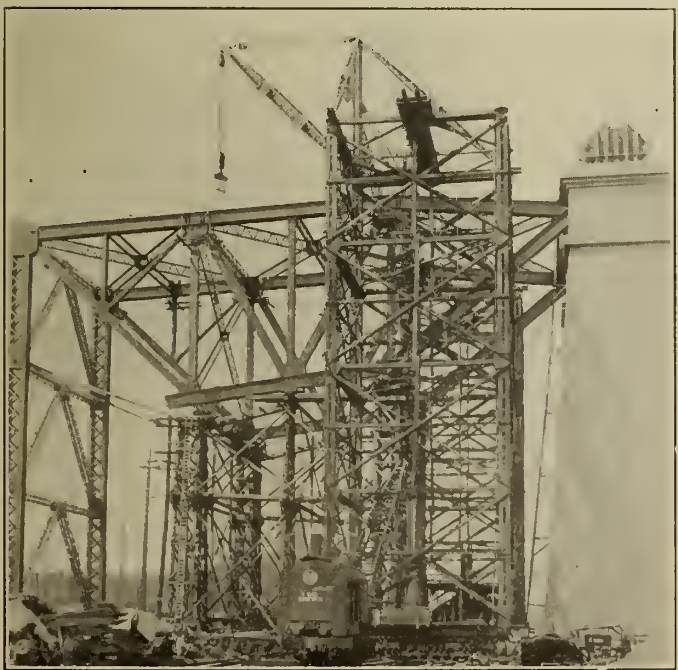

Figure No. 47.—Main Span, North Side—Erection of Falsework Tower and Span—Final Stage.

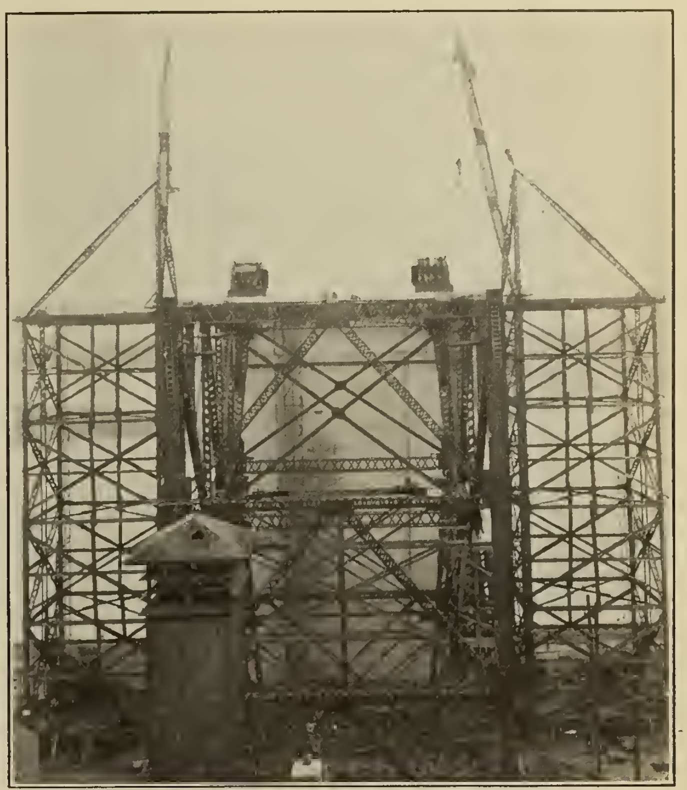

Figure No. 48.—Main Span, North Side—General Arrangement of Falsework and Travellers Nos. 5 and 6.

The south anchor arm is over the river but clear of the navigation channel, the current being approximately 7 miles per hour. Under mean summer conditions, the water is about 3 feet in depth at the south anchor pier, increasing gradually to about 12 feet at midspan, and then deepening rapidly to about 40 feet at the main pier. The river bottom in this section consists of a shallow layer of hardpan over irregular rock. The river usually freezes at this point in early January and is subject to intermittent ice shoves during the winter. The break-up occurs during late March or early April, causing ice jams in the vicinity which often build up to a height exceeding 30 feet at the site and overrun the dock walls. Tremendous pressure is exerted as these jams slowly break-up, reform, and finally move

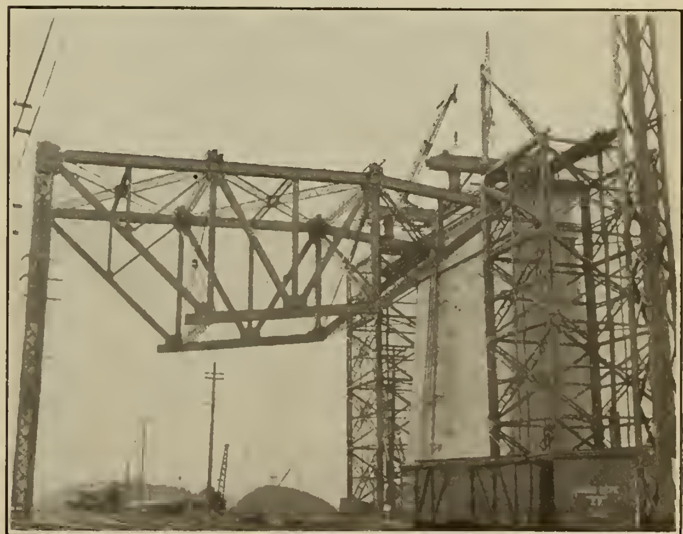

Figure No. 49.—Main Span, North Side—Placing Bottom Chord Sections of Anchor Arm—First Stage.

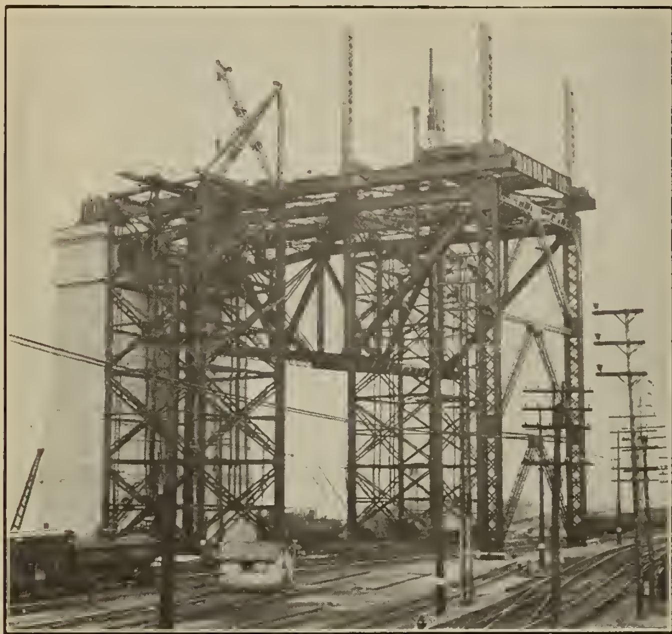

Figure No. 50.—Main Span, North Side—Erection of Bottom Chords and Floor System on Falsework Span.

down the river. The water level rises with great rapidity during this period, drops to more normal conditions after the ice movement is completed, and gradually falls a further 6 or 7 feet after May, commencing to rise again in the late autumn. It was obvious that no falsework could endure the ice movement unless supported above it on massive foundations.

Figure No. 51.—Main Span, North Side—Erection of Traveller No. 4 on Anchor Arm—First Stage.

It was apparent that on the north anchor arm, falsework was practicable under the three panels adjacent to the main pier only, it being necessary, therefore, to erect the remainder as a cantilever. These conditions required that a main point of support be established at *AL9*, three panels north of the main pier. (See figure No. 37.) A re-arrangement of the harbour tracks under the anchor arm made possible the location and construction of suitable foundations, and a steel tower was therefore determined on for this point as providing in conjunction with the main pier a satisfactory base for the support of the superstructure.

In the case of the south anchor arm, methods were first examined which might make possible its complete erection in a self-supporting condition in one season, thus avoiding the ice problem. It was the final consensus of opinion, however, that the prospect of such an accomplishment was too slight to justify the hazard, particularly as the work would be in serious jeopardy should labour troubles arise. The use of massive foundations for falsework was also discarded as lacking economy and it was decided to provide a temporary span the full length of the anchor arm, supported at each end directly by the piers.

As a further step, it was decided to make use of a portion of this span on the north side between the main pier and the steel tower at *AL9*. The resultant advantages were more positive support for the anchor arm during the early stages of erection and much less interference with handling operations on the ground where space was only too limited.

At first sight the falsework construction may appear elaborate and expensive. It must be borne in mind, however, that a disaster at this location would have had far-reaching results of the gravest nature and that the memory of the Quebec bridge was still fresh. Quite apart from the inevitable loss of life and property in case of a disaster, there also existed the contingency of the entire blocking of the main harbour for several months with incalculable loss to the entire country. The contractor

Figure No. 52.—Main Span, North Side—Erection of Traveller No. 4 on Anchor Arm—Second Stage.

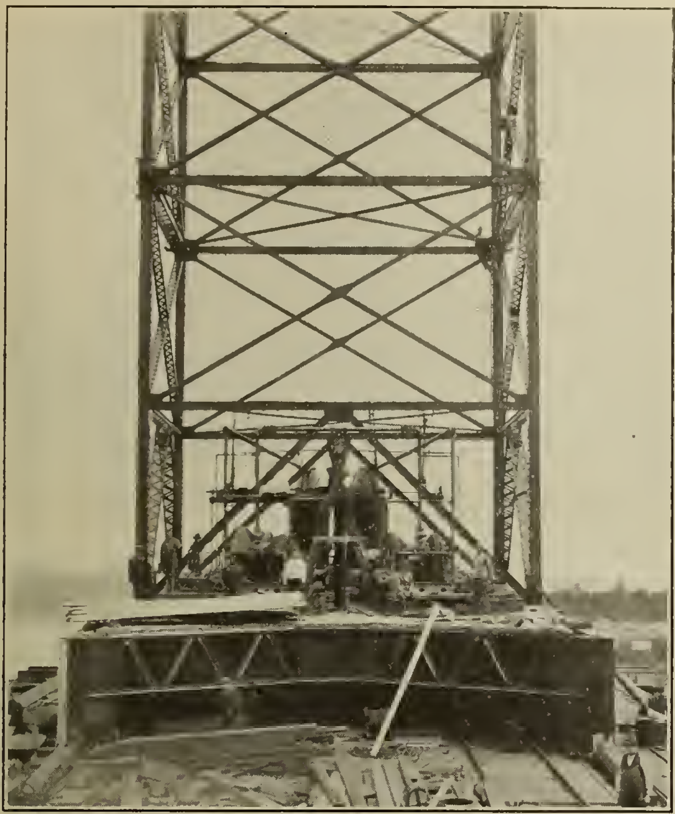

Figure No. 53.—Main Span, North Side—Rear View of Base—Traveller No. 4.

unhesitatingly accepted safety as the paramount consideration and spared no expense to achieve it.

Conditions Governing Erection Equipment

The second major problem was the type of handling equipment to be employed in the erection of the various parts of the structure. The weight of the members varied up to a maximum of 45 tons, but the greater proportion of the pieces to be handled were comparatively light. It was, therefore, important to provide speedy handling equipment for the lighter material, combined with the capacity for the heavier pieces.

At the main piers the trusses are 162 feet in depth, the height of the highest point above the floor being about 160 feet, exclusive of the light ornamental finials. This height diminishes rapidly panel by panel on either side of the main post, the greater portion of the span length being within the reach of equipment of reasonable proportions operating on the deck.

After a comparison of various methods for the erection of the high portions adjacent to the main piers, it was decided to adhere to the original plan of a tower traveller, operating between the trusses on the deck. In the plan of operations finally developed, the tower traveller erected these high portions, consisting of four panels of each anchor arm and five panels of each cantilever arm, the remainder of the structure being erected with deck travellers.

The peculiar conditions under the north anchor arm presented some difficulty. The distance from the ground to the top of the main pier is 134 feet, and to the floor at this point 150 feet, these heights precluding erection at floor level from the ground. After consideration of many schemes, it was decided to erect on the ground outside each truss a moveable timber tower carrying on its top a heavy derrick. These derricks erected the falsework span and tower; placed the shoes, bottom chords, laterals and floor system from the main pier to *AL9*; assisted in erecting the tower traveller on the deck; and throughout the first season handled all materials from the ground to the deck of the bridge. This arrangement permitted the erection of the temporary span on comparatively light timber falsework, and eliminated the need of pile footings.

The distance between the trusses of the span made possible a convenient arrangement of traveller and service tracks, the latter being laid on the lines of the tramway stringers at 50 feet 6 inches centres. For the former, two standard gauge tracks at 24 feet centres were adopted, carried in each case on two lines of longitudinal roadway stringers which were reinforced where necessary for the traveller loads. The traveller tracks consisted of 85-lb. rails carried on 8- by 10-inch ties 10 feet long, spaced as necessary for the loads to be carried. By restricting the overall width of the travellers to within 40 feet, the service tracks were at all times clear enabling material to be placed alongside each traveller as required, within the convenient reach of the booms.

The number and disposition of travellers was influenced by various factors and by the desire for as rapid construction as possible. The necessity has already been shown for the erection of a portion of the north anchor arm by cantilevering. It would have been possible to complete this anchor arm with the tower traveller, afterwards erecting the cantilever arm with the same equipment; this method, however, involved extremely heavy reactions on the tower at *AL9*, seriously stressed certain portions of the arm and lengthened operations considerably. A first alternative was concurrent erection of the cantilever arm with a tower traveller duplicating that on the anchor arm. A second and more attractive alternative was the method adopted, in which the tower traveller erected its allotment of the

Figure No. 54.—Main Span, North Side—Erecting First Sections of Main Post.

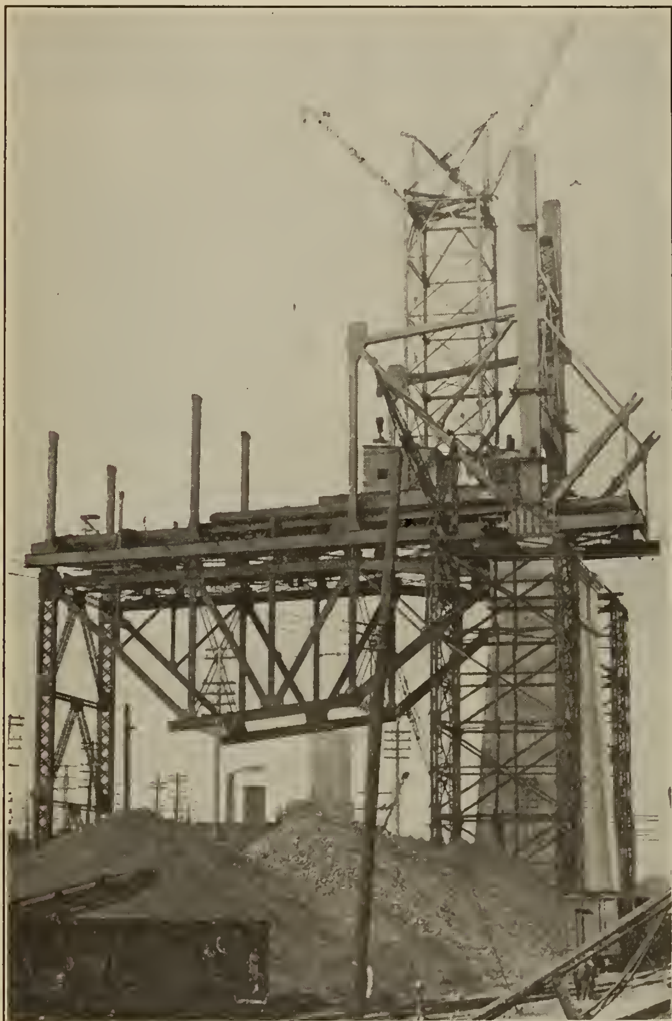

Figure No. 55.—Main Span, North Side—Erection proceeding on Main Posts and Adjacent Structure.

anchor arm, was then transferred to the cantilever arm and proceeded with its erection concurrently with the completion of the anchor arm by a deck traveller. As the weight and general arrangement of the tower traveller prohibited its use on the central portion of the channel span, a further utility was thus found for the less cumbersome deck traveller.

Rapid construction also required that erection be commenced on the south anchor arm before the equipment on the north side could be released, and the materials to be handled were entirely beyond the capacity of the equipment used on the south approach. The early stages on the south side being much more conveniently served by a deck traveller, that on the north side was duplicated for the south and operations planned on the basis that the single tower traveller would erect the similar sections of the superstructure on both sides. By erecting the cantilever arm concurrently with the rear portion of the anchor arm on the south side as on the north, operations were accelerated and a more economical design for the falsework span made possible.

Two deck travellers being thus available, concurrent erection towards the centre from both sides was provided for, as the work approached the final stage.

Closure of the Suspended Span

The final and outstanding problem was the connection of the two cantilever arms over the centre of the channel, or what may be briefly termed the "closure of the suspended span."

This central section of the channel span functions in the completed structure as a simple span suspended between the ends of two cantilever arms. The members *CUOSU2* and *CL2SLO*, (see figure No. 38), are subordinate, the former being entirely redundant and the latter affected only by wind and traction influences. During erection, however, each half of the suspended span became temporarily a prolongation of the corresponding cantilever arm, the stresses in its chords being of a reverse nature to those in the completed structuie. The sub-chords referred to above became integral parts of the top and bottom chord systems and were subjected to heavy erection stresses which governed their design.

The closure consisted of the bringing together of the arms at the centre of the span, the making of all connections at that point, and the subsequent transitiou of the suspended span from the cantilever to the simple span condition under fully controlled adjustment, during which process the stresses in the structure assumed their final nature, those in the sub-chords disappearing entirely.

Early consideration was given to the truss design of the suspended span to determine that arrangement of panels which would give the most favourable conditions at the centre while making the closure. The design as finally adopted contains seven main panels of which the central panel is bisected by the centre of the span. The members involved in the closure are indicated in figure No. 38 and consist of top chords and laterals *NSU6-SSU6*, bottom chords and laterals *NSL6-SL7*, and sub-diagonals *NS6-S7*. The top chords *NSU6-SSU6* were designed with butt joints at the panel points, the ends being chamfered slightly at each flange to ensure the bearing being taken on the central portion of the webs. The bottom chords *NSL6-SL7* were pin-connected at either end, the holes being slotted 3 inches back of the pins to provide ample clearance for the driving

Figure No. 56.—Main Span, North Side—Erection of Anchor Arm being completed to Tower at *AL9*.

Figure No. 57.—Main Span, North Side—Erection commenced on Cantilever Arm. Progress as at December 14th, 1927.

Figure No. 59.—Main Span, North Side—Erection proceeding on Cantilever Arm. Progress as at March 16th, 1928.

of the pins before the closure of the connections and for movement during the closure operations after the pins were in place. The arrangement of the members proved exceedingly flexible and prevented minor discrepancies of alignment in either plane from being bothersome, as these were readily corrected as soon as contact at the joints had been established.

In the cantilevered condition, the weight of the suspended span and erection equipment produced much heavier stresses in the anchor and cantilever arms proper than was the case after the change to the simple span condition, the stresses in the chords at the outer end of the cantilever arms being up to their safe capacity. The deflections of the arms at this time were sufficient to render impossible the placing and connecting of the final members at the centre without compensating adjustments. Expansion and contraction in the structure, due to temperature changes, also produced a continually varying condition at the centre between the two arms and it was important that the centre joints should not close prematurely under temperature expansion as the resultant arch action in the suspended span with consequent thrust against the main piers would have been objectionable if not serious under extreme conditions. It was, therefore, necessary that each half of the suspended span be erected in such a manner that adequate clearances would exist between the ends of the two arms before attempting the closure which implied providing for longitudinal adjustment in the planes of the top and bottom chords. This required that adjustable devices be provided in each plane capable of being operated under a load of approximately 800 tons on each and, after the consideration of many types, wedge mechanisms were finally adopted for each plane as the means whereby all the adjustments incidental to the closure would be made.

The wedge mechanisms were located in the sub-chords at each end of the suspended span in the positions most convenient for operating; those in the bottom plane being adjacent to *SLO* and in the top plane to *CUO*, as shown in figure No. 38. Manual operation was provided for as being most dependable and subject to perfect control. It was also considered both unnecessary and impracticable to design the wedge mechanisms for operation against their maximum load and they were, therefore, designed for slacking off only under full load. This necessitated an initial setting of the wedge mechanisms when first placed

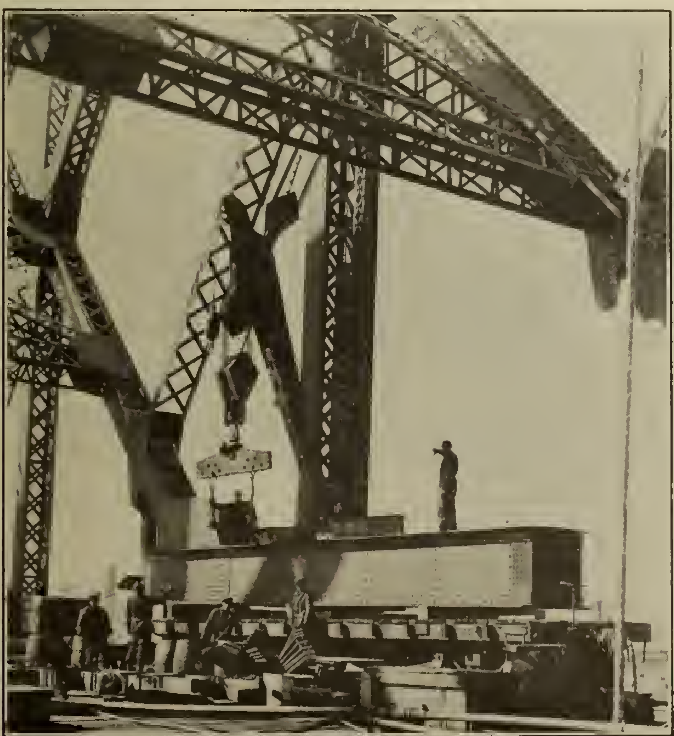

Figure No. 58.—Main Span, North Side—Arrangement of hoisting Derricks at *AL13*.

Figure No. 60.—Main Span, North Side—Erection proceeding on Cantilever Arm. Traveller No. 3 being set up on Anchor Arm.

Figure No. 61.—Main Span, North Side—Erection proceeding concurrently on Anchor and Cantilever Arms.

which would provide sufficient clearances at the centre for every contingency, all adjustments thereafter being in the nature of slacking off.

Before proceeding with the design of the mechanisms all the governing conditions were carefully reviewed and a study made of the data available on comparable operations, particularly the erection methods employed in the case of the Beaver bridge of the Pittsburgh and Lake Erie Railway, over the Ohio river at Beaver, Penn., in 1910. Although the mechanisms as finally designed are similar in many respects to those used in the bottom chords of the Beaver bridge, notable differences exist, particularly in the method of operating and in the use of wedges rather than toggles in the plane of the top chords. The loads to be carried were also considerably greater in the case of this structure and the range of movement to be provided for very much so.

It was a basic principle that the mechanisms be self-locking under load as uncontrolled slippage would have precipitated a disaster. It was desirable, however, to ensure the utmost ease of operation and singularly little data was available as to friction co-efficients under the conditions in question. The design was purposely very conservative in view of the importance of the operations, safety being the paramount consideration.

It was essential that the closure operations be planned and conducted with extreme care, not only to ensure geometrical accuracy in making the centre connections but also to guard against an uneven distribution of loading which, if sufficiently pronounced, might have produced serious stresses in different parts of the structure or in the wedge mechanisms themselves. A comprehensive memorandum was prepared on "The Erection of the Suspended Span," in which all important information was condensed and issued to those having a responsible connection with the operations, which followed rigidly the instructions laid down. This memorandum is reproduced in full in appendix "A," and reference to it is invited for detailed particulars. The actual operations will be discussed in the narrative dealing with the field-work.

Effect of Camber

It is common practice in bridge engineering to introduce "camber" into each structure with the object in view that the trusses will assume their geometric shape under dead load plus average or maximum live load, as may be specified, thus minimizing secondary bending stresses in the members at the time of maximum primary stress. This is accomplished by fabricating the members to lengths greater or less than the geometric accordingly as they are compression or tension members respectively. This change in length causes distortion in the structure when framed together with little or no stress in the members, such distortion being proportional to the permissible unit stresses and becoming particularly pronounced where the construction is of alloy steel with high permissible unit stresses.

In rivetted construction, the practice referred to above also requires that the members meeting at a point be

Figure No. 62.—Main Span, North Side—Further concurrent Erection Progress on Anchor and Cantilever Arms.

Figure No. 63.—Main Span, North Side—Stage completed. Tower at *AL9* removed and Traveller No. 4 being dismantled. Progress as at June 12th, 1928.

connected with true geometrical angles between their ends, the gusset connections being laid out accordingly during fabrication and all distortion being taken up by bending in the body of the members between their end connections. In ordinary construction the springing of the members is usually successfully accomplished by drifting at the connections during assembly. In large structures of heavy construction, however, where the distortions are pronounced, more elaborate methods must be adopted.

The chord sections and other members in which field splices occur must be held in proper alignment at the splices while these connections are being made and experience proves the necessity of at least partial rivetting of the splices before attempting to spring the members.

Figure No. 64.—Main Span, South Side—Traveller No. 8 being set up on South Approach. Temporary Piers at *AL7* under Construction. Progress as at June 22nd, 1928.

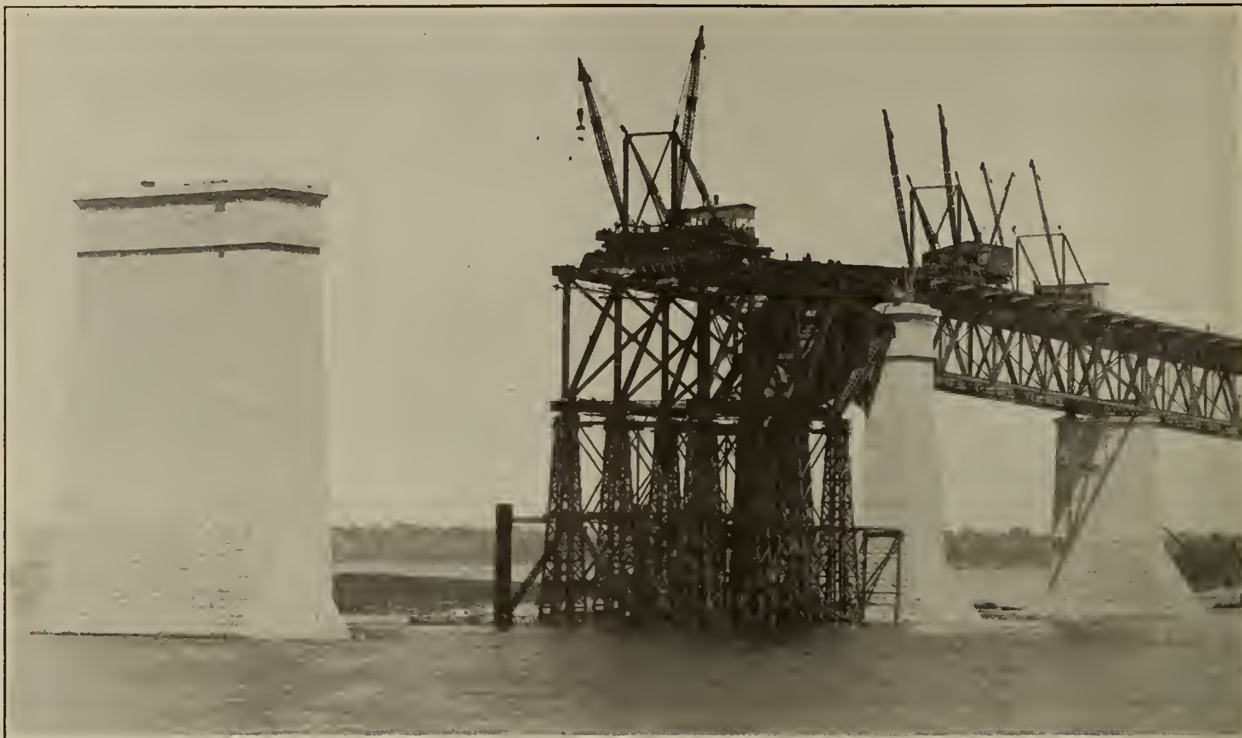

Figure No. 65.—Main Span, South Side—Erecting Falsework Span under Anchor Arm—First Stage.

After the making of the splices these members must then be sprung to meet the members they connect to, this necessitating the application of considerable force in the case of such heavy members as the chord sections.

In this instance the structure is cambered for dead load plus a specified live load of approximately 50 per cent on the channel span. The resultant springing in the main bottom chord sections was approximately ½ inch upward in each panel and required a force of about 10 tons at the ends of the heavier members. In the case of the main top chord sections the springing was in general about 1 inch upwards in each panel and required a force of about 20 tons at the ends.

In the latter instance the springing was accomplished without difficulty by means of the traveller booms. Jacking was resorted to in the case of those portions of the structure erected on the falsework spans as being simple and expeditious. For those portions erected by cantilevering, adjustable tackles were devised to support the bottom chord sections and lower diagonals during the making of the splices, being used thereafter in springing them to make their connections.

The arrangement of these tackles is illustrated in figure No. 39, the operating lines being carried to the spools of the hoisting engines.

Figure No. 66.—Main Span, South Side—Erecting Falsework Span under Anchor Arm—Second Stage.

Lifting Hitches

For convenience in handling at the shops and in the field, the heavier members were provided with "lifting hitch" brackets, these being bolted in place on the members in the shops. The position of these brackets was determined in advance to suit the handling conditions during erection, after the centres of gravity of the members had been located by calculation. The lifting tackle consisted of evener beams suspended on the derrick fall lines and connected to the lifting hitches on the members by wire rope slings with spools, using 3-inch diameter pins.

In the case of the main top chord webs, the lifting hitches were replaced by adjustable cradles which were placed on the members in the field prior to hoisting them.

Coating of Pins and Bushings

Before leaving the shop all pins, bushings and pin holes were given a protective coating of oil to prevent rust, the pins being crated to protect the finished surface from damage during shipment.

Immediately before the pins were driven in the field, the bearing surfaces of the pins, bushings and pin holes were thoroughly cleaned of all dirt and grease and were given a coating of hot paraffin.

Erection Falsework

North Anchor Arm

The falsework for the north anchor arm is shown in figure No. 49. It consisted of a steel tower at *AL9*, and a temporary span supported at its ends by the tower and main pier respectively, the span being a section of the long span provided for use the following season on the south side, with a few modifications at the end to be supported by the tower.

It was originally intended to use pile foundations under the tower but during the construction of the north main pier it was established that no suitable bearing stratum existed above rock, some 70 feet below ground level. It was also found that old wharf construction had previously been filled over in close proximity to the tower location, possibly presenting obstacles to the driving of piles. Pronounced settlements at the tower, particularly if unequal, were to be avoided and stable construction was decided upon.

Accordingly, two reinforced concrete caissons were sunk by the pneumatic process immediately under the respective trusses at *AL9* and carried down to rock about 80 feet below ground level at that point. The caissons

Figure No. 67.—Main Span, South Side—Arrangement for jacking of Falsework Span at *AL7*.

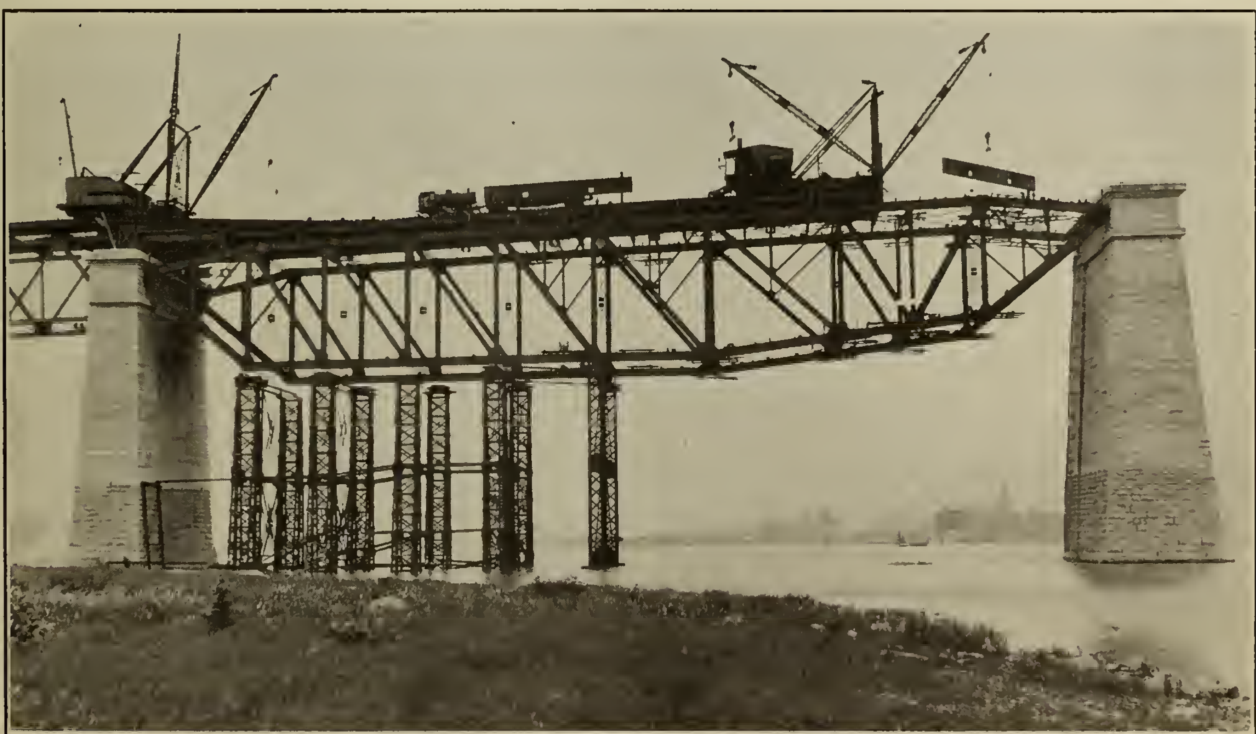

Figure No. 68.—Main Span, South Side—Erecting Falsework Span under Anchor Arm—Third Stage.

were 12 feet in diameter and consisted of a steel working chamber on top of which the concrete cylinder was built, stage by stage, as the working chamber was sunk. A shaft 3 feet in diameter was provided in the centre of each caisson with a combination man and material lock at the top. Four 2½-inch diameter anchor bolts were built into the caissons to stay the tower and the tops of the caissons were bush-hammered to a true surface at the proper level. This work was executed for the contractor by the Dufresne Construction Company Limited, of Montreal, contractors for the adjacent bridge sub-structure. It was commenced in January, 1927, and completed by the following April.

The tower consisted of two steel posts at 66 feet 6 inches centres, connected by substantial swaybracing. Each post was made up of two built webs 36 inches wide, spaced 5 feet apart, and connected by heavy lacing. The posts rested on planed steel slabs 4 inches thick which were set on the caissons on several layers of heavy canvas freshly coated with red lead. Each post was spliced in three sections with butt joints, the upper section being provided with large gussets for the connections to the falsework span. The posts were bored at the top for 15-inch diameter pins which engaged temporary shoes bolted to the underside of the bottom chords at *AL9* and were designed to transmit the load from the anchor arm to the tower.

After a review of the various conditions of loading on the tower an arbitrary maximum was adopted, provision being made for the weight of the structure and erection equipment, together with a 30-lb. wind pressure. Under the assumed conditions, the resultant maximum load on the top of each caisson was 1,500 tons and they were designed for this load. Silicon steel was used throughout the posts and in part of the bracing, the balance being of special carbon steel.

The temporary span, of which a description appears later, was connected to the top of the tower by pins of 11 inches diameter, independent pins connecting the chords and end diagonals to the post gussets. At the main pier end, the span was supported on rollers in recesses provided in the pier during construction. This end of the span was temporarily secured at the pier until the connection of the bottom chords to the tower had been made, after which it was released, the tower thereafter being braced from the main pier by the bottom chord and lateral system. The connection of the tower to the bottom chords was so located as to average the bending stresses due to temperature changes and varying deflections in the structure as erection progressed. Pedestals with jacking girders were provided at the main panel points for the temporary support of the upper structure.

Figure No. 69.—Main Span, South Side—Setting Main Shoe on Main Pier.

South Anchor Arm

The falsework for the south anchor arm is shown in figure No. 71. It consisted of a temporary span, 402 feet long between bearings and supported at its ends by the main and anchor piers respectively. It appeared unlikely that this span could be adapted for commercial use afterwards and it was, therefore, designed solely for convenience and economy during erection. It was necessary to provide ample clearance between the top chord of the span and bottom chord of the bridge to permit blocking and jacking under the panel points of the anchor arm. A pedestal was developed for the support of the main points with jacking girders incorporated, the difference in the chord widths being provided for in the pedestal design and the arrangement necessitating a uniform clear distance between the chords of 4 feet 9 inches. The design of the piers limited the location of the recesses for the support of the span to that selected, thereby governing the shape of the end panels. The depth of the trusses was chosen for economy, a portion of the bottom chord being made horizontal to facilitate its support during the erection of the span itself. The general arrangement, while hardly pleasing to the eye, nevertheless proved exceedingly practical.

The span was provided with top laterals and sway-bracing, but bottom laterals were omitted; it was assumed that the overturning effect of the wind pressure on the span would partially offset that on the anchor arm and the traveller. Methods were devised for making use of the permanent floor system in temporary position on the span during its erection, as the cost of an independent floor would have been excessive. The material required for the span was thus limited to the trusses, top laterals and bracing.

As previously outlined, the method of erecting the superstructure consisted in setting up four panels of the anchor arm with the tower traveller, followed by concurrent erection of the cantilever arm with the tower traveller and the rear portion of the anchor arm with a deck traveller. A complete schedule of operations was developed, a feature of which was that each anchor arm truss would have a single main point of support at all stages, this point being transferred backwards from the main pier panel by panel as erection progressed. This method of support undoubtedly required somewhat heavier material in the span than would have been necessary if the anchor arm had been left supported at each panel point. The uncertainty as to the weight distribution in the latter case would, however, have prevented full advantage being

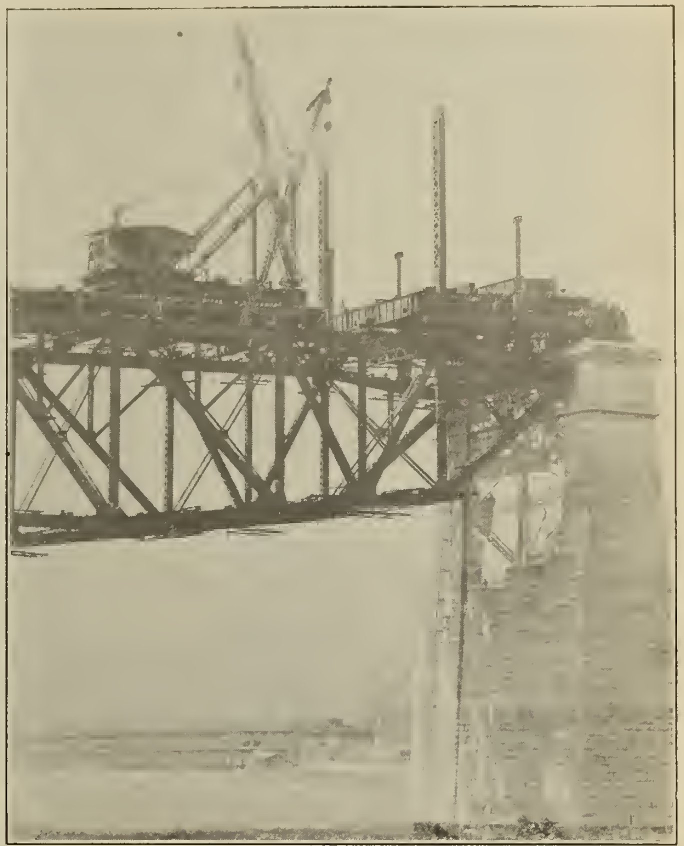

Figure No. 70.—Main Span, South Side—Erecting Bottom Chords and Floor System of Anchor Arm—First Stage.

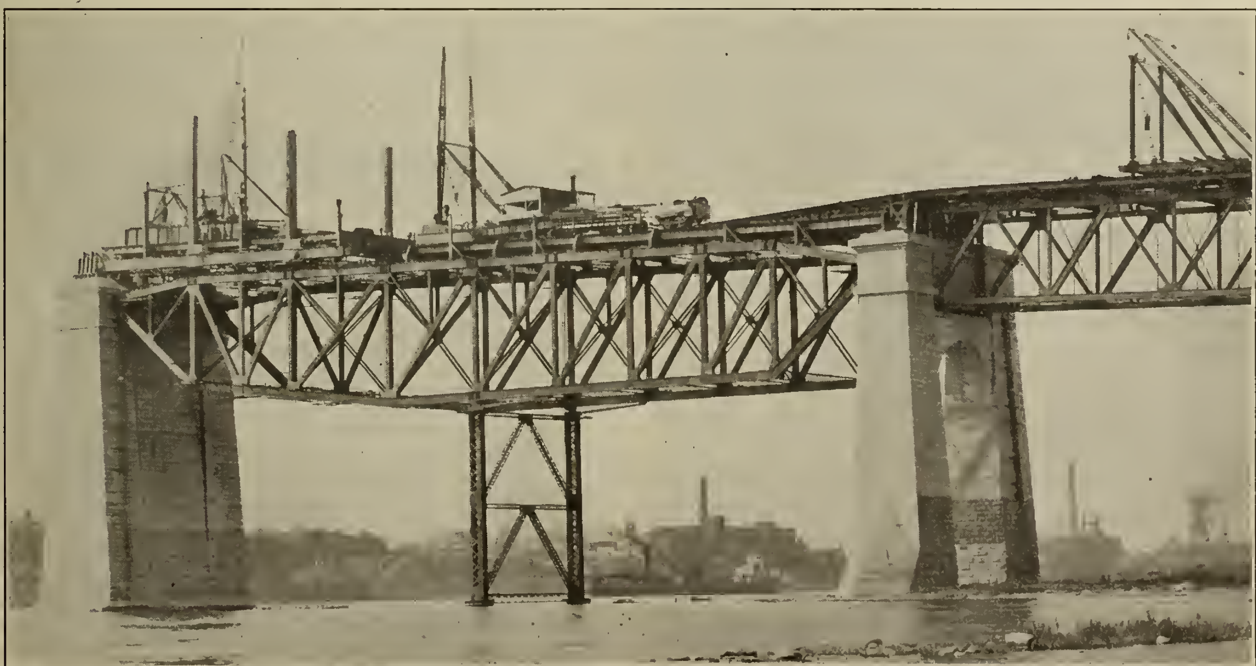

Figure No. 71.—Main Span, South Side—Erecting Bottom Chords and Floor System of Anchor Arm—Second Stage. Erection also commenced on Traveller No. 4.

Figure No. 72.—Main Span, South Side—Erecting Bottom Chords and Floor System of Anchor Arm—Third Stage. Erection proceeding on Traveller No. 4.

taken of the theoretical economy. The method adopted was much the safer, and very much more simple and expeditious in operation.

The loads on the span were calculated for the various stages and the span designed accordingly, provision being made for the weight of the structure and erection equipment, together with a 30-lb. wind pressure. Silicon steel was used throughout the trusses and in part of the bracing, the balance being of special carbon steel. The members were of standard design, the chords being 42 inches in depth with two webs 28 inches apart and with butt joints.

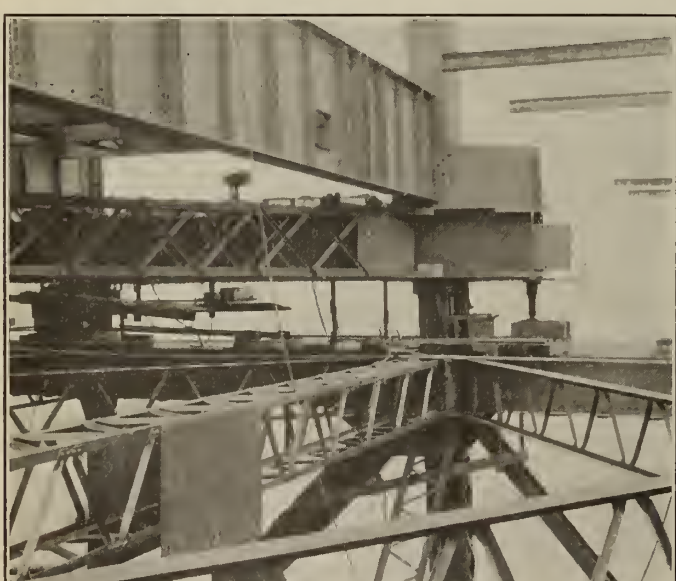

Figure No. 73.—Main Span, South Side—Method of supporting Bottom Chords on Falsework Span.

The erection of the temporary span was in itself a work of some importance. It was necessary to commence at the south anchor pier, and after a study of the river bottom conditions, it was decided to erect the first portion of the span on falsework and cantilever the remainder to the main pier, this necessitating a main point of support near the midspan in the form of a tower. This tower support was at first intended to be under *AL9*, but further examination of the bottom resulted in a change to *AL7*, from which point the distance to the main pier is 212 feet. As the maximum load to be carried on the tower during the erection of the span was 1,230 tons per truss, use was made of a steel tower composed of the lower two sections from the tower as used on the north side with special caps on

Figure No. 74.—Main Span, South Side—General Arrangement of Pedestals on Falsework Span.

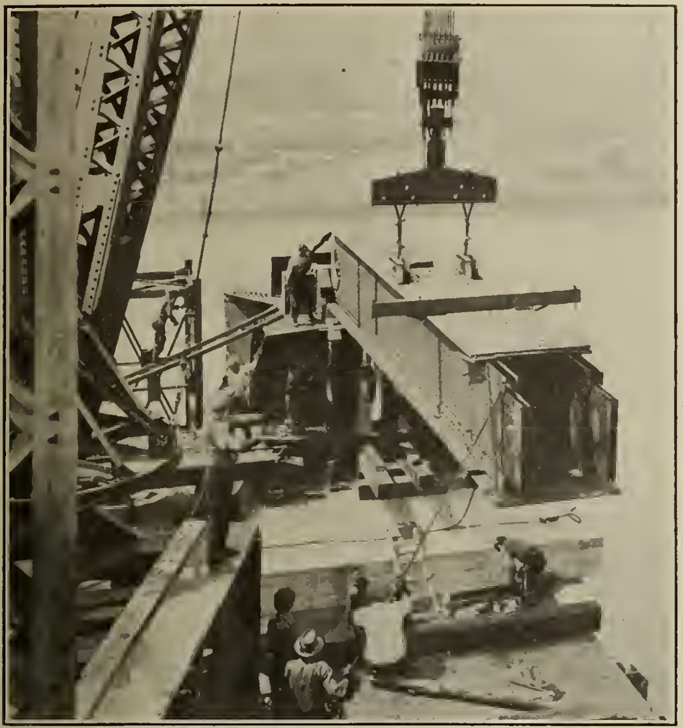

Figure No. 75.—Main Span, South Side—Placing First Bottom Chord Section of Anchor Arm.

the tops of the posts. These caps were designed to permit the span being jacked at that point during the process of landing on the main pier. The top of the tower was braced to the span by horizontal pin-connected struts extending from the top of each post to brackets on the underside of each truss at *AL5*. The magnitude of the erection stresses in the span required reinforcement in the trusses and bracing over the tower, this being liberally provided.

To provide adequate foundations for the tower, two circular piers were built under the respective trusses at *AL7*. Steel cylinders 12 feet in diameter were sunk to the bottom and anchored to protective cribs. The hardpan bottoms within the cylinders were shattered with explosives and cleared by clamshelling, after which the bottoms were sealed with sandbags by a diver. Concrete to a thickness of about 3 feet was then deposited under water, after the setting of which the upper shells were pumped dry and the remaining concrete poured to the desired level, anchor bolts being set at the same time. The tops of the piers were treated in the same manner as at the caissons on the north side. This work was executed for the contractor by Quinlan, Robertson & Janin, Limited, of Montreal, contractors for the substructure south of St. Helen's island.

The timber falsework under the temporary span was of the same general type of construction as used for the south approach. It was erected on low concrete pedestals which had been constructed the previous autumn.

The temporary span was placed on fixed bearings at the main pier to reduce to a minimum any difference in longitudinal movement at the points of support, due to temperature variations or changing deflections. At the anchor pier, the span was carried on rollers, this end being secured against movement during the erection of the span and released after its completion. Possible uplift at the anchor piers during erection of the span was provided for by blocking the ends in the recesses to engage the weight of the pier and by additional weight on the span adjacent to the pier.

Erection Travellers

The type and number of the travellers required by the erection programme has been previously outlined, with the considerations which led to their adoption. A brief description of the respective types follows.

Travellers Nos. 5 and 6

These travellers, (see figure No. 42), which were similar, were the towers set up on the ground on the north side for the first stages of erection. Each consisted of a well braced timber tower 40 feet square and 120 feet high, mounted on a structural steel base, which was in turn carried, on two runways parallel to the bridge. The runways were spaced 40 feet apart, the nearer one being 20 feet outside the line of the bridge, and consisted of lines of 85-lb. rails laid on timber cribwork. As the runways extended over the yard service tracks, the cribwork was arranged to permit any track being readily cleared by the removal of sections. As a track became blocked by the traveller in a working position, another track was cleared for the passage of material. The travellers were moved on the runways by means of solid 2½-inch diameter rollers, bearing slabs being provided under each corner of the base.

The tower posts were built of 12- by 12-inch B.C. fir, four being used at each inner corner and two at each outer. Each tower face was double-braced with 4- by 8-inch timber, and the whole additionally braced against sway by wire cables with turnbuckles.

Figure No. 76.—Main Span, South Side—Placing Second Bottom Chord Section of Anchor Arm.

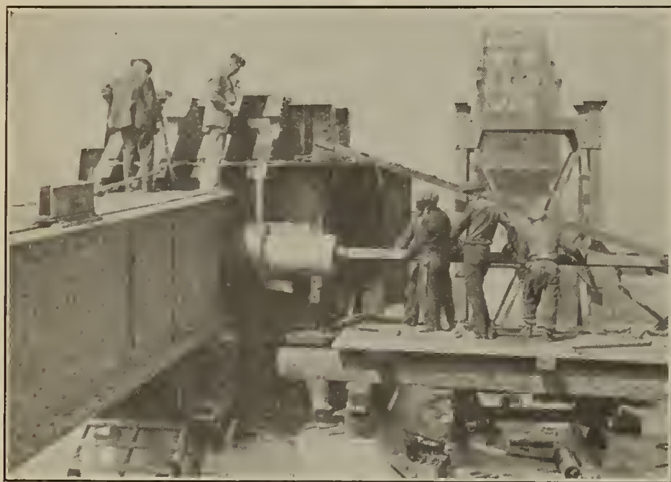

Figure No. 77.—Main Span, South Side—Driving Pin connecting Bottom Chord to Main Shoe.

A steel stiffleg derrick was mounted on the top of each tower with the mast over a forward corner, the derrick falls being led down inside the post to a special footblock at the base from which they were carried to a hoisting engine placed on the diagonally opposite corner of the base. Each derrick was equipped with a 75-foot boom provided with main falls of 50 tons capacity and an auxiliary line of 5 tons capacity for light loads. The main falls consisted of twelve parts and the boom falls of seventeen parts of ⅞-inch diameter special wire rope. Swinging of the booms was provided for by 9 feet diameter bullwheels, operated by independent single drum steam hoists on the top of the tower. The derrick falls were operated by 10- by 12-inch 3-drum steam hoisting engines specially designed and built by the Canadian Mead-Morrison Company, Limited. Steam was supplied by a 60-inch diameter vertical boiler.

The derricks and towers were designed for a load on the boom of 50 tons at 35-foot radius, at any point on the swinging arc of the boom. Uplift from the stifflegs was provided for by 1¼-inch diameter wire cables with turnbuckles, attached directly to the legs and carried down to the base of the traveller where counterweight was provided in the form of pig iron. Each traveller weighed 315 tons in working order.

TRAVELLER No. 4

This traveller, (see figures Nos. 54 and 78), was designed for the erection of the high portions of the structure adjacent to the main piers. It was of steel construction throughout and consisted of a tower 108 feet high mounted on a base consisting of two longitudinal girders connected by cross girders. The longitudinal girders were 8 feet 4 inches deep and 74 feet long, and were spaced 37 feet 2 inches apart. It was essential that the traveller be supported directly by the floorbeams of the bridge in all working positions; the longitudinal girders were, therefore, designed for the purpose, the underside being kept about 6 inches above the top of the floorbeams and shims placed at the points of support. The traveller was in general supported on floorbeams two sub-panels apart, the lengths of the girders being governed by special conditions at the main piers. The cross girders were 4 feet deep and connected near the top of the longitudinal girders. They carried the floor on which was placed the hoisting equipment and, during movement of the traveller, transferred the weight through special loading girders to four trucks placed below the base on the traveller tracks 24 feet apart. The trucks were 4-wheeled, and equipped with a 100-ton hydraulic jack on each by means of which the weight of the traveller was transferred to the trucks during movement from one working position to another. The trucks were so located as to divide the weight equally over all during the movement of the traveller.

The tower was carried directly on the longitudinal girders, the depth parallel to the girders being 27 feet as determined by the available space in the first position on the cantilever arm where it was necessary to clear the swaybracing of the main post. The tower was rigidly braced on all faces.

Two stiffleg derricks were mounted on the top of the tower with their masts on the centre line of the bridge, at the front and rear respectively. The derrick falls were carried down to guide sheaves near the foot of the tower and thence to the hoisting engines on the floor. The derricks were equipped with 70-foot and 60-foot booms respectively each provided with main falls of 35 tons capacity and an auxiliary line of 5 tons capacity. The main falls consisted of eleven parts and the boom falls of seventeen parts of ⅞-inch diameter special wire rope. These derricks were also provided with 9-foot bullwheels operated by independent swinging engines on the floor. Considerable ingenuity was required to obtain an arrangement at the top of the tower whereby the derrick backlegs cleared each other, this being finally accomplished by stepping the front derrick about 2 feet higher than the rear and by making the masts of different height. The derricks were operated by steam hoists similar to those on travellers Nos. 5 and 6, one boiler being found capable of supplying all the steam necessary.

The arrangement of the derricks permitted each boom a swinging arc of about 240°, it being thus possible to use one or both booms on either side. The capacity of the

Figure No. 78.—Main Span, South Side—Rear View of Traveller No. 4 and of Deck. Erection proceeding on Anchor Arm.

booms was governed by heavy lifts to the front and rear which could be handled by one boom only. On the other hand such long members as the top chords and upper diagonals were erected with the travellers alongside, permitting both booms to be used with moderate loads on each and ensuring perfect control during the hoisting and connecting of the members. The boom to the rear placed the swaybracing between the trusses as the traveller moved forward.

On the cantilever arm the tower was erected with its front face at the extreme forward end of the base. On the anchor arm, however, it was moved back 13 feet 6 inches to obtain a more convenient working position in this case for the derricks and permit the completion of the swaybracing in each panel immediately after the traveller had moved to its next position.

This difference in the tower position necessitated a re-arrangement of the hoisting equipment when the traveller was moved from the anchor to the cantilever arm, the trucks being also re-arranged to maintain equalized loads during movement. The clearance under the sway-bracing over the roadway made it unnecessary to remove any of the hoisting equipment from the traveller base during its transfer to the cantilever arm. Movement of the traveller along the floor was provided for by hauling ropes leading from a forward floorbeam to the main falls, over sheaves on the traveller base. The traveller was securely moored in each working position against movement down the grade.

The height of the tower was determined after the length of the booms had been decided, and was governed by the reach necessary when placing the links at the top of the main posts.

The traveller was stable in the working positions without counterweight or anchorage. The weight in working order was 320 tons.

Figure No. 82.—Main Span, South Side—Erecting Top Chord Web showing Method of Handling.

TRAVELLERS NOS. 3 AND 8

These were the deck travellers, (see figure No. 70), used for the erection of such portions of the structure as were within reach from the floor with the exception of the central panels of the suspended span. Each traveller consisted of a structural steel base on which were mounted two stiffleg derricks. Traveller No. 3 was used on the north side and traveller No. 8 on the south, both bases being alike in construction but the derricks on No. 8 being of greater capacity than on No. 3.

The base consisted of two longitudinal box girders 3 feet deep and 60 feet long with connecting beams and bracing, these girders framing into a transverse loading girder at the front 6 feet deep and 38 feet 6 inches long. The longitudinal girders were spaced 24 feet apart over the traveller tracks, each girder being carried on two 4-wheeled trucks spaced 40 feet apart. The rear trucks were designed to permit the elevation being changed to suit the varying gradient towards the centre of the span, the traveller deck being thus kept level at all times. In each working position the loading girder was kept over a floorbeam of the bridge and blocked from it by shims at points 37 feet 2 inches apart, the traveller base being first jacked clear of the front trucks. The beams between the longitudinal girders provided a floor on which was placed the hoisting equipment.

Two steel stiffleg derricks were mounted on the base of each traveller, the masts being placed at the junction of the cross girder and longitudinal girders, 24 feet apart. The masts were braced together in the front plane and the backlegs connected directly to the longitudinal girders. Traveller No. 3 was equipped with two 75-foot booms provided with main falls of 30 tons capacity and a 5-ton auxiliary line. Traveller No. 8 was equipped with the masts and booms from travellers Nos. 5 and 6 which were dismantled before No. 8 commenced operations. The backlegs of travellers Nos. 5 and 6 were used for the same purpose on the deck travellers. The boom swinging equipment, hoisting engines and boilers were of similar type to those used on the other travellers. An auxiliary 6-ton derrick was set up on the rear end of traveller No. 3 for the erection of the swaybracing on the north anchor arm.

The travellers were securely moored in all working positions against movement down the grade and were moved from one position to another by rigging similar to that employed on traveller No. 4. They were stable against overturning in most working positions, the rear ends being anchored to the floor by heavy cables in the case of a few heavy lifts. Each traveller weighed 180 tons in working order.

Wedge Mechanisms

The wedge mechanisms used for the final closure at the centre of the suspended span are illustrated in figure No. 40. For descriptive purposes, each unit may be divided into four parts, as follows:—(a) wedge unit, (b) shoes, (c) links, and (d) cross-head and operating unit.

(a) The wedge unit consisted of the wedge proper and the operating shaft.

The wedge proper was a steel casting 6 feet 6 inches long and 2 feet wide, tapering in the plane of the truss from 25 inches at the bottom to 12 inches at the top. The tapered bearing surfaces were machined and polished by hand to a bevel of 1 in 12 with respect to the vertical axis. The flanges were also machined on the edges to a uniform width.

The operating screw was of forged steel 6 inches in diameter and 14 feet 6 inches long. It was inserted in the wedge casting, the lower end being forged into a square head and fitted in a socket in the bottom of the wedge. The screw was rigidly secured in the wedge by a lock nut mounted on the projecting portion of the shaft which was threaded with ½-inch pitch Acme thread.

(b) The shoes were two in number, mounted on the opposite bearing surfaces of the wedge casting. Each shoe was a steel casting, bored to bear on the pins placed in the chords. The surface facing the wedge was machined and lined with ¾-inch "Lubrite" plates, these being of bronze and studded with holes filled with graphite. These liner plates were for the purpose of reducing the sliding friction: they were secured to the casting by stud screws and also held in place by flanges of the shoe which engaged the machined edges of the wedge casting. The upper portion of the shoe was cast in the form of lugs which were bored for 3¼-inch diameter pins.

(c) The links were built of structural steel in the form of box struts, bored at the ends for 3¼-inch diameter pins with which they were connected to the shoes and cross-head respectively.

(d) The cross-head and operating unit consisted of the cross-head, the operating nut with thrust bearings and wormwheel attached, the worm and shaft, and the hand-wheels.

The cross-head was a steel forging 4 feet long, 19 inches wide, and 12 inches deep. The centre was bored vertically to receive the operating nut and the ends were slotted vertically and bored for the pins connecting the cross-head to the links.

The operating nut was of bronze, 9½ inches diameter and 28 inches long, the lower end being enlarged to a diameter of 19 inches to form a shelf on which was placed a heavy-duty ball thrust bearing. The nut was threaded to fit the operating screw, on which it revolved in the cross-head.

The nut was first assembled in the cross-head, with the latter resting on the ball thrust bearing. The wormwheel was then threaded onto the top of the nut above the cross-head and secured to the nut with tap-bolts, a bronze washer of 14 inches diameter and ¾ inch thickness being first placed between the wormwheel and cross-head. The

Figure No. 83.—Main Span, South Side—Erection commenced on Cantilever Arm.

Figure No. 84.—Main Span, South Side—Ice Conditions on March 28th, 1929, just prior to Resumption of Erection.

wormwheel was of cast iron with a rim of Hy-ten-sl bronze bolted securely to it, the latter being cut to match the pitch of the worm.

The worm and shaft was forged and turned as a single unit of 0.40 carbon steel, the shaft being 3 inches in diameter and 4 feet 6 inches long. It was supported on bearings on a heavy steel plate, mounted at one end of the cross-head and firmly secured to it by stud-bolts. The bearings were bronze bushed, and a ball thrust bearing was also added.

Handwheels of cast iron, 28 inches in diameter, were placed on each end of the worm shaft for operating purposes, short handles being attached to the rims. The rims were also provided with sockets in which bars could be inserted at will to obtain a greater leverage.

A graduated vertical scale was attached to each wedge casting and a fixed pointer placed on each cross-head. In this manner, movement of the wedge with respect to the shoes was readily recorded.

Each wedge mechanism was fully assembled in the shops and operated to overcome the initial stiffness of the parts. Tests were then conducted on all wedges to determine the frictional resistance of the operating devices, it being found impracticable to carry out satisfactory tests on the sliding friction between the wedge and shoes. The results of these tests were remarkably uniform and agreed closely with the assumptions used in the design of the mechanisms.

Before leaving the shop each wedge was set carefully in a pre-determined position, all operating parts were thoroughly cleaned and lubricated, and grease cups filled. Metal hoods were then placed over the operating screws and worm drives to protect them from dirt and rain. Each mechanism was securely blocked and clamped for shipment as a unit, the exposed machined surfaces being protected by burlap wrapping.

The design of the operating parts of the mechanisms was governed by the frictional resistance between the moving parts. It was assumed that the sliding friction between the wedge and shoes would exceed the vertical component of the load on the wedge,—in other words, that the coefficient of friction would in this case exceed 0.083. Under this condition, the operation of the wedge would entail compression in the operating screw with resultant tension in the links, the torque required to operate the mechanism being governed by the sliding friction between the wedge and the shoes, the rotating friction of the nut on the operating screw and the rotating friction between the wormwheel and worm. Maximum coefficients of friction were assumed as being 0.18, 0.15 and 0.10 respectively and the operating parts designed accordingly for a maximum load on the wedge of 800 tons.

There remained the possibility, however, that the coefficient of friction between the wedge and shoes might prove to be less than 0.083, in which case the inclination of the wedge to slip out from between the shoes would entail tension in the operating screw and compression in the links. Under this condition the load from the operating screw would be transferred to the cross-head through the bronze washer above instead of through the ball thrust bearing below. Free movement of the wedge would be restricted by the friction on the washer as well as that of the nut on the screw and that of the worm drive. Investigation established that the mechanisms were self-locking under any conditions that might reasonably be expected.

As a matter of interest, it was found during the use of the mechanisms in the field that the coefficient of friction between the wedges and shoes was in all cases and at all stages less than 0.083, being apparently about 0.06. The load from the operating screw was transferred to the cross-head through the bronze washer, the ball thrust bearing being free of load throughout. The principal result of this action was that the advantage in ease of operation from the low friction between the wedge and shoes was offset by the friction on the bronze washer being considerably greater than would have been the case with the load on the ball thrust bearing. The effort required to operate the mechanisms was approximately equal to the maximum provided for and much greater than was actually expected. Had this condition been anticipated, a ball thrust bearing might have been used in place of the bronze washer and some parts of the mechanism reduced in size. The mechanisms, nevertheless, operated very satisfactorily as actually designed, no difficulties being experienced in the making of the required adjustments.

Field Operations on Main Span

The field programme for the main span resolved itself into three divisions,—north side, south side and centre section respectively. The operations will be described in narrative form with special reference to features of an unusual nature. Numerous illustrations have been included from which the details of the methods and equipment used may be better understood.

North Side

Season of 1926

The north anchor pier was built by the contractor for the substructure during the summer of 1926. During its construction, the anchorage grillages were set in place, the location and levels being carefully checked. (See figure No. 41.) The pier was thereafter completed, wells being provided for the members connecting the anchor arm trusses to the anchorage grillages.

Season of 1927

Commencing in May, 1927, the north storage yard was installed with the necessary railway sidings and other facilities. Travellers Nos. 5 and 6 were then erected on cribwork runways on either side of the anchor arm, the towers being set up by a locomotive crane with lengthened boom and the derricks assembled on the tower by auxiliary equipment. Owing to the limited ground space on the north side, the timbers for the traveller towers were cut to length, bored for bolting and framed in convenient handling units in the south storage yard, from which point they were shipped by rail to the north storage yard. Figure No. 42 shows these travellers in a nearly completed condition. The first operation was the assembling of the shoes in place on the main pier, (see figures Nos. 43 and 44), their setting being checked by means of previously established centre lines and the pin bearings of all four webs carefully aligned. Rivetting of the shoes was proceeded with immediately after their assembly as the interior connections became inaccessible for this purpose with the adjoining members in place.

Meanwhile the travellers were moved as far back from the main pier as possible and the steel tower set up on the caissons at *AL9*, the splices of the tower posts being fully bolted and the bracing connections rivetted. The temporary falsework span was then erected on timber falsework, commencing at the tower and working towards the main pier. The early stages are illustrated by figures Nos. 45 and 46, and special attention is drawn to the congested condition of the railway tracks and power wires at this point with the obvious restrictions imposed on the erection. The span was erected sufficiently high to enable the end members being entered in the recesses at the main pier and connected, after which the span was landed on its roller shoes in the recesses by jacking on the timber falsework under *AL13*. The final stage is illustrated by figure No. 47. As the stresses in the span were at all stages much lower than for those for which the members were designed, except in the diagonals adjoining the tower, the truss and bracing

Figure No. 85.—Main Span, South Side—Erection proceeding concurrently on Anchor and Cantilever Arms.

Figure No. 86.—Main Span, South Side—Arrangement for jacking at Anchor Pier.

connections were bolted sufficiently for the stresses to be carried, except in the case of the above diagonals which were rivetted. The general arrangement of the travellers and falsework is also shown in figure No. 48, a view from the top of the north anchor pier. On the completion of the temporary span, the timber falsework was dismantled and removed.

The bottom chords and laterals of the anchor arm were next erected on the temporary span, commencing at the main pier and continuing to *AL9* at which point the special shoes on the underside of the chords were connected to the tower by driving the pins. The temporary span which had been previously secured to the main pier was now released, the tower being braced longitudinally through the bottom chord and lateral system to the pier. The chords were supported at the main panel points on steel pedestals, shims being used to obtain the desired elevations. Timber trestles were used as temporary supports at the intermediate points. The placing of the first chord sections is illustrated by figure No. 49 which also shows the pedestals in place on the temporary span.

Particular care was taken to ensure good bearing at the chord splices, the ends of the members being thoroughly scraped before assembly to remove paint, and any burrs filed away.

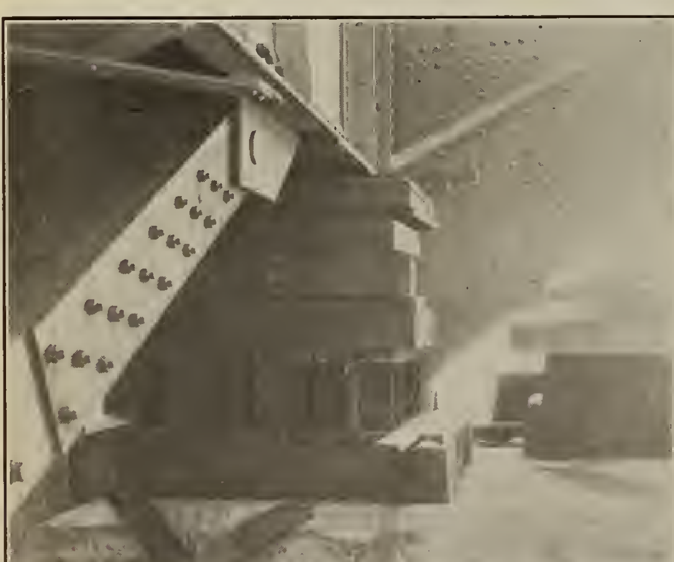

Figure No. 87.—Main Span, South Side—Arrangement of Shims and Blocking at Anchor Pier.

For the chord sections supported on the temporary span, the procedure in making the splices was to first connect the bottom flanges, using turnbuckles to ensure good contact. The bottom flange connections were then fully rivetted, after which the forward end of the chord being placed was raised carefully by jacking to bring the entire face at the splice in close contact. The joint was carefully inspected with "feelers" during this operation and not accepted until only occasional clearances of under seven thousandths of an inch were found. The splice was then bolted tightly to the extent of about 50 per cent and completely rivetted, it being found that after the rivets were cold the slight upsetting from the rivetting was apparently sufficient to take up all clearance at the joint and establish perfect contact. A certain amount of trouble was experienced at the first splices before satisfactory methods were fully developed but this was corrected, and eliminated in the making of the remaining joints.

On the completion of the chord splices and the connection to the tower at *AL9*, the lower verticals were erected together with the floor system, working from the tower to the main pier. (See figure No. 50.) At the sub-panel point *AL10* the sub-verticals, to which the floorbeam connects, were supported and braced directly on the chords; at the other sub-panel points the sub-verticals were replaced by temporary extension brackets to provide clearance while handling materials to the deck with travellers Nos. 5 and 6. The end connections of the floorbeams and longitudinal roadway stringers were at once rivetted and the service and traveller tracks laid on the deck.

Traveller No. 4 was now erected on the deck adjacent to the main pier, the lower portion being handled by lengthened booms on travellers Nos. 5 and 6 and the upper portion by auxiliary equipment. (See figure Nos. 51 and 52.) A rear view of the base is shown in figure No. 53 during the installation of the hoisting engines.

The first section erected by traveller No. 4 consisted of the three lower sections of each main post and the connecting portal strut, lower diagonals *AM13L15*, sub-diagonals *AM14M15* and sub-chords *AM13M15*, (see figures Nos. 54 and 55). The post sections were held upright by temporary connections at the base and each splice was partially rivetted immediately after assembly. The sub-chords were temporarily connected to the posts at *AM15* by adjustable details by means of which the distance between *AM13* and *AM15* was set to a pre-determined dimension which compensated for the shop camber in the members of the first panel and was intended to facilitate the connecting of the members at the top of the post. The traveller was next moved forward until its tower was immediately behind the portal strut, in which position it erected a portion of the first panel of the cantilever arm. This portion consisted of the first section of bottom chords and laterals, lower diagonals *CL13M12*, sub-diagonals *CM13M12* and the floor system to *CL12*, this providing a base for the future erection of the traveller on the cantilever arm. The outer ends of the chords were supported by adjustable tackles connected at one end to cradles bolted on the underside of the chords and at the other end to temporary brackets on the main post near its midpoint.

Traveller No. 4 having been moved back to its first position, completed the erection of the main posts, links and swaybracing between, the splices of the post sections being partially rivetted as placed. In the erection of the links, the inner sections were placed first and stabilized by a temporary connection to the main post on the cantilever arm side, the pins connecting the link sections to the extended wings of the upper post sections being driven part way through from the inside. The outer link sections were then placed and the pins just referred to driven home, thus providing a stable connection for the links with the sections in proper alignment. The link sections having been connected were rivetted together. The upper diagonals *AM13U15* were next erected, the pins at *AU15* being first driven and the connections at *AM13* then drifted home. This connection was made without difficulty as the result of the initial adjustment in the sub-chords *AM13M15*.

The upper verticals *AM13U13* having been placed, the top chords *AU13U15* were erected, each in two sections. Each section was about 84 feet long and weighed 45 tons. To avoid the difficulty of warping such long members through the trusses, each section was raised in turn from the ground on the boom of traveller No. 5 or No. 6 and transferred in mid-air to the booms of traveller No. 4, the falls of which were connected to special lifting cradles spaced about 30 feet apart on the chord section. These cradles were made adjustable for the varying depth of the chord sections and were placed on them on the ground in advance; they were specially designed for quick placing and removal. Such a detail was rendered necessary by the fact that it was impossible to provide holes in the top flanges of the chords for the usual type of hitch. Each inner section was placed first and the pin at *AU15* driven halfway through from the inside, thus engaging the chord section and two webs of the link; the other end was then bolted at *AU13*. The outer sections were placed last, the pins driven home, and the connections completed at *AU13*. Detail connecting the two webs of a chord, such as lacing or tieplates, was hoisted in bundles and assembled in place by hand.

Traveller No. 4 was now moved back into the second panel. In the typical moving operation the traveller was first raised sufficiently by means of 100-ton hydraulic jacks on each truck, to permit the removal of the shims from between the traveller girders and the floorbeams, after which it was lowered onto the trucks. The traveller was then eased back to its next position, being kept in control by cables leading from the traveller base to hooks engaging the top flange of a floorbeam and thence to the main falls of each boom. On reaching the next working position the traveller was jacked from the trucks and shimmed on the floorbeams in readiness for further handling. The entire moving operation was quickly executed, taking about two hours on the average to complete.

As soon as the traveller was in working order in the second panel, the swaybracing was placed behind in the planes *AU13M13M14*, this completing the first panel of the anchor arm. The diagonals for the second panel were next placed and connected at *AM11*. Four 285-ton hydraulic jacks were now placed on the jacking girders of each of the pedestals under the bottom chord at *AL13* and the load taken by them. The height at *AL13* was then adjusted by the jacks to enable the connections of the lower vertical to the diagonals at *AM11* after which the shims at *AL13* were removed, thus transferring the point of support from *AL13* to *AL11*. The panel was completed by the erection of the upper verticals and top chords, the latter members in this instance being placed on the floor by the booms of travellers Nos. 5 and 6 and there taken by the booms of traveller No. 4. The top chords were first connected at *AU13*, being held in alignment on the falls until the bolting was well advanced. The connections to the upper verticals at *AU11* were then made, the chords being sprung the required amount by means of the traveller booms.

The third panel was erected in similar manner. At the corresponding stage the hydraulic jacks were transferred to the pedestals at *AL11* and the connections completed at *AM9*, the shims at *AL11* being, however, left in place. This stage of erection is illustrated by figure No. 56 and attention is called to the arrangement of the top chord splices of which those at *AU9* are typical. The splices were designed as lap joints, the main material at each end

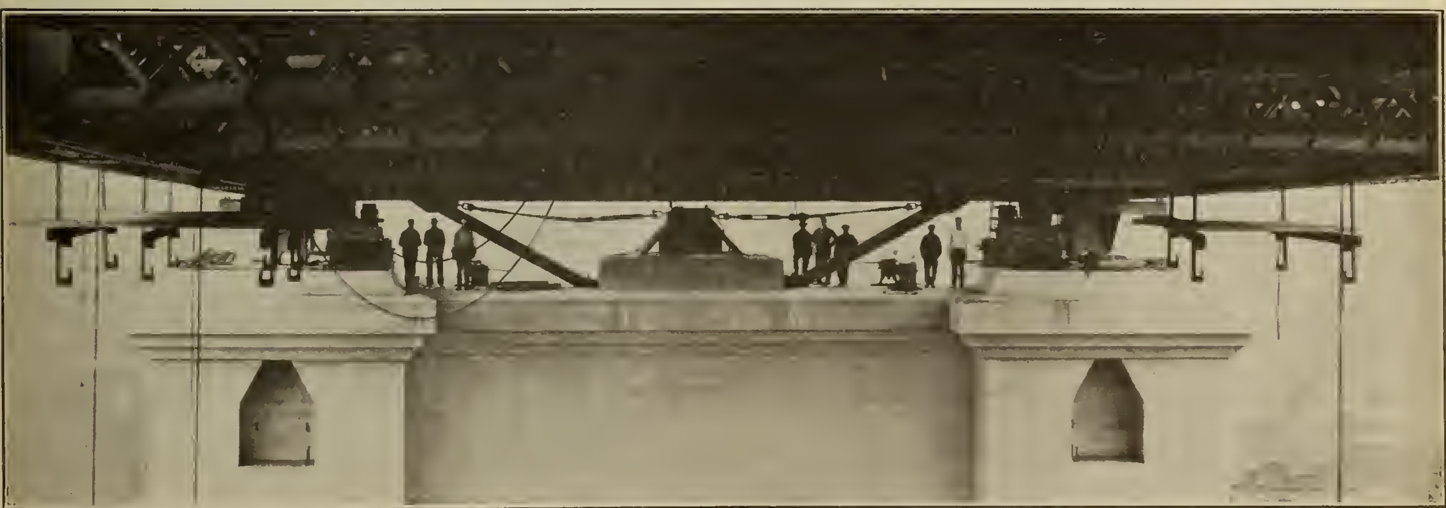

Figure No. 88.—Main Span, North Side—General Arrangement at Anchor Pier while jacking Anchor Arm for Connection to Anchorage.

Figure No. 89.—Main Span, Centre Section—Detail at *SL0* showing Erection Wedge Mechanism in Place.

of the chord sections being cut at several planes. The splice material was rivetted to the chords, that on one side of each web to one section and that on the other side to the adjoining section, resulting in a stepped arrangement at the end of the section, as illustrated, which eliminated forked ends and greatly facilitated the erection of the chords.

A temporary strut having been placed between the upper verticals at *AM9*, the traveller was moved back to just clear the strut and the panel beyond the tower erected, this completing the portion of the anchor arm which it was necessary to erect with traveller No. 4 on account of the height. The traveller, having been moved again to its first position in the third panel, erected the bracing at *AU9M9-M10*, after which the shims at *AL11* were removed. This operation relieved all load from the temporary span, the erected portion of the anchor arm being supported entirely by the main pier and the tower at *AL9*.

The temporary span was now dismantled for use on the south side and concurrently, traveller No. 4 was moved from the anchor to the cantilever arm. In this operation, the tower was dismantled, the base moved forward until its front stood at *CL12* on the cantilever arm, and the tower re-erected on the channel side of the main post. In this case the tower was mounted at the forward end of the base, this necessitating some re-arrangement of the hoisting engines and other equipment. Erection proceeded on the first panel of the cantilever arm, the second bottom chord sections being placed and supported by adjustable tackles similar to those already supporting the first sections. By means of these tackles, the adjoining sections were aligned and the splices rivetted. The procedure in this case differed somewhat from that where the chords were supported on the temporary span. The top flanges were first connected and rivetted, the outer end of the chord being then eased off on the adjustable tackles to establish close contact over the entire face. The remaining web members having been erected and connected, the chords were adjusted by means of the outer tackles and connected to the lower verticals at *CL11*. This stage is illustrated by figure No. 57, and was reached by December 15th, 1927, erection of the superstructure being then suspended for the winter.

Season of 1928

During the winter months preparatory work was carried on with a small organization. Travellers Nos. 5 and 6 were completely dismantled, thus releasing material and equipment for use elsewhere and increasing the storage area on the ground. To provide facilities for hoisting materials from the ground to the deck, a special hoisting derrick was set up in the plane of each anchor arm truss at *AL13*, (see figure No. 58). Each derrick consisted of a mast and short boom, the latter having main falls of 50 tons capacity and a 5-ton auxiliary line. The mast footblock was mounted on a pedestal supported by the bottom chord and the head of the mast was held by temporary brackets on the truss members near the swaybracing strut at *AM13*. The hoisting lines were operated from hoisting engines on the ground and the mast bullwheels by independent swinging engines on the deck. The booms were designed to swing through the trusses in the panel *AL13L15*, the sub-hangers at *AL14* being temporarily omitted for the sake of greater clearance. A flatcar was placed on each service track, operated by wire cables leading over snatchblocks and guide rollers to steam winches on the deck near the main pier. The method of handling materials thereafter was to hoist from the ground to floor level outside the trusses, swing inboard, and place on the flatcars for distribution over the service tracks.

Erection was resumed on the cantilever arm with traveller No. 4 early in March. Shortly afterwards the setting-up of traveller No. 3 on the anchor arm was commenced, the base with the hoisting engines being assembled on the floor near the main pier and moved back to *AL9* where the rigging was completed with the booms facing the anchor pier. During the erection of traveller No. 3 the first two panels of the cantilever arm were completed, the load on the tower at *AL9* being thereby considerably reduced.

Figure No. 90.—Main Span, Centre Section—Arrangement of Floorbeams and Lateral System Connection at North End of Suspended Span.

Traveller No. 4, having been moved forward to *CL11*, erected bottom chords *CL11L10*, the outer ends being supported on adjustable tackles from *CM11*. By means of the tackle the chords were aligned with the adjoining sections and the splices rivetted. The remainder of the sub-panel was then erected. (See figure No. 59.) The upper verticals *CU11M11*, and top chords *CU13U11* were next placed, after which the traveller was moved forward to *CL10*. The bottom chords *CL10L9*, having been erected on the adjustable tackles which were released from the adjacent chord sections and swung forward, were aligned and the splices rivetted. (See figure No. 60.) The lower diagonals were also erected, the upper ends being supported on adjustable tackles from *CM11* while the splices at *CM10* were rivetted. The upper diagonals were then erected, the lower diagonals being sprung by means of the adjustable tackles to enable the connections to be made at *CM9*. The lower verticals having been placed, were connected at *CM9* and the chords sprung by means of their tackles to make the connection at *CL9*. On the completion of the floor to *CL9* the traveller was moved forward to that point and the swaybracing *CU11M11M12* was at once placed. The erection of the upper verticals and top chords completed the panel. (See figure No. 61.)

Thereafter erection alternated on the arms in predetermined cycles which permitted the rivetting of the splices in the compression members immediately after assembly. Relative progress on the two arms is typified in figure No. 62. The load on the tower at *AL9* fluctuated within a narrow range, being at all stages moderate and much below the maximum during the erection of the first portion of the anchor arm.

The anchor pier was reached by the middle of May, concurrently with the completion of the five panels of the cantilever arm scheduled for erection by traveller No. 4. The load on the tower at *AL9* was at this stage 975 tons per post, exclusive of wind. During the completion of the rivetting of the connections, the wind anchorage was set in place on top of the anchor pier and concreted, and the anchorage struts at *AL0* lowered into the wells in the pier and connected to the anchorage grillages by pins. The end floorbeam of the anchor arm was also braced securely

Figure No. 91.—Main Span, Centre Section—Erecting First Panel of Suspended Span on North Side—First Stage.

to the wind anchorage by inclined timber struts and by 1¾-inch horizontal wire cables with turnbuckles. (See figure No. 88.)

Hydraulic jacks were next placed on the pier under each end of the floorbeam for the operation of releasing the tower at *AL9* and connecting the anchor arm to the anchorage struts at *AL0*. The arrangement at each point consisted of two 285-ton Dudgeon hydraulic jacks with 8-inch runout, operated in tandem through equalizing valves from two hand-driven pumps. The jacks were mounted on steel grillages and, beside them on the same base, steel blocking and shims for the following-up of the jacks, The general arrangement was similar to that used on the south anchor arm as illustrated in figure No. 86.

The end of the anchor arm was first jacked upwards about 8½ inches, the load being gradually transferred to the jacks from the tower at *AL9* and finally entirely relieved at that point. The pins and shoes at *AL9* were then removed, the top of the tower being temporarily lashed to the anchor arm. The jacks were then carefully lowered about 11 inches at which point the pins connecting the arm to the struts were driven. The jack movements

Figure No. 92.—Main Span, Centre Section—Erecting First Panel of Suspended Span on North Side—Second Stage. Erection proceeding at Outer End of South Cantilever Arm.

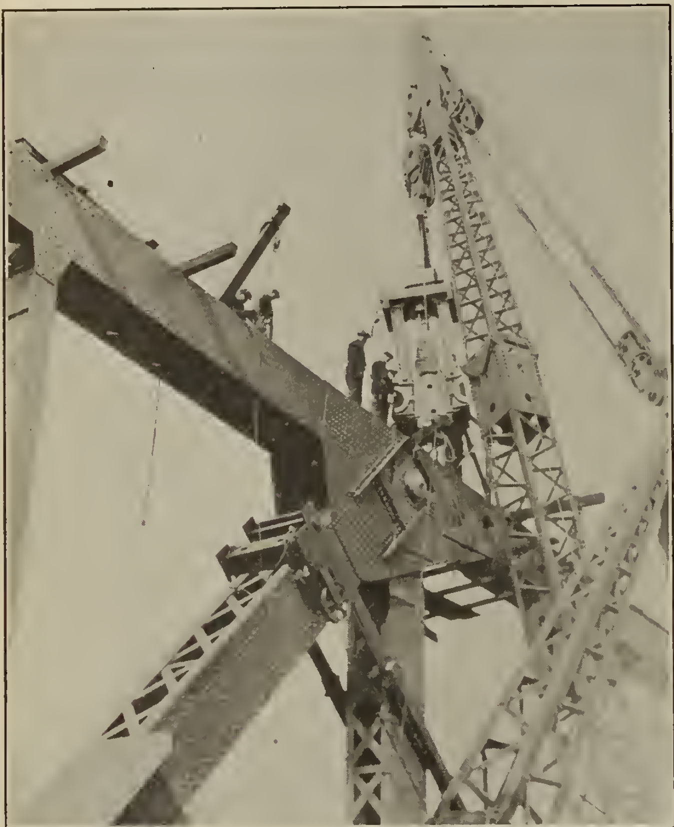

Figure No. 93.—Main Span, Centre Section—Detail at *CU0* showing Erection Wedge Mechanism being Placed.

were conducted in stages, the compressibility of the large thickness of shims reducing the net movement in each stage to about 3 inches. The jacks were followed closely by shims and the load landed on them during the process of fleeting the jacks. Cross anchorage was maintained by keeping the cables taut and the inclined timber struts tight by means of hardwood wedges.

The calculated jacking load during the landing of the anchor arm was approximately 400 tons per truss which agreed closely with the observed load as recorded on the jack gauges. The actual amount of jacking also conformed remarkably to that anticipated, based on the calculated deflections in the structure during the operation.

The permanent brackets which engage the wind anchorage were assembled temporarily and the position of the connecting holes marked, after which they were returned to the shops for drilling. They were then finally assembled in place and rivetted, after which the temporary cross-bracing was removed.

The tower at *AL9* was dismantled by means of auxiliary equipment for use on the south side, such portions as necessary being first returned to the shops for alteration. Subsequently traveller No. 4 was also dismantled and transferred to the south side, the condition at this period being illustrated by figure No. 63. Traveller No. 3 was left at the end of the anchor arm for later use at that point. The above operations were completed during June, and apart from incidental work, erection was suspended on the north half of the main span pending the completion of the south half to a similar stage.

South Side

Season of 1927

During the construction of the south anchor pier, the anchorage grillages were transported to the site from the north side on scows belonging to the pier contractor, and assembled in place, as on the north side.

Season of 1928

The south approach was completed to the south anchor pier by June 15th, 1928. By this date the construction of the temporary falsework piers under the anchor arm at *AL7* was also well advanced. Traveller No. 8 was immediately set up at the forward end of the approach deck, with booms facing the channel, conditions at this period being illustrated by figure No. 64.

Erection was then commenced on the temporary falsework span for the south anchor arm, the first portion being assembled on timber falsework, (see figure No. 65), with the rear end secured to the anchor pier to prevent longitudinal creeping on the rollers at that point. On reaching *AL5*, the modified steel tower was erected on the temporary piers just completed at *AL7*. The water level at this time was somewhat higher than had been anticipated, being about 2 feet above the base of the tower posts. The steel shells encasing the piers had been designed to meet such a condition, being well above water level, permitting the bearing slabs and lower post sections to be set on a dry top. The shells were then cut by burning and the bottom bracing strut connected without difficulty. The span having been completed to *AL7* was landed on shims on the tower, the latter being braced by horizontal pin-connected struts extending from the top of the tower to brackets on the underside of the bottom chords at *AL5*.

The remainder of the span was then erected as a cantilever, the bottom chords being supported on adjustable tackles for the rivetting of the splices before their connection to the diagonals. The reactions and stresses produced by the long overhang necessitated deck loads being minimized as much as possible on nearing the main pier. Uplift at the anchor pier was also provided for by moving traveller No. 1 onto the rear end of the span; by placing several heavy

Figure No. 94.—Main Span, Centre Section—Rear View of Wedge Mechanism in Place at *CU0*.

members on the rear chords, and by blocking the end of the span securely in the pier recesses. Figure No. 66 shows the span shortly before completion.

The size of the recesses in the main pier did not permit of jacking at that point. The top of the tower posts had, therefore, been designed for this operation and a cluster of four inter-connected 285-ton hydraulic jacks was now placed under each truss at this point, operated by three hand-driven pumps, (see figure No. 67.) As soon as the assembly of the trusses and the bracing in the end panel was complete, the span was jacked upwards at *AL7*, the shims at that point removed, and the span landed on the fixed shoes at the main pier, the rear end being simultaneously released. The remainder of the floor system was then placed on the span, thus providing access to the main pier. (See figure No. 68.) Subsequently the timber falsework was removed by traveller No. 1, the tower was, however, left in place with loose shims until the end of the season, principally for the psychological effect on the erectors.

The weight of the temporary span, with floor system included, was approximately 1,625 tons, the jacking load at the towers during the landing of the span being 960 tons per truss. The limited clearance in the pier recesses and the deflections under the heavy erection stresses in the span made accurate calculations necessary for the thickness of the shims at *AL7*, to ensure the span being completely free at the tower after being landed at the main pier, and also when subjected to its maximum load during a later stage. The elevation of the top of the tower was determined by these considerations, the thickness of the shims being such as to permit the assembly of the end members in the recesses clear of the shoes. The net downward movement at *AL7* during the jacking operation was 8¾ inches which agreed closely with the calculated amount.

During the erection of the temporary span, a working floor was provided by assembling the permanent floorbeams and longitudinal stringers on the chords of the span at an elevation about 10 feet below the final position, the service and traveller tracks being laid on the stringers. The floorbeams were supported on the chords by means of the sub-verticals and extension brackets, the chords being provided with diaphragms and stiffeners at the points of support. To permit the erection of the bottom chords, the floor system was shifted backwards about 11 feet to ensure each floorbeam being clear of the end of the adjacent chord section. As the stresses in the span were much below their maximum while this arrangement of the floor existed, the bending stresses in the chords produced by the offset floorbeams were not serious. The service and traveller tracks were carried down from the deck of the approach on ramps built up of timber blocking, the re-handling of material at the end of the span being thus avoided.

Immediately after the completion of the temporary span, the shoes were set in place on the main pier, the general assembly being well illustrated in figure No. 69. Traveller No. 8 was then moved backwards towards the anchor pier, placing panel by panel the bottom chords and laterals, lower verticals, and the floor system which was disconnected and re-assembled in its permanent position. On approaching the anchor arm the traveller was backed up the ramp to the deck of the approach, removing the ramp and completing the assembly. As soon as a portion of the floor adjacent to the main pier was completed, the erection of traveller No. 4 was commenced, the material being passed forward across the intervening gaps by traveller No. 3 and transferred to the front end on track lorries. Different stages during this period are illustrated in figures Nos. 70, 71 and 72.

Figure No. 95.—Main Span, Centre Section—Side View of Wedge Mechanism in Place at *CU0*.

The bottom chords were supported at the main panel points by the pedestals on the temporary span, timber trestles being used at intermediate points. The general arrangement is illustrated in figures Nos. 73 and 74, the large thickness of shims at each pedestal being governed by the later jacking requirements. The method of handling the heavy chord sections is shown in figures Nos. 75 and 76 and the driving of the pins at the shoes in figure No. 77. Each chord splice was aligned and fully rivetted immediately after assembly with fullest precautions to obtain tight joints. On reaching the anchor pier temporary connections were made between the end floorbeam and the wind anchorage which had been previously set on the pier top, thus completing the bottom lateral system which thereafter assisted the top lateral system of the temporary span in distributing wind load to the two piers.

Traveller No. 4 was completed shortly after the bottom chord and lateral system and erection of the upper structure was then commenced, the order of operations being similar to that the season previous on the north side until *AL7* was reached, four panels from the main pier. Progress at various stages is shown in figures Nos. 78, 79, 80 and 81 and the method of handling the top chord sections in figure No. 82. As on the north side, the points of support were transferred by jacking as each panel was completed, the ultimate support for the anchor arm trusses being at *AL7*. As the load on the temporary span approached its maximum, shims were again placed between the top of the tower and the span to moderate the stresses in the span, this step being taken as a general precaution rather than from necessity.

Traveller No. 4 was then transferred to the cantilever arm and erection commenced at that point, traveller No. 8 being shortly after moved forward to *AL5* where it dismantled the tower under the temporary span and proceeded with the erection of the anchor arm. (See figure No. 83.) Two panels of the cantilever arm were completed, after which operations were suspended for the winter.

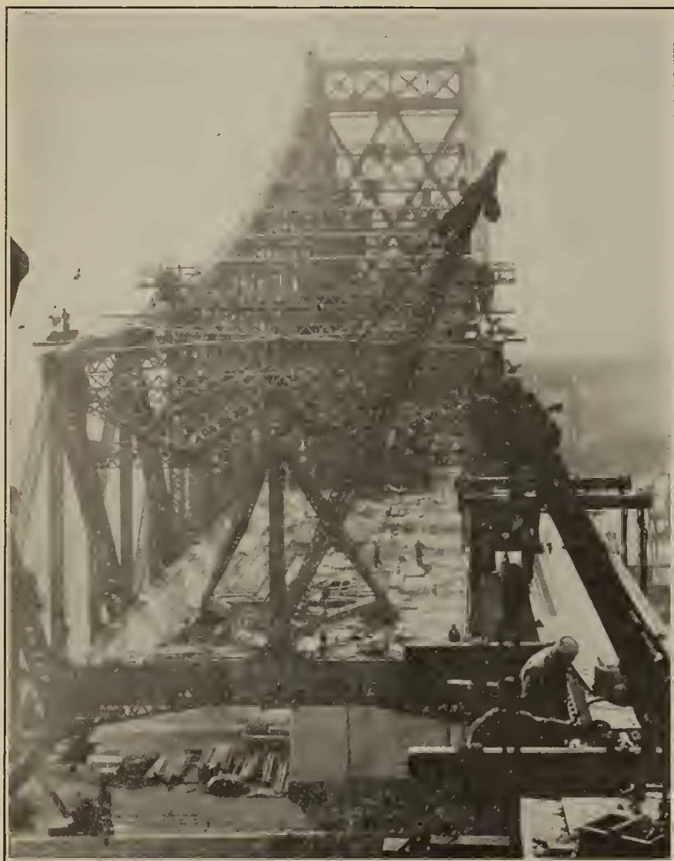

Figure No. 96.—Main Span, Centre Section—Arrangement of Moveable Derrick used in Erection of Centre Panels of Suspended Span.

Season of 1929

Erection was resumed about April 1st, 1929, by traveller No. 4 on the cantilever arm and traveller No. 8 on the anchor arm. Conditions at this date are illustrated in figure No. 84 which is of a special interest as showing the level in the channel during the ice breakup. The extreme variation in level may be noted by comparison with figure No. 85 which shows the condition about three weeks later, by which date the channel was clear of ice and the water level down about 20 feet to normal spring high water level. Erection followed a pre-determined programme of cycles similar in principle to that on the north side. In this case, however, the point of support for the anchor arm was transferred backward by jacking as each panel was completed until the entire arm was assembled and supported on the temporary span at *AL2*, coincidently with the completion of five panels of the cantilever arm.

A similar jacking operation to that on the north side was then carried out on the anchor pier, the general arrangement of the jacks and blocking during this stage being illustrated in figures Nos. 86, 87 and 88. The anchor arm was first jacked upwards sufficiently to permit the removal of the shims at *AL2*, being then lowered and the connection to the anchorage struts made by the driving of the pins at *AL0*. The amount of jacking in this instance was much less than on the north side, owing to the difference in the influence of deflections.

Traveller No. 4 having completed its operations was now dismantled and removed. Traveller No. 8 was partially dismantled, the base moved to the forward end of the cantilever arm, and the derricks re-erected. This stage was completed by the end of May.

Centre Section—1929

The centre section consisted of the suspended span and three panels at the end of each cantilever arm. As previously noted, erection had been suspended on the north side in July, 1928, pending further progress on the south side, traveller No. 3 being left at the anchor pier to participate in the erection of the north approach. During April, 1929, traveller No. 3 was dismantled and re-assembled at the forward end of the cantilever arm with booms facing the centre, and erection operations were resumed at that point concurrently with those on the south side outlined in the previous section.

On reaching the end of the cantilever arm, the hangers *CU0SL0* were erected and the pins driven at *CU0*. The special details at *SL0*, consisting of the main gussets, diaphragms, etc., had been built as independent units with field connections for the adjoining members, as the weight if combined with the bottom chord sections, would have been beyond the capacity of the booms at the necessary reach. These details were now connected to the hangers at *SL0* by the pins at that point, being blocked temporarily in position. The floorbeam at *SL0* was then placed and connected to the gusset details, and braced to the adjacent floorbeam by blocking and turnbuckles. The bottom wedges were next lowered carefully into position in the chords between *CL0* and *SL0*, the connecting pins driven, and the wedges adjusted to the prescribed initial setting. The general arrangement of the bottom wedges at *SL0* is illustrated in figures Nos. 89 and 90.

The first bottom chords of the suspended span were now placed, the forward ends being supported on adjustable tackles from *CU0*. (See figure No. 91.) The bottom laterals of the first panel were also placed and the chord connections to the gussets at *SL0* then rivetted. The sub-verticals at *SL1* and the diagonals *SL0M1* were next erected, followed by temporary links of pre-determined lengths between *CU0* and *SM1*. These links consisted of four 14- by ⅝-inch plates in each truss, connected by pins to brackets on the truss members. The load having been transferred from the adjustable tackles to the links, the remaining truss members of the first panel were erected, the general arrangement being shown in figure No. 92. The chord sections *CU0SU2* were next placed and the top wedges set in position at *CU0*. (See figure No. 93.) The arrangement of the top wedges after their erection is illustrated in figures Nos. 94 and 95, these views being taken prior to the construction of the proper working platforms. The wedges were first adjusted to transfer the load from the links to the top chords, the links being then removed and the wedges slacked off to the prescribed initial setting.

The second panel of the suspended span was now erected with traveller No. 3 standing at *SL2* and a moveable derrick was set up at *SL4* on the centre line of the deck for the completion of the remainder of the north half. The weight of traveller No. 3 prohibited its movement beyond *SL4* as otherwise the end chords of the cantilever arm would have been seriously overstressed, and the above alternative method was, therefore, adopted. The derrick was equipped with a 75-foot boom of 35 tons capacity from traveller No. 4, the general arrangement being illustrated in figure No. 96. Meanwhile the alignment and levels of this portion of the suspended span were carefully checked, the wedges being slacked off a small amount and re-set to accord with the check measurements. Traveller No. 3 was then moved back off the suspended span, erecting the swaybracing and top laterals on its way, after which it was partially dismantled and the base moved back to *CL3* to reduce the effect of its weight on the truss members. Hoisting lines were carried from the engines on the base to the derrick at *SL4* for the operation of the latter.

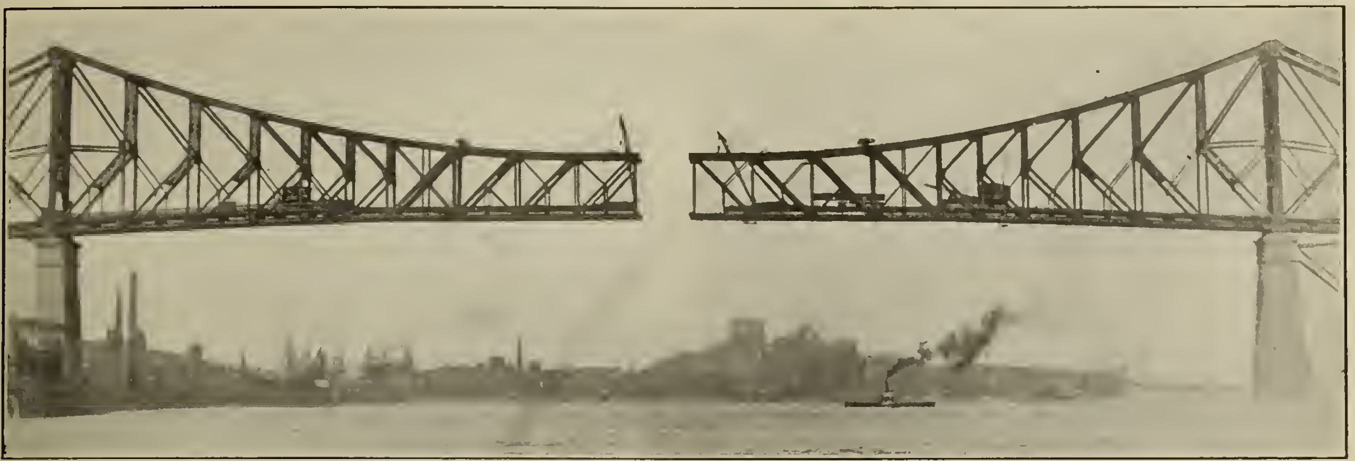

Figure No. 97.—Main Span, Centre Section—Progress as at July 1st, 1929.

The third panel of the suspended span was next erected by the moveable derrick, it being then moved forward to *SL6* in readiness for the erection of the centre panel. The wedges were slacked off a further small amount at this time, the load on each wedge being about 600 tons. This stage of the programme was reached by the end of June.

Meanwhile erection had been proceeding on the south half of the centre section, the corresponding stage being reached by July 1st. (See figure No. 97.) A portion of the centre panel was then erected, the only members left unplaced being those involved in the closure. A few days were devoted to rivetting and incidental work during which period precise field measurements were completed, the result showing a high degree of accuracy throughout.

A brief reference to the results of the field measurements may be of interest. After the completion of the main piers, the span length was checked by triangulation and found to be ¾ inch short between centres. This error was accepted without compensation, being readily taken care of by a slight inclination in the suspended span hangers. Final measurements in the centre panel before the closure indicated an error of ⅞ inch, which agreed almost exactly with the results obtained by triangulation.

On the completion of each cantilever arm, the alignment and levels at the end, *CL0*, were carefully checked. The lateral deflections were found to be ¼ inch on the north and ⅝ inch on the south, in each case downstream. The relative levels at the same points were,—north, downstream truss ⅛ inch high; south, upstream truss $\frac{1}{16}$ inch high.

With each side erected to *SL6*, the final measurements disclosed lateral deflections at *SL6* of ½ inch on the north and ¾ inch on the south, in each case downstream.

As noted above, the wedges were slacked off definite amounts at certain stages. It was a further rule, however, to make a few turns of all the operating hand-wheels each day, the intent of these preliminary adjustments being to maintain the mechanisms in free working order and guard against seizure of the bearing surfaces.

Closure Operations

These operations were commenced on Monday, July 8th, by placing the bottom chords *NSL6-SL7*, the pins being entered at *NSL6* and the chords supported freely at *SL7*. The bottom laterals of the centre panel were then placed with free ends at *NSL6*, followed by the diagonals which were connected at *SM7* but left free at the opposite ends. Finally, the top chords *NSU6-SSU6* were placed, followed by the centre top laterals, the laterals being left free at *SSU6*. The top chords were connected on their lower flanges at *NSU6* and supported freely at *SSU6*.

Adjustable tackles were connected in the plane of each truss and pulling jacks at the free ends of all laterals to assist in the making of the connections, (see figure No. 98). The wedge operating crews and observers were also assigned to their stations at the respective wedges and final preliminary adjustments made under full load by slacking off all wedges to the positions which resulted in the stipulated clearances for temperature movements at the open connections. The arrangement on the top of the suspended span in the final stage is illustrated in figure No. 99. All preliminaries were completed on July 9th and, as weather conditions appeared favourable, orders were issued for the final operations to be undertaken on the following day.

Work was commenced at 5 a.m. on July 10th, weather conditions proving ideal. The air was practically still and

Figure No. 98.—Main Span, Centre Section—Arrangement of Adjustable Tackles in Centre Panel of Suspended Span.

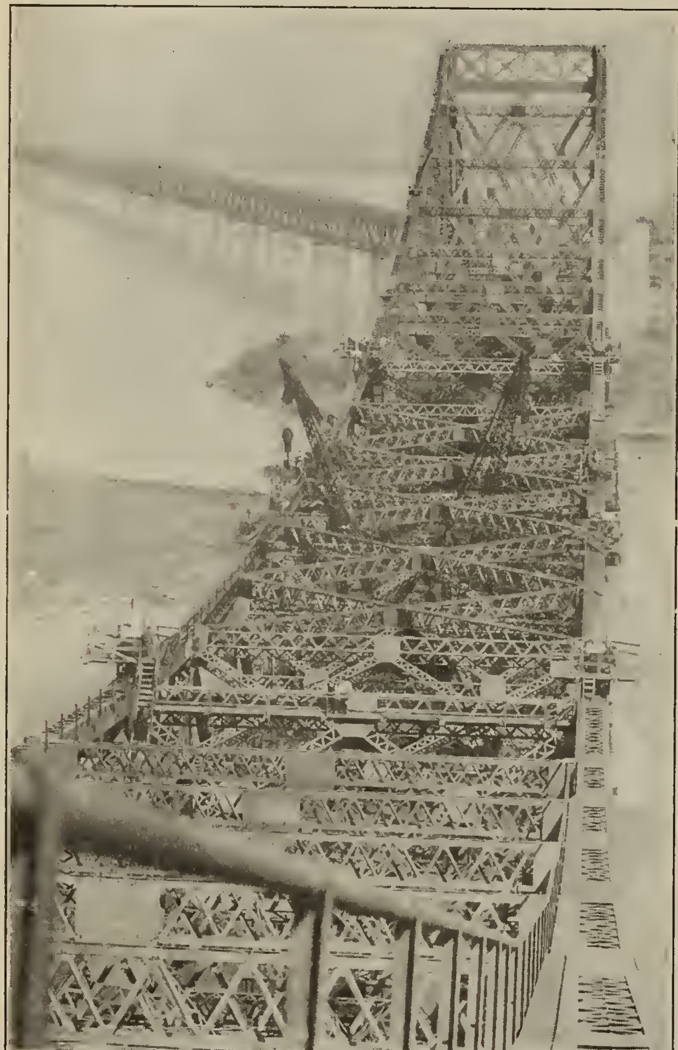

Figure No. 99.—Main Span, Centre Section—View of Top of Suspended Span just prior to Closure.

a dull cloudy sky persisted for several hours, the atmospheric temperature remaining practically constant at 72° F. The pins were immediately driven in the centre bottom chords at *SL7*. (See figure No. 100.) The slacking off of the wedges commenced at 5.20 a.m. and proceeded in regulated cycles until 8.30 a.m. when the top chord joints closed, the bottom chords being kept slightly slack. Wedge operations were temporarily suspended during the bolting of the chord splices; the top lateral connections, being found to match, were also bolted.

The bolting of these connections being well advanced by 9.00 a.m., the bottom wedges were then gently slacked off to bring the centre pins in bearing. At this stage the bottom lateral and diagonal connections all matched and were connected, it being found unnecessary to make use of the auxiliary tackles or jacks. Operations were resumed at all wedges about 9.30 a.m. with continuous slacking off in regulated cycles until a considerable portion of the load on the wedges had been relieved. At 9.45 a.m., it was obvious that the closure had been successfully accomplished, the event being celebrated by a brief informal ceremony in the presence of Hon. Dr. W. L. McDougald, president of the Board of Harbour Commissioners, (see figure No. 101), and other prominent officials identified with the enterprise.

After a brief interval, operations were continued until, about 11 a.m., all wedges were released and the suspended span was swinging freely between the ends of the cantilever arms. The wedges were run out sufficiently to provide clearance for temperature movement and work was then suspended for the day.

Final Operations

During the following period the wedges were dismantled and removed, and the remainder of the superstructure erected. The permanent connections were also made in the bottom lateral system at each end of the suspended span. The erection equipment was finally dismantled and removed, with the exception of traveller No. 8 which was again placed in working order at the south anchor pier.

The last major operation was the dismantling of the temporary span under the south anchor arm. The span was first suspended from the anchor arm trusses by long rods and brackets at the panel points, the nuts on the rods being tightened to partially relieve the sag in the span due to its own weight. The rivets in the connections were then cut out and replaced by sufficient bolts to carry the weight of the span, after which dismantling commenced at the anchor pier, the end panel being removed by traveller No. 8. The members were disengaged by lowering them on tackles lashed to the structure above and operated from the traveller engines and auxiliary hoisting engines on the deck. They were fleeted towards the anchor pier on the suspended tackles, several fleets being necessary for the more remote members. At the anchor pier, they were hoisted to the deck by the booms of traveller No. 8 and placed on cars for removal. All important operations were completed by September 30th, 1929. The completed span is shown in figure No. 102.

Field Rivetting

It was the policy to complete the field rivetting as closely behind the erection as practicable at all stages. Whenever possible the members were forwarded from the material yards with specially designed scaffold brackets bolted in place, thus greatly reducing the rigging and enabling the bolting of the connections, as well as the rivetting, to be proceeded with rapidly.

On the south side air was supplied in the early stages from a steam-driven compressor plant on the shore and distributed along the deck by piping. Later this compressor plant was transferred to St. Helen's island for the work beyond, and reinforced by portable gasoline compressors during the erection of the main span. For the north side, a steam-driven compressor plant was installed on the ground adjacent to the main pier and the air distributed by piping to and along the deck.

In the south approach the field rivets were of ⅞ inch and 1 inch diameter, the latter size being used in the trusses of the 245-foot spans. In the case of the spans which were erected by cantilevering, the field rivetting was in general about two panels behind the erection, as a result of which extra bolting for stress requirements was greatly minimized. The field rivets in the north approach were of ⅞ inch diameter.

In the main span the field rivets were of ⅞ inch, 1 inch and 1⅛ inch diameter, the latter size being used in the case of the longer grips. As noted previously, all important compression joints were rivetted immediately after the placing of the members. The end connections of the deck stringers carrying the main travellers were also rivetted before moving this equipment over them. The rivetting of the remaining main connections was carried along promptly after the erection, usually about two panels in the rear. In the case of the bottom laterals and sway-bracing which were fabricated to geometrical dimensions, it was anticipated that the shop camber in the lengths of the truss members would prevent the matching of the connections at the time of placing. Holes for 1-inch diameter rivets were, therefore, provided in all lateral and bracing connections, the number being based, however, on the use of ⅞ inch diameter bolts during the erection period. It was found necessary to use the ⅞-inch bolts in the connections of the diagonal members of the laterals and bracing to the trusses and at a few other points; elsewhere the connections were drifted to match and rivetted in due course. The bolted connections were drifted together without difficulty concurrently with the laying of the concrete floor slabs on the deck and were then rivetted.

In the case of the temporary span under the south anchor arm, all connections were fully rivetted on account of the high stresses in the members. The lateral and bracing connections in both the span and the steel tower were also fully rivetted to ensure maximum rigidity. On the north side, the bracing connections of the steel tower were fully rivetted, and such of the span connections as were heavily stressed. The compression butt joints of the tower were fully bolted.

In the rivetting of the heavier connections, driving and bucking-up guns were used on opposite sides to ensure proper upsetting. Pains were taken to avoid heavy paint films on the surfaces to come in contact in the field and the ends of the compression members were carefully scraped before being placed. Extremely rigid inspection while the rivetting was under way resulted in only a negligible percentage of the driven rivets being condemned and re-driven.

Conclusion

The contract date for the completion of the superstructure, exclusive of the field painting, was July 1st, 1930, this being afterwards extended to March 1st, 1931, owing to delays occasioned during the season of 1927 by backward progress on the substructure. The work was actually completed by October 1st, 1929, representing a saving in time in the opening of the bridge for traffic of more than a year.

Although three years may appear a lengthy period of field construction it should be borne in mind that the actual working period consisted of twenty-two months or less than two years. Considerably more work might have been carried on during the winter seasons but only at greatly increased hazard and expense. Winter ice conditions under the south anchor arm made it impossible in any event to commence operations at that end of the main span at an earlier date. Hence only the time saved by continuous erection during the final winter would have been of value and could not have exceeded two months. Considering the importance of this stage of the work it would have been unwise to incur the risks which would attach themselves to such operations during the winter or early spring.

It will have been noted that steam power was used throughout on all hoisting engines, in spite of the present-day tendency towards electric power on construction. Among the objections to the latter in this instance, however, were the expense of power transmission on the south side,

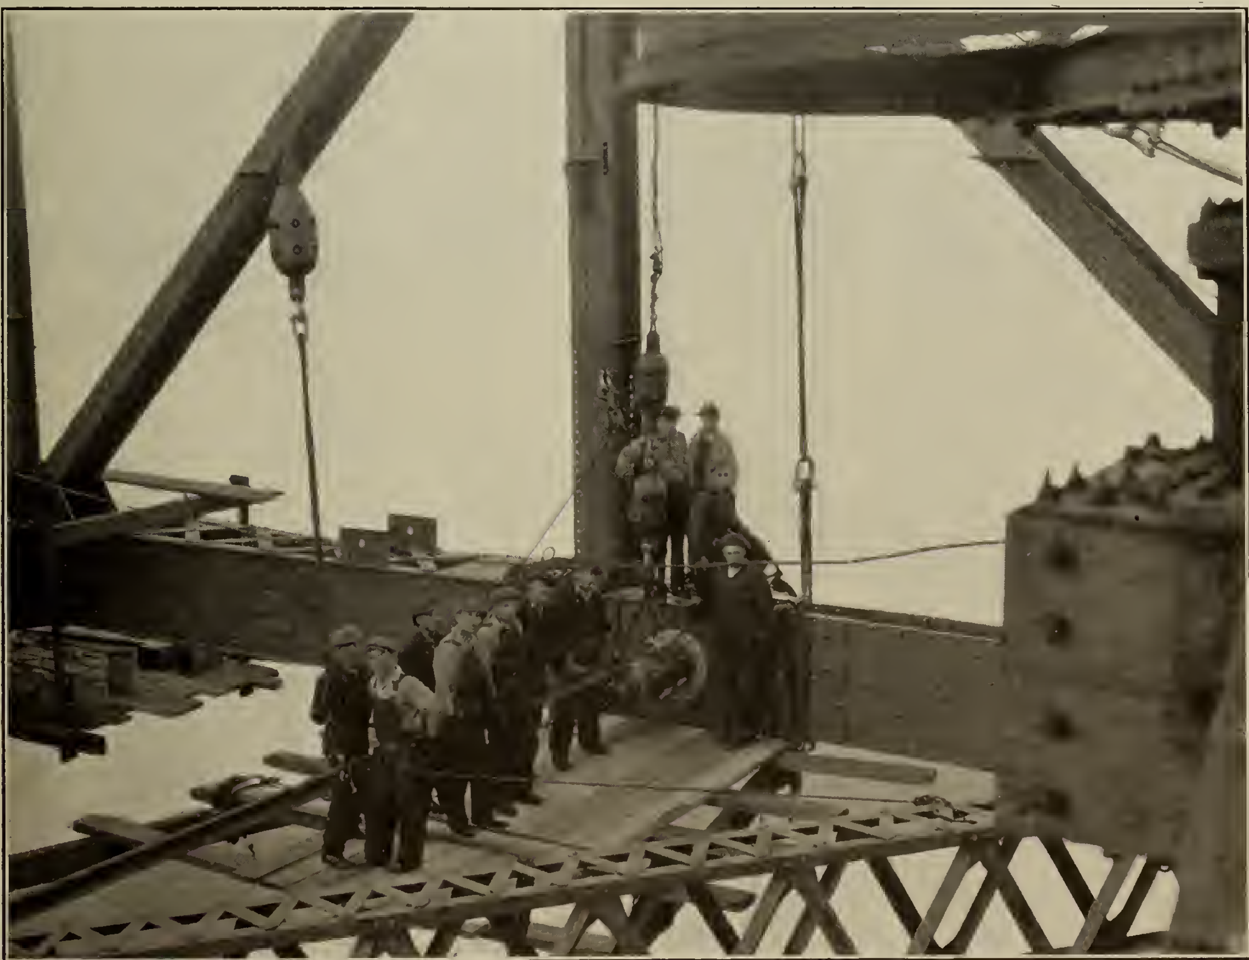

Figure No. 100.—Main Span, Centre Section—Driving Pin in Bottom Chord at *SL7* on Day of Closure.

Figure No. 101.—Main Span, Centre Section—Hon. Dr. W. L. McDougald, President of the Montreal Board of Harbour Commissioners, making the Last Turn of the Wedge Mechanism which released the Suspended Span.

greater difficulty in obtaining electric hoist operators experienced in steel erection, possible power shut-offs during critical handling periods, and maintenance problems. Investigation showed that no economy would result from the use of electric power and steam power was therefore adhered to, a further advantage being that the equipment provided would be more generally usable on future work.

In every instance the equipment provided proved even more satisfactory than was anticipated. The same may be said of the methods adopted and in this connection an interesting fact may be noted. It has been evident that the installation of the temporary falsework under the south anchor arm was a governing feature in the programme. The construction of a temporary pier in the river at this point was purposely delayed until the spring of 1928 although reluctantly, as it seemed certain that considerable loss of time would result. One of these piers was completely overturned by the ice shove in March 1929, fortunately long after its utility had ended. This fact demonstrates convincingly the wisdom of adopting methods which avoided the ice risk in the river.

The main span required only a small amount of reinforcement for erection stresses, chiefly in the floor system on account of the heavy concentrated loads from the travellers. It may be noted, however, that the suspended span was virtually the limit in length for economy, as the erection stresses from a longer span would have necessitated heavy reinforcement in the chords near the ends of the cantilever arms. The use of the K-system in the trusses, as in the case of the Quebec bridge, proved how excellently it is adapted to erection, no temporary members being required and all connections being readily made. It may also be safely said that the method actually employed in the erection of the suspended span was in this case more economical and very much safer than would have been any attempt at floating or lifting into place, even if such a method had been permissible.

A noteworthy point is the close agreement found throughout the field operations between the calculated and actual deflections in the various parts of the structure. This may be largely attributed to the rational and apparently accurate allowance in the calculations for the influence of local reinforcement from detail material and other factors. This influence was determined for each member independently and the resultant calculated deflections were found to be from 15 to 20 per cent less than if based only on the gross areas of the main material in the members.

The working force in the field varied considerably during the several seasons, reaching a maximum in the early summer of 1928 at which time approximately 350 men were employed, divided about equally between the north and south sides. Relations with the erectors were at all times satisfactory as is evident by their refusal to participate in a strike during May, 1928. As a further comment on their interest, loyalty and confidence, every man of the 150 required was on hand at 5 a.m. July 10th, 1929, the day of the final closure.

Every precaution was taken to guard the workmen against accident, as well as traffic passing under the bridge. A gasoline launch with life-saving equipment was stationed in the channel under the main span during working hours, and rowboats under the south approach. Flooring and scaffolding were used liberally, and all equipment or construction materials maintained in first class condition. During the final season, work over the navigation channel was suspended during the passage of vessels under the structure in spite of a considerable resultant delay in the erection.

The plans pertaining to the erection programme were fully discussed with and calculations verified by the engineers. It is a pleasure to record the cordial relations that existed at all times between the engineers and the contractor, and the valuable assistance rendered by the engineers, particularly by Mr. Pratley who was intimately associated with the work, in the capacity of supervising engineer. The shop and field inspection was ably and promptly performed under the direction of Mr. J. Rankin, M.E.I.C., chief inspector for the engineers.

The operations were planned and carried out in their entirety by the Dominion Bridge Company, Limited, under the supervision of G. H. Duggan, D. Sc., M.E.I.C., president; F. P. Shearwood, M.E.I.C., chief engineer; and the author who assumed the duties of engineer-in-charge. A special organization was created for the work entirely from within the staff of the company, consisting of D. B. Armstrong, A.M.E.I.C., and R. S. Eadie, A.M.E.I.C., assistant engineers; F. J. McHugh, A.M.E.I.C., chief draughtsman; D. Bell, general superintendent of erection; A. M. MacDermid and L. J. McMahon, erection superintendents; F. Bowman, A.M.E.I.C., W. E. Bell and C. Phillips, field engineers. The shop fabrication was under the direction of H. W. McMillan, A.M.E.I.C., works manager; R. E. Cape and L. Leclaire, superintendents; and T. Lochhead, chief inspector. F. Newell, M.E.I.C., mechanical engineer, collaborated in the design of the wedge mechanisms used in the erection of the suspended span. To the loyal and intelligent efforts of the entire organization associated with the operations is largely due the success of the undertaking.

Appendix A—Memorandum re Erection of Suspended Span

General

The suspended span will be erected by cantilevering each half from adjoining cantilever arm to centre of span. If no compensations were provided, however, centre top chord would be too long and centre bottom chord too short at normal temperature to permit final connections being made. To provide for this condition and also ensure adequate clearance under temperature movements while centre members are being placed, adjustable wedges will be placed at each end of suspended span in top and bottom chords at *CU0* and *SL0* respectively. Wedges will be so adjusted when placed that those at *CU0* draw suspended span top chord back and those at *SL0* move suspended span bottom chord forward.

Initial wedge settings are such that preliminary adjustments may be made as erection of suspended span proceeds, thus testing mechanisms under gradually increasing load and preventing seizure of contact surfaces where sliding or other movement occurs.

After both halves of suspended span are erected to *SL6* and before erecting centre panel, field measurements will be made on distance across centre panel in line of both chords and levels taken at all corners *SL6*. Alignment of trusses will also be checked. Any necessary compensations will be determined.

Zero on scales corresponds to geometric horizontal dimensions; i.e.,—when pointer is at zero, wedge is in that position which results in geometric distance between shoe pinholes.

Plus (+) *on scales* indicates distance between wedge pinholes greater than geometric.

Minus (−) *on scales* indicates distance between wedge pinholes less than geometric.

Wedges run in refers to movement which *increases* distance between wedge pinholes.

Wedges run out refers to movement which *decreases* distance between wedge pinholes.

Determination of Wedge Settings

Wedge settings are governed by clearance which must be provided in centre panel to permit members being placed with adequate provision for temperature movements.

If bottom wedges at *SL0* were placed with zero setting, centre bottom chord would be *short* by following amounts when both halves of span are erected—

3.28 inches due to calculated deformation of structure.
−0.75 " " " known error in distance between main piers.
1.70 " " " possible drop in average temperature of steel from 60° F. to 40° F.

———

4.23 inches total amount short at temperature of 40° F.

Figure No. 102.—The Main Span as at September 11th, 1929—Erection completed, Falsework Span removed and Last Equipment being dismantled.

Centre panel will then be erected and final preliminary wedge adjustments made. Wedge settings must permit expansion due to temperature of 120° F. after centre panel is erected. Notes following show wedge settings which may be expected to produce this result but actual settings before closing operations must be determined from field measurements referred to above and by check measurements at joints.

After centre panel has been erected and final preliminary wedge adjustments made, closing operations will be carried out. Wedges will be slacked off to bring all joints together for final connection. Wedges will then be all slacked off concurrently to release suspended span during which operation stresses change gradually from cantilever condition to that of simple span under its own weight. Wedges must be slacked off further to provide sufficient clearance at ends of suspended span for movements due to temperature variations between 40° F. and 120° F. and may then be removed when convenient.

While cantilevering each half of span to centre, governing stresses are produced in certain chords at ends of cantilever arms. Erection methods have been carefully planned to minimize these stresses and no modification will be permitted which increases them. During final stages of erection, load on suspended span and end of cantilever arm must be kept to minimum.

All wedge operations will be directed by the engineer and no adjustments will be made except on his personal instructions.

Wedge Adjustments and Operations

General

Erection wedges at *SL0* (bottom) and *CU0* (top) are provided with vertical scales which indicate vertical travel of wedges in inches, this being six times horizontal movement produced by wedges at centre line of chords.

Hence bottom wedges must be run in to compensate for ½ × 4.23 =2.12 inches at each end of span. This requires that bottom wedge setting when erected to centre = + 2.12 inches horizontal + 12.72 inches vertical.

If top wedges at *CU0* were placed with zero setting, centre top chord would be *long* by following amounts when both halves of span are erected.

1.60 inches due to calculated deformations of structure.
0.75 " " " known error in distance between main piers.
4.25 " " " possible rise in average temperature of steel from 60° F. to 110° F.

———

6.60 inches total amount long at temperature of 110° F.

Hence top wedges must be run in to compensate for ½ × 6.60 =3.30 inches at each end of span. Since bottom wedge adjustments also affect horizontal centre distance in top chord, further compensation must be provided for bottom wedge centre setting = 0.12 × 2.12 = 0.25 inches. Total compensation required is 3.30 + 0.25 = 3.55 inches at each end of span. This requires that top wedge setting when erected to centre $= 3.33 \times \frac{1}{0.88} = +4.03$ inches horizontal + 24.18 inches vertical.

Operations and Wedge Adjustments

(1) *Shop adjustment*
- (*a*) Bottom wedges — set at + 21.00 inches vertical (+3.50 inches horizontal).
- (*b*) Top wedges — set at + 21.00 inches vertical (+3.50 inches horizontal).

(2) *Initial setting and adjustments*

(*a*) Bottom wedges —
Place with shop setting.
Run in to +24.00 inches vertical (+4.00 inches horizontal) and remove blocking between floorbeams *CF0* and *SF0*. Leave thus until suspended span erected to *SL4*.

(*b*) Top wedges —
Place with shop setting.
Run in to +27.00 inches vertical (+4.50 inches horizontal). Leave thus until suspended span erected to *SL4*. Temporary links *CU0 SM1* will be released at 24.0 inches vertical (+4.0 inches horizontal) and should be then removed.

(3) *Preliminary adjustment at SL4.*

After suspended span has been erected to *SL4*, wedges will be run out to test operating mechanisms under moderate load of 280 tons each approximately.

(*a*) Bottom wedges—
Run out to +21.00 inches vertical (+3.50 inches horizontal).

(*b*) Top wedges—
Run out to +26.50 inches vertical (+4.41 inches horizontal). Leave thus until suspended span erected to *SL6*.

(4) *Preliminary adjustment at SL6.*

After suspended span has been erected to *SL6*, and before placing centre panel, wedges will be run out to test operating mechanisms under heavy load of 600 tons each approximately.

(*a*) Bottom wedges—
Run out to + 18.00 inches vertical (+3.00 inches horizontal).

(*b*) Top wedges—
Run out to +26.00 inches vertical (+4.33 inches horizontal).

(5) *Final preliminary adjustment at centre.*

After centre panel has been erected, check field measurements will be made at all joints, particularly top chord. Final adjustments will be made under maximum load on wedges of 720 tons each to establish required centre clearances for closing operations. After allowance for all compensations, clearances must be provided for expansion due to temperature 120° F., (assumed average of steel 110° F.). Theoretically, wedge adjustments required are as follows:—

(*a*) Bottom wedges—
Run out to +12.72 inches vertical (+2.12 inches horizontal).

(*b*) Top wedges—
Run out to +24.18 inches vertical (+4.03 inches horizontal).

(6) *Closing operations at centre.*

At commencement of closing operations, wedges will be run out to enable final connections being made, during which period load on wedges is maximum = 720 tons each. They will be then run out to swing suspended span free as simple span. They will be run out further to provide adequate clearance at ends of span for temperature expansion until wedges have been removed. Theoretically, adjustments required are as follows:—

(*a*) Bottom wedges—
Run out to +7.62 inches vertical (+1.27 inch horizontal) at 60° F.

(*b*) Top wedges—
Run out to +9.00 inches vertical (+1.5C inch horizontal) at 60° F.

At this stage, top chords joints should close, bottom chord pins should bear, web members and lateral connections should match, thus enabling all connections to be permanently made.

(*a'*) Bottom wedges—
Run out to −1.50 inch vertical (−0.25 inch horizontal) at 60° F.

(*b'*) Top wedges—
Run out to −4.44 inches vertical (−0.74 inch horizontal) at 60° F.

At this stage, suspended span should swing free as simple span, thus releasing all load off all wedges.

(*a''*) Bottom wedges—
Run out to −16.75 inches vertical (−2.80 inches horizontal).

(*b''*) Top wedges—
Run out to −12.50 inches vertical (−2.08 inches horizontal).

Wedges will be left in this position until removed. Clearance is provided for movements due to a temperature range between +30° F., (top chord), and +120° F., (bottom chord).

Field Measurements

During erection of suspended span, accurate field measurements will be necessary as follows:—

(1) Length of span—surveys have already determined that distance between main piers, (i.e. main shoes), is ¾ inch less than geometric.

(2) Wedge settings at *SL0*—points *SL0* at each end of span must be exactly opposite each other with respect to axis of suspended span.

(3) Vertical relation of trusses—when erected to *SL4* and before any swaybracing is placed, levels will be taken at all points *SL0* and *SL4*. Levels will be compared on both halves of span and top wedge adjustments made as may be determined to maintain correct relations between trusses. After swaybracing is erected, relations will be verified by check measurements.

(4) Alignment of span—check measurements will be made at each panel as erection proceeds to ensure true alignment top and bottom with respect to axis of suspended span.

(5) Check measurements at *SL6*—when both halves of span are erected to *SL6*, levels will be taken at all points *SL6*. Alignment of each half will also be checked. From information obtained, any necessary compensating adjustments will be determined. Distance between ends of chords at *SU6* and *SL6* will also be checked and compared with expected distances at normal temperature.

(6) Final check measurements—after centre panel is erected, all joints will be checked before and after final preliminary adjustments to ensure that expected conditions are realized.

Final Instructions re Closing Operations

Final closing operations will be carried out during a single day after all members are in place and all preliminary work completed, including necessary field measurements. Everything will be in readiness to commence wedge adjustments immediately as soon after daybreak as possible to ensure the maximum of daylight in case of delays and to minimize the effect of rising temperature.

Wedges will be run out in prescribed manner to bring centre panel connections together. Bottom chord pins will be driven but a little slack maintained at pinholes until top chord joint is closed. As soon as top chords make contact, wedge operations will be suspended briefly until splices are well started and top lateral connections made. Special care must be taken that chords come to good bearing. Further wedge adjustments will then be made carefully to bring bottom chord pins to bearing and match web members which will then be connected. Bottom laterals will also be connected.

All wedges will then be run out concurrently with least delay possible to release suspended span. Simultaneously all connections will be proceeded with and should be at least 50 per cent bolted before span is released.

Drift pins and bolts will be started in all connections during these operations at earliest moment possible.

Open Joints.

When centre top chords come together, joints at each end *SU6* will be slightly open at upper side. Ends of centre top chords are chamfered top and bottom to permit bearing on central portion of end face only. As joint comes together it should close by drifting and if necessary help may be provided by upward springing of chord at its centre.

Relative Speed of Wedge Adjustments.

During all operations, both top wedges at one end of span, or alternatively both bottom wedges, must be operated together at same speed to avoid stresses in bracing and elsewhere due to twisting action on span.

During preliminary operations, wedge adjustments may be made independently at each end of span. Top and bottom wedge adjustments may also be made independently.

During closing operations, adjustments will be regulated as follows:—

(*a*) While bringing joints together in centre panel to make final connections, top and bottom wedge adjustments may be made independently but both ends of span must be operated at same speed to ensure symmetrical movements of both halves of suspended span.

(*b*) While swinging suspended span free all wedges must be operated concurrently, both ends of span at the same speed. If normal temperature conditions prevail (i.e., 60° F.) top wedges will be operated at rate 48 per cent faster than bottom wedges, respective movements being top 13.44 inches vertical (2.24 inches horizontal) and bottom 9.12 inches vertical (1.52 inch horizontal). If temperature varies during period of releasing span any necessary compensations will be determined at time.

(*c*) After suspended span swings free all further wedge adjustments may be made independently.

Wedges must never at any time while under load be run out beyond setting required as they are designed for movement outward only under load and cannot be moved back.

Approximate Time Schedule, (at normal temperature 60° F.).

(*a*) Time required from commencement of wedge operations until joints are closed.................................2.0 hours
This is governed by required movement in top chord wedges from +24.18 inches vertical to +9.00 inches vertical = 15.18 inches vertical travel.

(*b*) Time required to make connections during which wedge operations are suspended.............................0.5 hours
(*c*) Time required to release suspended span...............1.5 hours
This is governed by required movement in top chord wedges from +9.00 inches vertical to −4.44 inches vertical = 13.44 inches vertical travel.
Total elapsed time until span released.................4.0 hours

Temperature Effects and Allowances

Coefficient of expansion for steel = 0.0000065.
Total change in length in channel span (1,100 feet) due to variation of 10° F. = ±0.85 inches.
Normal average temperature of steel assumed as +60° F.
Maximum " " " " " " +110° F.
Minimum " " " " " " +40° F.

(*a*) *Top chord.*
After centre top chord is placed and connected at one end, gap at other end should be 5.95 inches at 40° F., 4.25 inches at 60° F., 0 at 110° F.

(*b*) *Bottom chord.*
After centre bottom chord is placed, pins may be driven at any temperature between 40° F. and 110° F., pinholes in chord being slotted 6 inches total. Chords should just clear adjoining members at 120° F. which requires a clearance for expansion of 5.10 inches at 60° F.

Pins should not be driven until day of closing operations.

During closing operations it is probable that expansion will occur due to slowly rising temperature. This will accelerate top chord adjustments as joint will close and span be released with less wedge movement. Bottom chord adjustments will be retarded with corresponding increase in wedge movement. Should sun be shining, top chord will probably be effected considerably more than bottom chord which will accelerate top chord adjustments relatively to those in bottom chord. Modified adjustments to compensate for these influences can only be determined at time of operations to suit actual conditions that may exist.

Unless compensated for by wedge adjustments, compressive stress will be induced in top chord of suspended span, should expansion occur due to rising temperature after centre top chords are in contact. This results in arch action of suspended span between ends of cantilever arms, thrust from which produces bending in main piers. Similarly, falling temperature after bottom chord pins are bearing produces suspension action between ends of cantilever arm which also causes bending in main piers. Investigation shows that stresses under either of above cases are not serious even under extreme conditions.

In principle, however, every care should be taken to minimize above action by proper co-ordination of top and bottom wedge adjustments.

Relative Movements and Times

(1) 100 revolutions of hand wheel =1.5 revolutions of screw.
=0.73 inch (¾ inch) vertical wedge travel.
=0.12 inches (⅛ inch) horizontal wedge travel.
1-inch vertical travel of wedge =136 revolutions of hand wheel.
1-inch horizontal travel of wedge =6-inch vertical wedge travel
=816 revolutions of hand wheel.

(2) *Time Coefficients.*
Under operating conditions with load on wedges, it is estimated that rate of movement can be maintained equivalent to 20 revolutions per minute of hand wheel after starting friction is overcome.
Average time per revolution of hand wheel = 3 seconds
Time required for 1-inch vertical wedge travel = 7 minutes
" " " 1-inch horizontal " " = 42 "

(3) *Influence of Wedge Movements at Centre.*
At Top Chord—SU6
Bottom wedge movement of 1-inch horizontal produces at *SU6*
−0.12 inch horizontal
2.64 inches vertical.
Top wedge movement of 1-inch horizontal produces at *SU6*
−0.88 inch horizontal
2.65 inches vertical:
At Bottom Chord—SL6.
Bottom wedge movement of 1-inch horizontal produces at *SL6*
−1.00 inch horizontal
2.64 inches vertical.
Top wedge movement of 1-inch horizontal produces at *SL6*
−0 inch horizontal
2.65 inches vertical.
Transversely
Bottom wedge movement of 1-inch horizontal produces at *SL6*
−2.43 inches cross.
Top wedge movement of 1-inch horizontal produces at *SU6*
−2.43 inches cross.

Independent transverse adjustments cannot be made at *SU6* and *SL6* owing to rigidity of sway bracing.

Power Required to Operate Wedges

Wedge mechanisms have been designed for assumed frictions as follows, each wedge being operated by two hand wheels:—

	Max. per cent	Probable starting per cent	Probable turning per cent
Sliding friction on wedge surfaces....	18	12½	10
Turning " between screw and nuts.............	15	12	10
" " on worms and wheels	10	8	6
Force required on two hand wheels (22 inches dia.)			
to operate under 720-ton load...	350 pds.	110 pds.	30 pds.
to operate under 720-ton load using bars in wheel sockets to increase effective diameter to 60 inches..................	135 "	40 "	11 "

Tests made on wedges under nominal loads indicate the following as required effort under 720-ton load for various assumed values of sliding friction on wedge surfaces.

	18 per cent	12½ per cent	10 per cent
Force on two hand wheels (22 inches dia.)...........................	380 pds.	160.0 pds.	65.0 pds.
Force on two hand wheels (60 inches dia.)...........................	140 "	60.0 "	25.0 "

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XIII JANUARY 1930 No. 1

Council's Proposal to Increase the Annual Fees

The activities of a society like The Institute, and the services it renders to its members, are limited by the funds available. It would seem fair to take the revenue per member as a measure of the possibilities for service, and the expenditures per member as an indication of the efficiency of administration.

The Institute's gross revenue per member, (from members' fees), is thirty-nine per cent of the same item for one of the larger engineering societies in the United States, whose standards approximate to our own. Our net revenue per member available for headquarters activities (gross revenue less local rebates) is twenty-three per cent of the American figure.

On the other hand the ratio as regards operating expense, as shown by headquarters expenditure per member, is forty-seven per cent, and as to expenditure on meetings, seventy-two per cent.

Our net cost of publications per member, (i.e. total cost, less revenue from sales and advertising), is one-seventh of the corresponding figure in the other society.

The Institute has no reserve fund from which unforeseen but desirable expenses can be defrayed. This year, for example, it was necessary to incur the cost of preparing a report on, and giving publicity to, the question of the salaries of technical men in the Civil Service.

For some years successive Finance Committees of The Institute, in order to obtain balanced budgets, have had to refuse authorization for desirable items of expenditure. Under this head come such features as increased rebates to Branches; additional expenditure on the meetings of The Institute; the publication of Transactions and Year Book; improvement in the Journal; further development of our Employment and Information Services; adequate representation of The Institute at international conventions, and a number of others.

Prizes for Students and Juniors

The rules governing the award of prizes for the best papers presented by Students and Juniors of The Institute are given below:—

(1) Five prizes may be awarded annually for the best papers presented by Students or Juniors of The Institute in the Vice-Presidential zones of The Institute, as follows:—

The H. N. Ruttan Prize,—
in Zone A—The four western provinces.

The John Galbraith Prize,—
in Zone B—The province of Ontario.

The Phelps Johnson Prize,—
for an English Student or Junior in Zone C—The province of Quebec.

The Ernest Marceau Prize,—
for a French Student or Junior in Zone C—The province of Quebec.

The Martin Murphy Prize,—
in Zone D—The Maritime provinces.

(2) Awards shall only be made if, in the opinion of the examiners for a Zone, a paper of sufficient merit has been presented to a Branch in that particular Zone.

(3) The winner of a prize shall be required to specify such technical books or instruments as he may desire to the total value of approximately twenty-five dollars when suitably bound and printed or engraved, as the case may be.

(4) The award of prizes shall be for the year ending June thirtieth. On that date, each Branch secretary shall forward to the examiners for his particular Zone all papers presented to his Branch by Students and Juniors during the prize year, regardless of whether they have been read before the Branch or not.

(5) The prizes shall be awarded only to those who are in good standing as Students or Juniors of The Institute on June thirtieth following the presentation of the paper.

(6) The papers must be the bona fide production of those contributing them and must not have been previously made public or contributed to any other society in whole or in part. It is to be understood, however, that a paper which has won or been considered for a Branch prize is nevertheless eligible for The Institute Prize. No paper shall be considered for more than one of the five prizes.

(7) The examiners for each Zone shall consist of the Vice-President of that Zone and two Councillors resident in the Zone, appointed by Council. In the case of Zone C, two groups of examiners shall be appointed under the two Vice-Presidents, one for the English award and one for the French award. The awards shall be reported to the Annual Meeting of The Institute next following the prize year, and the prizes presented as soon thereafter as is reasonably possible.

Forty-Fourth Annual General and General Professional Meeting

The Annual General Meeting will be convened at Headquarters, 2050 Mansfield street, Montreal, on Thursday, January 23rd, 1930. After the reading of the Minutes of the last Annual General Meeting, the appointment of Scrutineers to count the Officers' Ballot, and the appointment of Auditors for the ensuing year, the meeting will be adjourned to reconvene at the Chateau Laurier, Ottawa, Ontario, February 12th, 13th and 14th, 1930.

Programme of Meeting at Chateau Laurier, Ottawa

(*Subject to Revision*)

Wednesday, February 12th

9.00 a.m. *Registration.*

10.00 a.m. *Annual General Meeting* (Assembly Hall).

Reception and discussion of Reports from Council, Committees and Branches. Discussions of proposed amendments to By-laws and other matters.

12.45 p.m. *Luncheon* (Banquet Hall).

(Complimentary to visiting ladies).

Welcome to members by J. McLeish, M.E.I.C., Chairman of the Ottawa Branch, who will preside. Brief address by His Worship Mayor Plant.

2.15 p.m. *Annual General Meeting* (Assembly Hall).

Scrutineers' report and elections of officers.
Retiring President's address.
Induction of new President.

4.30 p.m. *Ladies Tea* (Details later).

8.30 p.m. *Smoking Concert* (Ball Room and Banquet Hall).

Thursday, February 13th

Technical Sessions:

9.30 a.m. *Assembly Hall.*

Rigid Air Ships,—by Group Captain E. W. Stedman, M.E.I.C., R.C.A.F., Department of National Defence, Ottawa.

The Engineer's Work in Surveying and Mapping, —by F. H. Peters, M.E.I.C., Surveyor General, Department of the Interior, Ottawa.

9.30 a.m. *Ladies Cafe.*

Radio Communication as an Aid to Aviation in Canada,—by Major W. A. Steel, A.M.E.I.C., Radio Engineer, R.C.C.S., Department of National Defence, Ottawa.

Development of Radio in Canada,—by A. N. Fraser, A.M.E.I.C., Chief Engineer, Radio Branch, Department of Marine and Fisheries, Ottawa.

Recent Improvements in Mechanical Transport Vehicles, with Particular Reference to Multi-wheeled Cross Country Commercial Types,—by Captain N. G. Duckett.

12.45 p.m. *Luncheon* (Banquet Hall).

(Complimentary to Visiting Ladies).

Address by Dr. H. M. Tory, Chairman of the National Research Council of Canada.

2.15 p.m. *Assembly Hall.*

The Application of Aerial Surveys to Engineering Problems,—by A. M. Narraway, M.E.I.C., Controller of Surveys, Topographical Surveys Branch, Department of the Interior, Ottawa.

Ladies Cafe.

Aeronautical Laboratories of the National Research Council of Canada,—by J. H. Parkin, National Research Council, Ottawa.

3.00 p.m. Through the courtesy of the Department of National Defence, a demonstration will be staged of six wheel vehicles working across country in snow. Busses will be provided at the Chateau.

4.30 p.m. *Ladies Tea* (Details later).

9.00 p.m. *Reception and Engineers' Ball* (Ball Room).

Friday, February 14th

Technical Session.

9.30 a.m. *Assembly Hall.*

Fabrication and Erection of the Superstructure of the Montreal-South Shore Bridge,—by Major LeRoy Wilson, M.E.I.C.

Ladies Cafe.

Water Power Resources of Canada, by N. Marr, M.E.I.C., Chief Hydraulic Engineer, Dominion Water Power and Reclamation Service, Department of the Interior, Ottawa.

12.00 p.m. *Visit to Engineering Works.*

Through the courtesy of the Gatineau Power Company, a special train will leave the Union Station for Paugan Falls, Quebec, for an inspection of the power plant at that site. Luncheon will be served on the train. The train will return to Ottawa in time for dinner.

2.30 p.m. Through the courtesy of the Department of Mines, a visit has been arranged to the Fuel Research Laboratory and the Ore Dressing and Metallurgical Laboratories of the Department of Mines on Booth Street. Busses will be provided at the Chateau Laurier.

7.30 p.m. *Annual Dinner of the Institute* (Banquet Hall).

A special programme of the functions prepared for the ladies will be available at the registration desk.

Toronto Branch Honours President Mitchell

In recognition of the signal honour that has been bestowed on the Toronto Branch by the election of one of its members to the position of President of The Engineering Institute of Canada, that Branch tendered a banquet to Brigadier General C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., on the evening of December 4th. The banquet was fittingly held in the comfortable quarters of the Engineer's Club and was attended by some eighty members of The Institute. Among those present at the head table were T. Taylor, M.E.I.C., chairman of Toronto Branch; Sir Robert Falconer; Professor DeLury, Dean of the Faculty of Arts; Canon Cody; R. J. Durley, M.E.I.C., our general secretary; Mr. Justice Middleton and Mr. R. C. Harris, Commissioner of Works, City of Toronto. These comprised a truly representative gathering of the leaders in the various spheres of activity of our Canadian life and all were present to do honour to one who had shown his leadership not only as an engineer but as a soldier, an educationalist and the one who now holds the highest honour that can be conferred in our Institute.

Brig.-Gen. C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C.

Professor DeLury in proposing the toast to General Mitchell recalled those days some forty years ago when he was an undergraduate with Charley Mitchell and H. J. Cody, and referred to the activities of the Literary and Scientific Society and the friendly rivalry of the members of the Arts Faculty and the School, especially at election time.

In replying to this toast General Mitchell expressed in a fitting way his gratitude of the honour that was being given to him. Continuing General Mitchell said, "These are days of prosperity in Canada and in running over briefly all the engineering works at present under construction in the Dominion, one can read of stupendous tasks performed by the engineer. Right from Halifax to Victoria there are monuments to engineering skill and knowledge." General Mitchell then enumerated some of the work at present under construction from coast to coast. Speaking of The Institute the General said "The Engineering Institute of Canada is of inestimable value to the whole of the Dominion, and though we here are members of the profession I take no exception to saying that the world in general little realizes what the engineer is doing to make the average citizen's life more comfortable and pleasant."

Col. Hertzberg proposed the toast to "Our Guests" in a very able manner. Sir Robert Falconer replied paying tribute to the great work that General Mitchell had done as an intelligence officer in the Great War. Canon Cody in his remarks stated that "One cannot but thrill with pride at what the engineers of our country are doing. Forty years ago this year I graduated from the University of Toronto, and recall with every happiness my association, remote though it was, with the engineering fraternity. I have to thank General Mitchell for a very lovely stained glass window which was unveiled in St. Paul's Church, the pieces of glass of which it is composed being collected by him from many ruined churches and cathedrals in France. I like to think of him as a soldier and an engineer, but I also like to think of him as my old church warden and with all his wonderful abilities General Mitchell has remained a plain, honest Christian gentleman."

Third (Triennial) Empire Mining and Metallurgical Congress

The Third (Triennial) Empire Mining and Metallurgical Congress will be held in March 1930 in South Africa, when meetings and technical sessions will take place in the following centres: Cape Town, Kimberley, Johannesburg, Bulawayo and Durban.

Delegates to this Congress will have the opportunity of touring the Union of South Africa and Rhodesia in special trains, which will visit the principal mining centres and other places of interest. The organization of the Congress and its tours is similar to that which made the Second Congress such an outstanding success in Canada in 1927.

Information regarding the Congress and conditions of participation can be secured from the Secretary's office.

Dimensional Standards of the Canadian Engineering Standards Association

A publication of a new type has been received from the Canadian Engineering Standards Association, beginning a series which will be published in loose-leaf form in a special binder for the convenient use of engineers, designers and purchasing agents. Hitherto the work of the Association has consisted largely in the preparation of standard specifications for engineering material or equipment, dealing with standards of quality or performance. There is, however, a wide field of work for the Association in promoting agreement among manufacturers and users regarding the limitation of sizes and varieties of engineering products, and in agreeing on the standards of accuracy which are desirable as governing the cost and finish of the work.

The publication now issued* deals with stove bolts and machine screws, and presents the results of considerable discussion in regard to these products along the above lines. For example, if the lists now published are adhered to by the manufacturers of machine screws, the forty-three varieties now in the market will be reduced to a working list of twenty-one, which will still provide a range sufficient for all practical purposes. The adoption of this list by manufacturers and users would be of mutual benefit, relieving the manufacturer of the extra expense involved in tooling up machines to fill small orders for sizes of screws subject to infrequent call, and enabling him to manufacture for stock with the assurance that the market demand will be adequately met. The user will be assured of quicker delivery and will derive benefit from reduced manufacturing costs. Work of this kind cannot fail to enhance the reputation of the Canadian Engineering Standards Association as an organization mutually beneficial to engineers, manufacturers and users of engineering equipment.

*C.E.S.A. Established Lists of Dimensional Standards:
B18-1929 Established list of Stove Belts.
B29-1929 Established list of Machine Screws.
Canadian Engineering Standards Association, Ottawa.

The Canadian General Electric Company, Ltd. is now distributing its latest Industrial Control Catalogue. This catalogue, which will prove invaluable to every control user, contains over 250 pages of the most up-to-date information on industrial control. There are listed the latest developments in motor-starters and controllers for fans, pumps, elevators and other electrically operated equipment to which industrial control is now applied. Considerable space has been given to a detailed description of the devices listed, particularly regarding the operation of the automatic and magnetic controllers. Special attention has been devoted to the question of thermal overload protection and definite time acceleration—two desirable features now standard in practically all Canadian General Electric magnetic controllers. Copies of the catalogue may be obtained from the nearest office of the company.

ELECTIONS AND TRANSFERS

At the meeting of Council held on December 3rd, 1929, the following elections and transfers were effected:

Member

FELLHEIMER, Alfred, B.Sc., (Univ. of Ill.), architect and engineer, 155 East 42nd Street, New York, N.Y.

Associate Member

YACK, Wilfrid Laurier, B.A.Sc., (Univ. of Toronto), mech'l. dept., Price Bros. & Co. Ltd., Kenogami, Que.

Juniors

McCRONE, Donald Gordon, B.A.Sc., (Univ. of Toronto), junior designer, Chapman & Oxley, Architects, Toronto, Ont.

MINARD, Guy McRae, B.Sc., (Queen's Univ.), lab. foreman, Spruce Falls Power & Paper Co. Ltd., Kapuskasing, Ont.

Transferred from the class of Junior to that of Associate Member

PATTERSON, Thomas Bilton, B.Sc., (Univ. of Sask.), res. engr., constrn. dept., C.N.R., Saskatoon, Sask.

WINTER, Thomas Henson, B.Sc., (N.S. Tech. Coll.), senior dftsman., New Jersey State Highway Dept., Newark, N.J.

Transferred from the class of Student to that of Junior

BALLARD, Bristow Guy, B.Sc., (Queen's Univ.), rly. motor engrg. dept., Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

MILLAR, James Wallace, B.A., B.A.Sc., (Univ. of B.C.), P.O. Box 170, Field, B.C.

THOMPSON, William Lennox, B.A.Sc., (Univ. of Toronto), sales service engr., Bailey Meter Co. Ltd., Montreal, Que.

Students Admitted

BENNETT, George Francis, (Undergrad., McGill Univ.), 1126 Sherbrooke Street West, Montreal, Que.

CAPELLE, William A., (Undergrad. Univ. of Man.), 79 Cobourg Avenue, Winnipeg, Man.

CLARK, Samuel Findlay, (Undergrad., Univ. of Man.), 519 Sherburn Street, Winnipeg, Man.

CLARKE, George F., (Undergrad., McGill Univ.), 1126 Sherbrooke Street West, Montreal, Que.

CLARKE, Owen Mawbey, (Undergrad., McGill Univ.), 1126 Sherbrooke Street West, Montreal, Que.

EGAN, Edward J., (Undergrad., N.S. Tech. Coll.), 2 Summer Street, Halifax, N.S.

EMERSON, Robert Alton, (Undergrad., Univ. of Man.), Plum Coulee, Man.

FOGARTY, James William Patrick, (Undergrad., McGill Univ.), 461 Sherbrooke Street West, Montreal, Que.

GOODERHAM, Walter James, (Undergrad., Univ. of Man.), 759 Simcoe Street, Winnipeg, Man.

HENDERSON, Robert Pritchard, (Undergrad., Univ. of Man.), 1-A Wellington Apts., Winnipeg, Man.

JONES, Llewellyn Edward, (Undergrad., Univ. of Man.), Transcona, Man.

KENT, William Leslie, (Undergrad., Univ. of Alta.), 7805-107th Street, Edmonton, Alta.

MITCHELL, John, B.Sc., (McGill Univ.), 3429 Peel Street, Montreal, Que.

MURRAY, Walter M., (Undergrad., Univ. of Man.), 194 Montrose Street, Winnipeg, Man.

NIX, Charles Edward, (Undergrad., Univ. of Alta.), 10219-115th Street, Edmonton, Alta.

ODDLAFSON, Axel Leonard, (Undergrad., Univ. of Man.), 590 Victor Street, Winnipeg, Man.

SKELTON, C. Hastings, (Undergrad., McGill Univ.), 379 Roslyn Avenue, Westmount, Que.

STARR, Charles Harry, (Acadia Univ. 1927-29), Engineering Department, Northern Electric Co. Ltd., Montreal, Que.

THOMSON, Elihu, (Undergrad., McGill Univ.), 695 Grosvenor Avenue, Westmount, Que.

WALLACE, Keith B., (Undergrad., McGill Univ.), 195 Belgrave Avenue, Montreal, Que.

The Combustion Engineering Corporation, New York, have reprinted for distribution two papers; one is entitled "Test of Boiler No. 4, East River Station The New York Edison Company" by W. H. Lawrence, chief operating engineer, New York Edison Company, and the other is "High Pressure Steam in the Paper Industry" by J. B. Crane, of the Combustion Engineering Corporation. Additional copies of these papers are available, and will be sent upon request to those interested.

OBITUARIES

Edmund Wragge, M.E.I.C.

Members of The Institute throughout Canada and abroad have learned with sincere regret of the death of Edmund Wragge, whose passing has taken from The Institute one of its first members. The late Mr. Wragge was widely known in Canada, England and South Africa in connection with his work on railway construction.

At the time of his death, which occured at his home in Toronto, Ont. on November 27th, 1929, he was in his ninety-third year, and was the oldest member of The Institute.

Mr. Wragge was born in Worcestershire, England, and received his education at Rossall school. From 1854 to 1858 he was apprenticed to the London firm of Messrs. Fox Henderson and Company, with which he acquired his first ideas of railway construction.

On the completion of his term of apprenticeship at the age of twenty-two, Mr. Wragge accepted a commission to go to South Africa, where, from 1859 to 1862 he was district engineer on the Cape Town and Wellington Railway, constructing the first railway in that country between Cape Town and Stellenbosch. Returning to England on the completion of this work in 1863, he became assistant engineer with the London, Chatham and Dover Railway. In 1864 he was appointed engineer in charge of the works of the London, Chatham and Dover, London, Brighton and South Coast and London and Southwestern Railways at Battersea and Victoria. In 1867-69 he entered private practice in London, during which time he carried on the works of the Waterloo and Whitehall Railway, and went to Costa Rica for the government of that country.

In 1869 Mr. Wragge came to Canada, and from that time until 1883 was chief engineer of the Toronto Grey and Bruce Railway, now part of the Canadian Pacific Railway, and from 1869 to 1875 he was also chief engineer of the Toronto and Nipissing Railway, now part of the Canadian National Railways, and from 1875 to 1883 he was also general manager of the Toronto Grey and Bruce Railway.

In 1883 Mr. Wragge was appointed Toronto manager of the Grand Trunk Railway, and remained in that capacity until 1896 when he returned to England to build the Marylebone terminal of the Great Central Railway. He returned to Canada eight years later, and was appointed consulting engineer to the Canadian Pacific Railway Company. From that time until 1914, when he retired, Mr. Wragge was associated with the improvement projects undertaken by the railway.

Mr. Wragge was the oldest member of the Toronto Club and the Toronto Golf Club. He was a Member of the Institution of Civil Engineers to which he was admitted as a Member on January 11th, 1870, and was the recipient of the Telford Medal and the Telford Premium from that Institution.

The late Mr. Wragge was one of the few remaining members of The Institute whose membership dates back to January 20th, 1887, prior to the incorporation of the Canadian Society of Civil Engineers. In the early days of the Society he took a very active part in its affairs, and served on its Council during the years 1889 and 1890.

Stephen Williams, Jr.E.I.C.

Deep regret is expressed in recording the death of Stephen Williams, Jr.E.I.C. which occurred following a brief illness in the Montreal General Hospital, Montreal, on December 17th.

Mr. Williams was born at Toronto, Ont., on January 8th, 1900, and received his primary education at Ridley School at St. Catharines, Ont. He graduated from the Royal Military College at Kingston in 1920, and received the degree of B.A.Sc. at the University of Toronto in 1922.

During summer vacations Mr. Williams was variously employed in engineering work with the Toronto Harbour Commission, the John Inglis Company, Toronto, the Dominion Ship Yards, Toronto, and the Chapman Double Ball Bearing Company, Toronto. Following graduation in 1922, he was, for a time, instrument man with the Toronto Harbour Commission and was later a surveyor with the Ontario Department of Public Highways. Mr. Williams joined the staff of the Imperial Refineries Ltd. at Sarnia, Ont., at the end of 1922, and has remained with that concern ever since that time.

In 1926 he was transferred to Montreal and at the time of his death was chief engineer of the Montreal refinery of the company.

Mr. Williams joined The Institute as a Student on July 20th, 1920, and transferred to the class of Junior on July 7th, 1924.

James W. Moffatt, M.E.I.C.

Members of The Institute will learn with deep regret of the death of James W. Moffatt, M.E.I.C., which occurred at his home in Toronto on October 28th, 1929.

The late Mr. Moffat was one of the earliest members of The Institute, having joined The Canadian Society of Civil Engineers as Member at the time of its establishment on February 24th, 1887. He was perhaps best known through his work as a metallurgist and as construction engineer on important works for the Canadian Pacific Rilway.

Mr. Moffat was born at Walkerton, Ont., in 1860, and received his education at Brantford Collegiate, the School of Practical Science, Toronto, and McGill University, graduating from the latter institution in civil engineering in 1883.

Following graduation he joined the engineering staff of the Canadian Pacific Railway Company, and was employed on the construction of the bridge over the St. Lawrence river at Lachine, Que. Later, he was in charge of a party which ran the initial survey through the Sudbury district. He was also in charge of construction of the Canadian Pacific Railway bridge at Sault Ste. Marie. Mr. Moffat later practised as a consulting mining engineer in Denver and then in Nelson, B.C. In 1905 he took up his residence in Toronto, Ont., where he operated a plant for the reduction of iron ores by electricity. In 1912 he built the Moffat Electric Steel plant at Toronto, and for several years operated an electrical furnace plant on a commercial basis. His initial experiments having proved successful, he closed down the Moffat Iron Works in order to carry on further research along similar lines. He was endeavouring to develop a process which would be suitable for smelting Ontario ores, and at the time of his death this process was on the point of successful application.

PERSONALS

A. D. Porcheron, A.M.E.I.C., is now a member of the staff of the Asbestos Corporation, Ltd., and is located at Vimy Ridge Mine, Que.

John Stewart, A.M.E.I.C., who, since 1920, has been a member of the firm of Black McKenney and Stewart, consulting engineers, Washington, D.C., is now in private practice in Washington.

B. K. Boulton, S.E.I.C., who was formerly with the Duke-Price Power Company at Arvida, Que., is now electrical engineer with the Beauharnois Construction Company at Beauharnois, Que. Mr. Boulton graduated from McGill University in 1925 with the degree of B.Sc.

R. H. Keefler, S.E.I.C., has been appointed general commercial engineer, with the Bell Telephone Company of Canada Ltd., at Montreal. Mr. Keefler, who graduated from the University of Toronto in 1924 with the degree of B.A.Sc., has been with the Bell Telephone Company since 1927.

E. L. Baillie, Jr.E.I.C., who was formerly on the staff of the Nova Scotia Power Commission at Halifax, N.S., is now with the Department of Highways in the same city. Mr. Baillie who graduated from the Nova Scotia Technical College in 1926 with the degree of B.Sc., was at one time professor of mathematics and later professor of engineering at the St. Francois Xavier College, Antigonish, N.S.

G. H. Kingston, S.E.I.C., has joined the staff of the Alcoa Power Company at Arvida, Que. Mr. Kingston, who graduated from McGill University in 1927, with the degree of B.Sc., was with the Bell Telephone Company of Canada, Ltd. in Montreal, at one time, and prior to accepting his present position was connected with the Fraser-Brace Engineering Company also in Montreal.

C. A. Wakeham, S.E.I.C., is at present employed by the Shawinigan Water and Power Company at Joliette, Que. Mr. Wakeham, who graduated from the University of New Brunswick in 1928 with the degree of B.Sc., was for a time on the staff of the Northern Electric Company, at Montreal, and later took the Canadian Westinghouse Company's test course, at Hamilton, Ont.

J. P. Fraser, A.M.E.I.C., is now electrical engineer with the Northwestern Power Company at Winnipeg, Man. Mr. Fraser graduated from the University of Manitoba in 1914, with the degree of B.E.E. Following graduation he joined the staff of the Canadian Westinghouse Company as an engineering apprentice, and has remained with that firm up to the present time. Since 1923 he had been designing engineer on switching equipment, and was located at Hamilton, Ont.

H. W. Small, Jr., M.E.I.C., who was formerly chief engineer with the Alcoa Power Company, Ltd., at Arvida, Que., has accepted a position with the W. S. Lee Engineering Corporation and will be located at Charlotte, N.C. Mr. Small was for a time with Stone and Webster Inc., on the supervision of design, investigations, reports and appraisals on steam and hydro-electric power plants, and later was connected with the Fargo Engineering Company at Jackson, Mich., as principal assistant on the same kind of work.

S. B. Wass, A.M.E.I.C., terminal engineer with the Canadian National Railways, has been transferred from Toronto to Montreal. Mr. Wass, who is a graduate of the University of Toronto of the year 1903, has been with the Canadian Government Railways since 1918, when he was division engineer at Moncton, N.B. He was appointed terminal engineer for western lines in 1922, when he was located at Fort William, Ont. Prior to joining the staff of the Government Railways, Mr. Wass was inspection engineer, Highways Branch, of the Department of Railways and Canals for the provinces of Nova Scotia and Prince Edward Island.

M. du Bois, Jr.E.I.C., who has been in Canada and the United States for several years, has returned to Switzerland, and will live in Geneva. Mr. du Bois graduated from the Federal Polytechnical Institute at Zurich in 1926, and was awarded the degree of M.Sc. by the Massachusetts Institute of Technology in 1927. In 1928 he was, for a time, marine engineer with Alex. McKay Company, Ltd., at Quebec, Que. and was later in the hydraulic department of the Dominion Engineering Company, Ltd. at Montreal. The last position Mr. du Bois held prior to his departure was in the construction office of the Consolidated Mining and Smelting Company at Trail, B.C.

W. G. MacNaughton, M.E.I.C., who until recently has been connected with the News Print Service Bureau, New York, N.Y., is now with the manufacturing department of the International Paper Company, New York, N.Y. Mr. MacNaughton is a graduate of McGill University of the year 1904, and for three years following graduation he was employed as chemist with the Canadian Consolidated Rubber Company, Montreal, and also had supervision of rubber cement department and crude rubber preparation. In 1908, he became chemist for the Nekoosa Edwards Paper Company, at Port Edwards, Wis., and in 1912 he was promoted to the position of plant manager. In 1917 Mr. MacNaughton was appointed general manager of the Inland Empire Paper Company at Spokane, Wash., and in 1921 he became secretary of the Technical Association of the Pulp and Paper Industry, New York, N.Y.

R. G. Barbour, S.E.I.C., is now electrical engineer with Messrs. McDougall and Friedman, consulting engineers, Montreal. Mr. Barbour graduated from the University of New Brunswick in 1924 with the degree of B.Sc., and obtained the degree of M.Sc. from the same university in 1927. From 1924 to 1926 he was with the Canadian General Electric Company, Ltd. at Peterborough and Toronto, including test course, engineering offices, draughting room and engineering sales offices. From 1926 to 1929, Mr. Barbour was with the Aluminum Company of Canada at Arvida, Que., during which time his work included the installation of a 65,000-kw. rotary converter station and industrial power equipment; the operation, as assistant chief operator, of rotary and transformer stations; and the designing and installation for transmission, power and lighting for the alumina electrical reduction plant. Subsequently Mr. Barbour was electrical engineer in charge of construction, operation and maintenance, in connection with the electrical equipment.

G. Lorne Wiggs, A.M.E.I.C., has recently been appointed manager of the Montreal sales office of the C. A. Dunham Company, Ltd. Following graduation from McGill University in 1921 with the degree of B.Sc., Mr. Wiggs was engaged on test work with the Canadian Westinghouse Company at Hamilton, Ont., later becoming sales engineer with the Canadian Crocker Wheeler Company. During

G. LORNE WIGGS, A.M.E.I.C.

1922-1923, he was sales engineer with the Mechanics Supply Company, Ltd., at Quebec, Que., and in 1923 he was for three months with the C. A. Dunham Company at Chicago, Ill., on heating design work. From 1924 to 1929 Mr. Wiggs was manager of the engineering department of the Mechanics Supply Company at Quebec, being in charge of all designs, plan work, etc., in that department. In June 1929 he entered private practice in Montreal as a consulting engineer on the mechnical and electrical equipment of buildings, and has given up that practice to accept his present position.

C. H. McL. Burns, A.M.E.I.C., has succeeded Mr. G. L. Grass who has for some years been chief engineer of the Dodge Manufacturing Company, Ltd., Toronto, Ont. Mr. Burns will have direct charge of all engineering as manager of the company's engineering department. Mr. Burns after some years' engineering experience in coal and metalliferous mining in eastern Canada, having been chief engineer of the Maritime Coal, Railway and Power Company from 1911 to 1920, spent a number of years with the Link-Belt Company in the United States, first as designing engineer in the engineering department, and later as construction and development engineer in charge of important changes and construction of the company's own plants in the United States. In 1928, Mr. Burns returned to Canada to join the engineering staff of the International Nickel Company at Copper Cliff, Ontario, taking charge of the general arrangement and design of the ore handling equipment from their new crushing and screening plants, concentrator and smelter.

F. M. Byam, M.E.I.C., is now connected with the National Bridge Company Ltd., at Montreal, Que. Following his graduation from the School of Practical Science, University of Toronto, in 1906, Mr. Byam was for a time structural draughtsman with the Canada Foundry Company, Toronto. From September 1907 to June 1908 he was structural draughtsman and checker with the Riverside Bridge Company of Wheeling, West Va., and from June to October 1908 he was structural checker and designer and mechanical designer for the Dickson Bridge Works Company at Campbellford, Ont. In 1908, Mr. Byam joined the staff of Messrs. Smith, Kerry and Chace, Toronto, as stuctural and hydraulic designer, and in November 1909 he was placed in charge of the civil engineering drawing office, having charge of all the structural and hydraulic design. In 1911 he became associated with Messrs. McGregor and McIntyre, Ltd., structural steel and bridge manufacturers, as chief engineer, and remained in that position until December 1919 when he went into private practice with Messrs. Ewart and Jacob under the name of Ewart, Jacob and Byam, Ltd., engineers and architects, Toronto. In 1928 Mr. Byam returned to McGregor and McIntyre Ltd., as chief engineer, and has remained with that firm up to the present time.

M. V. Sauer, M.E.I.C., until recently with the Winnipeg Electric Company, Winnipeg, Man., is now hydraulic engineer for the Beauharnois Construction Company, at Beauharnois, Que. Mr. Sauer is a graduate of the School of Practical Science, University of Toronto, of the class of 1901, and took a post graduate course in 1902, receiving a fellowship in 1903.

After his university course Mr. Sauer, was with the Ontario Power Company at Niagara Falls, first as draughtsman, and the following year as assistant to the mechanical engineer. He was appointed chief designer of the Niagara Falls Power Company, Niagara Falls, N.Y. in 1905, and the following year was construction engineer for the Iroquois Construction Company, Buffalo, N.Y. In 1907 he again became associated with the Ontario Power Company as chief designer, then as mechanical assistant to the engineer-in-charge, and subsequently in 1912, as mechanical engineer in full charge of design, field, and inspection department. He later became associated with the Hydro-Electric Power Commission of Ontario, and occupied a prominent position in connection with the design and construction of the Queenston-Chippawa power development.

In 1923 Mr. Sauer became hydraulic engineer for Canadian Vickers Limited, with headquarters at Montreal, and in 1925 he was transferred to Toronto, and was chief engineer of the hydraulic department of the then recently incorporated Vickers and Combustion Engineering Ltd., which was a consolidation of the Canadian Vickers Ltd., and the Combustion Engiheering Corporation Ltd. Shortly afterwards, in 1926, he was appointed vice-president of William Hamilton, Limited at Peterborough, Ont.

M. V. SAUER, M.E.I.C.

BOOK REVIEW

Practical Television

By E. T. Larner, with a foreword by John L. Baird. D. Van Nostrand Company, New York, 1929, buckram, 5¼ x 8½ in., 223 pp., front., illus., figs.

Many people, including even technicians of various kinds, hear or read of television ("seeing from afar") and remark on its marvels to their friends, but wish they knew how it came about and how the process may be accomplished.

This little book of twelve chapters and two hundred and twenty pages purports to tell the tale in easy and non-mathematical language for the general reader, who may not be too well versed in the principles of physics. Although the book is small, illustrations abound; there are one hundred and twenty-seven figures altogether.

The book treats concisely the history of television and shows how it was thought of and striven for even before telephony ("hearing from afar") was accomplished. Modern physical devices, electron tubes, photo-electric cells and radio, discovered since telephony was developed, have brought television near to practical and commercial achievement. The author brings out the distinction between television and phototelegraphy and telekinematography, and gives short descriptions of "phonovisor" and "noctovisor" perception.

In the history (chapters 2 and 5) the older attempts at television are reviewed, including those by help of beams of cathode rays. It clearly stands out that it is one thing to transmit silhouettes and shadowgraphs but another and more difficult thing to transmit the images of actual scenes and persons. For the benefit of those who need it there is a chapter on the now superseded selenium cell (chapter 3) which has given way to the photo-electrical cell, "the magic lamp of physics," (chapter 4); a chapter on the cathode ray (chapter 6), and even one on the elementary principles of optics which the television process involves (chapter 7).

The rest is modern television and the details of television technique, including the methods of subject illumination, image formation and its modulation in light and shade, synchronization, and transmission and reception of the image by radio or by wire. All of these essentials are quite simply explained, and must be read to be understood.

Of the modern systems, that of Baird is starred. Possibly it would have brought a better balance to the concluding portion of the book if a little more attention in detail had been given to the system of the American Telephone and Telegraph Company and their successes, even though these were attended by so much labour and expense. From what the reviewer has seen of television he ventures the opinion that no system is yet quite ready for the public.

R. W. Boyle, M.E.I.C.,
Director, Division of Physics and Engineering Physics, National Research Council of Canada, Ottawa.

Recent Additions to the Library

Proceedings, Transactions, etc.

Presented by the Societies:
- Royal Philosophical Society of Glasgow: Proceedings, 127th Session, 1928-29.
- The Institution of Civil Engineers: Engineering abstracts, series 41. Proceedings, Meeting, February 18, 1929.
- American Society for Testing Materials: Index to A.S.T.M. Standards and Tentative Standards, as of Sept. 3, 1929.

- Basic Principles of Concrete Making.

The Canadian Ingersoll-Rand Company, Limited have just published a new booklet entitled "Drill Steel—Instructions for Selecting, Preparing, Forging, Heat Treating, and Tempering."

A concise treatise on modern rock drill steel preparation, written in plain language while retaining the necessary technical data, this booklet should be of great value to users of steel.

In addition to the text matter dealing with essentials to be looked for in a properly formed drill steel, tables for ready reference are given. A few of their titles are "Length of steel required for shanking and forging shank," "Weights of drill steel," "Length of steel required for forging four-point bits," "Length of steel required for forging six-point bits." An interesting and very practical feature appears on page 6, in the form of a working drawing of a proposed smith shop, which shows, conveniently arranged for speedy work, an outfit consisting of drill steel sharpener, oil furnace, grinder for shanks, quenching tank, steel racks, etc. Correct temperatures at which steel should be worked, are also explained, supplemented by a handy reference table showing the dangers of working steel below certain temperature or heating it to too high a degree. Copies of this booklet will be gladly furnished by the Canadian Ingersoll-Rand Company, Limited, 10 Phillips Square, Montreal, Que.

BRANCH NEWS

Halifax Branch

Wm. J. De Wolfe, A.M.E.I.C., Secretary-Treasurer.

The regular monthly supper meeting of the Halifax Branch of The Engineering Institute of Canada was held on November 20th, at 6.30 p.m., at the Halifax Hotel.

Previous to this meeting a conference of the executive was held at which various matters relating to Branch affairs were discussed, particularly with regard to the year's work, and the reception of the Nominating Committee report.

At the regular meeting, Chairman Harry Bennett, A.M.E.I.C., presided and there were 27 present, including Prof. F. H. Sexton, principal of Nova Scotia Technical College, who had been invited to address the meeting.

After the conclusion of supper, the meeting came to order, when the October minutes were read and approved. Chairman Bennett then praised the work of the October meeting committee for the excellent arrangements, the large number present and the general success of meeting. He also made reference to a proposal that there be no banquet at our annual meeting in as much as it had been suggested that our Branch join with the Professional Association to stage a joint banquet on the occasion of the annual meeting of the Association, instead.

The suggestion was well received and, on motion, was approved and Prof. W. P. Copp, M.E.I.C., Messrs. H. W. L. Doane, M.E.I.C., and J. Lorne Allan, M.E.I.C., were appointed the Branch Committee to assist in arranging the banquet.

Two auditors were appointed, they being Prof. F. R. Faulkner, M.E.I.C., and Prof. H. C.Burchell, M.E.I.C.

The report of the Nominating Committee was then received and ballots were ordered printed.

Chairman Bennett announced that the general executive of The Institute is preparing a case to present to the Civil Service Commission in behalf of the engineering services of the federal government. In that connection there had been a suggestion that letters of an editorial nature be sent the several newspapers but the suggestion was not well received by the Branch.

Chairman Bennett made a few introductory remarks in relation to the closer co-ordination of The Engineering Institute and the various Professional Associations throughout Canada, and introduced Prof. Sexton, who is chairman of the local joint committee in that connection.

Professor Sexton, on arising to speak, said he had been asked to open the discussion in this matter and began by explaining that several meetings of the committee had been held in order to try to find some basis on which closer co-operation of the two bodies could be founded.

He remarked that most engineers in Nova Scotia are members of the two bodies and there is not a great distance to be traversed to effect the co-operation aimed at. He read the objects of The Institute and stated that they are comprehensive and cover about all that may be desired of the social and technical and ethical aspects of our profession for which we stand before the public, but they do not cover the legal standard for which we contend and, hence, the Professional Association.

The Association was formed by a small handful of men who have striven to make The Institute the success it is but since a federal association could not immediately be formed, by enactment, provincial ones were formed and now there is a Professional Association in each province, excepting Saskatchewan. Each association has an act under which it operates to safeguard the practice of engineering, by setting standards designed to enable engineers to be of greater value in the general public interest and to protect themselves.

Due to the fact of different standards set up in different provinces the several acts vary in their make up. It is the aim to get all the acts into closer agreement and to have all engineers registered that gives rise to the present movement and also to have one body to cover all the different aspects of the profession.

Perhaps not every member of either organization favours co-ordination, but Professor Sexton was sure that most members will be found in agreement with the scheme.

We say little in these Maritimes about many things, especially the payment of dues. He favoured small dues but there must be one fee large enough to cover the cost of operating the two bodies, in the event of co-ordination. The Professor asserted that there should be one body to cover the social, technical and legal sides of the profession, and the fee must be large enough for the purposes outlined. There are, no doubt, those who contend that the present fees are too high, without giving thought to the large values obtained from membership. Compared with the fees required for hawker's licenses our fees are very low and all should be willing to pay what may be required to carry on.

The committee, he said, will not at this time propose a concrete method for co-ordination but, when we read of business mergers and the advantages of them, The Institute should go far in trying to get both organizations joined up for the mutual value to be obtained and the association should do the same to the end that there be, finally, unity of purpose and uniformity of effort and standards throughout the Dominion.

Other professions had had a long struggle to reach such a goal but it should not be so for us and Professor Sexton said, in conclusion, that he hoped to see this unity and uniformity an accomplished fact in the near future.

Prof. F. R. Faulkner was the next speaker and he said that the working out of a scheme of co-ordination is not all pleasure but it is a work in which we are all interested and for which we hope to find a solution. Prof. Faulkner gave a résumé of the meeting at Montreal in that connection and while he could not give details of the discussion there he could say that it was quite diversified and profitable. He read some extracts from the minutes of the meetings to bring out the point that there is a fast growing desire all over for some kind of co-ordination. He read a report to the Branch covering the meeting and said that, in his opinion, this co-ordination is very desirable and very possible of consummation.

Many angles must be considered before a final solution is found but the present Institute Committee is being continued and further, and greater, effort will be made to attain to the solution.

Mr. H. W. L. Doane said that he had nothing to add to the remarks already made but stressed the point that all the delegates at the meeting had been strongly for some one organization to co-ordinate all the activities of The Institute and the Professional Associations in order to get the best possible results for the profession throughout Canada.

A letter was read from Mr. C. E. W. Dodwell, a Past Vice-President of The Institute, and an Honorary Member, outlining his views with regard to the difficulties in the way to co-ordination of the two bodies.

Several members present expressed their views. It was agreed that the Committee had done excellent work to date and that we must do our part to bring about a happy and satisfactory scheme of co-ordination; that it is not a question of whether it is advisable but, really, of how soon it can be brought about.

Chairman Bennett summed up the situation as favourable and commended our Branch Committee for their active interest.

A motion was carried that our present committee be continued.

It was announced that the annual meeting will be held on December 19th and that, in view of the joint banquet to be held later, no special speakers will be invited but full reports of all the year's work will be presented.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, A.M.E.I.C., Branch News Editor.

Meeting of September 27th

The opening meeting of the Branch took the form of a dinner meeting and was held on September 27th at the Wentworth Arms. H. A. Lumsden, M.E.I.C., chairman of the Branch, occupied the chair. The guests were A. J. Grant, M.E.I.C., vice-president for Ontario, and E. G. Cameron, A.M.E.I.C., chairman of the Niagara Peninsula Branch, as well as other members of the Niagara Peninsula Branch. There were about forty at dinner including the guests.

E. G. Cameron, A.M.E.I.C., spoke on Institute affairs from the Branch viewpoint. He advocated decentralizing control of Institute affairs by throwing more work on the Branches. This would result in reduction of work at headquarters and could be effected by increasing the responsibility of the Branches regarding The Institute at large. As a particular instance, he mentioned the question of admission and transfer, which he thought could be handled by having the Branch make a thorough and complete report. By increasing interest in The Institute, its standing would be improved. Mr. Cameron referred to the discussion at the last annual meeting regarding increased dues. There was very little adverse discussion at the annual meeting but the increase was defeated in the vote when only 900 votes were recorded out of 3,600 corporate members.

Other points touched on by Mr. Cameron covered the use of questionnaires to get members of the Branch to express an opinion, the co-operation with the provincial associations by the Branches, management of Branch affairs and question of rebates. He felt that the rebates should be just sufficient to finance the activities of the Branch from year to year.

A general discussion followed in which a great number of those present took part.

Regular Meeting November 6th

A regular meeting of the Branch was held in the Technical Institute with Mr. Lumsden in the chair.

The speakers were all members of the Hamilton Branch. Mr. Graham Bertram gave a very interesting address on "Machine Tools" and showed photographs and models of a new line of tools for railroad shops.

R. K. Palmer, M.E.I.C., Branch Councillor, spoke on some of the matters discussed at the Plenary meeting of Council, stressing most particularly the question of Institute publications. A general discussion followed terminating in a motion that a resolution regarding publications be prepared by the chairman, the secretary and Mr. Palmer and that it be submitted to the Branch for discussion.

J. E. Grady, A.M.E.I.C., spoke on "Coke Ovens at the Steel Company of Canada's Plant." An interesting development is the use of a supply of calcium chloride to provide a dustless coke for domestic use.

J. R. Dunbar, A.M.E.I.C., spoke on the subject of "Power Factor" and showed the reduction in power cost possible by the use of condensers.

Refreshments were served after the meeting.

MEETING WITH INSTITUTE OF RADIO ENGINEERS

The members of the Hamilton Branch were the guests of the Institute of Radio Engineers at a meeting held in the Westinghouse auditorium on November 15th. K. S. Weaver of the Westinghouse Lamp Company, Bloomfield, N.J., spoke on the "Production Testing of Vacuum Tubes."

JOINT MEETING WITH NIAGARA PENINSULA BRANCH

On Wednesday, October 23rd, a joint meeting of the Buffalo Engineering Society, the Frontier and Toronto Sections of the A.I.E.E. the University of Toronto Engineering Society and the Hamilton and Niagara Peninsula Branches of The Institute was held. The early part of the day was devoted to inspection of the Welland ship canal followed by a dinner and meeting in the evening.

EXECUTIVE MEETING NOVEMBER 20TH.

A dinner meeting of the executive committee and past chairmen was held in the Royal Connaught hotel on November 20th at 6.30 p.m. to meet R. J. Durley, M.E.I.C., general secretary.

Among other matters discussed was the report of Mr. Porter's committee on the Professional Engineers' Associations.

Kingston Branch

L. F. Grant, M.E.I.C., Secretary-Treasurer.

On Thursday, November 22nd, the members of the Kingston Branch had the privilege of listening to an address by the President, Brig. Gen. C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C.

The President, who was introduced to the meeting by Dean A. L. Clark, M.E.I.C., of Queen's University, spoke first of Institute affairs, giving much interesting information on the activities of other Branches. He pointed out that each Branch had its own individuality instancing the large university element in the case of Kingston, and pointed out the advantage to young engineers in being members of a Branch in which all phases of the profession are represented. In speaking of the fact that The Institute has no less than twenty-five Branches he said that the only other truly national engineering society was that in Germany. He emphasized the growing influence of The Institute and the increase in membership during recent years. He urged upon the younger members the advantages of membership and of taking part in all Institute activities, and described how the Branches were making their influence felt through the medium of Branch councillors and the Plenary meetings of council, giving a brief résumé of the work of the last meeting.

Turning to the status of the profession generally, the President gave a most interesting and gratifying list of the large number of engineering projects which are at present under way in Canada, instancing harbour development and elevator work in the Maritime provinces, and on the St. Lawrence, power development on the Mersey river, Grand Falls, N.B., the Saguenay, Gatineau and proposed work in British Columbia; the Montreal-South Shore bridge; harbour development at Prescott, Kingston and Toronto and elsewhere on the Great Lakes; the numerous large buildings, both public and industrial, which are a feature of every growing Canadian city; the important municipal works which are either in hand or projected, and the machinery which is being produced in Canadian mechanical and electrical shops.

Lastly the President stressed the importance of the engineer being more than simply engineer, and becoming a factor in the public life of the country.

The vote of thanks was moved by Prof. A. MacPhail, M.E.I.C., who took the opportunity of congratulating Gen. Mitchell on having attained the high honour of President of The Institute.

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.

THE SULLIVAN MINE

The regular meeting of the Lethbridge Branch was held at the Marquis hotel on Saturday, November 16th. There were thirty-five members and affiliates present. The meeting was preceded by the usual dinner, following which a musical programme was enjoyed. Besides the notorious community singing of the Branch, vocal solos by Mr. G. Evans, pianoforte solos by Mr. R. Williams and banjo selections by Mr. Solomon were excellently rendered.

The speaker of the evening, Mr. J. R. Giegerich, was introduced by the chairman, J. B. de Hart, M.E.I.C. Mr. Giegerich, who is on the engineering staff of the Consolidated Mining and Smelting Company, addressed the meeting on "The Sullivan Mine."

This mine, located at Kimberley, B.C., was discovered in 1892, and after varying fortunes, was acquired by the Consolidated, who, after several years of development, have brought it to a high stage of production: some 5,400 tons of ore a day being recovered.

The ore body is a replacement deposit in beds of argillaceous quartzites underlain by diorite sills. The chief minerals are pyrrhotite, pyrite, galena and sphalerite.

Mining is carried on at five levels over a depth of 700 feet. Raises are driven from the drifts, and cross cuts and stopes opened up from the raises. The ore is removed by drilling bench rounds. The inclination of the stope is sufficient to permit the ore to drop by gravity to loading chutes above the drifts.

At present about thirty per cent of the ore is left as pillars, but experiments are being made in the use of concrete replacement pillars. Electric haulage is used throughout the mine, the tracks in the main haulage ways being of 70-lb. steel. The movement of ore trains is controlled by a phone despatching system.

On the surface, a compressor plant of 21,000 cubic feet per minute capacity is located and also large machine shops, warehouses and office buildings. On the townsite near the mine, a complete community has been built up. A fine recreation hall is provided and an up-to-date hospital is operated. Even a company owned greenhouse provides flowers and plants for the employees at a nominal cost.

Mr. Giegerich's address was greatly appreciated and a hearty vote of thanks was expressed on the motion of J. A. Carruthers.

THE KIMBERLEY CONCENTRATOR

The regular fortnightly meeting of the Lethbridge Branch was held on November 30th, at the Marquis hotel. Following an excellent dinner, community singing was indulged in under the violent and jovial leadership of Bob Lawrence. During dinner a musical programme was rendered by A. Morgan's orchestra, after which pianoforte solos by Miss D. Glasser and vocal solos by Tom Smith were well received.

The speaker of the evening was H. B. Banks, assistant superintendent of the Kimberley concentrator of the Consolidated Mining and Smelting Company, who described the operation of that plant.

Two weeks previously, J. H. Giegerich of the same company described the Sullivan mine which supplies the ore for the Kimberley concentrator.

London Branch

Frank C. Ball, A.M.E.I.C., Secretary-Treasurer.
Jno. R. Rostron, A.M.E.I.C., Branch News Editor.

The December meeting took the form of a dinner at the Hotel London, on Thursday, December 12th, with Brig.-Gen. C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., dean of Faculty of Applied Science and Engineering of the University of Toronto and president of The Engineering Institute of Canada, as the guest of honour.

After the company had done full justice to a good dinner the chairman, Capt. W. M. Veitch, A.M.E.I.C., in introducing the speaker, explained that the meeting was in reality semi-military for a large proportion of those present were military men and in fact several who were in full uniform were due to attend a military inspection which was to take place at the Armouries at 9.00 p.m.

The General, in his opening remarks, complimented the engineers and the citizens of London on the fine civic spirit they had shown in supporting by an overwhelming majority the proposal for grade separation of the Canadian National Railways at the recent municipal elections. He said they had recognized the principle as good and were willing to back it and he wished that other cities had that spirit.

The speaker then outlined several developments which were considered at headquarters, notably a proposed arrangement between The Engineering Institute and the various provincial associations of engineers. Details of this had not yet been worked out but proposals had been put forward and a committee had been formed to investigate and report on a workable scheme which would be satisfactory to all. He was careful to explain that there was no idea of either body dominating or absorbing the other but that the object was to devise a scheme where The Institute and the Associations would work together in unison for the protection and advancement of the profession generally. He pointed out that The Institute during the last ten years had made rapid progress with a very much larger increase in membership than formerly. In fact, the prestige and standing of The Institute together with the advantages of membership were now fully recognized.

The question of the proposed increase in fees was still in abeyance and would be brought forward again at the next Annual General Meeting. The benefits that would accrue from the increase were stressed by the speaker.

With regard to the publications of The Institute he said that there had been some discussion regarding the present form and size of the Journal and in this connection he pointed out that consideration was being given to the publishing of the proceedings of The Institute in the form of Transactions, in addition to the Journal.

The E.I.C. News had been very much appreciated and was a distinct success.

The General spoke of his visits to many of the Branches and the work which was being accomplished in the various localities by them. The work of the engineer and his contribution to the progress of the community was manifest everywhere in daily life. He urged all engineers, although they were mostly of a retiring nature when it came to public life, to come forward and take a more prominent part in the affairs of their community as their views, necessarily of a trained and practical nature, were valuable and helpful in the development of available resources and of advancement generally.

He spoke strongly of the industrial development which had taken place throughout Canada in recent years and stressed the fact that in his opinion the country was now on the eve of a great wave of prosperity and industrial expansion. In support of his argument he cited a long list of works, engineering and otherwise, from one end of the Dominion to the other, that were either completed, or in progress, or in commencement. In the latter class he mentioned the Beauharnois power development which he said might be considered as a unit in the St. Lawrence deep waterway and power project. With regard to the latter he said that he did not wish to say much about it because he was officially connected with it, but he said it is receiving very careful and urgent consideration.

Among the items of engineering work he mentioned the building of the 6000 class of Canadian National Railways locomotives at Kingston, the heaviest locomotive in the world. It was a notable fact that these were designed by members of The Institute and were all built by Canadian labour. Other works enumerated were the building of the Manoir Richelieu hotel at Murray Bay, built of reinforced concrete in zero weather and in record time, the Welland ship canal now approaching completion and also a link in the proposed St. Lawrence deep waterway, and many hydro-electric power developments throughout the country.

He also spoke of the value of the research work which was now being done in the direction of by-products from the low grade coal deposits in Alberta and Ontario made possible under Premier Ferguson's scheme of the government advancing dollar for dollar subscribed by numerous industrial firms for this purpose; the funds now available for this purpose running into hundred of thousands of dollars. He also touched on the lead mining industry and indicated a big future for this work. He pointed out the great advances for which engineering had been responsible in the development of agricultural machinery and the benefits derived therefrom.

In closing, the General stated that "indispensability," "versatility" and "ingenuity" should be the motto of all engineers and reminded his hearers that the word engineer came from the French word "ingénieur."

Brig.-Gen. C. J. Armstrong, M.E.I.C., moved a hearty vote of thanks to the speaker, and related how he and General Mitchell were old comrades in the war and reminded him of their journey to the front in France. The train took three days and nights to make the trip and the General, himself, and three others were occupants of a compartment in which two only could sleep on either seat and the fifth had to sleep on the floor. The honour of occupying the distinguished couch was decided by flipping a coin and the General always won.

Col. H. J. Lamb, M.E.I.C., seconded the vote of thanks and also reminded the General that he was one of the illustrious five on that memorable journey and that on the third night war nearly broke out amongst the party on the question of who should have the doubtful honour of sleeping on the floor.

Captain W. M. Veitch, A.M.E.I.C., in excusing those in uniform who had to attend the inspection, including himself, said he would like to inform the Generals that he also was a passenger on that same train to the front but the journey seemed more like three weeks rather than three days as he was in a box car.

On the retirement of the military members the chair was taken by W. G. Ure, A.M.E.I.C., vice-chairman of the Branch, and a discussion followed. Col. Lamb called attention to the good work being done by the National Service Council and asked the General to say a few words on this head.

Gen. Mitchell said he was glad to have his attention called to this and described the need for such a body and the results that were being achieved. One of the objects of this Council was to prevent the outflow of Canadian graduates to the United States by finding them berths in this country, and their efforts in this connection were most successful.

He said the industrial expansion was so great that in a short while there would not be sufficient graduates to fill the positions open. Another phase of this situation was the fact that many of the industrial workers who had left Canada for the United States were returning.

The General said he was glad to see present Mr. Angus, Sr., who would be able to appreciate the rapid strides engineering had made in Canada during the last decade or two, and paid a high tribute to Mr. Angus' son, Professor R. W. Angus, M.E.I.C., of Toronto, who was doing wonderful work and with whom he was closely associated.

After a general discussion in which several members spoke, the chairman adjourned the meeting.

Toronto Branch

J. J. Spence, A.M.E.I.C., Secretary-Treasurer.

Archie B. Crealock, A.M.E.I.C., Branch News Editor.

On Thursday evening, November 7th, 1929, the Toronto Branch of The Institute held a joint meeting with the American Society of Mechanical Engineers and the American Institute of Electrical Engineers, the speaker being Professor R. W. Angus, M.E.I.C., of the University of Toronto. The lecturer described a visit to the continent of Europe extending over a period of many months, in which engineering matters of interest were studied. The lecture was fully illustrated with lantern slides.

The first place mentioned was Delft, Holland, where a very fine engineering college exists with large numbers of engineering students. The hydraulic laboratory was particularly interesting on account of the work being done with hydraulic models.

After leaving Holland an extensive visit was made to Germany, covering first the cities of Braunschweig, Hanover and Göttingen. The former two places contained large engineering schools and extensive research work was in progress in both of them, and Göttingen has long been celebrated for its aerodynamic laboratory, which is under the direction of Professor Prandtl. This laboratory contained many things of value, besides the wind tunnel.

Proceeding next to Berlin, which proved to be a real centre of engineering interest, the first place visited was the headquarters of the German Society of Engineers, where every kindness was shown and where the speaker was placed in contact with many engineering matters. This society works harmoniously with the larger engineering societies, both in Britain and America, and there are helpful exchange arrangements amongst them. Berlin, of course, contains the very large shops of Siemens-Schuckert and the General Electric Company, the former employing 55,000 workers in its Berlin plant. These shops proved models of efficiency and were turning out some very large work, the 80,000-k.w. steam turbines for the new Klingenburg station at Berlin having been made at the General Electric shops. The Klingenburg steam station with three 80,000-k.w. turbines and three 10,000-k.w. turbines, was a fine piece of the latest type of engineering and the application of 16 Ruths accumulators at the Charlottenburg power station showed development along the line of steam storage. The University Engineering Department at Berlin was also mentioned and the names of some well-known men visited by Professor Angus were given. In the same part of the city is the large government river flow laboratory and ship channel, in which extensive experiments are made to solve problems connected with ships, river flow and harbour design. In addition to this a brief description of the extensive outdoor laboratory at Marquardt, near Potsdam, was given and slides shown of some of the work done.

Dresden, the speaker said, contained many interesting things, but the one attractive engineering feature was a large water storage and pumping plant being erected to look after peak load conditions there. This plant when completed will have 240,000 h.p. in eight water turbines, and during off-peak hours, will lift the water from a lower reservoir to an upper one, and during the peak hours the water will flow back through the turbines developing power. The electric power for pumping is produced by steam at power stations about sixty miles away.

At Prague, mention was made of the well-known Skoda works and at Vienna the engineering laboratories of the university, as well as those of the government water power development were described.

A water power plant at Pernegg on the Mur river near Graz was next described, this being one of the many low-head plants visited on the tour. Following through Austria, the Achensee power plant near Innsbruck was shown, this plant having a total capacity of 117,000 h.p. Pumping is also used here to get some of the water which would otherwise go away from the storage lake.

Returning to Germany, the Deutsches Museum at Munich and the fine engineering school were described in some detail, and from this point the large turbine building shop of Voith in Heidenheim was visited and also a low head water power plant at Donaustetten on the Danube where four Kaplan wheels have been installed for a head of 21 feet and with a specific speed of 172.. Another plant visited from Munich was at Walchensee, where 144,000 h.p. is being produced, with a head of about 630 feet, and close to this plant there has been established a fine hydraulic research laboratory at a cost of about $200,000 in which all sorts of river flow and open channel flow problems may be studied, the water available for the purpose being 140 cubic feet per second. These were all illustrated by slides.

In addition to the other points, the plants on the Middle Isar adjacent to Munich were also of importance, these producing a total of about 135,000 h.p. at four different power houses.

Passing through into Switzerland, the fine engineering shops of Escher Wyss and Company and the excellent Engineering University at Zurich received some attention, and from Zurich the extensive shops of Sulzer Bros. at Winterthur were visited, these containing many Diesel engines and pumps under construction.

From Zurich the power plants at Wäggital were also visited, there being two stations, an upper and lower, with a total of 160,000 h.p. There was nothing unusual about the turbines the speaker said except the high head of 805 feet on the Francis turbines in one of the stations, but pumping is also resorted to here during the off peak hours, and four pumps of 5,000 h.p. each have been installed for this purpose.

Passing on next to Lucerne, the large turbine shops of Theodor Bell with its testing flume were described, and from this point the power station at Amsteg for the Swiss Federated Railroads was also visited. This plant is on the Reuss river and contains six 14,000 h.p. turbines under a head of 905 feet

The Lake Lungern plant near Brunig Pass, and in addition a very large low head plant at Eglisau on the River Rhine were also illustrated. The next place of engineering interest was Berne, from which several plants were visited, the most extensive one being that at Muhleberg on the River Aar where 65,000 h.p. is being produced under a head of 56 feet.

Passing on next to Geneva, where are located the shops of Ateliers des Charmilles, the plant at Chancy-Pougny was described, this plant being on the Rhone river, the transformer station being in France and the power house itself in Switzerland. The head here is only 29 feet and the horse power developed 43,000.

Leaving Switzerland Professor Angus visited Italy and a stop was made at Milan to see some of the plants of the Edison Electric Company and the shops of the Riva Construction Company, this latter company making many large turbines. It was here that the original turbines at De Cew falls were constructed.

At Rome the chief engineer of the State Railways kindly gave information about the work being done in Italy on electrifying railways. Many of the lines use three-phase current and the state owns about one third of the power plants used in operating its lines.

Returning from Rome through Switzerland the last plant described was that at Ryburg-Schworstadt on the Rhine near Rheinfelden. This plant is now being built and will contain four of the largest Kaplan turbines yet constructed, these having a capacity of 35,000 h.p. each, under 35 feet head and with a runner diameter of 23 feet.

Very brief mention was made of the work being done in the Engineering University at Karlsruhe, and time did not permit anything but a bare mention of what was seen in Great Britain, but which is quite familiar to people in Canada.

At the close of this very interesting and educative lecture a very hearty vote of thanks was rendered to the speaker for his splendid lecture which was so well illustrated by lantern slides.

Planning and Development Act of Ontario

On the evening of Thursday, November 21st, the Toronto Branch of The Engineering Institute were privileged to hear a lecture on "Planning and Development Act of Ontario and its Operation in Toronto" by Mr. Tracy D. Le May, M.E.I.C., the city surveyor.

In this lecture Mr. Le May gave a very complete explanation of the subject of town planning, explaining the fundamental features of the subject and describing the ideals which were desirable but which in a city already grown up are exceedingly difficult to apply. In his lecture Mr. Le May dealt with the skyscraper and its effect on the occupants of adjacent buildings; the report of the Advisory Town Planning Commission; the obligation of the provincial governments in town planning and the need of a central bureau in each province for the co-ordination of town planning and the dissemination of town planning spirit.

The question of streets and traffic was dealt with by the speaker and he also explained the City and Suburban Plans Act and its application in Toronto and suburbs, at the same time taking up the subject of street widths and jogs where streets intersect.

The lecture was illustrated by lantern slides and at its conclusion a hearty vote of thanks was tendered to Mr. Le May for his lucid explanation of this important subject.

Toronto Waterworks

On the evening of Thursday, December 5th, the members of the Toronto Branch were privileged to hear a lecture on "Toronto Waterworks" by William Gore, M.E.I.C., of Gore, Nasmith and Storrie, consulting engineers.

Mr. Gore in his lecture dealt with the subject in a general way, emphasizing more particularly the works now in course of construction. The speaker traced the history of the Toronto waterworks from 1841 when the first pumping station was erected and opened down to the present time when there is under construction additions to the present system capable of insuring a supply of pure and palatable water for the needs of over 1,000,000 persons and eventually 1,500,000 persons.

The extensions are being designed so that construction will be carried out in two stages, providing in each stage for an additional supply of 75 million gallons daily, but wherever it is more economical to do so, provision is made in the first construction for the complete scheme. The speaker then described in detail the layout of the new work and described the different parts, namely the submerged intakes, the intake tunnel, the filter plant at Victoria Park to eventually have a capacity of 200 million gallons daily of which one half is being put in at the present time, a pure water reservoir of 12,000,000 gallons at Victoria Park, the pumping stations, the distributing tunnels, the St. Clair Avenue reservoir which will be 23 feet deep contain 50,000,000 gallons in two equal compartments, the ornamental overhead expansion tank in district No. 3 which will contain at normal water level 300,000 gallons and the various other parts incidental to the work.

In conclusion the speaker stated that the estimated cost of the works to be constructed is $14,317,000.00 and that the work is being carried out under the direction of R. C. Harris, Commissioner of Works, with G. G. Powell as deputy. James Milne is in direct charge of water works with A. U. Sanderson as assistant. H. G. Acres and Co. Ltd. of Niagara Falls, Ont., and Gore, Nasmith and Storrie, Toronto, are the consulting engineers.

Preliminary Notice

of Applications for Admission and for Transfer

December 23rd, 1929

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in February 1930.

R. J. Durley, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for a least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BENT—EDGAR DELAP, of Montreal, Que., Born at Paradise, N.S. May 28th, 1906; Educ., B.Sc., Acadia Univ., 1928; June 1928 to Mar. 1929, junior engr., Atlantic Divn., Hydrographic Service of Canada; 1929 (Mar.-Oct.), Physical Testing Lab., Ottawa; at present, cable engr., cable engrg. lab., Northern Electric Co. Ltd., Montreal.
References: A. Sutherland, N. L. Dawson, W. G. Tyler, F. H. Peters, F. Anderson.

BRIDGES—FREDERICK, of Sorel, Que.. Born at London, England, March 1st, 1868; Educ., 1884-1888, Kings College, London. 1886-1890, private tuition, naval arch'ture and maths.; 1884-89, articled pupil, 1889-1892, dftsman., Samuda Bros., Poplar, shipbldrs. and engrs.; 1892-94, seagoing engr. (and B.O.T. Cert.); 1895-1908, chief dftsman., Edwards & Co., Millwall, shipbldrs. and engrs., becoming asst. mgr. and later manager and secretary; 1908-1918, chief hull dftsman., Govt. Shipyard, Sorel, Que.; 1918-22, mgr. and naval arch't. to Leclaire Shipbldg. Co., Sorel, and their successors, The Transportation & Shipping Co. Ltd.; 1922-24, independent ship surveyor at Montreal; 1924-28, govt. steamship inspr., Montreal; 1928 to date, supt., Govt. Shipyard, Sorel, Que.

FOR TRANSFER FROM THE CLASS OF JUNIOR TO A HIGHER CLASS

CRATCHLEY—REGINALD HENRY, of Hawkesbury, Ont., Born at Stroud, England, Nov. 1st, 1896; Educ., 3 years, Stroud Technical School; 1917-18, R.A.F. Sch. of Aeronautics for Officers; Complete Struct'l. Engrg. Course, I.C.S.; 1910-14, ap'ticeship in mech'l. engrg., G. Waller & Sons Phoenix Ironworks, Stroud; 1914-19, overseas, 2nd Lieut., R.A.F.; 1919-21, jig and tool designer, The Hampton Engrg. Co., Stroud, latterly responsible for plant mtce.; 1921-22, steam pumps design, Whitehead Torpedo Works, Weymouth, England; 1924-25, grain elevator work in design office and inspection staff during constrn., C. D. Howe & Co., Port Arthur, Ont.; 1925 to date, plant layout and design, constrn. dept., Canadian International Paper Co., Hawkesbury, Ont.
References: C. B. Shaw, S. Wang, H. P. Beaudoin, S. H. Wilson, L. S. Dixon, P. N. Libby.

INGS—JASPER HAROLD, of Ottawa, Ont., Born at Charlottetown, P.E.I., July 15th, 1902; Educ., B.A.Sc., Univ. of Toronto, 1925; Summer work: 1920, chainman, C.N.R.; 1921, asst. mechanic, Dominion Shipyards Ltd., Toronto; 1922, rodman, Frank Barber & Associates, Toronto; 1923, 24, 25, rodman and instr'man., Duke-Price Power Co., Isle Maligne, Que.; 1926 (Mar.-Dec.), res. engr. (rly.), Dec. 1926-June 1927, asst. engr. (hydro), Morrow & Beatty, Ltd.; 1927 (June-Sept.), engr., Spruce Falls Power & Paper Co., Kapuskasing; Sept. 1927 to date, engr., Gatineau Power Company, Ottawa, Ont.
References: H. A. Morrow, J. A. Beatty, G. B. Dodge, W. E. Blue, R. H. Reid, A. C. D. Blanchard, F. H. Cothran.

KNAPP—EDWARD WINSLOW, of Montreal, Que., Born at Sackville, N.B., Oct. 31st, 1894; Educ., B.Sc. (E.E.), McGill Univ., 1923; 1923-24, student test course, Can. Westinghouse Co., Hamilton, Ont.; 1924 (May-Oct.), with same company at LaGabelle, on elec. installn. of power plant; 1924-25, elec. demonstrator, Queen's Univ ; 1925 (Apr.-Oct.), power plant operation, St. Maurice Power Co., LaGabelle; 1925-26, with Shaw. Water & Power Co., at Shawinigan Falls, on gen. engrg. problems and dfting., and from Feb. 1926 to date, with same company at Montreal in operation dept.
References: C. V. Christie, E. Brown, F. S. Keith, P. Ackerman, J. A. McCrory.

VON ABO—CECIL VIVIAN, of Johannesburg, South Africa; Born at Kroonstad, Orange Free State, S.A., Oct. 10th, 1895; Educ., B.A., Univ. of Cape of Good Hope, 1913. M.A. (Pure Maths.), 1918. M.A. (App. Maths.), 1919, B.Sc. (Hons.), 1917, Univ. of Cape Town. Ph.D in Civil Engrg., 1922, McGill Univ.; 1923-25, lecturer in mech'l. engrg. and maths., Cape Technical College, Cape Town; 1925-27, asst. engr., chief civil engr's dept., South African Railways and Harbours, and with same concern to date as follows: 1927-28, research engr.; 1928-29, research engr. and asst. chief dftsman., and May 1929 to date, research engr. and district engr. (bridges.)
References: H. M. MacKay, E. Brown, R. DeL. French, G. J. Dodd, R. S. Eadie.

WATERHOUSE—GEORGE KERBY, of 1290 Bernard Ave. West, Outremont, Que., Born at Montreal, July 7th, 1897; Educ., B.Sc., Queen's Univ., 1919; 1916 (summer), shopwork, Can. Locomotives Co. Ltd.; 1917 (summer), No. 5 Field Co., Can. Engrs., road constrn.; 1919-20, instructor in steam and gas engrg., D.S.C.R., Kingston; 1920-21, mech'l. dftsman., Brompton Pulp & Paper Co. Ltd.; 1921-24, pulp mill supt., Can. Paperboard Co. Ltd., Frankford, Ont.; 1924-27, asst. engr., on design and process studies and specifications for new equipment, Howard Smith Paper Mills, Ltd.; 1927-28, engr. on constrn. for location of mach'y., and 1928-29, district purchasing agent and supt. of supplies for mill mtce. and alterations following constrn., Lake St. John Power & Paper Co. Ltd.; July 1929 to date, asst. purchasing agent, gen. purchasing dept., preparation of specifications and ordering of mech'l. and elect'l. equipment with special attention to all technical problems, Aluminum Co. of Canada Ltd., Montreal, Que.

THE ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

Published monthly at 2050 Mansfield Street, Montreal, by The Engineering Institute of Canada, Incorporated in 1887 as The Canadian Society of Civil Engineers.

ENTERED AT THE POST OFFICE, MONTREAL, AS SECOND CLASS MATTER.

THE INSTITUTE as a body is not responsible either for the statements made or for the opinions expressed in the following pages.

VOLUME XIII | MONTREAL, FEBRUARY 1930 | NUMBER 2

Water Power Resources of Canada

N. Marr, M.E.I.C.,

Chief Hydraulic Engineer, Dominion Water Power and Reclamation Service.

Paper presented at the Annual General Meeting of The Engineering Institute of Canada at Ottawa, Ont., February 14th, 1930

In a programme designed to portray the development of Canada's natural resources special significance attaches to the utilization of the water powers of the Dominion, inasmuch as the low-cost energy derived therefrom is applied to and to a large extend renders possible the economic development of the other natural resources. Water power is the vital force behind the great and growing pulp and paper industry, the mining industry, electro-chemical and electro-metallurgical industries, and a multitude of others which are included in the extensive and rapidly expanding industrial life of the Dominion. Moreover, hydro-electric energy is utilized in Canadian homes to an extent unequalled in any other country, and its extension to rural areas is proceeding with marked rapidity in certain districts.

The resources which have made this development possible are ample in extent, are favourably distributed throughout the various provinces of the Dominion, and are fortunately located with respect to the principal industrial centres and the extensive mineral and forest resources. Development has proceeded from coast to coast on an orderly and well conceived basis with the object of providing an ever increasing flow of energy to meet the expanding needs of industry. Capital for this development has been readily secured on favourable terms and governmental control has been sympathetic and constructive. There is abundant evidence that the rate of growth in water power utilization witnessed in past years will not only be sustained but will be increased and the resources are ample to provide for such expansion for a considerable period of time.

Available and Developed Water Power

In a country of the extent of Canada and with great areas remote from ready means of communication a precise estimate of the water power resources is not possible. Nevertheless a systematic inventory has been under way for a number of years through the efforts of the Dominion Water Power and Reclamation Service of the Department of the Interior, in close co-operation with the various provincial organizations dealing with such matters. As a result, a fairly dependable estimate of the Dominion's resources has been made, which of course is subject to revision as more and more data are secured with respect to river flows and the physical features which govern the feasibility of water power concentrations.

In table No. 1 is given the most recent estimate of these resources. Figures for each province and for the Dominion, of available twenty-four hour power at developed and undeveloped sites, calculated at an efficiency of eighty per cent under conditions of ordinary minimum flow and ordinary six months flow are shown in columns 2 and 3 respectively. In column 4, figures of installation in horse power are given for each province and for the Dominion as at January 1st, 1930. These figures which were compiled in October 1929 anticipated the completion of a number of installations before the end of the year. Final figures compiled at the end of the year may therefore show the totals different in some respects. Columns 5 and 6 show figures of population and installed horse power per thousand of population respectively. For the Dominion it will be noted that the available power is estimated to total 20,347,000 h.p. under conditions of ordinary minimum flow or 33,617,000 h.p. for ordinary six months flow. On a commercial basis the available water power resources would probably warrant a total installation of about 43,700,000 h.p. The total installation of 5,710,802 h.p. therefore may be said to represent slightly more than thirteen per cent of the resources at present recorded. In installation per thousand of population column 6 indicates an average of 583 for the whole Dominion, a figure which places Canada in an outstanding position amongst world nations in the per capita utilization of water power.

Outline of Development 1900 to 1930

In table No. 2 are tabulated year by year the figures of installation at the end of each year from 1900 to 1929 for each province and for the Dominion as a whole.

Prior to 1900 water power was utilized to a comparatively small extent, the total for the end of that year being only 173,000 h.p. Developments up to 1895 were largely in connection with grist, saw, paper and other mills, the power being mechanically applied, although with the introduction of the electric generator in the late eighties,

Table No. 1—Available and Developed Water Power in Canada*

Province	Available 24-hour power 80 per cent efficiency		Turbine installation h.p.	Population June 1, 1929	Total installation per 1,000 population
	At ordinary minimum flow h.p.	At ordinary six months flow h.p.			
1	2	3	4	5	6
British Columbia	1,931,000	5,103,500	560,042	591,000	948
Alberta..........	390,000	1,049,500	70,532	646,000	109
Saskatchewan...	542,000	1,082,000	35	866,700	...
Manitoba........	3,309,000	5,344,500	311,925	663,200	470
Ontario..........	5,330,000	6,940,000	1,959,675	3,271,300	599
Quebec..........	8,459,000	13,064,000	2,572,418	2,690,400	956
New Brunswick..	68,600	169,100	112,131	419,300	267
Nova Scotia.....	20,800	128,300	108,406	550,400	197
Prince Edward Island........	3,000	5,300	2,439	86,100	28
Yukon and N.W. Territories....	294,000	731,000	13,199	12,400	1,063
	20,347,400	33,617,200	5,710,802	9,796,800	583

*The estimates of available power are based upon sites where the head is definitely known or well authenticated. They omit many falls, rapids or possible concentrations, regarding which information is not reasonably definite and reliable. The estimates may therefore be looked upon as representing the minimum power possibilities of the Dominion.

All estimates of available power represent continuous twenty-four hour power at an efficiency of generation of eighty per cent. The figures in column 2 are based on "Ordinary Minimum Flow" which is the average over all the years for which records are available, of the mean flow for the two lowest seven-day periods in each year. Six-month power in column 3 is based on the "Ordinary Six-month Flow" which is the average over all the years for which records are available, of the mean flow for the lowest seven consecutive days in the lowest of the six high months in each year.

The figures in column 4 represent the rated capacities of all water wheels and turbines installed throughout the Dominion. These figures should not be directly compared with the available power figures in columns 2 and 3. The actual water wheel and turbine installation throughout the Dominion averages about thirty per cent greater than the corresponding ordinary six-month figures calculated as in column 3. On this basis, therefore, the available water power resources of the Dominion as at present recorded would permit of a turbine installation of about 43,700,000 h.p. In other words, the present installation represents about thirteen per cent of the present recorded water power resources.

a few towns situated immediately adjacent to water falls secured electric power at generator voltage — as for instance, the city of Ottawa, where electric power was produced and sold about 1890. In 1895 the first high tension electric power transmission system in Canada and incidentally in the British Empire was completed. This was an 11,000-volt line carrying power from a 1,200-h.p. plant on the Batiscan river, Quebec, to the city of Three Rivers. Similar systems rapidly followed: Montreal received power from Lachine, Quebec city from Montmorency falls, Hamilton, Ont., from De Cew falls, Victoria B.C., from the Goldstream river, and Nelson, B. C., from the Kootenay river, all in the year 1898.

The introduction of high tension transmission thus accomplished, a decided stimulus was provided to the development of water power and the ten year period 1900-1910 witnessed a very substantial increase in installation, the total at the end of 1910 having reached a figure of 977,000 h.p. This was a net increase for the period of 803,848 h.p., more than a quarter of which, or 218,450 h.p., was installed in three hydro-electric developments at Niagara falls from whence power was first transmitted to Toronto in 1906. The Shawinigan Water and Power Company's development at Shawinigan falls was commenced in 1900 and in 1903 power therefrom was delivered to Montreal to supplement that from the earlier sources at Lachine and Chambly. Fort William, Ontario, received power from the Kakabeka falls plant of the Kaministikwia Power Company in 1906 and in the same year the Winnipeg Electric Railway Company brought hydro-electric power to Winnipeg from its plant on the Winnipeg river. Vancouver received its first supply of hydro-electric power in 1904 from the first Coquitlam-Buntzen plant of the Vancouver Power Company and the mining district in and around Rossland, B.C., was supplied by the West Kootenay Power and Light Company from the Kootenay river in 1906. Many installations were also made during the period by manufacturing organizations but of the total increase more than 70 per cent was accounted for by central electric stations, this predominance being consistently increased in subsequent periods.

The next decade 1910-1920 showed a sharp increase in development for the first four years, when more than 974,000 h.p. was installed but war and post war conditions greatly retarded growth so that during the last six years the increase amounted to only 564,000 h.p. This period is chiefly notable as marking the commencement of power delivery by the Hydro-Electric Power Commission of Ontario, which took place in October 1910 with the bringing into operation of a line extending from Niagara to Kitchener. The commission secured its first supply by purchase from plants at Niagara falls, but in 1914 commenced the production of power by building a small plant at Wasdells falls which was quickly followed by others, and in 1917 construction was begun on the great Chippawa-Queenstown project. The installations in the period 1910-1920 included substantial additions to existing stations at Niagara falls, Shawinigan falls and elsewhere, while several large new developments were made such as that at Cedars rapids on the St. Lawrence river controlled by the Montreal Light Heat and Power Consolidated, at Grand'Mere on the St. Maurice river by the Laurentide Power Company, at St. Timothee on the St. Lawrence river by the Canadian Light and Power Company, in the Lake St. John district in Quebec by Price Brothers, at Point du Bois on the Winnipeg river by the city of Winnipeg and on the Jordan River, B.C., by the Vancouver Island Power Company.

Following 1920 a period of intensive development commenced which has continued up to the present time. In the past nine years 3,200,000 h.p. has been installed, a figure which exceeds the total installation at the end of 1920 by almost 700,000 h.p. To instance only a few of the large new developments which went to make up this total may be mentioned the 502,000-h.p. Queenston plant of the Hydro-Electric Power Commission of Ontario, the 495,000-h.p. plant of the Duke-Price Power Company on the Saguenay river, the three Gatineau river plants of the Gatineau Power Company with installations totalling 436,000 h.p., the 120,000-h.p. plant of the Shawinigan Water and Power Company at La Gabelle on the St. Maurice, the Great Falls plant of the Manitoba Power Company on the Winnipeg river with 168,000 h.p., and two new plants of the West Kootenay Power and Light Company on the Kootenay river in British Columbia totalling 135,000 h.p. Much of the power developed during this period went to supply the needs of the rapidly expanding pulp and paper industry. Mining operations in Ontario, Quebec and British Columbia required increasingly large amounts of power, while the demands of general manufacturing industries, coupled with steadily growing commercial and domestic consumption accounted for large blocks of new power.

Current Progress and Estimated Future Growth

That the substantial growth of recent years in water power development will not only be maintained but will be increased is indicated by the number of large undertakings at present under construction and others in active prospect. The initial installations of new undertakings now under construction, together with additions to existing developments, amount to 550,000 h.p., and when these have been completed to their ultimate designed capacities the total installation for the Dominion will be increased by more than 2,500,000 h.p. Much activity is also in evidence in connection with the investigation of other large developments, a number of which will undoubtedly materialize in the near future.

With this programme in view it is safe to predict that the rate of growth of the past six years will be maintained, and a reference to table No. 2 and figure No. 1 indicates that this rate was about 420,000 h.p. per annum. Accordingly if the curve on figure No. 1 is projected at this rate it shows that in 1940 the total installation for the Dominion will probably have reached a figure of 10,300,000 h.p. This is considered to be a conservative estimate and there is reason to believe that it will be considerably exceeded.

Capital Invested in Water Power

The capital invested in water power development in Canada inclusive of transmission and distribution systems is estimated to be $1,250,000,000 or more than that for any single manufacturing industry. Applied to the existing installation, this corresponds to an average of $219 per installed horse power. In view of the steady earning power shown by the industry even in times of industrial depression, it would appear that the capitalization is reasonable and one which the industry is well able to carry.

Based on the estimate of future growth and the present investment per installed horse power it would appear that new funds to the extent of at least $92,000,000 per annum will be required to provide for new development during the next few years. The stability of Canadian water power investments is widely known, securities have been marketed under most favourable terms and new capital required for future expansion should be readily secured.

Coal Equivalent of Developed Water Power

The extensive utilization of water power in Canada has had a pronounced effect in reducing the consumption of coal, but it is very difficult to assign a precise figure for the coal equivalent of developed water power, since the matter is comparative only and assumptions must necessarily be made dependent upon the conditions under which the power is developed. However, taking into account all present conditions surrounding water power development in Canada and comparing them with somewhat similar conditions of fuel power development elsewhere, it is reasonable to state that a saving of coal of six tons per annum is capable of being effected by each installed horse power. This means that the total present water power installation of 5,710,800 h.p. is capable of effecting a saving of about 34,000,000 tons of coal per annum.

The actual saving in any year is dependent upon the output from the installation, and for the year 1929 an approximate estimate of the output expressed in electrical units has been made which indicates a figure of 20,500,000,000 kilowatt hours. The average coal consumption of all public utility electric power plants in the United States is now 1.76 pound per kilowatt hour. Applying this figure to the estimated figure of output would indicate a saving for the year 1929 of 18,000,000 tons of coal.

Utilization of Developed Water Power

The present turbine installation of 5,710,802 h.p. is classified in table No. 3 under the headings, central electric stations, pulp and paper mills and other industries. It is difficult to make a more detailed classification of the

Figure No. 1.

ultimate use of power because of the large proportion in central electric stations from which power is sold for a multitude of uses.

The table shows that 4,802,263 h.p. or 84.1 per cent of the total is installed in central electric stations from which power is distributed for all purposes, 577,976 h.p. or 10.1 per cent is installed in pulp and paper mills, in addition to which these mills purchase some 860,000 h.p. of electrical energy from central electric stations, and 330,563 h.p. or 5.8 per cent is installed in other industries including mines, mineral reduction works, electro-chemical plants, saw, grist and textile mills, machine shops, municipal water supply stations and street railways; all of these industries also purchase power extensively from central electric stations.

Water Power in the Central Electric Station Industry

The central electric station industry has rapidly assumed an outstanding position in the social and economic life of the country and has had a very marked effect upon industrial conditions by the adaptability of electricity to utilization remote from its point of production. As already indicated the growth of hydro-electric central station installation, from 62,192 h.p. at the end of 1900 to the 4,802,263 h.p. estimated for the end of the present year, is largely due to this faculty of remote utilization, and the intensive research constantly being conducted to extend the radius of high tension transmission bids fair to keep pace with the development of our more accessible power sites by giving commercial value to those at present too distant for economic development.

As most of the larger central electric station installations have been actuated by the demand due to centres of population an outline of the sources of hydro-electric supply for the various cities of the Dominion may be of interest at this point. An analysis by provinces of the utilization of hydro-power in central stations is shown in table No. 4 and the same order will be followed in regard to the centres of population.

British Columbia

In British Columbia, the distribution of electricity in Vancouver and Victoria and the adjacent surburban areas is provided by the British Columbia Power Corporation Vancouver and district receive power from four plants, two on the North Arm of Burrard inlet deriving water from Lakes Coquitlam and Buntzen, and two on the Stave river, the first at Stave falls, 36 miles from Vancouver, and the second, 10 miles above Stave falls on the shore of Stave lake and operated by water drawn through a tunnel from Alouette lake whose natural flow was reversed by damming to provide the necessary power for the upper plant and to augment the power already in use at Stave falls. The Coquitlam-Buntzen plants are at the outlet of Buntzen lake whose flow is supplemented by water drawn by tunnel from Coquitlam lake reversed as in the case of Alouette lake by damming.

The Coquitlam-Buntzen plants operate under an average head of 395 feet and have an aggregate installation of 84,000 h.p. The Stave Falls plant operates under an average head of 113 feet and has an installation of 77,500 h.p. while the Alouette station which is automatically controlled from Stave Falls has an average head of 125 feet and an installation of 12,500 h.p. The extensive transmission system serving Vancouver and district is shown on figure No. 2.

The growing power demands of this district already necessitate further development and the British Columbia Power Corporation is now engaged upon two extensive installations. The first is situated at Ruskin near the mouth of the Stave river where the initial installation of 42,500 h.p. is expected to be in operation during the autumn of 1930. The ultimate designed capacity of the plant is 170,000 h.p. The second project is on the Bridge river, where by a series of dams the water is to be diverted through a tunnel 13,200 feet in length and thence through penstocks to a power house on Seton lake where under a head of some 1,300 feet 80,000 h.p. is expected to be in operation by 1932. Further stages of this development involve the construction of additional storage dams, and the enlargement of tunnel and power house capacities until an ultimate installation of 550,000 h.p., to 700,000 h.p. is reached.

Power for Victoria and district is generated in three stations, one on Goldstream river, 12 miles from Victoria, where under an average head of 670 feet, 3,400 h.p. is installed, and two at the mouth of the Jordan river, 36 miles from Victoria, where under an average head of 1,145 feet 25,000 h.p. is installed in one plant and 2,000 h.p. in a second recently completed automatically controlled plant drawing water from the same diversion dam. Figure No. 3, illustrates the transmission systems serving the Victoria area.

TABLE NO. 3—DEVELOPED WATER POWER IN CANADA—DISTRIBUTION BY INDUSTRIES

Estimated at January 1, 1930

Province	Turbine Installation in Horse Power			
	In Central Electric Stations	In Pulp and Paper Mills	In other Industries	Total
1	2	3	4	5
British Columbia	418,210	81,000	60,832	560,042
Alberta	70,320	....	212	70,532
Saskatchewan	....	....	35	35
Manitoba	311,925	....	....	311,925
Ontario	1,624,393	240,880	94,402	1,959,675
Quebec	2,216,150	220,810	135,458	2,572,418
New Brunswick	83,910	19,278	8,943	112,131
Nova Scotia	76,979	16,008	15,419	108,406
Prince Edward Island	376	....	2,063	2,439
Yukon and Northwest Territories	....	....	13,199	13,199
Canada	4,802,263	577,976	330,563	5,710,802

Column 2 includes only hydro-electric stations which develop power for sale.
" 3 includes only water power *actually developed* by pulp and paper companies. In addition to this total, pulp and paper companies purchase from the hydro power central electric stations totalled in column 2 approximately 860,000 h.p. A considerable amount of off-peak power is also purchased for use in electric boilers.
" 4 includes only water power *actually developed* in connection with industries other than the central electric station and pulp and paper industries. These industries also purchase power from the central electric stations totalled in column 2.
" 5 totals all turbines and water wheels installed in Canada.

Power for the Nelson and Southern boundary districts is at present supplied from four plants on the Kootenay river a few miles west of the city of Nelson. One of these, distributing power in Nelson and its environs and owned by the municipality of Nelson, is at Upper Bonnington falls and has an installation of 6,570 h.p. operating under a head of 60 feet. The West Kootenay Power and Light Company operates three plants, Upper Bonnington falls, Lower Bonnington falls and South Slocan. The first mentioned has an installation of 3,400 h.p. operating under a head of 70 feet; the second, replacing a former plant of 4,016 h.p. which was dismantled in 1925, has an installation of 60,000 h.p. and the third, completed in the fall of 1928, an installation of 75,000 h.p. under a head of 70 feet. This company now proposes to install an 80,000 h.p. plant on the Pend d'Oreille river and is considering a fifth development, one of 20,000 h.p. to 40,000 h.p. on the Adams river. The extensive transmission system operated by this company extends from Nelson on the east to Princeton on the west, south to the international boundary and north to Kelowna on Okanagan lake and is shown on figure No. 4.

The Fernie and Eastern boundary district receives power from two plants operated by the East Kootenay Power Company, one on the Bull river near Aberfeldie

TABLE NO. 4.—DEVELOPED WATER POWER IN CANADA—UTILIZED IN THE CENTRAL ELECTRIC STATION INDUSTRY

Estimated at January 1, 1930

Yukon and Northwest Territories	...	...	......	.....	.....	...	...	......	.....	.....
Canada	211	576	3,508,515	16,628	6,091	97	235	1,293,748	13,337	5,505

Commercial stations include all privately owned.
Municipal stations include all publicly owned.

NOTE.—Statistics in this table are based upon a census of the industry made by the Dominion Bureau of Statistics in co-operation with the Dominion Water Power and Reclamation Service. In addition to the central electric station organizations included above certain industrial hydraulic plants sell small amounts of electricity, i.e., the sale of electricity is only incidental to their main industries.

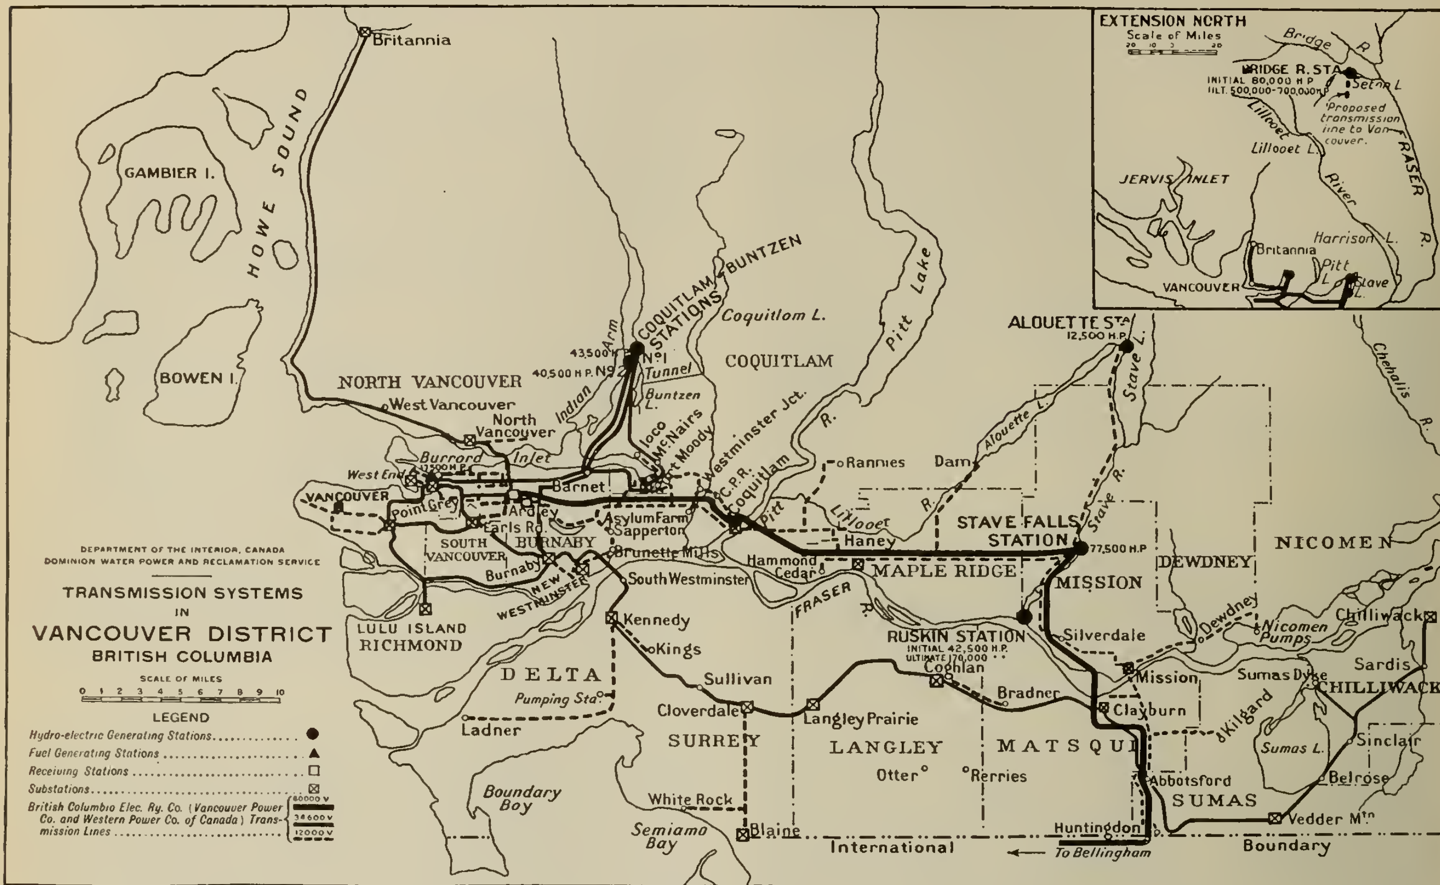

Figure No. 2.

where 7,200 h.p. is operated under an average head of 275 feet and one at Elko on the Elk river where 15,000 h.p. is installed and operated under an 85-foot head. The company operates a one hundred and thirty mile transmission system, (shown on figure No. 5), connecting its two hydraulic plants with its fuel auxiliary plant on the Alberta-British Columbia boundary and extending from Kimberley, British Columbia, through the Crow's Nest pass to Bellevue, Alberta, and is now investigating the possibilities of a further development of 15,000 h.p. on the Elk river at Phillips canyon.

In addition to the outstanding central electric stations described there are many smaller hydraulic developments operated by municipalities or private companies to supply electricity for public use.

Alberta

The City of Calgary and most of the western portion of the province of Alberta from Edmonton south to the international boundary receives power from three developments on the Bow river owned by the Calgary Power Company. The first of these, Kananaskis falls, has an installation of 11,600 h.p. operating under a head of 72 feet, Horseshoe falls, two miles east, an installation of 20,000 h.p. under a head of 71 feet and a recently completed station at Ghost falls where 36,000 h.p. has been installed. The company also controls the 780-h.p. development formerly operated by the Calgary Water Power Company in Calgary. The transmission systems in southern Alberta are shown on figure No. 6.

Manitoba

Winnipeg and environs, and the transmission system of the Manitoba Power Commission which covers the district from Winnipeg westerly to Boissevain and southerly to the international boundary, receive power from three plants on the Winnipeg river which include 310,800 h.p. or 99.6 per cent of the total water power installation of the province. The municipality of Winnipeg operates a plant at Point du Bois 77 miles northeast of the city where 105,000 h.p. is installed under a head of 46 feet and has recently commenced a new development at Slave falls on the same river of an ultimate designed capacity of 100,000 h.p. The Winnipeg Electric Company and a subsidiary, the Manitoba Power Company, have plants of 37,800 h.p. and 168,000 h.p. respectively, the first at Pinawa and the latter at Great falls. Another subsidiary of the Winnipeg Electric Company, the Northwestern Power Company, is now engaged on a 225,000-h.p. development at Seven Sisters falls which will necessitate the abandonment of the Pinawa development, the water being rediverted from the side channel at present in use to the main stream. Figure No. 7 shows the transmission system in southern Manitoba.

Ontario

The Hydro-Electric Power Commission of Ontario, the largest single distributor of hydro-electricity in the Dominion, serves the greater part of the populous portion of the province through eight systems. The largest of these, the Niagara system, embraces the thickly populated south western peninsula extending from Toronto to Windsor and is supplied with power from three developments at Niagara falls, supplemented by power purchased from the Gatineau Power Company in Quebec province. The three Niagara plants include the Queenston station constructed by the commission, and the Ontario Power Company and Toronto Power Company stations, both of which were acquired by purchase. The Queenston station has an installation of 502,000 h.p. which is now being enlarged to

560,000 h.p. and operates under a head of 305 feet. The Ontario Power Company station has an installation of 208,200 h.p. operating under an average head of 180 feet and the Toronto Power Company station has 164,500 h.p. under a head of 130 feet. In addition to these the contract with the Gatineau Power Company provides for a further supply of 260,000 h.p. of which 150,000 h.p. was being taken in October 1929, the contract calling for the delivery of the full amount in 1931. This power is carried over a 220,000-volt transmission line 230 miles in length extending from Paugan falls, Quebec, to Toronto.

The Georgian bay system embraces the territory adjacent to Lake Huron and Georgian bay extending from Kincardine on the west to Huntsville in the Muskoka district on the east, and including such centres as Owen Sound, Collingwood, Midland and Barrie. Power is supplied from six plants on the Muskoka, Severn and Beaver rivers having a total installed capacity of 25,050 h.p. Additional power is purchased from the town of Orillia and the system is interconnected with the Niagara system so that power may be interchanged as required.

The Nipissing system which includes the city of North Bay and adjacent municipalities is supplied from three plants on the South river with installations totalling 5,700 h.p.

The Central Ontario system embraces territory extending from Whitby on the west to Kingston on the east and northerly to Lindsay including other large centres such as Oshawa, Cobourg, Trenton, Belleville and Peterborough. Power is supplied from nine plants of the commission along the Trent waterway with installations totalling 57,980 h.p. and additional power is purchased from the town of Campbellford, and other organizations in the district.

The St. Lawrence system includes the territory bordering the St. Lawrence river from Brockville on the west to Lancaster on the east, thirteen municipalities being served. Power for the supply of this system is purchased from the Cedars Rapids Transmission Company and the Gatineau Power Company.

The Rideau system embraces a territory in Eastern Ontario chiefly in the county of Lanark. Five municipalities are served, the larger centres being Smiths Falls, Carleton Place and Perth. Power is generated in two plants on the Mississippi river totalling 4,449 h.p. and additional power is purchased from the Gatineau Power Company and the Rideau Power Company.

The Ottawa system, which includes the city of Ottawa and adjacent rural areas, is supplied with power purchased from the Gatineau Power Company. The commission also

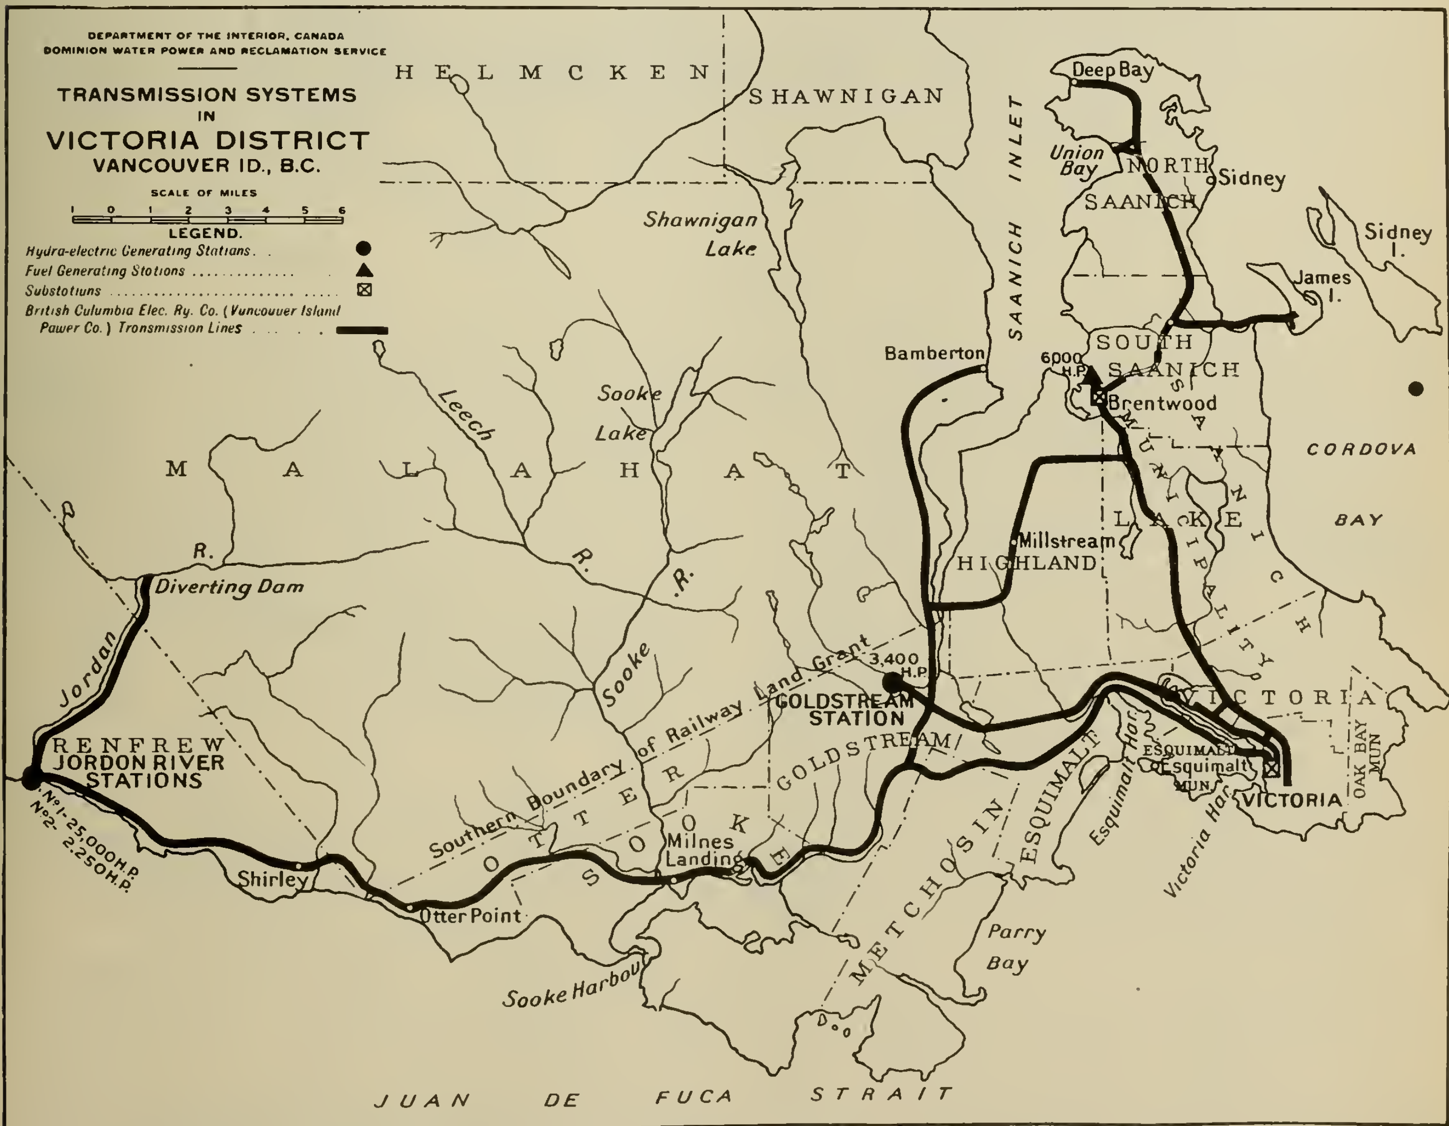

Figure No. 3.

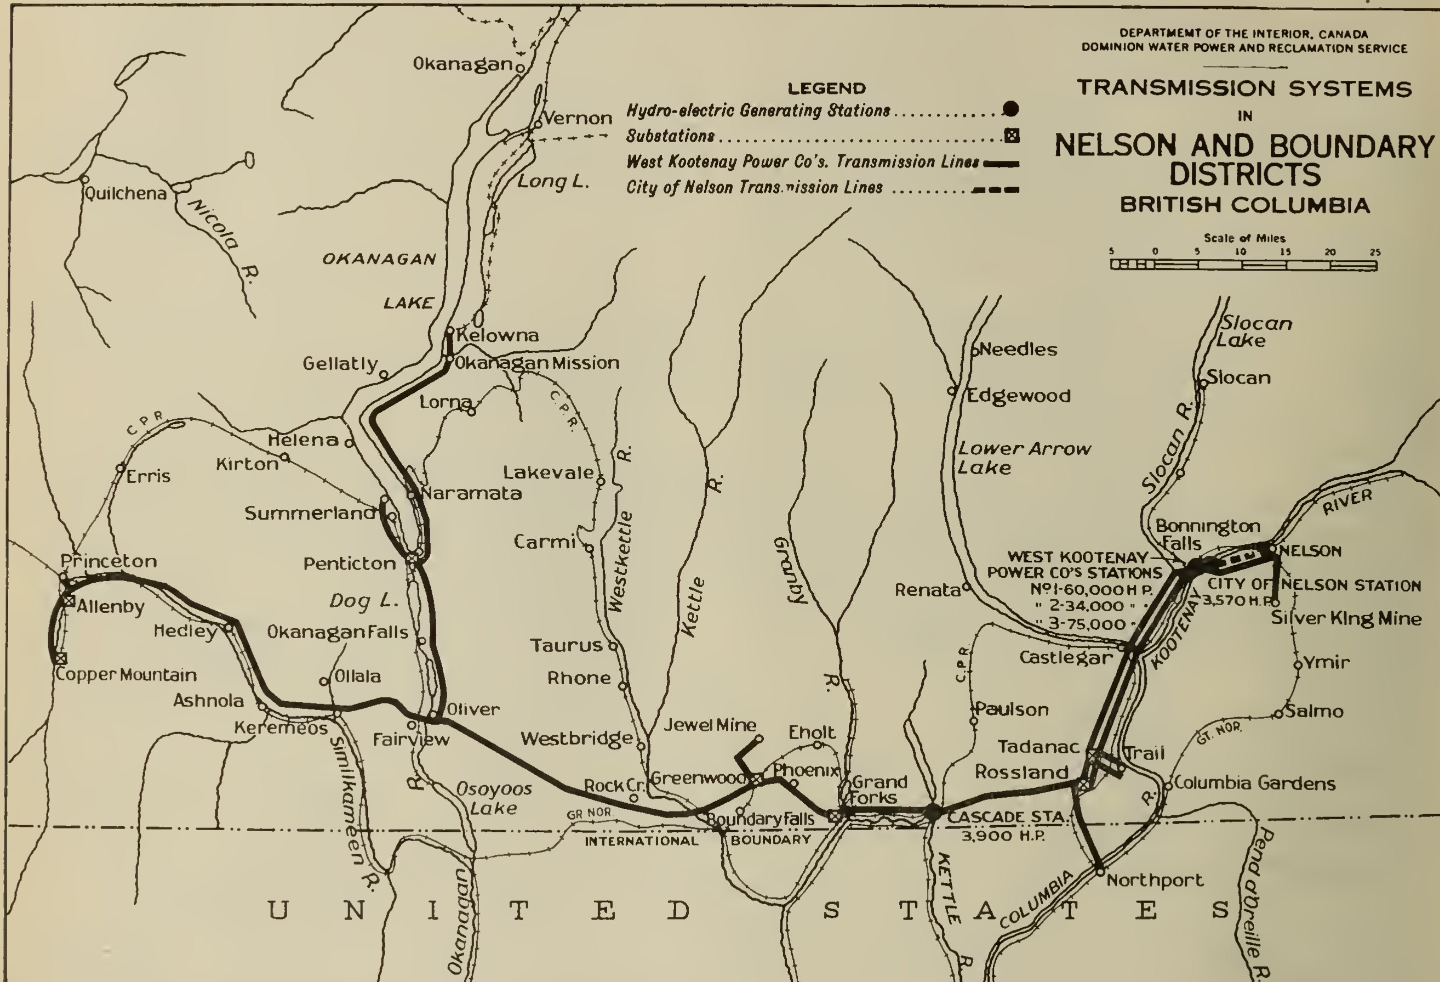

Figure No. 4.

acquired by purchase during 1929 the properties of the Calabogie Light and Power Company and the Galetta Power and Milling Company including two hydro-electric stations totalling 7,400 h.p. which serve Renfrew, Arnprior and other municipalities in the Ottawa river valley.

The Thunder Bay system includes the cities of Port Arthur and Fort William, power being supplied from the commission's 75,000-h.p. development at Cameron falls on the Nipigon river. A second plant of 54,000 h.p. is at present under construction at Alexander Landing on the same river.

Apart from the operations of the Hydro-Electric Power Commission, private power organizations provide service in certain districts. Hamilton, St. Catharines, Brantford and environs, in addition to receiving power from the commission's Niagara system, are supplied by the Dominion Power and Transmission Company from a 45,000-h.p. plant at De Cew falls on the old Welland canal. Ottawa is also served with power from plants of the Ottawa Electric Company. Sault Ste. Marie is supplied by the Great Lakes Power Company which operates a 28,000-h.p. plant on the St. Mary river and purchases power from the Algoma District Power Company's 11,000-h.p. plant on the Michipicoten river.

The heavy power demands of the gold and silver mining areas of northern Ontario are met from seven stations in Ontario with an aggregate installation of 53,340 h.p. and one in Quebec of 40,000 h.p., all controlled by the Canada Northern Power Corporation. The corporation has also commenced the construction of a new 13,000-h.p. plant on the Montreal river. The Sudbury mining area is served by the International Nickel Company of Canada which operates through subsidiary companies five plants on the Vermilion and Spanish rivers with installations totalling 62,500 h.p., while a further supply is secured from the Wahnapitae Power Company, (recently purchased by the Hydro-Electric Power Commission of Ontario), with three plants totalling 16,900 h.p. In the extreme western part of Ontario the town of Kenora is supplied with power by the Keewatin Power Company which operates two stations at the outlets of the Lake of the Woods where 30,875 h.p. is installed for public distribution and for supplying the mills of its parent company, Kenora Paper Mills, Limited.

The extensive transmission systems in the province of Ontario are shown on figure No. 8.

Quebec

The province of Quebec, in which 99 per cent of the total hydro-electric central station installation is owned by joint stock companies, has five major organizations which distribute over 90 per cent of the power sold in the province. The transmission systems of these four companies are interconnected for the exchange of power.

The city and district of Montreal is served by Montreal Light, Heat and Power Consolidated, which operates three plants on the St. Lawrence and one on the Richelieu river and purchases large amounts of power from the Shawinigan Water and Power Company. The company's largest plant, at Cedars rapids on the St. Lawrence river, operates under an average head of 30 feet and has an installation of 197,400 h.p. The other two plants on the St. Lawrence, the Soulanges and Lachine stations have installations of 16,050 h.p. under a 52-foot head and 15,800 h.p. under a 14-foot head respectively. The Richelieu river station at Chambly has an installation of 21,600 h.p. under a head of 31 feet. An additional supply of power for this system will be provided by the completion of the Montreal Island Power Company's 120,000 h.p. development on the Riviere des Prairies, Montreal Light, Heat and Power Consolidated having contracted to purchase the entire output of the plant.

The district south of Montreal to the international boundary, which in recent years has been rapidly changing from an agricultural to an industrial area, is served by the Southern Canada Power Company. This company operates two stations on the St. Francois river, one in Drummondville where 19,500 h.p. is operated under an average head of 30 feet and one two miles further upstream, at Hemmings falls where 33,600 h.p. is operated under a 50-foot head. A third plant is situated on the Magog river in the city of Sherbrooke where 4,050 h.p. operates under a head of 57 feet while two smaller stations, one of 1,130 h.p. on the Yamaska river in Farnham and one of 300 h.p. at the outlet of Brome lake, are also operated by this company. The districts along the north shore of the St. Lawrence from Montreal to Murray Bay, east of Quebec city and between the St. Lawrence and the international and New Brunswick boundaries are covered by an extensive transmission system owned by the Shawinigan Water and Power Company and subsidiaries and supplied with power from sixteen stations with an aggregate installation of 647,850 h.p. Four of these stations are on the St. Maurice river, two at Shawinigan falls, drawing water from the same headworks, of 58,500 h.p. and 221,500 h.p. respectively, one at Grand'Mere formerly owned by the Laurentide Company where 176,000 h.p. is installed, and one of 120,000 h.p. at La Gabelle. A fifth power house is situated on the Batiscan river near St. Narcisse. The present installation of 22,400 h.p. succeeds an earlier development of 1,600 h.p., from which power was transmitted to Three Rivers in 1898 over the first high tension transmission line in the British Empire. Further east on the Ste. Anne river near St. Alban a 4,000-h.p. plant is operated under a head of 65 feet. Close to Quebec city four power houses are operated, two on the Montmorency river with installations of 2,000 and 5,000 h.p. respectively, one on the Jacques Cartier of 3,000 h.p., and one on the Chaudière where 4,800 h.p. is installed. Thirty-five miles east of Quebec city near St. Fereol on the Ste. Anne river a 24,000-h.p. plant acquired from the Laurentide Power Company is operated, while opposite on the south shore, two plants of 4,500 h.p. and 400 h.p. respectively, acquired from La Corporation d'Energie de Montmagny, supply local demands and are also connected to the main transmission system. Some other smaller stations are also operated, all being connected to the main transmission system which includes a 135 mile 168,000-volt line from Quebec city to the Duke-Price Power Company's great station at Isle Maligne on the Saguenay.

The rapidly expanding power demands of the Lake St. John area are supplied by the Duke-Price Power Company which operates a 495,000-h.p. installation on the Grand Discharge from Lake St. John at Isle Maligne, and

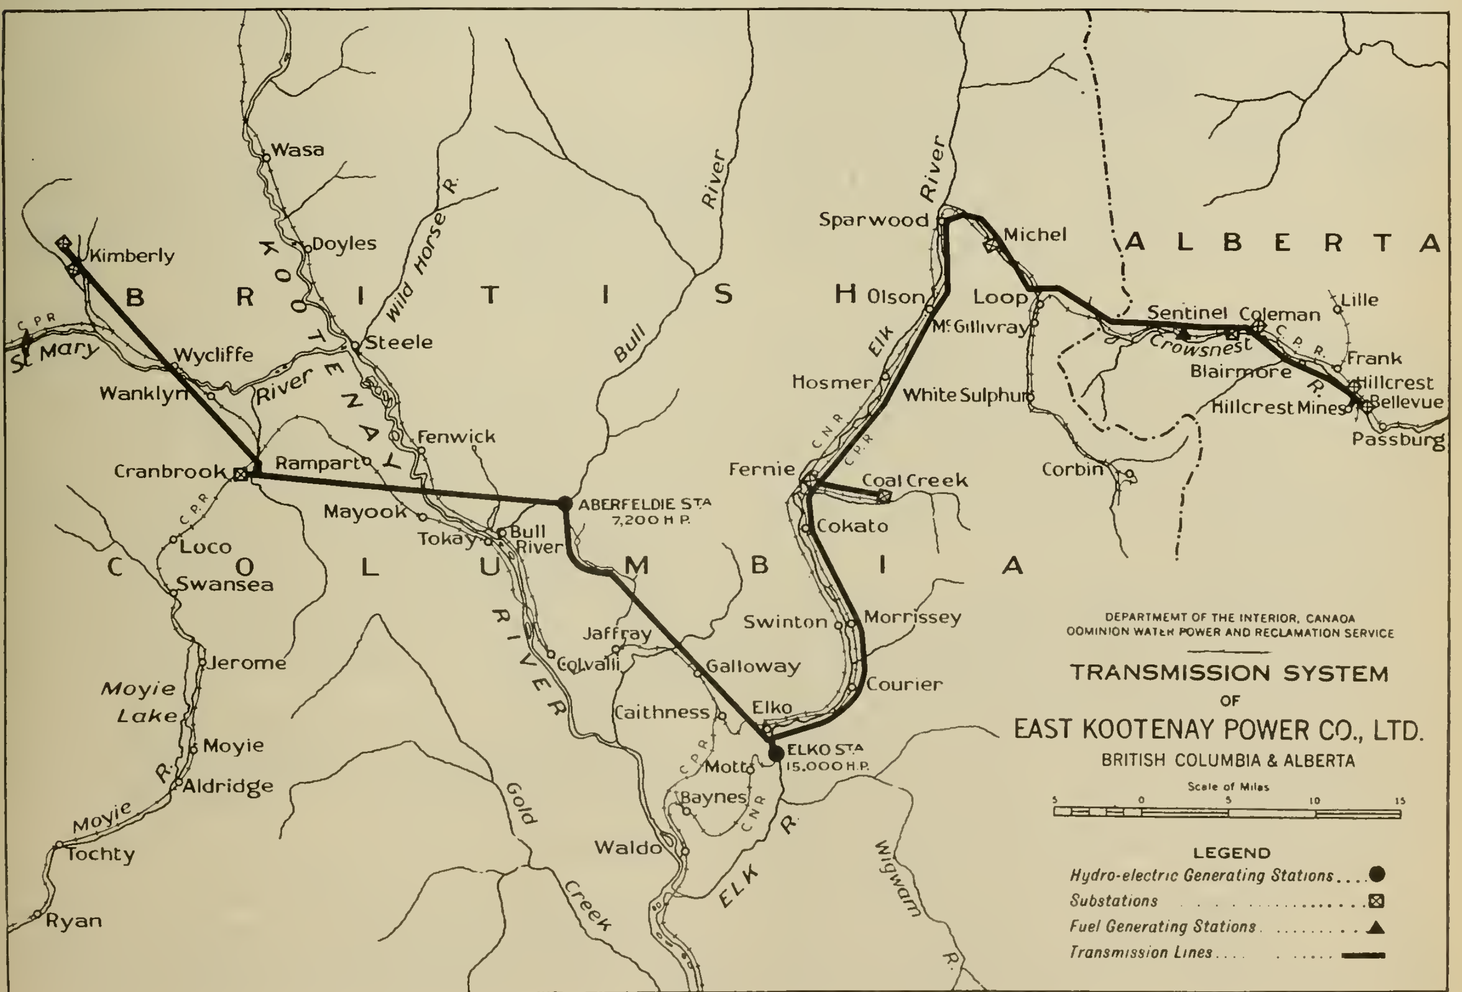

Figure No. 5.

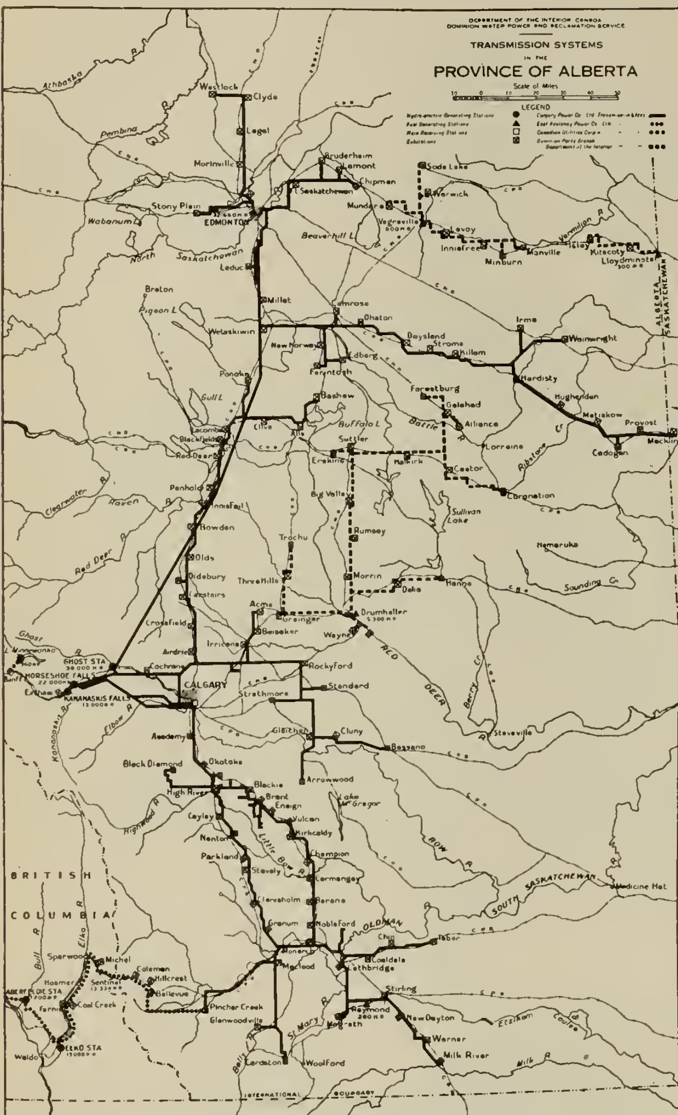

Figure No. 6.

by power generated in connection with its pulp and paper mills by Price Brothers and Company which operates five plants with an aggregate installation of 70,100 h.p. on the Au Sable, Shipshaw and Chicoutimi rivers. The Aluminum Company of Canada, at present buying power for its works at Arvida from the Duke-Price Power Company in which it has a substantial interest, has under construction an 800,000-h.p. development at Chute-à-Caron on the Saguenay river.

The newest entrant into the central station industry of Quebec, the Gatineau Power Company, already has an installation of 567,565 h.p. in twenty stations on the Gatineau and Ottawa rivers and tributary streams. The largest of these, built by the company, are the Paugan, Chelsea and Farmers stations on the Gatineau where 204,000 h.p., 136,000 h.p. and 96,000 h.p. respectively are installed. This company sells power to the Hydro-Electric Power Commission of Ontario, having completed a contract for the sale of 260,000 h.p. over a period of 30 years, delivery being made at 220,000 volts by a line from Paugan station connecting with the Commission's 220,000-volt line to Toronto at the Ontario-Quebec boundary opposite Quyon, Quebec. Power is also sold for the commission's Rideau, St. Lawrence and Central Ontario systems, delivery being made at Remic rapids on the Ontario-Quebec boundary. The mills of the Canadian International Paper Company at Kipawa, Gatineau and Hawkesbury, together with the distribution system of the Gatineau Electric Light Company, which retails power along the north shore of the Ottawa between Hull and Montreal and on the south shore from Alfred to Montreal, utilize the remainder of the power produced. The extensive transmission systems in the province of Quebec are shown on figure No. 9.

There are many other smaller central electric stations in Quebec each providing ample and efficient service in its particular field but space precludes mention of more than the five outstanding organizations referred to above.

New Brunswick

The city and district of Saint John, New Brunswick, and the area between Saint John and Shediac is served by the New Brunswick Electric Power Commission which operates a 11,100-h.p. station at the mouth of the Musquash river, the commission also purchasing power for distribution in Newcastle and Douglastown from the 14,000-h.p. plant of the Bathurst Company on the Nipisiguit river. In the western portion of the province along the Maine boundary the Maine and New Brunswick Electrical Power Company, (controlled by the Central Public Service Company of Chicago), operates a plant of 11,400 h.p. on the Aroostook river, while at Grand falls on the St. John river the St. John River Power Company, under the same control as the Gatineau Power Company, has installed 60,000 h.p. of an ultimate installation of 80,000 h.p., the power being sold for the operation of the newsprint mills of the Fraser Companies, Limited, and the New Brunswick International Paper Company, a stated portion being reserved for distribution by the New Brunswick Electric Power Commission and in the province of Quebec and the state of Maine.

Nova Scotia

In Halifax, Nova Scotia, the distribution of power is made by the Nova Scotia Light and Power Company from plants operated as the St. Margarets Bay system of the Nova Scotia Power Commission. This system comprises three plants on the Northeast and Indian rivers with an aggregate installation of 15,820 h.p. The commission also operates four other systems, the Mushamush system serving Riverport, Lunenburg, Mahone Bay and environs from an 1,155 h.p. plant on the Mushamush river; the Sheet Harbour system with two plants on the East River Sheet Harbour with an aggregate installation of 11,849 h.p., power from one of these stations, Malay falls, being sold in bulk to the Pictou County Power Board for distribution at various points in Pictou county; the Mersey river system comprising three plants totalling 31,050 h.p. on the Mersey constructed during 1929 for the supply of power to a newly constructed paper mill of the Mersey Paper Company near Liverpool and a fourth acquired by purchase from the town of Liverpool; and finally the Tusket system, comprising one plant of 3,000 h.p. on the Tusket river constructed in 1929 to supply the Western Nova Scotia Electric Company and Cosmos Imperial Mills Limited, both of Yarmouth.

In addition to the stations already described there are many smaller organizations serving local needs, the locations of generating stations and transmission systems in the Maritime provinces being shown on figure No. 10.

Water Power in the Pulp and Paper Industry

It has already been shown that in the utilization of developed water power, the pulp and paper industry affords a large market. An installation of 578,000 h.p. is directly maintained by the industry, about 860,000 h.p. is purchased from central electric stations, while considerable off-peak and surplus energy is also utilized to produce steam in electric boilers. As the production of newsprint requires an installation of approximately 100 h.p. per ton of daily output, it is apparent that the cost of power is a most important element in the economics of the industry and in this respect Canada is most fortunate in having large sources of low-cost hydro-electric energy in close proximity to her ample forest resources. As a result of these circumstances the output of newsprint in Canada for the past few years has exceeded that of any other country.

More than 90 per cent of the motive energy in the industry is derived from water power, and table No. 5 analyzes the water power installations in the various provinces and the Dominion devoted to this purpose. The figures in column 6 are of particular interest as showing the extent to which the electric drive has been adopted in the industry.

The sources of hydro-power for the principal mills of the country are briefly indicated in the following paragraphs.

British Columbia

There are seven pulp and paper mills in British Columbia using hydro-power, two of which operate with purchased power while the others have their own installations. The Powell River Company has a total turbine installation of 49,860 h.p. of which 35,460 h.p. is connected to electric generators, the remainder being used directly to drive mill machinery. The Pacific Mills, Limited, situated on the Link river at Ocean Falls, has a turbine capacity of 26,850 h.p. of which 17,250 h.p. is connected to electric generators. The British Columbia Pulp and Paper Company has pulp mills at Port Alice, Woodfibre and Swanson Bay and installations totalling 4,290 h.p., while the Sydney Roofing and Paper Company at Victoria and the Westminster Paper Company at New Westminster operate by purchased power.

Manitoba

In Manitoba the pulp and paper mill at Fort Alexander of the Manitoba Paper Company, a subsidiary of the Abitibi Power and Paper Company, operates with power purchased from the Manitoba Power Company.

Ontario

There are forty-eight pulp and paper mills in Ontario operated by hydro-power, more than half of which develop all or part of the power necessary for their operations. The mills producing their own power have an aggregate installation of 238,880 h.p., of which approximately 60 per cent is hydro-electric and the remainder directly connected to mill machinery. Much of the purchased power is secured from central electric stations controlled by the pulp and paper companies which they supply. The Abitibi Power and Paper Company with mills at Iroquois falls, Smooth Rock falls, Sturgeon falls, Espanola, Sault Ste. Marie and Fort William, owns or controls hydro-electric developments with an aggregate installation of 174,340 h.p. of which a comparatively small proportion is sold for public use. The Spruce Falls Company with mills at Kapuskasing has a 56,250 h.p. development at Smoky falls on the Mattagami river and 2,500 h.p. on the Kapuskasing river. The Backus interests, with mills at Kenora, Fort Francis and Fort William, control hydro-electric developments at the outlets of the Lake of the Woods and on the Rainy and Seine rivers with installations totalling 82,725 h.p. These are classified as central electric stations but most of the power is utilized in the pulp and paper mills. The J. R. Booth Company at Ottawa, has an installation of 28,789 h.p.; while numerous other lesser mills have installations of smaller capacities throughout the province.

Quebec

In the province of Quebec fifty-three pulp and paper mills utilize hydro-power, by far the greater proportion of which is purchased from central electric stations. The mills developing water power directly for their own operations have installations totalling 215,736 h.p. of which about 33 per cent is connected to electric generators. Of the companies maintaining their own installations Price Brothers and Company have 70,100 h.p. on the Chicoutimi, Shipshaw and Au Sable rivers, the Brompton Pulp and Paper Company 21,000 h.p. on the St. François river, the Quebec Pulp and Paper Company 27,500 h.p. on the Chicoutimi and Ouiatchouan rivers, the Canada Pulp and Paper Corporation 24,000 h.p. on the St. Maurice and

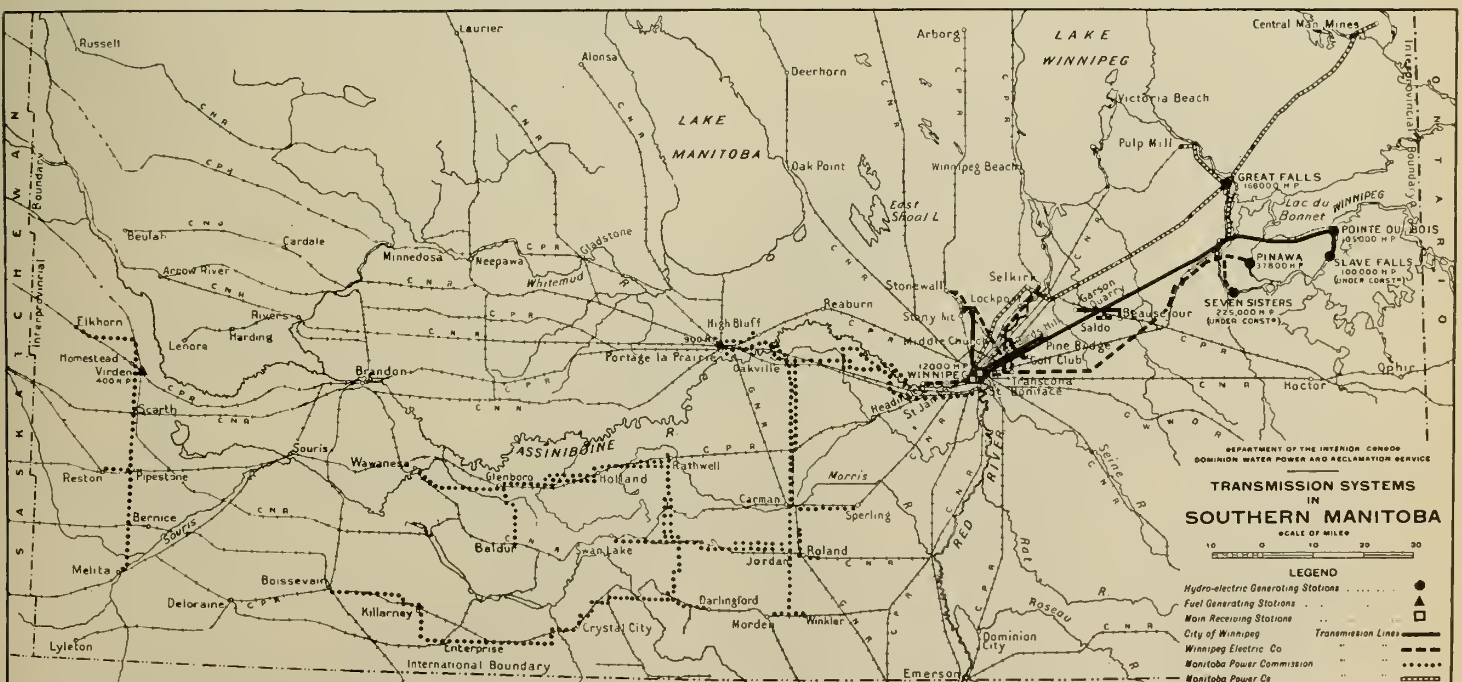

Figure No. 7.

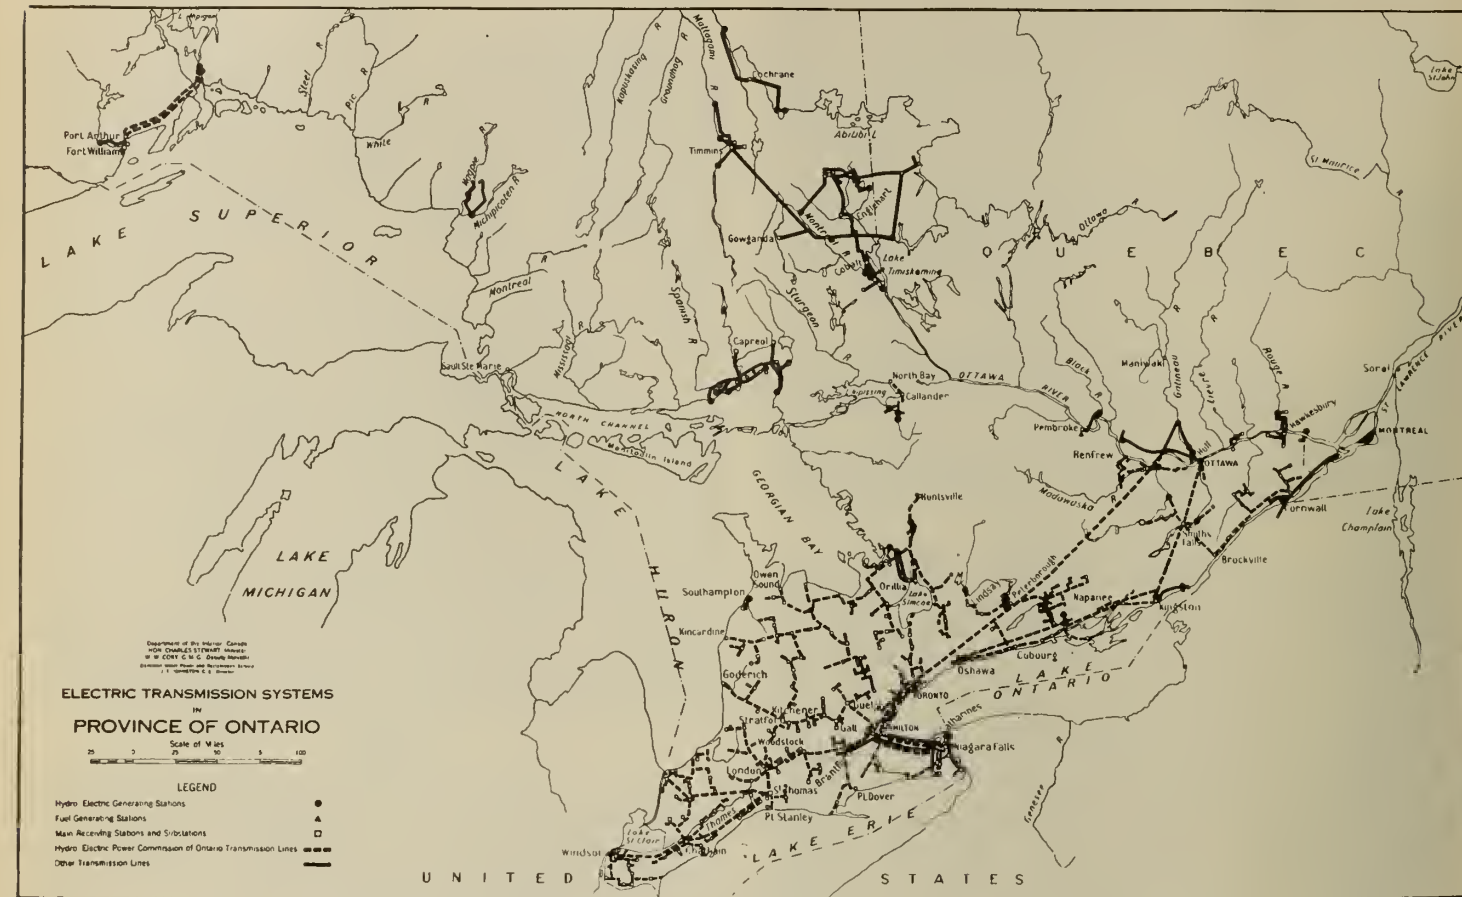

Figure No. 8.

St. François rivers, the Gulf Pulp and Paper Company 11,000 h.p. on the St. Marguerite river, the Abitibi Power and Paper Company 9,000 h.p. at Murray Bay and the E. B. Eddy Company 13,500 h.p. on the Ottawa river at Hull. Numerous other mills maintain installations of lesser amounts while practically all mills in the province purchase electric energy in large quantities from central electric stations.

New Brunswick

Of the six mills in New Brunswick three have water power installations, the Fraser Companies Limited at Edmundston with 2,060 h.p., the St. George Pulp and Paper Company at St. George with 2,668 h.p., and the Bathurst Power and Paper Company at Bathurst with 14,000 h.p. The mills of the New Brunswick International Paper Company now being completed at Dalhousie will receive power from the 60,000 h.p. Grand Falls development of the St. John River Power Company. Fraser Companies Limited also purchase power from this source.

Nova Scotia

In Nova Scotia the Clyde and Sissiboo Pulp Company, (sold to the Mersey Paper Company in 1929), has a total installation of 5,340 h.p. on the Clyde and Sissiboo rivers, the MacLeod Pulp and Paper Company 6,974 h.p. on the Liverpool river, the Lahave Pulp Company 1,500 h.p. on the Lahave river, and the Nova Scotia Wood Pulp and Paper Company 1,614 h.p. on the Medway river. The Mersey Paper Companies mills now under construction at Liverpool will be supplied with power from three developments being constructed on the Mersey river by the Nova Scotia Power Commission. The commission also supplies power to the mill of the A. P. W. Pulp and Power Company at Sheet Harbour. The Minas Basin Pulp and Paper Company, which commenced operating a new mill at Hantsport in March last, purchases its power from its parent company the Avon River Power Company.

Water Power in the Mineral Industries

Water power plays an important part in the mineral industries of the Dominion. In the mining of metals hydro-electric energy is almost wholly used, while even coal mines receive a part of the energy necessary for their development from hydro-electric developments. Low cost power in ample quantity makes possible the exploitation of large deposits of low grade ores which otherwise would have no commercial value, and it is a fortunate circumstance that water powers are widely and favourably distributed in the great pre-Cambrian shield which occupies so large a part of Canada and offers so many opportunities for mineral discovery.

The total installation in water power plants directly utilized in connection with the mineral industries amounts to about 100,000 h.p., while approximately 380,000 h.p. is purchased from central electric stations. This power is used for the extraction of ore, crushing, smelting, refining and other purposes.

In British Columbia the Granby Consolidated Mining, Smelting and Power Company has a water power installation of 13,200 h.p. and the Britannia Mining and Smelting Company 19,070 h.p., whilst on Vancouver Island there is a 12,000-h.p. plant on the Puntledge river supplying power to Canadian Collieries Limited for coal mining. The large mining and smelting operations of the Consolidated Mining and Smelting Company in the Rossland district are carried on with power supplied by the West Kootenay Power and Light Company from hydro-electric developments on the Kootenay river, and in the east Kootenay and Crow's Nest

Table No. 5—Developed Water Power Utilized in the Pulp and Paper Industry

Estimated at January 1, 1930

Province	Installed and Purchased Water Power in Horse Power					
	Turbine Installation in the Industry			Purchased Hydro-Electric Power	Total Hydro-Electric Power Col. 3 and Col. 5	Total Hydro-Power used in the Industry Col. 4 and Col. 5
	Direct Drive	Hydro-Electric Drive	Total			
1	2	3	4	5	6	7
British Columbia	26,155	54,845	81,000	2,550	57,395	83,550

*The pulp and paper mills of Manitoba and New Brunswick purchase hydro-electricity totalling 51,062 h.p.
Column 2 includes all turbines actually installed in the industry directly driving mill equipment.
" 3 includes all turbines actually installed in the industry transmitting power through electric drive.
" 4 totals the turbine capacity actually installed in the industry.
" 5 includes only power purchased from central electric stations for the operation of pulp and paper mills.
" 6 totals the hydro-electric power used in the industry.
" 7 totals the water power used in the industry.

Pass districts coal mines are supplied with power from the East Kootenay Power Company's plants on the Bull and Elk rivers.

In Northern Manitoba and Saskatchewan the mines of the Hudson Bay Mining and Smelting Company at Flin Flon and the Sherrit Gordon mine at Cold lake will shortly be supplied with power from the Island falls development of the Churchill River Power Company on the Churchill river. In south-eastern Manitoba the mining area receives power from the plant of the Manitoba Power Company on the Winnipeg river.

In Ontario, which ranks first amongst the provinces in diversity and value of mineral production, practically all power requirements are met from water power plants. The nickel-copper mines of the Sudbury region are supplied from plants of the International Nickel Company of Canada on the Spanish and Vermilion rivers, also from plants of the Wahnapitae Power Company which has recently been acquired by the Ontario Hydro-Electric Power Commission. The silver mines of the Cobalt district and the gold mines of the Timmins, Kirkland and Larder Lake areas are supplied from plants of the Canada Northern Power Corporation on the Montreal and Mattagami rivers in Ontario and the Quinze river in Quebec. Power for mining in the Algoma district is supplied from plants on the Magpie and Michipicoten rivers, while the Ontario Hydro-

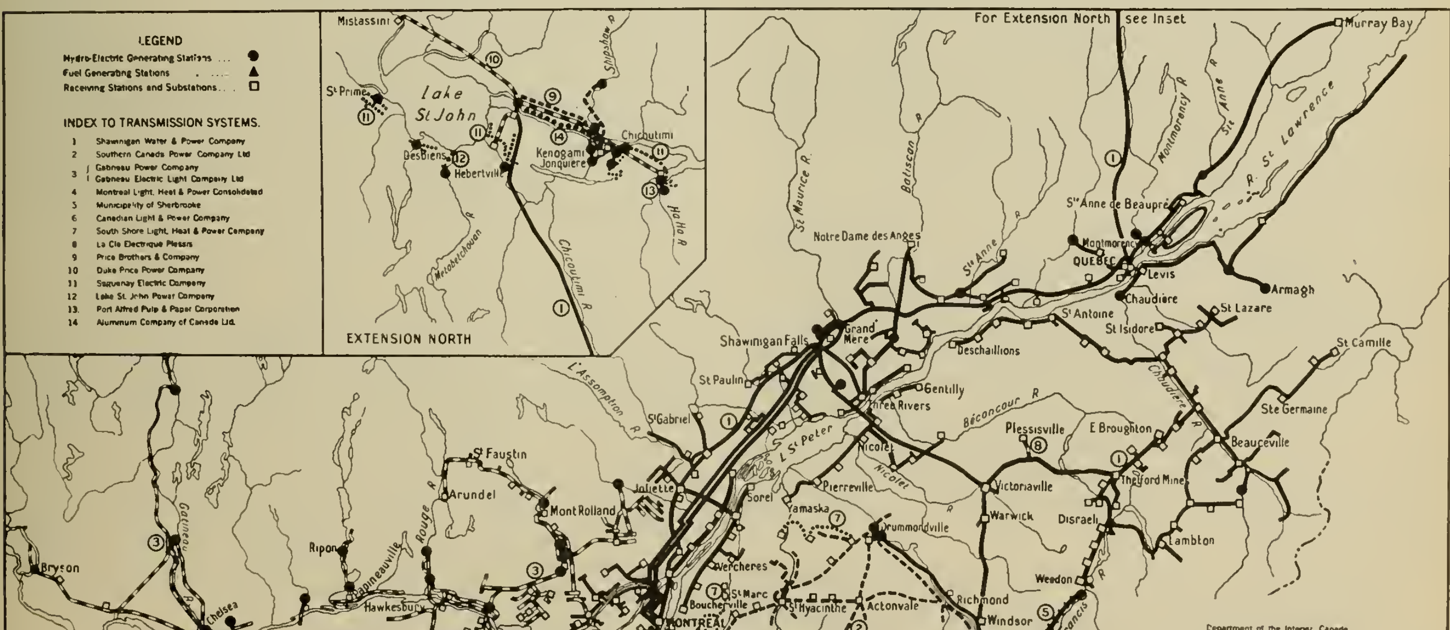

Figure No. 9.

Figure No. 10.

Electric Power Commission has recently completed a 5,000 h.p. installation at Ear falls on the English river for the supply of the Red Lake mining area.

In Quebec the copper-gold mines of the Rouyn and north-western district receive power from the Quinze river development of the Canada Northern Power Corporation, and the asbestos mines at Thetford Mines and Black Lake are supplied through subsidiaries of the Shawinigan Water and Power Company.

In Nova Scotia, where coal mining is the principal mineral industry, the power needs are largely supplied by fuel power plants, but in the Pictou area hydro-electric power is also utilized and other mining operations in various parts of the province are supplied from water power plants.

In the Yukon Territory water power plants have furnished energy for gold dredging operations for many years while new mineral discoveries being made in the Yukon and North West Territories will undoubtedly result in water power developments being made in the future in these great areas.

Water Powers Available for Future Development

In the comment following table No. 1 it was indicated that the present turbine installation represents about thirteen per cent of the total recorded water power resources of the Dominion. There is therefore a large reserve of undeveloped resources and while many of the rivers on which these are found are situated in districts remote from a ready market, there are, nevertheless, large resources awaiting development within reasonable transmission distance of existing centres of population.

British Columbia

In British Columbia large reserves are available, and the opportunities for storage combined with diversions from one watershed to another and the high heads offered by a mountainous region will undoubtedly greatly increase the estimates of available power already made. In the coastal region such rivers as the Nass, Skeena, Bulkley, Khatada, Falls, Madeline, Dean, Cheakamus, Eagle, Homathko and Klinaklini have powers totalling more than 1,000,000 h.p., a figure which will probably be greatly increased by storage. The Fraser river and its tributaries afford many power opportunities which it is estimated aggregate over 1,600,000 h.p. although development on the Fraser itself may be difficult to achieve on account of railways situated along its course. The Columbia and its tributaries have possibilities exceeding 1,250,000 h.p., some of which are marked for early development, such as the powers of the Pend d'Oreille river. On Vancouver Island powers of magnitude are found on the Campbell, Nimpkish, Kokish, Gold, Stamp, Nanaimo and other rivers aggregating more than 280,000 h.p., the Campbell river powers being now investigated for early development.

Alberta

Undeveloped power resources of Alberta are estimated as capable of yielding more than 1,000,000 h.p. Several sites still await development on the Bow river, whose capacities may be materially increased by the provision of storage. The larger resources are found in the northerly part of the province where powers of magnitude exist on the Peace, Athabasca and Slave rivers.

Saskatchewan

The resources of Saskatchewan are also estimated to exceed 1,000,000 h.p., all of which are found in the northerly part of the province. The Churchill is the most important power river with approximately 300,000 h.p. undeveloped. Other rivers with powers of magnitude are the Saskatchewan, Reindeer and Black.

Manitoba

Manitoba's undeveloped water powers are estimated to total about 5,000,000 h.p., of which almost 4,000,000 h.p. is accounted for by the powers of the Nelson river. The other large rivers are the Churchill and the Saskatchewan, while two sites still await development on the Winnipeg river at McArthur and Pine falls; Slave falls and Seven Sisters falls being at present in course of construction. Other powers of lesser magnitude are found on rivers tributary to Lake Winnipeg and the Nelson river.

Ontario

In southern Ontario the principal undeveloped water power resources are found on the International reach of the St. Lawrence river, where Ontario's share amounts to about 1,000,000 h.p., and on the Interprovincial reach of the Ottawa river where Ontario has about 500,000 h.p. still available for development. Further power from the Niagara river can only be secured by an enlargement of the permissible diversion by international treaty. Powers of lesser magnitude exist on tributaries of the Ottawa river such as the Madawaska, Bonnechere, Mississippi and Petawawa and on rivers tributary to Georgian bay such as the Musquash or Muskoka and Magnetawan.

In northern Ontario rivers flowing to James Bay offer many opportunities for development, those of greatest magnitude being found on the Abitibi with about 275,000 h.p., and on the Mattagami with about 170,000 h.p. still undeveloped. Of rivers flowing to Lake Huron the Mississagi and Aux Sables have the principal undeveloped powers, while in the Lake Superior drainage the Nipigon river has two sites of magnitude still available for development and the Michipicoten, White and Montreal rivers have undeveloped sites of importance. In the far western part of the province more than 100,000 h.p. may be developed on the English river, and good opportunities are also offered on the Winnipeg river, while lesser powers are found in abundance on the smaller streams of this district.

Quebec

The province of Quebec has the largest reserve of undeveloped water power resources of any of the provinces of the Dominion and although much of this is found in territory remote from an immediate market, large powers still await development on rivers immediately adjacent to the populous areas. The St. Lawrence river has more than 2,000,000 h.p. available, of which a part will shortly be harnessed by the Beauharnois development, while Quebec's share of the Ottawa river powers together with undeveloped sites on the Ottawa tributaries on the Upper St. Maurice and lower St. François rivers provide for a large future installation.

On the Saguenay river the remaining site at Chute-à-Caron is now being developed, but the tributaries of Lake St. John such as the Peribonka, Mistassini, Mistassibi and Ashuapmuchuan rivers have undeveloped powers of magnitude for the future supply of the district.

In the territory tributary to the lower north shore of the St. Lawrence river and gulf, undeveloped resources in excess of 2,400,000 h.p. are found, among the larger rivers being the Bersimis, Outarde, Manicouagan, St. Marguerite, Sheldrake, Magpie, St. John, Romaine and Natashquan.

In northern Quebec many large rivers flow into James, Hudson and Ungava bays with water powers estimated on meagre data to aggregate about 3,500,000 h.p., some of which on the Harricana, Bell and Megiskan rivers being adjacent to mining areas and railway communication may be of more interest for early development than those on other rivers in remote territory.

Maritime Provinces

While the undeveloped water power resources in the Maritime provinces are of lesser magnitude than those in the other provinces, there are a number of sites which are favourably situated and will undoubtedly be utilized within the next few years. There is also the possibility of developing power from the tides in the Bay of Fundy. In New Brunswick there are additional opportunities for development on the St. John river and its tributaries the Shogomoc, Pokiok and Eel rivers. Undeveloped sites are also found on the St. Croix, Lepreaux, Magaguadavic, Upsalquitch, Nipisiguit, Tetagouche and Miramichi rivers. In Nova Scotia undeveloped sites are found on such rivers as the Bear, Sissiboo, Nictaux, Paradise, Gaspereaux, St. Croix, Medway, Lahave, Gold, Ingram, Tangier, East River Sheet Harbour and Liscomb, while in Cape Breton Island there is a project at Lake Ainslie.

Yukon and North West Territories

Water power investigations in this vast territory have been very few, so that it is possible to make only a very provisional estimate of the resources, but it is safe to say that these exceed 730,000 h.p. Opportunities are offered on rivers tributary to Great Slave lake such as the Hay, Lockhart, Taltson and Tazin, while on many others which traverse the territory rapids and falls have been noted which if market should offer, would provide ready sources of power.

Recent Improvements in Mechanical Transport Vehicles

With Particular Reference to Multi-Wheeled Cross-Country Commercial Types

Capt. N. G. Duckett, B.A. (Cantab), R.A.S.C.,
Department of National Defence, Ottawa.

Paper presented at the Annual General Meeting of The Engineering Institute of Canada at Ottawa, February 13th, 1930

It is intended in the first place to outline the salient factors which have affected the evolution of mechanical transport in general and of multi-wheeled vehicles in particular since the conclusion of the Great War. In 1918 there remained as a residue of the war a large number of mechanical transport vehicles fitted in the most part with solid tires. These vehicles had been produced to meet the requirement of the Services in the various theatres of war but many of them were never used, and were therefore available for absorption into commercial life. It might be reasonably expected that the presence of so large a number of these vehicles would have accelerated the development of mechanical transport for heavy-load carrying as well as passenger carrying. In point of fact their presence actually retarded the development of mechanical transport because they first had to be absorbed commercially, thus delaying the demand for an improved type of vehicle, and the incentive to manufacturers to produce something new was not nearly so strong as it would have been had these vehicles not been available.

Action by British War Office

In view of the continued development of tanks, aeroplanes, and other military machines, it was realized that the transport services would have to be speeded up. A definite move was, therefore, made by the War Department to supersede the solid-tired type vehicle and what later became known as the "1½-ton subsidy type" lorry was as a result introduced.

The Light 1½-ton Subsidy Lorry

This vehicle possessed the increased mobility sought for together with a greater radius of action than that of the ex-war-solid-tired vehicle, and was produced to the specifications of the War Department. Its chief features being,—

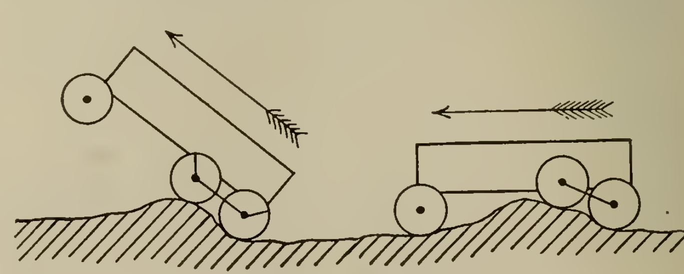
(1) Weight as low as possible
(2) High torque-weight ratio
(3) Comparative high speed
(4) Special cooling.
(5) Large pneumatic tires
(6) Standardization of various features and design, control and equipment, and the use of British Engineering Standards Association standards as far as possible; and
(7) Suitability for commercial use.

The service for which the War Department required this vehicle was the mechanization of the second line transport of the army. It was, however, only by reducing the useful-load-carried to 1½ tons, by most careful design eliminating all non-essential material, and by employment of pneumatic tires, that a design of vehicle could be achieved which would give a fair cross-country performance. It is of interest to note that at the time of the introduction of this vehicle there was a prejudice against the use of pneumatic tires for heavy-load carrying purposes, but this was very largely overcome by the general adoption of cord tires as opposed to canvas,—the cord having a much longer life.

Also, in order to overcome the reluctance on the part of the manufacturers to produce this class of vehicle and the potential user to purchase it, the War Department in 1923 introduced a subsidy of £40.0.0., (approximately $200.00), per annum, payable for a maximum period of three years, to the purchaser of every vehicle of the approved type. This subsidy had the desired effect and in a comparatively short time the subsidy roll, which had a maximum membership of 1,000, was filled, and the pneumatic-tired load-carrying vehicle came into common use. This class of vehicle did not satisfy the War Department entirely, however, because still further developments in aircraft, high-speed tanks and tractors necessitated the production of a vehicle possessing even greater cross-country mobility than that possessed by the light 1½-ton pneumatic-tired lorry. Further, since the 3-ton lorry had been the previous standard in the supply service, in some respects this vehicle had been retrograde, in that its useful-load was reduced to 1½ tons. This meant more vehicles, more men and more road space to move a given tonnage,—all being undesirable from a military point of view. With such considerations in mind, a new vehicle was now visualized which should possess the following improved features:

(*a*) Lower intensity of pressure on the ground.
(*b*) Increased useful-load capacity.
(*c*) Higher speed.
(*d*) Higher torque-weight ratio.
(*e*) Greater powers of adhesion to make use of the tractive effort available.
(*f*) Increased flexibility in construction, giving ability to traverse rough ground without setting up undue stresses in the chassis.
(*g*) Reasonable initial cost.
(*h*) Economy in running and manufacture.
(*i*) Commercially attractive.

At this time there was sharp division of opinion as to the type of vehicle which would embody the maximum number of these desirable features. On one hand, there was a strong advocacy of the semi-track machine; on the other hand, an equally strong school in favour of the multi-wheeled machine. In respect to the features outlined above,



Figures Nos. 1 and 2.

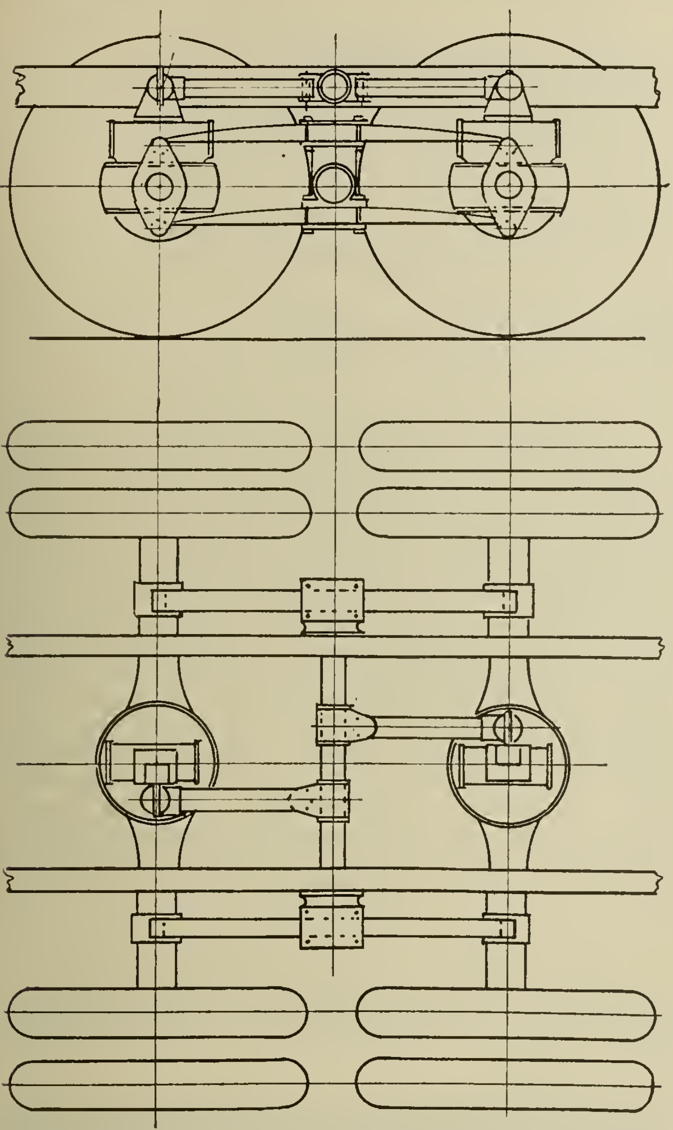


Figure No. 3.—Principle of War Department's Rear Suspension.

the semi-track machine meets the requirements of (*a*), (*b*), (*e*), and (*f*), only. Again, the great drawback to the adoption of the semi-track machine for military purposes is the fact that it is not commercially attractive, has a comparatively poor speed performance and is noisy. The commercial attractiveness of a vehicle is very important because, in emergency, the military authorities have to depend on the vehicles in commercial use to fill their establishments. On the other hand, however, since there is a great commercial demand for multi-wheeled vehicles, it is desirable that as many military features as possible should be embodied in these types.

The Rigid Six-Wheeled Vehicle

As a result of the decision of the military authorities to pursue the development of the multi-wheeled vehicle, the rigid six-wheeler was produced. The provision of the additional wheels increased the area of contact with the ground and thus, in addition to preventing sinkage on soft ground, provided means for applying tractive effort over greater ground area, hence securing better adhesion.

After much experimenting, it was decided that the essential factors on which the success of the rigid six-wheeler depends are,—

(1) That the suspension of the driving axles must be such that the exertion of driving torque shall not disturb the distribution of weight of the four driving wheels on the ground in any way.

(2) That the suspension must also permit of free articulation of the driving axles within as wide limits as is practicable in such a way that the springs are not distorted, nor the weight distribution of the four wheels disturbed. This enables the wheels to conform to rough ground without affecting the drive whilst causing the minimum of chassis displacement and distortion.

(3) High tractive effort being on occasions essential it was decided, in order to obtain this, to encourage producers to gear down a moderately sized engine rather than to provide a large engine. This is particularly important in England where vehicles are taxed at £1.0.0. per horse power per annum.

(4) There should be a low intensity of pressure between the driving wheels and the ground to reduce sinkage; and in addition, some form of non-skid arrangement is essential in order to make use of the maximum tractive effort available when negotiating soft and pliable ground.

War Department Patented Suspension

It should be noted in connection with this suspension that it was patented by the War Department in order to prevent its monopoly by any one maker, but it was not intended in any way to retard its development,—in fact, its use is permitted free to all British manufacturers and under certain conditions this has now been extended to include manufacturers in Canada, and other parts of the Empire.

There are three axles. The foremost axle,—the wheels of which do not drive,—is provided with the Ackermann type steering and is connected to the chassis by semi-elliptic springs. The two rear axles,—carrying the load,—are situated close together. These are live axles capable of independent relative movement with certain limits, and the necessity for this movement in the rear bogie will be readily seen from figure No. 1.

Take a vehicle with three wheels on each side practically rigidly fixed to the chassis, they will behave, as shown, when the machine meets an obstacle. If, on the other hand, two rear axles are allowed to articulate about a common point, (figure No. 2), they will lift in turn to overcome the obstacle without affecting the longitudinal stability of the vehicle. In this connection, however, one point needs very careful consideration and that is, unless properly designed, the suspension will permit the rearmost driving wheel to sink in soft ground with an accompanying tilt of the leading driving-wheel which in effect renders the vehicle a two-wheel drive for the moment. These disappointing and undesirable points were met with when trying out certain foreign types of rigid six-wheelers in the early experiments of 1924. They were overcome, however, by the introduction of the War Department's rear suspension.

Principle of the War Department's Rear Suspension

The principle of this suspension is shown diagrammatically in figure No. 3. The special features of this design are described below,—

(1) It will be seem from figures Nos. 3 and 4 that the axles are free to rise and fall independent of each other within certain limits.

(2) To avoid uneven weight distribution over the four driving wheels caused by the application of driving torque, the torque reaction is taken from

each axle to the main frame of the vehicle (figure No. 3)and not from axle to axle. In certain types tried out in Canada during the last two years the torque reaction is taken from axle to axle, and thence to the chassis frame. With this type of reaction gear, the tendency of the vehicle is to convert itself into a two-wheel drive when the drive from all four rear wheels is most needed.

(3) The rear bogie assembly permits an action which ensures that the worm shafts remain parallel over all relative positions of the driving axles. On this account the instantaneous angular velocity of the worm shafts and wheels are unaffected; the transmission stresses are, therefore, kept to a minimum; maximum adhesion is obtained between driving tires and the ground; and tire-wear is much reduced.

(4) In order that the two driving axles may be given lateral articulation, that is, horizontal movement without distorting the road spring leaves, the members carrying the spring ends are mounted by means of a universal or spherical joint. This action can be clearly seen in figure No. 4. To keep this horizontal movement within certain limits steel straps are provided, (figure No. 4), which are bolted to side chassis members.

(5) The tractive effort is transmitted to the chassis through the road springs which are of the duplex inverted semi-elliptic type and which, in addition to carrying out their normal functions, are used to locate the two driving axles by means of four master leaves.

Transmissions

In the War Department rigid six-wheeler the standard transmission units have been utilized as far as possible, and the low gear ratios have been obtained by fitting an auxiliary gear box immediately in the rear of the main gear box unit. The auxiliary gear box, being usually of the sliding gear type, is controlled by a lever from the driver's seat and gives a further reduction in the normal gear ratios of approximately one-third. (Details of gear ratios and other particulars of a typical "light" and "medium" six-wheelers are given in appendix 1.)

The fitting of this auxiliary gear box in the rear of the main gear box has the advantage of keeping the extra torsional stresses, caused by the increased gear ratios, behind the main gear box. Further, this design gives additional tractive effort without having to resort to high powered engines—a most important feature in countries where vehicles are taxed on horse power.

The rear axles are generally of the normal worm type and, as previously stated, the worm shafts are permitted to remain parallel during all relative movement to rear axles. Both propeller shafts are universal-jointed at both ends. However, owing to the wide angle through which they have to work, particular attention has been paid to their design and to their lubrication.

Tire Equipment

The War Department, in conjunction with the Dunlop Rubber Company, (England), has recently introduced a new type of "bar-tread" tire. The object of this tire is to give maximum adhesion to the ground, and also to give maximum adhesion between tire and the overall chain when used. It has a helical design tread which is supposed to be self-clearing. The appearance of this "bar-tread" tire is shown in figure No. 4.

In Canada, during the last two years, considerable experience has been had with this form of tire and its superiority over the normal tread is well established. In all six-wheeler tests carried out during the past two years with vehicles having tires of ordinary tread, one of the chief difficulties has proved to be the securing of sufficient driving adhesion between the ground and the tires when negotiating soft and boggy surfaces. This is equally true even when overall chains are fitted, the mud or snow,—as the case may be,—simply packs between the tire and the chain and adhesion is completely lost,—the wheels merely spinning inside the overall chain. When the "bar tread" tires are used this trouble does not occur.

Overall Non-Skid Chains

Experiments showed that some form of device to increase the area of contact with the ground, to give increased adhesion and to make use of the tractive effort available when traversing particularly bad surfaces, was needed. For this purpose, what is now known as the "War Department overall chain" was designed. It is made up of a number of rolled steel shoes connected by links made of very cheap stampings. The terminals of the bases of the shoes project inwards to form a tongue, and so act as a guide to ensure the chains centralizing in the space separating the twin tires. The chain can be fitted in approximately two minutes, and the vehicle is then to all intents and purposes a semi-track machine. It should be noted that since both wheels drive, the chain is not normally in tension—the drive being obtained through the weight of the driving wheels running over the chain in contact with the ground. Also, on the inner surface of the shoes, are small studs so placed as to engage between the treads of the tires, and increased adhesion between the chain and tire is therefore obtained.

The Department of National Defence has carried out several experiments in Canada with the present type of War Department overall chain under varying conditions of weather, temperature and terrain, and from these experi-

Figure No. 4.—View showing Extent of Flexibility of Rear Suspension without affecting Level of the Chassis Frame.

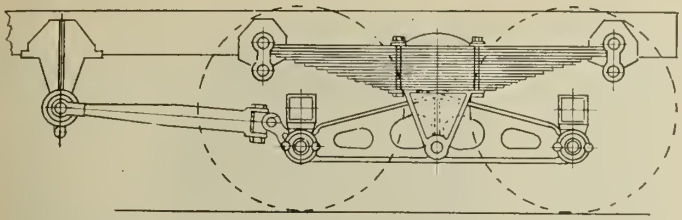

Figure No. 5.—Typical American Rear Axle Mounting for Six Wheel Truck.

ments it would appear that several improvements could be made and, indeed, if the chain is to be used successfully in mud, clay, sand and snow in Canada, will be absolutely necessary. The present type gives admirable results when traversing all natures of ground in summer time, but in the winter—at temperatures when snow will bind—results in snow were not at all satisfactory. It was found that the snow packed solidly on the inner surface of the shoes and either increased tension on the chain to such an extent as to reduce seriously the vehicle's tractive effort, or raised the chain so far off the tires that the tongue of the connecting links, which normally rests between the twin tires, mounted the tire, resulting in the chain coming off. In order to overcome this difficulty, holes approximately one half-inch in diameter, were drilled through the shoes and it was found that a considerable quantity of snow worked through these holes with the result that clogging did not take place nearly so soon. This did not completely eliminate the trouble, however, and it is intended during the coming winter to experiment with shoes which are merely skeleton in form and which will allow the easy passage of snow from the inner surface of the shoes to the exterior.

Types of Rigid Six-Wheeler in Production

Many manufacturers of motor trucks in England to-day are manufacturing the rigid six-wheeler, and the War Department has issued specifications for a "light" and a "medium" type for their guidance. The manufacturers have, therefore, with a few exceptions, confined their attention to manufacturing these two types—the load-carrying capacities of which are, as follows:—

The "light" six-wheeler has a useful load-carrying capacity of 1 ton across country, and 1½ tons on good roads; and

The "medium" six-wheeler has a useful load-carrying capacity of 2 tons across country, and of 3 tons on good roads.

Another type visualized by the War Department is the "heavy" six-wheeler, the role of which will be the carrying of laboratories and other technical loads in the back areas. This machine will, in all probability, drive on all six wheels but specifications have not, up to the moment, been prepared.

In addition to the production of six-wheelers which is going on in England, other makes of six-wheelers are being produced throughout the United States. From information on hand, however, the rear suspension of these six-wheelers does not possess the flexibility or the performance of the War Department design, and the British manufacturer of the six-wheeler has on this account a great initial advantage in Canada, which, if he were alive to the potentialities, could be exploited with considerable success.

Comparison Between War Department's Rear Suspension and Other Forms in General Use Throughout America

At this point it would be of interest to compare the rear suspensions of American and British six-wheelers in order that the main advantages and disadvantages may be seen. The construction of the British rear suspension has been already explained in detail, and it now remains to explain the common type of suspension as used in the United States.

Taking the rear axle six-wheel Hendrickson mounting for example, (see figure No. 5), it will be seen that certain articulation of the rear wheels is possible and that the axles are free to move independently within certain limits. The torque reaction, however, is taken from axle to axle, and thence to chassis frame, instead of being taken from axle direct to chassis frame, and is, therefore, not balanced between axles. As previously pointed out, the tendency of this construction when a gradient or other obstacle is being negotiated is for the leading wheel to rise off the ground and the rear wheel to dig itself in. An advantage claimed for this type of suspension, however, is that the driving stresses are spread over a larger section of the chassis, a large powerful semi-elliptic spring being anchored at its front and rear, direct to the chassis, instead of in its centre, through a bracket, as is the case with the War Department suspension. This, in the writer's opinion, is a good point about this suspension as the driving stresses are distributed more evenly over a large area of the chassis frame, but its one big disadvantage is that the torque reaction between the two rear axles is unbalanced and the unit, therefore, lacks real flexibility.

Use of Skis with Six-Wheelers

During the past year certain trials were carried out to ascertain the serviceability of the six-wheeler in snow, and it might be of interest to relate briefly the results of one of these trials.

When fitted with the overall chain, (the shoes of which had previously been drilled to allow the escape of snow), the factor limiting the performance of the six-wheeler when operating across country in deep, virgin snow was that the front wheels cut their way into the snow thus allowing the radiator to foul the surface and to pile up in front of it an unsurmountable barrier which very quickly stopped all progress. This was especially so when the driving wheels were turned out of the direct-forward position. To overcome this limiting factor, it was decided to fit skis on the front wheels. Experimental skis were made, and eventually those shown in figure No. 6 proved to be successful. Before this design was arrived at, several disappointing results were experienced, the main one being the difficulty in steering the vehicle over ice, or hard snow, in the desired direction—the tendency being for it to continue in a straight line irrespective of the angle at which the steering gear was set. This was overcome by fitting a fin of increased depth and length on the under-surface of the main ski. With this, it was found that steering was quite satisfactory whether

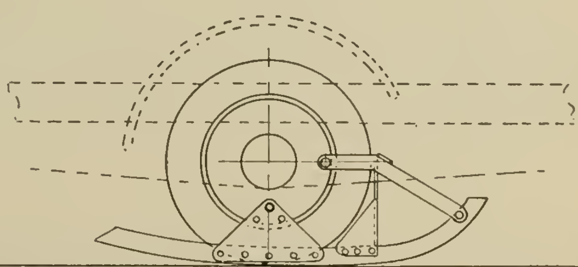

Figure No. 6.—Diagram of Ski for Lorries, 4-6 Tons, Mark I.

traversing deep or shallow snow, in fact, even when passing over ice the fin made the steering of the vehicle almost as easy as when driving under normal conditions.

The mobility of the six-wheeler across country, over mud, sand, clay and snow, is infinitely superior to that of any other type of load-carrying wheeled-vehicle. At the same time its performance on good roads is not impaired. In other words, it has the advantages of the semi-track machine with none of the latter's disadvantages.

The initial cost of the six-wheeler is reasonable; its maintenance cost is low on account of its easy riding qualities; and, owing to the low intensity of pressure, between the tires and the ground the legal load is greater than that allowed to the four-wheel vehicle.

In Canada, under certain mud, sand and snow conditions the four-wheeler is often unable to operate. The six-wheeler on the other hand, with its skis and overall chains for extreme conditions, can operate economically the whole year through.

Improved Form of Front Axle Springing

Experiments have been made recently in England with a new form of front axle springing. Instead of the normal semi-elliptic springs, a transverse semi-elliptic inverted spring has been designed. This is secured to the centre of the chassis front cross-member and it is mounted at this point on a trunnion joint, and at either end by means of shackles to the front axle. The advantage of this form of springing will be immediately apparent as with this arrangement not only now will the rear wheels be capable of independent horizontal movement but the front wheels also will be capable of independent action in similar manner. This arrangement reduces the chassis distortion and stresses to an absolute minimum, and is likely to become standard equipment on at least the "light" six-wheeler.

Factor of Performance

During the preliminary experiments and investigations carried out by the War Department, it was found necessary to introduce a formula which would give the comparative cross-country potentialities of the various vehicles under consideration. This formula later became known as the "factor of performance." This is taken from the War Department's specification for six-wheeled vehicles, and is as below,—

$$\text{Factor of performance} = \frac{A \times 2S \times N \times R}{W \times T}$$

Where A = area of piston in square inches.
S = stroke in inches.
N = number of cylinders.
R = overall gear reduction (engine to roadwheels) in lowest forward gear.
W = gross weight of vehicle ready for the road.
T = effective circumference of tire in inches.

The figure arrived at represents cylinder volume swept per unit of advance of the vehicle in its lowest gear per ton of gross weight. For example, the specification under consideration which is for a "medium" six-wheeler calls for "factor of performance" of 55.

Conclusion

It is hoped that the foregoing has given a fair idea of multi-wheeled vehicle development, and the position in which it stands at the present time. In the writer's mind, there is no doubt that the rigid six-wheeler provides a field of very profitable research. It combines the dual qualities of being able to travel over good surfaces at a speed equal to any other four-wheeled vehicle and at the same time has cross-country performance equal,—if not superior,—to many semi-track vehicles. Its use, at the moment, is spreading rapidly throughout India, Egypt, South Africa and Persia where good roads are comparatively few; and also in Europe and America where roads are for the most part good.

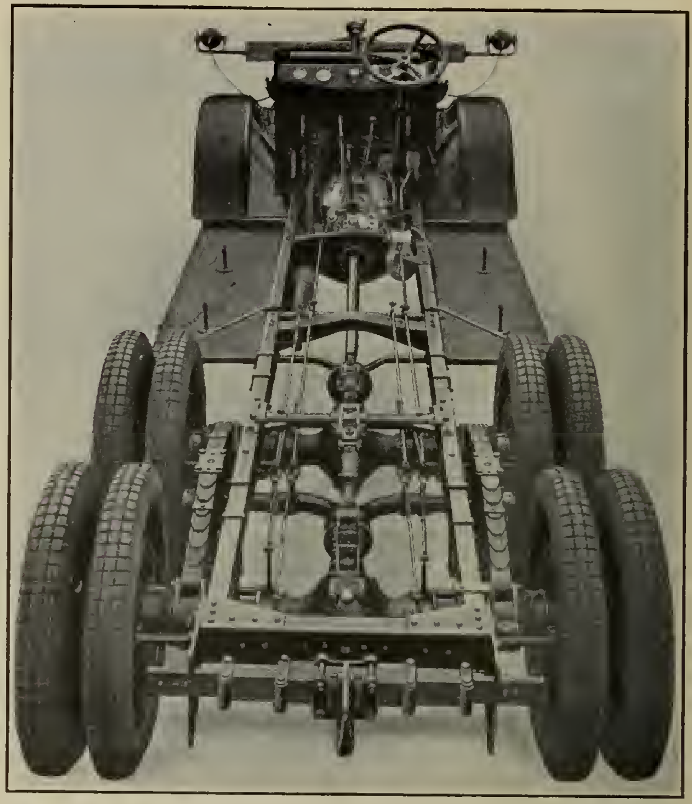

Figure No. 7.—General Layout of a Six-Wheeler Chassis.

Canada is behind so far as the production, and employment, of the six-wheeler is concerned. It is of interest to note that the largest user, at the moment, is the Department of National Defence, for the simple reason that this vehicle embodies a greater percentage of desirable military features than most vehicles and, at the same time, is commercially attractive. Some idea of the six-wheeler's commercial value can be gathered from the variety of uses to which it is being successfully put in various parts of the world.

Among these are:—

(1) Work in connection with railroad and road construction.

(2) As feeders to railways in districts where roads do not exist.

(3) For logging in virgin country. Its special winch equipment, when fitted, makes it particularly well suited for this class of work.

(4) For general farm work.

With the lead given by the Department of National Defence to this type of vehicle in Canada, its use is gradually becoming more general, and it is considered that in the comparatively near future the outstanding qualities of this vehicle will be appreciated and a correspondingly greater demand will result.

APPENDIX I

Schedule of Technical Details

1. Type of vehicle...	"Light" six-wheeler.		"Medium" six-wheeler.	
2. Weight with body and equipment ready for the road	4,536 pounds.		6,496 pounds.	
		X		X
3. Useful loads..... (Military loads)	On road.	country.	On road.	country.
tons	1.5	1.	3.	2.
4. Engine	4 cyl.		4 cyl.	
Bore	3⅛″		3¾″	
Stroke	5″		5″	
Treasury rating..	15.9 h.p.		22.5 h.p.	
		X		X
5. Gear Ratios.....	Road use.	Country.	Road use.	Country.
Engine to road wheels.	21.56	69.0	46.1	95.4
	15.04	48.4	22.8	47.3
	10.8	33.2	13.8	28.6
	6.25	20.0	8.75	18.1
	R. 27.87	R. 89.25	R. 72.00	R. 148.9
6. Road speed miles per hour....	35-40		25-35	
7. Average gasoline consumption miles per gallon	15		11	

Note:—In commercial life these vehicles are sold to carry greater loads than those for which they are used in the army.

The Aeronautical Laboratories of the National Research Council of Canada

J. H. Parkin, M.E., F.R.Ae.S., M.E.I.C.,

Assistant Director in the Division of Pure and Applied Physics, in charge of Aeronautical Research, Ottawa.

Paper presented at the Annual General Meeting of The Engineering Institute of Canada, at Ottawa, February 13th, 1930

The dependence of national development and progress on transportation is nowhere more marked than in Canada. The settlement and development of the Dominion first followed the natural waterways, later the railways, and may now be said to be following the airways. Regions formerly regarded as inaccessible and doomed to remain forever undeveloped are now not only being explored but are actually in process of development practically wholly by means of aircraft.

In perhaps no other country are aircraft being put to as great a variety of useful and practical tasks as in the Dominion. Immediately following the war Canada set about making use of aircraft and taking advantage of their characteristics in everyday peacetime pursuits with such success that aircraft have now become an important factor in the life of the country.

In the use of aircraft for exploration, reconnaissance and surveying, Canada has taken a leading part and has brought the practice of aerial surveying to a high state of development. The value of aircraft in developing and protecting the timber wealth of the country was quickly appreciated in the Dominion, and great strides have been made in the use of aircraft for the detection and suppression of bush fires, for timber cruising and forest sketching. In the last few years aircraft have played an important part in development of the mineral resources of the Dominion and have been intensively and successfully employed for prospecting, geological exploration, and in development work, particularly in the great north country known to be geologically favourable but hitherto practically inaccessible. Aircraft are also being employed in the warfare being waged against different pests and blights attacking the forests and crops. The air mail lines are being steadily extended and improved and the use of aircraft for the carriage of express and passengers is continually increasing. For customs and fisheries patrol and many other everyday civil and commercial tasks aircraft are being employed with success in the Dominion.

The success with which aircraft have been used in Canada is remarkable when it is remembered that the operations were in many cases commenced using military types of aircraft and that even now few of the aircraft are specially designed for the service and conditions under which they are operating. The success of the few machines designed for specific purposes indicate what can be accomplished. To make fullest use of aircraft in the country, machines suited to Canadian requirements and conditions must be developed.

In developing aircraft suited to the special services and peculiar conditions, an aeronautical laboratory is essential. Recognizing this fact and the national importance of aviation in Canada, the National Research Council has undertaken, with the approval of the Sub-committee of the Privy Council on Scientific and Industrial Research, the establishment at Ottawa of completely equipped aeronautical laboratories. The laboratories planned will compare favourably in extent and capacity with the best in other countries.

Scope and Nature of the Work of the Laboratories

While the whole field of aeronautical research embraces most branches of engineering activity as well as many other sciences, the three principal divisions are aerodynamics, hydrodynamics and power plant. Accordingly, the National Research Council is installing a wind tunnel for aerodynamic research, a test tank for the study of problems connected with floats and hulls and power plant equipment for the testing of aircraft engines, fuels, etc.

The work of the laboratories will be principally aeronautical research for the purpose of improving the performance of aircraft, developing new types and solving problems arising in connection with the design, construction and operation of aircraft in Canada. Aeronautical testing will also be undertaken for designers, constructors and operators, and the laboratories will be found very useful for many investigations of a non-aeronautical character.

Not the least important work of the laboratories will be the facilities offered for training in aeronautical research. The experience gained by young men in one or two years of research will be of material benefit not only to them but to the Canadian aircraft industry and aviation.

Figure No. 1.—Exterior—Wind Tunnel Building.

Figure No. 2.—Interior—Wind Tunnel Building.

Aerodynamic Laboratory—Wind Tunnel

Aeronautical Research

The information forming the basis for the development of aircraft has been derived in different ways. The pioneers in the art generally employed direct methods and worked with full scale complete machines, with power driven models, with gliders and with kites. The obvious advantages of conducting experiments on machines and models under somewhat definite control lead to the use of the carriage and track and of the whirling arm. These devices suffer in turn from difficulties inherent in making observations on a moving object and to overcome these troubles the wind tunnel was introduced. While free flight testing still forms a well recognized and much employed method of investigation for certain types of aeronautical problems, the wind tunnel at the present time is the most generally used, and most important source of information on which the design of aircraft is based.

Historical

It appears that the wind tunnel was first used by Phillips in England, in 1893, in determining the most suitable form for the wings of his multiplane. Later, in 1900, Maxim used a wind tunnel in developing the design of his huge machine. The first tunnel in America was that designed and built by Dr. A. F. Zahm at Washington in 1901. The Wrights, whose experiments with gliders had shown existing data to be unreliable, employed a small tunnel in the winter of 1901 to secure the information on which was based the design of their successful aeroplane, and Stanton in England in the same year employed a wind tunnel in certain researches. In Canada, a small tunnel was used by Mr. W. R. Turnbull, of Rothesay, N.B., about 1902, for experiments on wing sections. Between 1904 and 1909 several tunnels were built in Europe including those of Riabouchinsky at Moscow 1904, Finzi and Sodati 1905, Prandtl at Gottingen 1908, Rateau and Eiffel in France 1909, and the National Physical Laboratory in 1909. In 1917, the University of Toronto installed a 4-foot tunnel

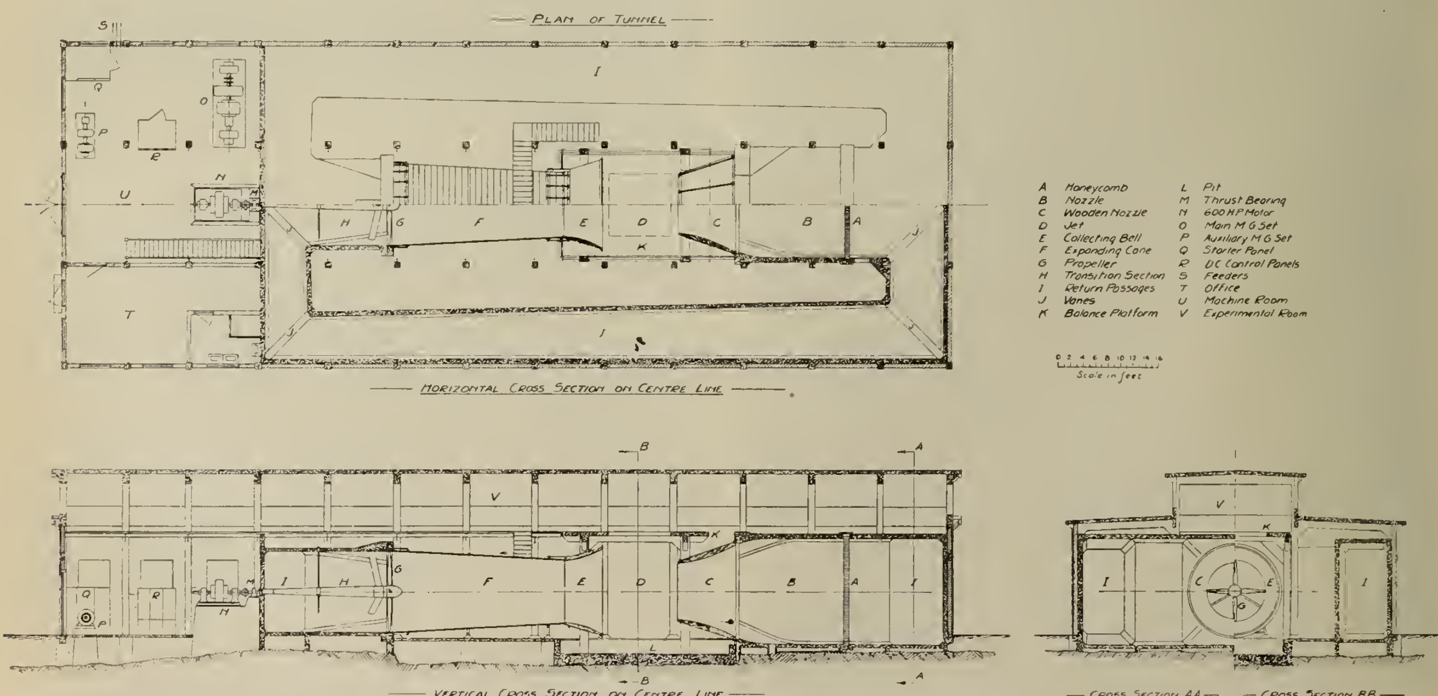

Figure No. 3.—Arrangement of Wind Tunnel.

which was, up to the present time, the only tunnel in Canada.

The Wind Tunnel in Aeronautical Research

The use of the wind tunnel in aerodynamics is based on the principle of relative motion. Instead of moving a model through still air, the air is moved past a stationary model. Under these circumstances the reactions on the model are the same as though it were in motion and the difficulty of properly supporting a moving model is avoided. In the wind tunnel, a uniform steady current of air is drawn at known speed past an exact replica or model of the aircraft to be studied, mounted on a sensitive balance, by means of which the forces on the model are measured. From these measurements the performance or characteristics of the full scale machine in free flight can be accurately predicted at much less cost, in less time and without the inconvenience, difficulties and hazard of free flight testing, while, at the same time, the exact conditions can be readily duplicated.

Requirements for Wind Tunnel Testing

In order that the results of model tests may be applicable to full scale aircraft, it is necessary that the conditions of flow about the model be the same as about the full scale machine. To secure such similitude of flow, not only must the model be geometrically similar to the original, even to surface roughness, but the ratio $\frac{Vl}{\nu}$*, known as Reynolds' number, must have the same value in both model test and full scale flight.

As in atmospheric tunnels, the kinematic viscosity ν of the air is the same as for the outside air, it is only necessary to maintain Vl the same in both cases. To satisfy this requirement, however, necessitates impossible air speeds in the wind tunnel, since, with say a 1/5 scale model the air speed must be 5 times full scale speed. Hence wind tunnel tests are ordinarily carried out at values of Vl less than those for full scale and an experimentally determined "scale correction" applied.

In an endeavour to reduce the uncertainty due to this correction, the size and air speed of wind tunnels has been progressively increased, the usual size at present ranging from 6 to 10 feet in diameter, with speeds from 125 to 200 or more miles per hour.

Full scale values of Reynolds' number can be attained in wind tunnel tests by reducing the kinematic viscosity ν, thereby increasing Reynolds' number. Thus, in the compressed air wind tunnel, air compressed to as high as 300 pounds per square inch is employed and the value of $\frac{Vl}{\nu}$ thereby brought up to full scale values.

* V—velocity, l—linear dimension.
ν—kinematic viscosity.

It is the endeavour in wind tunnel practice to make conditions as nearly as possible ideal, not because such conditions are easy of attainment or are met with in actual flight but largely because of difficulty in properly defining any other conditions and uncertainty as to the effect of departures from the ideal. Besides, if the tunnel air stream is ideal, it is relatively easy to render the stream otherwise, but the reverse cannot so readily be accomplished. The requirements of the air stream in a wind tunnel are therefore:

(1) Velocity of flow uniform throughout.
(2) Velocity of flow constant, i.e., non pulsating.
(3) Direction of flow constant.

These requirements, if fully met, would result in laminar flow in the air stream with complete absence of turbulence. This cannot be attained in practice, but by careful design and construction an air stream of remarkable smoothness and steadiness can be secured in a wind tunnel.

Types of Wind Tunnel

Depending upon their form, modern wind tunnels are classified as (*a*) free or closed return, depending upon whether the air after being drawn past the model by the propeller or fan passes back to the nozzle through the room quite unconstrained, or is returned through closed passages. Free return tunnels, while more efficient from a power standpoint, require very large buildings to house them if satisfactory steadiness of the air stream is to be secured. The small building required to house a closed return tunnel is one of its greatest advantages. (*b*) Open or closed tunnels depending upon whether the air stream in which the model is placed is a free unconfined jet issuing from a nozzle or is confined in a closed tube. The open jet is generally more convenient to work with since the model is readily accessible and troubles with pressure seals, etc., are obviated. The open tunnel is, however, somewhat less efficient than the closed tunnel.

Elements of Wind Tunnel

All wind tunnels, while differing in form, comprise the same main elements, namely:—

(1) Nozzle in which velocity of the air is increased.
(2) Straightening devices (honeycomb).
(3) Experimental room or test chamber in which the tests are made.
(4) Expanding cone in which the air is decelerated before reaching the propeller.
(5) Propeller or fan for moving the air.
(6) Motor or other means for driving the propeller.
(7) Means for controlling the air speed.
(8) Balance for measuring reactions on the model.

The Wind Tunnel of the National Research Council

An open jet closed return form of tunnel has been adopted for the National Research Laboratories. The

Figure No. 4.—South Elevation—Test Tank Building.

Figure No. 5.—North Elevation—Test Tank Building.

tunnel has a 9-foot diameter jet, two return passages and a 13-foot diameter propeller driven by a 600-h.p. motor which it is anticipated will develop a maximum air speed in the jet of over 125 miles per hour. Provision will be made for enclosing the jet should this be desirable for certain work or to improve the efficiency.

An existing building, see figures Nos. 1 and 2, on the site of the laboratories was used to house the wind tunnel. The building is of reinforced concrete and brick construction, 142 feet long by 51 feet wide, 25 feet high at centre and 18 feet high at the sides. The cross section of the building in size and form was such as to accommodate a tunnel 9 feet in diameter, with double return passages, while the length enables a separate motor room and office to be provided at one end.

The tunnel will permit aeroplane models of span up to 5 feet to be tested at a speed of 125 m.p.h. or say 200 f.p.s. corresponding to a *Vl* of 150 as compared with a full scale value of from 500 for a small aeroplane to 1,500 for a large machine.

The general arrangement of the tunnel is shown in figure No. 3 and a somewhat detailed description of the elements is given in the following:

Nozzle

The form of nozzle is one that has been found very satisfactory in practice. In the whole nozzle there is a change of section from a 17-foot square to a 9-foot diameter circle. Part of this is accomplished in a concrete section and part in a wooden nozzle proper.

This form of nozzle possesses several important advantages. It permits the honeycomb to be located in a region of low velocity and the power lost in the honeycomb is consequently much reduced as compared with that resulting if the honeycomb is placed in a high-speed region.

Vortices produced by the honeycomb have a relatively long way to travel and are hence much reduced before reaching the experimental region.

In the nozzle the area is reduced from 289 square feet to 63.6 square feet and the velocity increased therefore in the ratio 4.54:1 while the kinetic energy is increased over 20 times. This increase is produced by the pressure difference between the inside of the tunnel and the experimental region. The pressure difference being constant and responsible for 95 per cent of the kinetic energy, it follows that variations of kinetic energy due to velocity fluctuations in the air entering the nozzle cannot exceed 5 per cent and normally will be much less than 2 per cent corresponding to 1 per cent velocity variation. The nozzle thus ensures a very uniform distribution of velocity throughout the cross section of the jet. Velocity variations of less than $\pm$ 0.5 are not uncommon with nozzles of this form.

As is seen in figure No. 3, the entrance section of the nozzle of the Ottawa tunnel is constructed in heavy reinforced concrete, the section changing here from a 17-foot square to a 14 feet 9 inches diameter in a length of 11 feet. The nozzle proper is constructed of cedar staves, and the diameter here changes from 14 feet 9 inches to 9 feet diameter in 9 feet.

The wooden nozzle is supported from the concrete portion by eight tie rods running to shackles bolted to a steel ring anchored in the face of the concrete. The tie rods enable the nozzle to be adjusted slightly to properly align the jet. The joint between the wooden and concrete sections is of special design to permit this being done.

Honeycomb

The honeycomb is made of 20 gauge metal, in the form of 2-inch cells, 9 inches long parallel to the air flow. The cells are fabricated in strips and suspended from steel beams in the roof of the square section of the nozzle.

Jet

The jet leaves the nozzle and traverses the experimental room to enter the expanding cone. The free length of the jet is 12 feet. It is in this jet that the models are suspended for test. Since the velocity in the jet is 4½ times that at the entrance to the nozzle, the pressure at the jet and hence in the experimental room is much less than that at the entrance to the nozzle or anywhere else in the air circuit. Hence if the pressure in the experimental room is atmospheric, that elsewhere in the tunnel and passages is above atmospheric. For a jet speed of 125 m.p.h. the pressure in the 17-foot square entrance to the nozzle will be over 50 pounds per square foot.

While it is possible by bleeding at suitable points in the air circuit to adjust the pressure in the experimental room to any desired pressure between atmospheric and a suction of 50 pounds per square foot, it is probable that the experimental room will be kept at atmospheric pressure for sake of convenience of manipulation.

Since the friction of the air in the jet on the air in the experimental room is higher than that of the air on a smooth solid surface, the efficiency of a tunnel can be improved by enclosing the jet. It is proposed to provide a nine-foot diameter section to be fitted between the nozzle and expanding cone of the Ottawa tunnel so that it may be converted into a closed tunnel should this be desirable for any special work.

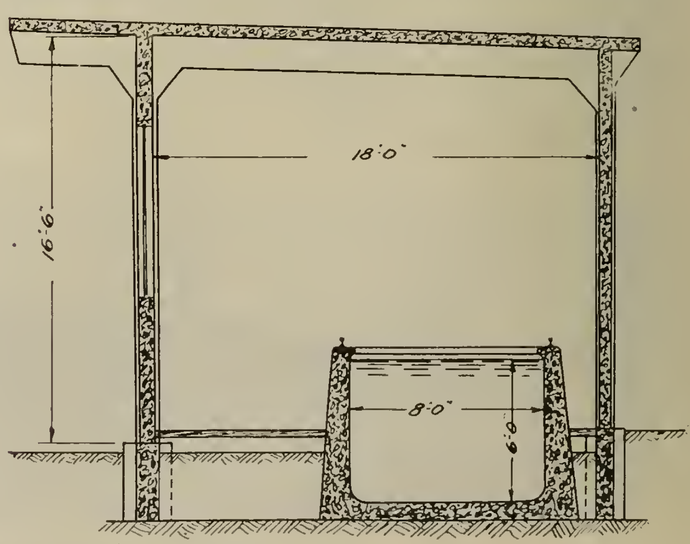

Figure No. 6.—Cross Section of Tank and Building.

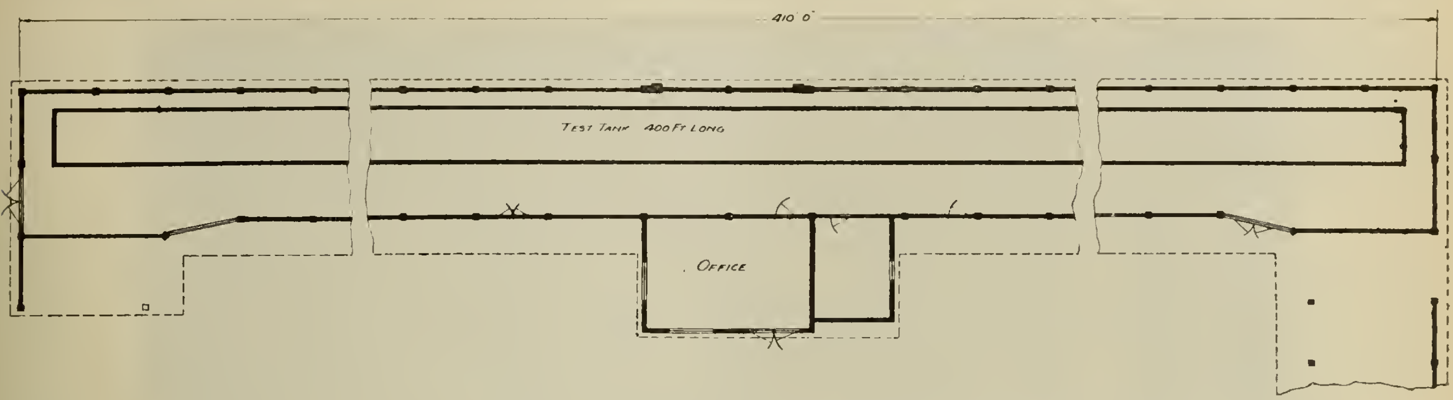

Figure No. 7.—Plan of Tank and Building.

Collecting Bell

The air jet from a nozzle such as this, in passing across the experimental room suffers a certain amount of dispersion. The outside periphery of the jet intermingles with the surrounding air setting up a boundary region of eddies which increases in thickness with distance from the nozzle. The inner core of air with a velocity constant in magnitude and direction throughout, and initially of diameter about 85 per cent the diameter of the nozzle, grows gradually smaller in diameter, the included angle being about 9°, while the overall diameter of the jet including the boundary vortex region increases in diameter. The velocities in the boundary region decrease rapidly from that of the jet to zero at the periphery.

In order that there may be little spilling of the jet, with consequent setting up of undesirable air currents in the experimental room, the small end of the expanding cone leading to the propeller is made larger in diameter than the nozzle (10 feet) and is provided with a flared collecting bell with a maximum diameter of 14 feet. The collecting bell is of wood constructed in a similar way to the nozzle.

Expanding Cone

Entering the collecting bell the air passes into the expanding cone in which its velocity is decreased before reaching the propeller rotating in a cylindrical ring at the end of the cone. The expanding cone acts in the same way as the draft tube in an hydraulic turbine. Its function is to reduce the velocity of the air and permit a large diameter slow speed propeller to be employed. Such a propeller is somewhat more efficient than a small diameter high-speed propeller. It is also desirable to decelerate the air as rapidly as possible after the experimental region is passed in order to reduce power loss in friction on the walls of the passages. Care must be taken that the expansion in the cone does not take place too rapidly, however, as otherwise the air will leave the surface and vortices will be set up with consequent power loss. The cone of the Ottawa tunnel is of wood stave pipe construction and is supported on structural steel cradles. The joint between cone and collecting bell is such as to accommodate shrinkage and contraction.

Propeller Assembly

A four-blade metal propeller, 13 feet in diameter, is used. The propeller will have blades of duralumin anchored in a nickel steel hub in such a way as to permit adjustment of the incidence of the blades for the finer tuning up of the tunnel.

The propeller is mounted on a shaft extending through the end wall of the tunnel to the motor. At the propeller end the shaft is carried in a roller bearing supported on three cast-iron stream line radial arms extending from a cast-iron ring set in the concrete of the tunnel. The arms are inclined backward from the propeller to avoid as far as possible interference with the blades and three arms are used to avoid synchronization with the blades that might result if two or four arms were used. The cast-iron ring surrounding the propeller is machined inside to 13 feet 0 inches $\pm \frac{1}{16}$ inch. The accurately turned ring permits operation of the propeller with only ¼-inch clearance between blade tips and ring.

A steady bearing, (roller), held by three tie rods supports the shaft midway between propeller and wall.

The propeller is fitted with a spinner and the two bearings are enclosed in a tapering sheet metal casing, the whole forming a neat housing offering little resistance or obstruction to the air.

At the wall the shaft passes through a sealing plate to prevent air leakage from the tunnel.

On the motor side of the wall the shaft is carried in a third roller bearing mounted in a pedestal bolted to the motor foundation. This bearing takes up the propeller thrust. The propeller shaft is thus in tension. The shaft beyond the bearing is coupled through a flexible coupling, (to permit motor armature to float), to the motor.

The maximum speed of rotation of the propeller, when absorbing 600 h.p. is 1,000 r.p.m. At this speed the tip velocity is only about 680 feet per second.

Return Passages and Vanes

Behind the propeller there is a short transition section in which the section changes from a 13-foot circle to a 13-foot square. At this point the air divides and returns via two return passages to the nozzle.

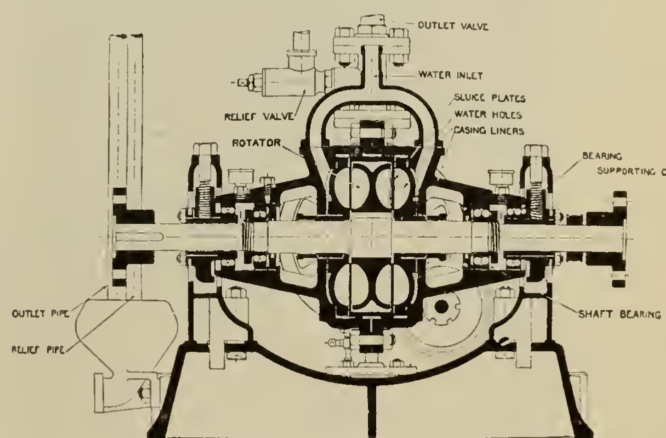

Figure No. 8.—Section of Dynamometer.

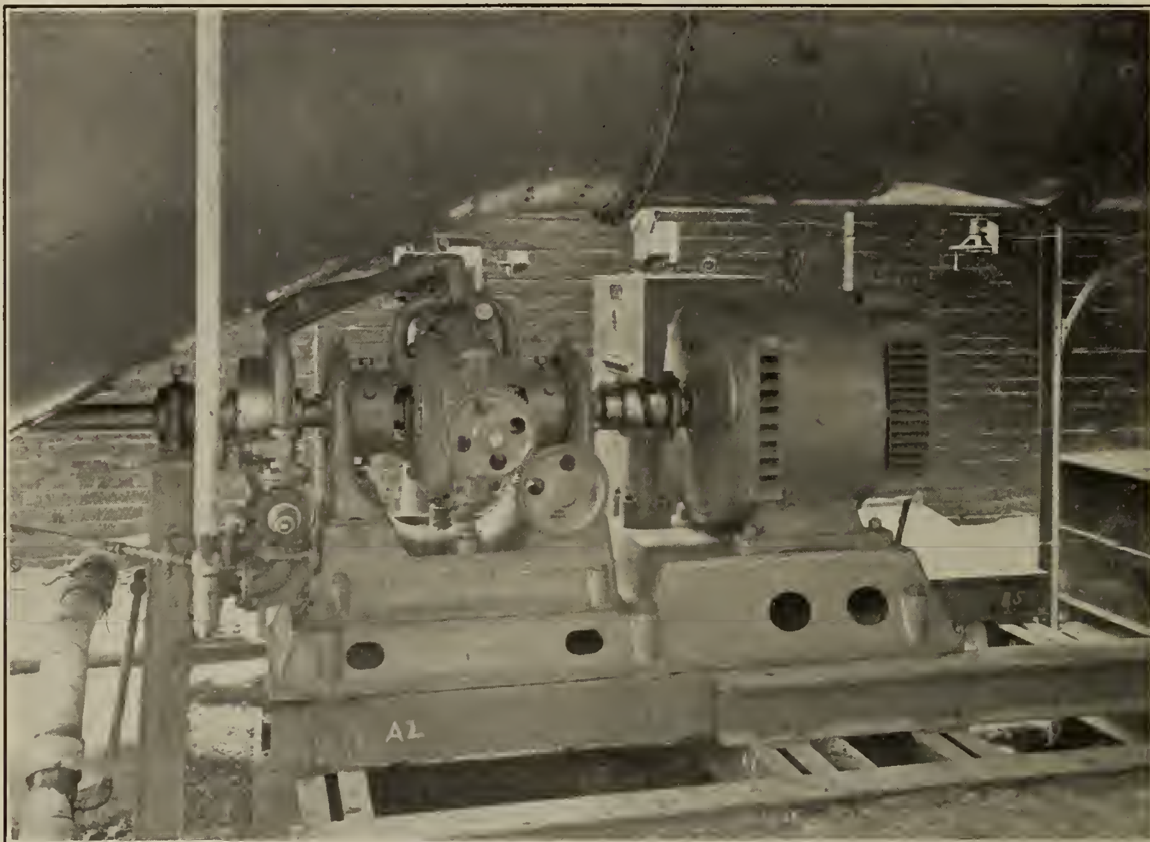

Figure No. 9.—Dynamometer.

The return passages are rectangular in section with height everywhere twice the width. In each passage there is a gradual enlargement from the initial 6 feet 6 inches by 13 feet 0 inches section to the final 8 feet 6 inches by 17 feet 0 inches where the passages join in the nozzle.

Because of the pressures on the walls of the return passages these have been made of reinforced concrete and are quite independent of the building proper. The footings for walls, foundations, etc., all extend to bedrock, see figure No. 3, which fortunately is here close to the surface.

The directing of the air around the corners in the passages with a minimum of loss and turbulence and without disturbing the uniformity of velocity is a matter of some difficulty. In certain tunnels the bends are of large radius with one or two large radius guide vanes to keep the air from sliding to the outside of the bend. Prandtl employs a large number of relatively small aerofoil shaped vanes made of concrete and metal, (similar vanes of welded sheet steel have also been used). The proper form, arrangement and construction of vanes to use at Ottawa is the subject of a research now in progress at the laboratories. It is hoped to improve on existing constructions.

Electrical System and Speed Control

It is not feasible at this time to describe in detail the electrical installation and control equipment being installed and a brief description only is therefore given.

The propeller motor is of the shunt type with commutating poles, a continuous rating of 600 h.p. at 1,000 r.p.m. with 40°C. rise of temperature and a 2-hour 25 per cent overload at about 1,075 r.p.m. A speed range from under 100 r.p.m. to the overload maximum is provided.

The propeller motor is supplied from a motor generator set consisting of 2,200 volt, 3-phase, 60-cycle synchronous motor and a 250-volt variable voltage d.c. generator, together with necessary exciters. The starting of the set is by semi-automatic starter and the set may be stopped by push button from a number of operating stations.

Speed control of the propeller motor initially is manual from any one of three control stations. An automatic control, actuated directly by the air is being developed.

Complete protective devices, rheostats and meter equipment are provided.

The synchronous motor is supplied from a 1,000-kw. alternator in the hydraulic plant of the Council on the site of the laboratories. The plant develops the power of the Rideau falls.

The electrical machines and control panels are installed in a machine room in one end of the wind tunnel building as shown in figure No. 3.

There is also installed in the machine room a smaller motor generator set comprising a 50-h.p. induction motor and variable voltage d.c., generator, complete with control panels. This set is used to supply the motor of the aircraft propeller testing dynamometer.

Cooling

When the tunnel is operating at maximum capacity some 600 h.p. will be dissipated as heat in the air in the tunnel. As this quantity of heat cannot pass through the walls to the outside air, there will be a rise in temperature of the air circulating in the tunnel which may prove excessive, particularly in summer. Hence provision has to be made for removing artificially some of the heat. Two methods have been considered: (1) By bleeding a portion of the heated air from the tunnel at a suitable point and drawing in a corresponding quantity of cooler air at another point, or (2) By use of auxiliary water cooled surfaces. Satisfactory means of putting each of these methods into practice for the Ottawa tunnel have been developed. One or the other will be employed as a safety measure although it is probable that the temperature rise will not be excessive except in the case of a run at full capacity extending over a considerable time.

Balances

The balances for the tunnel are now being designed. They are to be of the wire suspension type supported on a rigid concrete platform carried on concrete posts extending from a massive concrete block resting on bedrock. The balances will be made in the shops of the Council now being erected and equipped.

Balance Room

A floor has been built in the upper portion of the building at the level of the balance platform over the motor room and expanding cone and a room thus provided from which the balances are operated. The balance room is reached by stairs from the motor room and a stair extends down to the floor of the experimental room.

Hydrodynamic Laboratory—Test Tank

Because of the large water areas present in most sections of the country, aircraft of the flying boat type or equipped with floats are much used in Canada. There is perhaps a larger proportion of marine aircraft in use in the Dominion than in any other country. The improvement of the type is therefore of great and immediate importance to the Dominion.

Efforts made up to the present in Canada to develop new types of marine aircraft for special services have been seriously handicapped by the complete lack of experimental facilities in the country. The National Research Council, realizing the need of such facilities, is providing suitable experimental and research facilities. A towing tank for the testing of floats and hulls is being built at Ottawa. This tank will be the only one in Canada, and will be invaluable in improving the water performance of aircraft floats and hulls.

In marine practice the towing basin or test tank has proved of inestimable value to the naval architect and ship builder. No important vessel is now built without first making model trials in a test tank. By so doing, not only is the performance very often much improved, but in many cases failure to attain the anticipated performance is prevented. Most recent developments have been due to systematic work in test tanks.

The ship test tank has been used for many years for testing models of aircraft floats and hulls, but, as the conditions in marine and in aeronautical work differ materially, such ship test tanks are not altogether satisfactory for testing aircraft models. In spite of the handicaps, however, a great deal of aeronautical testing is done in the ship tanks and much valuable information secured. A few tanks of small size, built for aircraft work, are in successful operation, and larger ones are projected, if not already under construction. In a test tank, unlike a wind tunnel, the model, attached to a dynamometer or balance, carried on a towing carriage, is drawn through still water. As in the wind tunnel, the test conditions are made as nearly ideal as possible, largely because of the difficulty of adequately defining any other conditions. Hence, the water in the tank is perfectly still, free from waves, surface dust, floating matter, etc.

To secure these conditions the water is skimmed daily and special devices installed for quickly suppressing waves to reduce the time lost in waiting for the waves to subside between test runs.

The information derived from a model test in a towing tank includes:

(1) Resistance at different speeds, attitudes and drafts.

(2) Attitude and behaviour under different conditions.

(3) Cleanness and wave formation.

(4) Influence of air control surfaces on behaviour.

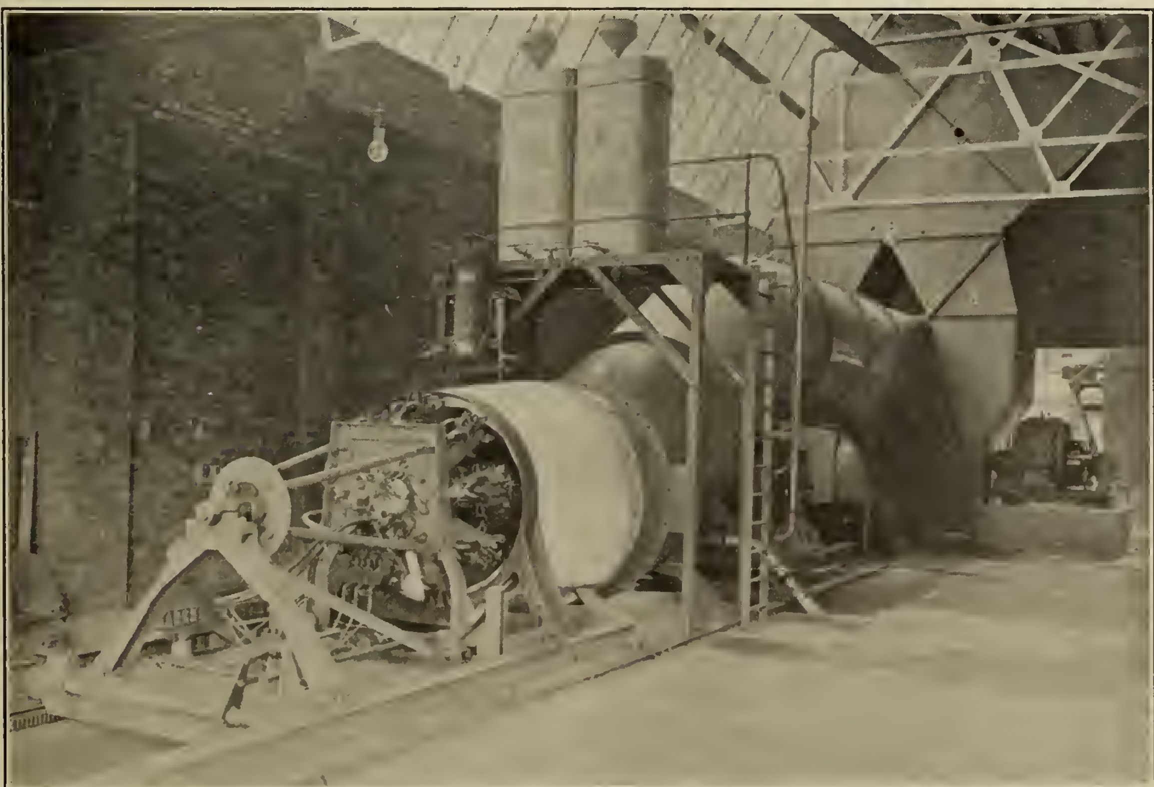

Figure No. 10.—Dynamometer showing Nozzle, Air-duct, etc.

Conditions Governing Tank Tests and Size of Tank

The conditions to be satisfied in making a hydrodynamic test of a model float or hull are different to those in the case of an aerodynamic test. In the hydrodynamic test Froude's Law is applicable. This law states that for similarity of conditions, enabling model results to be applied to corresponding full scale craft $\frac{v^2}{lg}$ must be the same for both model and full scale. $\frac{v^2}{lg}$ is the so-called "wave-making term" of the general equation for the reaction on a body moving in a fluid, derived by application of the theory of dimensions.

It follows from Froude's law that if results of tank tests on a model of dimensions l are to be applicable to a full size hull of corresponding dimension L at a full scale speed of V, the model must be tested at a speed v such $\frac{v}{\sqrt{l}} = \frac{V}{\sqrt{L}}$ or $v = \sqrt{\frac{l}{L}}\,V$. In other words, if a 1/9 scale model is used, it must be tested at ⅓ full scale speed; if ¼ scale, at ½ full scale speed. As the model size increases, the speed of test also increases. The problem thus appears simpler than in the case of aerodynamic tests in a wind tunnel, since, by reducing the scale of the model, quite low speed can be used. There are, however, serious disadvantages in using a small model. Not only is it difficult to secure the necessary accuracy in form, but the forces to be measured become so small as to render their accurate measurement difficult, and the effects of dust, etc., on the surface, become serious. If a model sufficiently large to overcome these difficulties is employed, the test speeds must be high. The low speed is one of the chief handicaps encountered in using existing ship tanks for aeronautical work. No existing ship tank is capable of testing a model of usual scale up to flying speed.

Test tanks for aeronautical work are hence designed for high speed. This, in turn, involves a tank much longer than ship tanks since the carriage has to be accelerated to this high speed and later decelerated. In Canada, unless the tank is to be useless during a large part of the year, a test tank must be sheltered in a heated building, and the cost of the building necessary to house a tank of adequate length is prohibitive.

There are also definite restrictions on the ratio of model size to tank cross section to avoid boundary effects. Lamb has deduced theoretically that for a model of usual proportions, if the tank width is twice the length of the model, the resistance measurements will be in error 1 per cent and 6 per cent in error if tank width equals the length of the model. These deductions have been confirmed experimentally.

To avoid wall interference effects, the bow wave must meet the wall aft of the model. This means that the higher the speed the narrower may be the tank for a given model size.

Dimensions of the National Research Council Tank

In deciding on the dimensions to be adopted for the tank of the National Research Council it was necessary to compromise. Fortunately, the decision was somewhat simplified in that a building or rather two buildings (see figures Nos. 4 and 5) were available on the site of the laboratories, which, with comparatively little alteration, could be converted into a single building 410 feet long. The cross section is 18 feet wide by 16 feet high. This building also is of reinforced concrete and brick construction and bedrock, most important in the case of a tank, is but a few feet below the surface. Accordingly, the tank at Ottawa is 400 feet long, 8 feet wide and 6 feet deep. Of the length, 150 feet will be used for acceleration, 150 feet for the constant speed run and 100 feet for deceleration. The 8-foot beam of the tank will permit the testing of models 4 feet long.

Construction of Tank

The tank is constructed of heavy reinforced concrete with tapered walls, heavy base, and rounded corners. A cross section of the tank and buildings is shown in figure No. 6, and a ground plan of the tank and building in figure No. 7. The carriage runs on rails laid on top of the tank sides. The rails are planed level on top, welded together, and will be ground to bring the top surface parallel to the water surface. The head of one rail will, in addition, be ground on the two sides to as nearly a straight line as possible to serve as a guide rail.

Carriage

The carriage of the tank is constructed of structural steel. It is carried on four cast iron wheels, turned accurately to the same diameter, mounted on shafts carried in roller bearings. There is, in addition, a pair of guide rollers at each end of the carriage on one side, each pair consisting of one rigidly mounted roller running in contact with the machined outside of the rail head and one roller mounted on a swinging arm held in contact with the inside of the rail head by a stiff spring. Two similar devices, but provided with shoes operating on the other rail, are used for decelerating the car. The use of shoes acting in this way provides more positive braking, little affected by water on the rails, and without danger of wearing flats on the track wheels or damaging the ground rail surface due to slipping. The shoes are applied automatically with the cutting off of the power at the end of the constant speed portion of the run.

A 25-h.p. shunt motor provides the motive power for accelerating and driving the carriage. As the greater the acceleration, the longer will be the period of the constant speed or testing part of the run, a high rate of acceleration is desirable provided the balance and model can be arranged to withstand the large inertia forces resulting from the high acceleration. Relying on the traction between turned metal wheels on smoothly machined rails, often wet from the waves thrown up by the model, the maximum acceleration possible will likely be low, hence other methods of drive are under consideration. At this time a decision has not been reached regarding the type of drive to be used.

A speed of at least 20 feet per second (about 12 knots per hour) will be secured. With a constant speed run of 150 feet, the period for measurement will be not over 7½ seconds. Any attempt to adjust the speed to an exact figure of say 20 f.p.s. in this short time is thus futile and the runs will be made by adjusting the rheostats to give a speed near that desired and the run made without any attempt at speed control during the run.

The carriage is also provided with a side outrigger for carrying an observer in a position convenient for observing wave formation and also a camera for photographing the wave formation.

Towing Balance of Dynamometer

Owing to the very short time available for measurement at constant speed, the balance must be made self-recording. Further, it must permit the model to assume its natural attitude in the water (under the applied forces) without restraint. It must permit of the application to the float of forces representing the dead weight of the machine and lift of the wings and of adjustment of the centre of gravity of the float assembly to a position corresponding to that in the full scale machine. It must also permit of the application of moments to the model corresponding to those due to propeller thrust and control surfaces of the aircraft.

A balance fulfilling all of these requirements is now being designed. It will record on a drum, automatically, attitude, draft, resistance, distance and time.

Distance will be recorded electrically through accurately spaced contacts along the rail. Time will be electrically recorded by accurate chronometer on shore. These two records will enable the velocity to be determined with precision.

Power Plant Equipment

There are now, in Canada, three firms assembling aircraft engines primarily to supply the Canadian demand, but already Canadian assembled engines are being exported. Under Air Regulations 1920, the Dominion Government is required to carry out tests to establish the airworthiness of aircraft engines for export. At the present time, there is no equipment in the country for this purpose.

The testing of engines for this purpose is very properly a function of the National Research Council and the Council is accordingly installing equipment for the performance testing of aircraft engines. The equipment, due to its flexibility and range will enable much research work to be carried on in connection with internal combustion engines. Being the only equipment of its type and size in the country, investigations of a character not otherwise possible may be made.

A complete engine testing plant is being installed capable of accommodating aircraft engines of any type, air or water-cooled, tractor or pusher, right or left hand rotation, and of absorbing powers up to 1,000 h.p. at speeds up to 2,500 r.p.m.

The equipment is unique in that provision is made for applying thrusts to the crankshaft corresponding to propeller thrusts up to 6,000 lbs. This is accomplished by means of weights acting through a bell crank on the carriage on which the dynamometer is mounted.

The dynamometer is of the hydraulic type, built by Messrs. Heenan and Froude of Worcester, England. A section through the dynamometer is shown in figure No. 8. In this dynamometer the shaft carries a rotor, in the faces of which are formed semi-elliptical pockets. The internal faces of the casing are similarly recessed. The pockets in rotor and casing together form elliptical chambers around which water courses at high speed, the vortices thus formed absorbing the power developed by the engine. The water circulated through the casing not only provides the hydraulic resistance but carries away the heat generated thereby.

The load applied by the dynamometer is regulated by a handwheel which controls the radial position of diaphragms between rotor and casing by which the power absorbing cups may be masked to any desired extent.

For testing air-cooled engines, a large, centrifugal fan, driven by a 250-h.p. motor, discharges a blast of air through a cylindrical duct and adjustable nozzle, past the engine cylinders. Air-speeds up to 130 m.p.h. are obtainable.

Complete auxiliary apparatus is provided such as starting motor, tachometer, flow meters, oil coolers and heater.

Equipment similar to that of the National Research Council is shown in figures Nos. 9 and 10.

There is also in the laboratories, a small single cylinder unit for testing engine fuels in which routine tests of fuels are made, and investigations of detonation carried on.

Conclusion

It will be apparent from the foregoing that the aeronautical laboratories being installed by the National Research Council of Canada, satisfy a national need in providing research and testing facilities that exist nowhere else in the Dominion. The aeronautical researches rendered possible and the training afforded young men by the laboratories will do much to improve Canadian aircraft and extend their usefulness.

Thus aviation in Canada will be advanced, the development of the country accelerated and the Dominion rendered independent and self-supporting in aeronautics.

Rigid Airships

E. W. Stedman, M.E.I.C.,

Group Captain, R.C.A.F., Chief Aeronautical Engineer, Department of National Defence, Ottawa.

Paper presented at the Annual General Meeting of The Engineering Institute of Canada at Ottawa, Ont., February 13th, 1930.

Men have always had an ambition to fly and the folk lore of practically all nations is full of myths relating to flight through the air.

Phrixos and his sister Helle flew over the sea on the ram with the golden fleece. Daedalus and his son Icarus attempted to escape from the Isle of Crete by making wings of feathers, but Icarus flew so near the sun that the heat melted the wax which fixed the wings to his body, and he fell into the sea.

We have read of Bellerophon who, mounted on the winged horse Pegasus, killed the dragon; and also of Hermes the messenger of the gods. Abaris travelled around the world on a golden arrow, while Gellius tells of a wooden pigeon which flew by means of a mechanism of balancing weights.

In the realm of legendary history we are told that Xerxes was given a winged throne, (figure No. 1), which flew by the aid of four tame eagles.

The Chinese are reported to have sent up a balloon on the day of the coronation of Emperor Fo-Kien in 1306. Sketches of flying machines by Leonardo de Vinci still exist. Cyrano de Bergerac fastened air bags to his body, and allowed them to heat in the sun with the idea that the heated air would lift him.

Francisco de Lana seemed to have some sound ideas upon airship construction by his assumption that a body lighter than air would rise. He proposed to construct four metal spheres attached by ropes to a boat, and to exhaust the air from the spheres, thus creating a vacuum to supply the necessary lift. (figure No. 2). He finally came to the conclusion that his scheme could scarcely hope to be successful as God would prevent such a revolution in human affairs.

Probably the first really successful navigation of the air was that done by the Montgolfier brothers, who constructed a hot air balloon in 1783. (Figure No. 3). From then the development of the balloon as we have it today and of the dirigible balloon was largely a matter of detail.

In this paper it is intended to deal only with that type of lighter-than-air craft now known as the rigid airship.

Lighter-than-air craft can be described as aircraft which depend upon a lifting gas for support, thus distinguishing them from heavier-than-air craft which depend upon the lifting force produced by the motion of a plane surface through the air, and which will not remain in the air when the relative motion between the lifting surface and the air is diminished below a predetermined figure.

Lighter-than-air craft have all been developed from the free balloon, which is usually a gas tight envelope containing coal-gas or hydrogen, and to which is suspended a basket for carrying personnel.

The *dirigible balloon* is evolved from the free balloon by the addition of a motor and propeller for propulsion and means for steering in a desired direction.

When ballooning had reached a stage where it could be carried out with comparative safety, men soon became ambitious to travel in a desired direction rather than be dependent on winds. It was, therefore, natural that they should fit an engine and propeller to a balloon. The envelope of a free balloon is approximately spherical in form, but this shape is not at all suitable for a dirigible balloon which has to be driven through the air, so that as a result streamlined shaped envelopes were developed.

The desire to carry larger loads at higher speeds led to increases in size, which brought new problems, such as,

Figure No. 1.
Xerxes on his Winged Throne.

Francisco de Lana's Airship.

Figure No. 3.
Montgolfier's Hot Air Balloon.

Figure No. 4.—Schwartz' Balloon after the Accident.

maintenance of the shape of the envelope itself, and the proper method of carrying rudders or other steering devices. This development divided the dirigible balloon, now known as the airship, into three distinct classes:—

(*a*) The *non-rigid airship*, which is practically the same thing as the original dirigible balloon.

(*b*) The *semi-rigid airship*, in which the fabric gas bag together with the carriage for power plants and the stabilizing surfaces are all connected by a rigid frame, but in which the shape of the envelope depends upon the gas pressure, and

(*c*) The *rigid airship*, in which the outside shape of the envelope is maintained by a rigid frame, which also carries all the machinery, passenger cars, stabilizing devices, etc. The lifting gas is contained in cells placed inside this rigid framework. It is this latter type of airship that will be dealt with in the present paper.

History

The history of the development of airships from the time of the first hot air balloon is full of interest, and it is with considerable regret that this period is omitted in the present paper.

The first rigid airship bearing any resemblance to those used today was built by David Schwartz in St. Petersburg in 1893. It was composed of aluminium plates rivetted to an aluminum framework, but this collapsed during inflation. In 1895 Schwartz designed a second airship, which was built in Berlin. The whole framework was made of aluminum, 155 feet long, elliptical in cross-section, having a volume of 130,500 cubic feet.

This airship hull had a pointed nose and a rounded stern. It had twelve main transverse frames, sixteen longitudinal girders and numerous intermediate members. Steering was carried out by a propeller, which could be turned about a vertical axis.

The car was rigidly attached to the hull by a lattice framework, and the whole structure was covered with aluminum sheeting 0.008 inch thick. The airship was equipped with a 12 h.p. Daimler motor, driving two aluminum propellers by means of a belt.

In 1897 the airship was inflated by placing a number of bags within the balloon, then filling them with hydrogen. These bags were then torn allowing the hydrogen to escape into the interior of the airship hull. During the first trials with a wind of about 17 miles per hour the airship ascended, but the belt slipped off the pulleys and the airship floated at the mercy of the wind. Very little damage was done on landing, but the hull began to break up by deflation, and it was completely destroyed by the spectators, (figure No. 4).

In 1898 Count Von Zeppelin conceived the idea of constructing a large rigid airship, and for this he built a large floating shed near Friedrichshafen on Lake Constance. His first airship was 420 feet long and 38.3 feet in diameter, made up of an aluminum framework of lattice girders. There were twenty-two longitudinal girders running from the nose to the stern, and these were drawn together at the ends. Sixteen rings or transverse frames reinforced with diagonal wires joined these girders, thus dividing the hull into seventeen compartments containing fabric gas bags. Between the gas bags and the outer covering there was an air space, which served to protect the gas from undesirable variations of temperature. Below the hull was a long external girder, or keel, to which the two motor gondolas were attached. The capacity was approximately 400,000 cubic feet. A sliding weight was used for changing the trim. The two gondolas each contained a 16 h.p. Daimler motor, driving propellers situated on the side of the hull through a transmission of steel tubes and universal joints. The airship had a speed of about 13½ miles an hour. During the years 1900 to 1902 it made three flights, but lack of funds and lack of public support or interest forced the dissolution of the company, (figure No. 5).

In 1905, with the assistance of King William of Württemberg, Zeppelin started on his second airship. This ship was of much the same size as the previous one, but the engines were now of 85 h.p. instead of 16 h.p. This ship was wrecked by storms under circumstances which had nothing to do with the construction of the ship, but which were mainly due to trouble in keeping the power plant running.

In April, 1906, Zeppelin commenced a third ship, which was completed in October. This ship was very much like the second, but had stabilizers added, (figure No. 6). Experiments with this ship were very successful, and resulted in considerable recognition by the public. The German Government also showed its interest by providing a new floating shed. On October the 1st, 1907, an eight hour flight of 218 miles was carried out.

Zeppelin No. 4 was probably the most notable of the early ships. It was built in 1908 and had a capacity of about 530,000 cubic feet. It was equipped with two Mercedes engines of 110 h.p. each.

In July 1908 the ship was taken over the Swiss Alps to Lucerne and back again, a journey which was acclaimed throughout the whole of Germany. On October 4th Zeppelin planned to travel down the Rhine valley, but on the return flight motor trouble caused a forced landing, and during a storm the ship was blown away and destroyed by fire.

Public sentiment was so great that an endowment fund was raised by providing $1,500,000 to be turned over to Count Zeppelin to be used as he saw fit in carrying out his experiments. From this fund the Zeppelin Endow-

Figure No. 5.—Zeppelin L.Z.1 First Ascent July 2nd, 1900.

Figure No. 6.—Zeppelin L.Z.3.

ment was formed for the propagation of air navigation. This became a holding company which was the exclusive shareholder of the airship construction company and controlled a number of subsidiary companies.

The endowment fund provided the money for the construction of the new sheds and workshops at Friedrichshafen. The great war later gave an opportunity for greatly improving the methods of construction and the performance of these airships. A total of over 100 airships were constructed at Friedrichshafen and other factories in Germany during the war period. Two airships constructed towards the end of the war are illustrated in the photographs, (figures Nos. 7 and 8).

Zeppelin L. 59 made a non-stop flight over 4,000 miles to Khartum in Africa and back during the war period.

Figure No. 9 shows the inside of one of the early airships dating about 1913.

Figure No. 10 shown the Bodensee, a comparatively small airship constructed for passenger carrying after the war and used for trips between Friedrichshafen and Berlin.

Figure No. 11 illustrates the construction of the Bodensee.

Figure No. 12 shows an inside view of the Bodensee, and figure No. 13 shows the power gondolas of the Bodensee.

By 1912 the success of the Zeppelin type of airship had brought a number of imitators. Chief amongst them was the Schütte-Lanz Company, which produced a rigid airship, having a wooden framework, wire braced.

The Schütte-Lanz airship had slightly better form than the Zeppelins, due to the fact that it had no parallel portion and conformed more nearly to what is now termed a streamline form. In all, about twenty-two ships were built by the Schütte-Lanz Company for use throughout the war. As can be seen from the photograph, (figure No. 14), the interior construction is very much like that of an early Zeppelin except that the duralumin girders are replaced by wooden girders.

In France most of the work was done on non-rigid or semi-rigid airships, but in 1912 the Zodiac Company constructed a rigid airship called the "Spiess" for the French Government, having a capacity of 575,000 cubic feet. This ship had a wooden framework divided into 14 gas cells, but its performance was unsatisfactory and it was dismantled in 1914, (figure No. 15).

In Great Britain attention was first directed to rigid airships by a contract placed with Messrs. Vickers by the Admiralty in 1908. This was the naval airship No. 1, designed for the purpose of carrying out the duties of an aerial scout for the navy. The length was fixed at approximately 500 feet with a diameter of 48 feet. The shape adopted was that recommended by Professor Zahm, which consisted of a parallel portion with a curved bow and stern, the stern having much larger radius than the bow, (figure No. 16).

Aluminum was the material selected for the construction of the airship, but the samples supplied did not reach the required strength, and in 1909 duralumin was discovered and adopted for the construction. The structure consisted of 12 longitudinal girders with transverse frames at 12½ feet centres throughout the length of the ship. Each bay in the outside framing was cross braced by wires, and the frames were supported by radial wiring similar to the spokes of a wheel. An external keel was fitted to provide communication between the two gondolas, but this keel did not add to the structural strength of the ship. The gas bags were made of rubber fabric as used by Zeppelin, goldbeater's skin having been abandoned owing to shortage of material. Valves were placed in the top of the bags contrary to the current Zeppelin practice, in which there were automatic valves at the bottom of the gas bags and hand operated valves at the top.

The ship was completed in May, 1911, and some tests on her suitability for riding at a mooring mast were made. The ship was, however, badly damaged in September when being taken from its shed, and it had to be dismantled. For sometime airship construction was discontinued, but the great success obtained by the Zeppelin Company was such that it encouraged a decision to make another attempt to build a rigid airship.

The contract for rigid airship No. 9 was signed in March, 1914. This ship was intended to be generally in conformity with Zeppelin practice. Its length was 526 feet with a maximum diameter of 53 feet. The hull shape was that recommended by Zahm, and its tranverse section was a 17-sided polygon, (figure No. 17).

The construction was practically the same as contemporary Zeppelin airships, having an external V-shaped keel through the greater part of the length. Seventeen gas bags were provided of rubber proofed fabric, lined with goldbeater's skin, and the capacity was approximately 890,000 cubic feet. The original engine equipment was four Wolseley engines of 180 h.p. each. This airship was inflated in 1916, but was not finally accepted till March, 1917. It was then used very largely for the training of officers and men, who formed the crew of later rigid airships.

The next British airships were known as the 23 class, built by Messrs. Vickers, Messrs. Beardmore and Armstrong-Whitworth. They were very similar to the 9 class, except that the length was increased to 535 feet

Figure No. 7.—Zeppelin L.71, the Last German Naval Airship.

Figure No. 8.—Zeppelin L.59 Naval Airship.

and the number of gas cells was increased to eighteen, giving a total volume of 1,000,000 cubic feet.

The system of valves was entirely different, as in these ships an automatic valve was fitted on the side of the gas cells with a top valve controlled entirely by hand. The engines consisted of four Rolls-Royce engines of 250 h.p. The later airships of this class were modified and called the 23X class, embodying a number of improvements, one of which was the abolition of the external keel, (figure No. 18). These airships were quite successful, and in spite of the radical change in the structure due to the suppression of the keel they were flown throughout their life without a mishap.

R. 31 Class

Later on the R. 31 class was built, following the type of construction employed by the Schütte-Lanz Company in Germany, incorporating a wooden structure, (figure No. 19).

These ships were 615 feet long, having a diameter of 66 feet and a capacity of 1,500,000 cubic feet. Longitudinal and transverse frames were composed of 3-ply wooden girders braced in the usual manner with wire bracing. In order to prevent excessive transverse loads due to deflation of the gas bags and the pressure of adjacent gas bags on the radial bracing, a wire was fitted along the axis of the ship and secured to the centre point of the radial wiring,—a feature not previously used on airships.

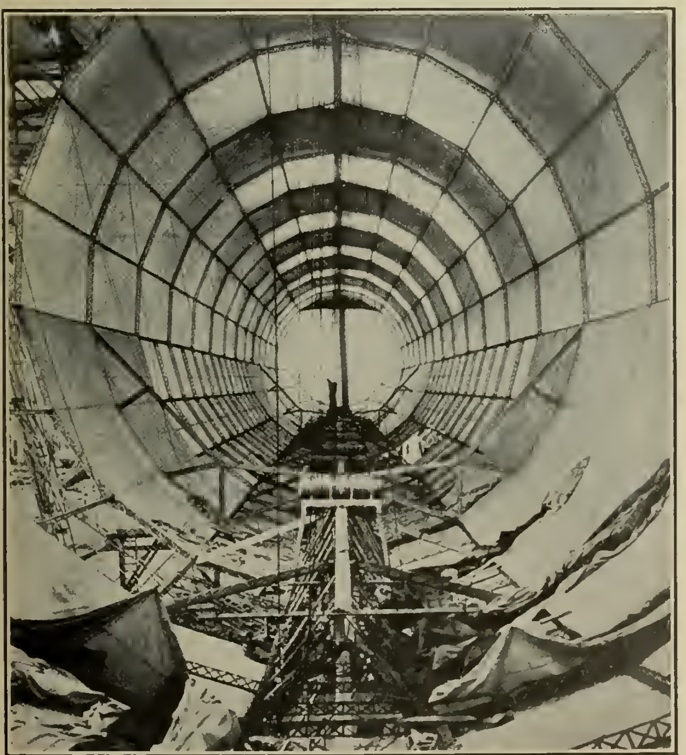

Figure No. 9.—Zeppelin L.2 Interior.

The trials were very satisfactory, but the wooden structure weathered badly, and this method of construction was given up.

R. 33 Class

In September, 1916, the German Zeppelin L. 33 was brought down in England in practically an intact condition. This airship was one of the latest German ships, having been completed only a short while before the disaster.

In January 1917, five airships were started which were to be practically the same as the L. 33. Two of these were built, the R. 33 and the R. 34, of which the R. 33 became famous, because while it was moored out to a mast it broke away from its moorings, and was brought back to its base by a small crew in a damaged condition.

The hull of these ships was of a much more nearly streamline shape, being 643 feet long with a diameter of 79 feet. The hull was fitted with an internal triangular keel containing water ballast, fuel, crew accommodation, etc. These ships were equipped with five engines of 250 h.p. each.

The R. 34, which was a sister ship, was rather more successful than the R. 33. It was employed in 1919 for the return trip across the Atlantic and with conspicuous success even although there was some anxiety when approaching the American shore on the outward journey due to adverse winds and a shortage of fuel, (figure No. 20).

Two other ships were constructed in England after the war, the R. 38 of 2,750,000 cubic feet capacity, built for the United States Government, and the R. 80 of 1,500,000 cubic feet capacity. This latter embodied many new features of design, including a considerably shorter length to diameter ratio, but was dismantled on the disbanding of the airship service in England. The R. 38 which was built for the United States Government was destroyed during its manoeuvring trials.

In the United States a rigid airship was constructed after the war called the "Shenandoah." This airship embodied all the experience collected by the allies during the war period, and was successfully used for approximately two years, but eventually came to disaster during a bad storm in 1925.

The accidents to the R. 38 and the "Shenandoah" led to a re-examination of all the conditions which related to the problem of airship construction and operation, with the result that Great Britain decided to make some radical changes in the methods of design employed for airships of this type. Similar influences may be seen in the proposed airships to be built for the United States.

Before entering into a detailed description of these more modern airships it is desirable to examine briefly the theoretical considerations which enter into the problem.

Aerostatics

The Atmosphere

When a body is floating immersed in a liquid we know by the Law of Archimedes that the weight of the body is equal to the weight of liquid displaced by the body.

An airship standing still in the air is floating immersed in a liquid, i.e. the atmosphere, and, therefore, the weight of the air displaced by the airship is equal to the weight of the airship, which in turn can be divided into the weight of the gas, the weight of the structure and other fixed loads, together with the weight of the fuel, crew, ballast and other movable loads. The difference between the weight of the air displaced, and the weight of the gas is

Figure No. 10.—Delag Passenger Zeppelin "Bodensee."

called the "gross lift." The "net lift" is obtained by deducting the weight of the structure and other fixed loads from the "gross lift."

It becomes necessary to study the properties of the air before studying the properties of the lifting gases employed in airships.

The air may be considered as a mixture of gases containing 79 per cent of nitrogen and 21 per cent of oxygen, with traces of other gases. The weight of a cubic foot of dry air at 60° F. and a pressure of 29.92 inches of mercury is 0.0764 lbs. The air acts as an almost perfect gas under the conditions to be considered here, and follows the well know law $PV=RT$, from which the effect of pressure P can be seen, and the effect of temperature is such that the density of the air is inversely proportional to absolute temperature.

Changes in barometric pressure at sea level have comparatively little effect on density, because these pressure changes are small and take place slowly, but changes in temperature have large effects on density. A change from $-20°$ F. to 100° F. decreases the density by some 27 per cent. Clouding over of the sky may cause an increase in density of some 3 per cent. Changes in humidity also have sufficient effect to warrant consideration.

The *effect of altitude* is very important, because of the large diminution in pressure which is involved and the consequent decrease in the density of the air.

Lifting Gases

Of the gases, lighter-than-air, which are available for airship use all may be neglected except hydrogen and helium.

Hydrogen is by far the most widely used gas at present. Its weight per cubic foot at a temperature of 60° F. and pressure of 29.92 in. of mercury is 0.0053 lbs. Hydrogen is seldom pure, and it is impossible to inflate an airship with 100 per cent pure gas. The purity when first put into the ship may be 98 per cent but quickly deteriorates, and a figure of 96 per cent purity is usually taken. When the hydrogen becomes mixed with too much air it has to be changed. A serious disadvantage in the use of hydrogen is its inflammability, but with care in the design of an airship allowing for ample ventilation of the hull, the risk can be minimized. The lift to be obtained from 1,000 cubic feet of 96 per cent pure hydrogen under standard conditions is equal to the difference between the weights of the air and hydrogen or $(76.4-5.3)\times0.96=68$ lbs. approximately.

Helium

This gas is slightly heavier than hydrogen, but has the great advantage of being non-inflammable. Until recently the cost was excessive, but in the United States helium is now available in sufficient quantities for their present airship programme. The weight of a cubic foot of helium under standard conditions is given as .0105 lbs. so that the lift obtained from 1,000 cubic feet of 96 per cent pure helium is $(76.4-10.5)\times0.96=63$ lbs. approximately.

Superheating

A difference of temperature usually exists between the gas in the cells of an airship and the surrounding air, due to the absorption of heat from sunshine. The outside covers of airships are usually treated with an aluminum coloured dope to reduce this effect, and ventilation of the space between the cells and the outer cover also assists.

The reverse effect may also be obtained when an airship is taken out of a comparatively cool shed into the atmosphere, which has been warmed by sunshine.

Some interesting remarks upon this subject may be found in the "log of R. 34," which airship was frequently purposely flown in clouds to obtain protection against superheating during its transatlantic flights.

Airship Aerostatics

When a balloon or airship is at rest at an altitude such that the gas cells are just full, their lower ends being open to the atmosphere, the ship is said to be at its "pressure height." If ballast is thrown out, the ship will rise and gas will flow out of the cells, until a new pressure height is reached corresponding to its changed weight.

During the greater part of a flight a rigid airship is operated with the gas cells partially empty, the lower part of each cell hanging as a wrinkled mass of fabric.

When starting on a long flight with the maximum possible load it is necessary to start with the maximum possible lift, and the gas cells will be nearly filled at starting, but in this condition the airship will have a low pressure height which will increase as the consumption of fuel reduces the load. After a certain time it will become necessary to let out gas, thus putting the gas cells again into the partially empty condition.

It is, of course, desirable to avoid letting out gas and to keep the weight as constant as possible. For this reason the recovery of water from the exhaust gases is very desirable. With a nearly constant weight it is possible to start with the gas cells partially empty to the extent that the pressure height of the ship is the maximum altitude that the ship is expected to reach during the trip.

With partially empty gas cells it is possible for a rigid airship to operate at any height between sea level and the predetermined pressure height, by means of dynamic controls without releasing either gas or ballast.

Dynamic Lift

In addition to the control of altitude by the discharge of gas or ballast, an airship may be forced up or down whilst in flight by the aerodynamic forces on the hull

Figure No. 11.—Crew's Quarters "Bodensee."

and control surfaces due to the motion through the air. A very great lifting effort may be obtained in this way.

Ballast

In a rigid airship the ballast required for manoeuvring is generally carried in the form of water distributed in waterproofed fabric containers along the keel of the ship. These containers can be discharged rapidly by controls from the control car. An antifreeze mixture is necessary under many conditions, but in addition the containers can themselves be dropped if the water should become frozen.

Fuels

In common with the automobile and aeroplane, the development of the airship commenced when a suitable internal combustion engine became available; consequently practically all airships have used gasoline as a fuel. There are many disadvantages connected with the use of this fuel for airships, not the least of which is that, for a given energy equivalent the net load to be carried by the aircraft is high compared with a gaseous fuel, and the fire risk is always present, but particularly in case of damage to the airship structure.

Heavy oils having much higher flash points than gasoline appear to offer good possibilities by removing a great deal of the fire risk, and if combined with water recovery from the exhaust gases, the loss of weight due to consumption of fuel can be considerably reduced.

When considerable weight has been lost it may become necessary to release gas to maintain equilibrium, and, therefore, it has been suggested that instead of valving out the gas it should be used as a fuel in the engines in conjunction with a liquid fuel, and in such proportions that the static equilibrium of the airship would be maintained. This system seems attractive, but has yet to be worked out practically.

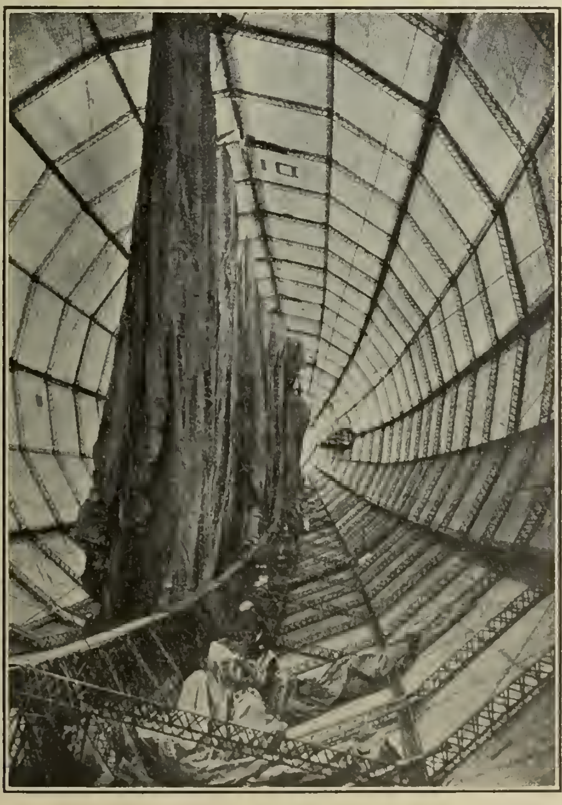

Figure No. 12.—Inside View of "Bodensee."

The "Graf Zeppelin" employs a fuel gas in addition to gasoline. The fuel gas is contained in cells extending over the central portion of the ship and up as high as the middle line, thus occupying a portion of the space usually given to the lifting gas. The "Blau" gas used has a specific gravity about equal to air, and consequently consumption of this fuel is automatically corrected by the air which displaces it without causing any loss of weight.

It is a matter of some argument as to whether a gaseous fuel of this type is more dangerous, as regards fire risk, than gasoline.

Hull Design

In the chapter on History an endeavour has been made to show how the design of rigid airships commenced on independent ideas in Germany and Great Britain, but the advance made by Germany and the needs of war caused Great Britain and the United States to follow information obtained from German ships. Then came a series of disasters, the R. 38 in Britain, the "Shenandoah" in the United States, and the "Dixmude" (ex Zeppelin) in France.

Investigation at this time showed that the theory of airship design as used in Britain omitted several important factors which influenced very considerably the strength of the ship.

New design methods were suggested, and these have since been considerably extended. It was shown that the air forces on a ship were not known, as only a few experiments for measuring air pressures on ships in flight had been made, and extrapolation from a small model to a full sized ship was hardly likely to give useful figures.

Considerable criticism has appeared in the press upon this subject, objecting that the large step in size taken in designing the present 5,000,000 cubic feet ships was made without sufficient design information being available. In order to insure sufficient strength in the airship structure it is, of course, necessary to know all the loads and forces that will be imposed upon that structure; a very exacting requirement when it is remembered that the atmosphere can at times produce storms of a very complex nature, which cannot always be avoided, and in which the wind velocities may show great variation in direction and intensity over a space of a few feet.

The *static loads* can be determined from the known buoyancy of the various compartments and the known weights of the structure and distributed loads. It is, therefore, possible to construct shearing force and bending moment diagrams for the ship under static loads. Provision must be made for the deflation of one or more gas cells and the subsequent readjustment of trim. Deflation of each gas cell in turn must be considered, and the envelope of the diagrams thus obtained must be used as the working diagram from which to design the various members.

The condition of flight fully loaded and fully inflated must be considered together with all other conditions of flight, such as at maximum height or with a light load and gas cells partially inflated. It is readily appreciated that all these combinations give plenty of work, but deal only with conditions which are known and can be allowed for.

In early ships the speeds were very low and the static loads were the only ones considered. Increase in speed, however, caused great increases in dynamic loads, which now become of the greatest importance.

The *aerodynamic loads* are very complex, and the data available incomplete. When an airship is manoeuvring in a light or heavy condition, the surplus lift or weight is balanced by aerodynamic lift obtained by driving the ship forward under power with the nose up or down as

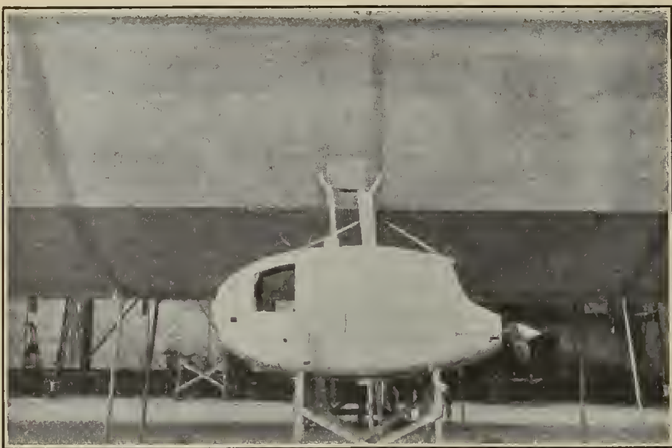

Figure No. 13.—Power Gondola "Bodensee."

may be required. Experiments have shown that the air forces on the hull in a pitched conditions are concentrated towards the ends of the ship producing large bending moments amidships. Running into a gust, or changes in the position of the control surfaces have the effect of shifting the peak of the bending moment curve. These latter effects may, of course, also occur in the lateral direction as well as in the vertical plane.

As practically all flight is not in a straight line, changes of direction occurring all the time, but particularly during maneouvres, it is necessary to consider the distribution of centrifugal forces which, of course, follow the mass distribution and are opposed by the aerodynamic forces on the hull generated by the movement of the airship.

One of the most severe conditions occurs when the airship runs into a vertical gust; this produces heavy bending moments, causing sagging of the airship structure. These gusts may reach very high velocities under certain storm conditions.

Local loads may occur due to many causes. One particular condition is that which occurs when an airship is moored to a mast. For this purpose it is necessary to reinforce the nose to carry the mooring attachment and to provide a swivelling attachment which will allow the ship to swing or roll without imposing loads in the structure.

It is possible to have the airship at the mast in such a condition that heavy loads are imposed, without any apparent change of trim of the ship. If the ship becomes heavy, and at the same time down by the nose, the nose may be supported by the mast and the ship itself still floating horizontally. The up load imposed by the mast may cause large sagging bending moments on the airship structure.

There are, of course, many other local loads due to engine cars and other concentrated loads, which need to be considered during the progress of the design. In ships constructed with radial bracing in the transverse frames, the accidental deflation of a gas cell allows adjacent cells to press against the radial bracing and thus impose large loads in the frame.

The *load factor* to be used in the design, after all possible conditions of loading have been considered, has been a subject of considerable controversy. A figure of 2 seems to have been used consistently for airships for war purposes, but for commercial ships this has now been increased considerably.

The *distribution* of loads amongst the various structural members must now be considered. Up to this point the airship hull has been considered as a whole. It is, however, only necessary to glance at one of the illustrations showing the construction of a hull for an engineer to realize that the structure is full of redundant members, and that the assumptions to be taken in the design of the members need to be very carefully reviewed.

The following extract from a paper by Mr. W. T. Sandford (Journal of the Royal Aeronautical Society, November, 1927) seems to summarize rather well the present assumptions:

"It may be of interest here to mention the methods previously employed in ships of the Zeppelin type. The gasbag loads were transmitted directly through mesh wiring as a lateral load on the longitudinals. It was assumed that the resistance to bending was supplied by the longitudinals, the shear wires taking the whole of the shear loads. Working on these assumptions, there were two methods of proceeding; incidentally these two methods gave discordant results except in special cases where the longitudinal and shear wire sizes bore a particular relationship to each other. We will call these two methods the bending and shearing methods. In the bending method the loads due to bending were calculated from the ordinary formula for beams ($M/I = f/r$) and it was assumed that the shear wires supplied the longitudinal forces required by the bending moment. In the method of shears it was considered that one frame moved down relative to the next, the tensions produced in the wires being dependent upon their elastic properties. For the longitudinals, the longitudinal components of wires were summed up at each joint right through the ship, no account being taken of the elastic properties of the girders. It is probable that the bending theory gave optimistic values and the shearing method pessimistic, since it is found by methods based on the minimum strain energy of the members that, in general, the longitudinals take a considerable part of the shear, but that bending tends to reduce the shear wire loads. It is evident that more accurate estimations are required than are supplied by these two approximate methods.

In any method of stressing it must be assumed that the principle of superposition holds, that is, the loads due to any component of the loading mentioned may be evaluated and superposed upon the loads found due to any other components. The two basic assumptions made in employing methods of redundant stressing are:—

(1) That transverse frames remain plane, i.e., they do not distort out of their own plane.

(2) All loads are applied at the joints which are assumed as pin-jointed.

Figure No. 14.—Interior View "Schütte-Lanz Airship."

Figure No. 15.—Spiess Airship.

"It is fairly obvious that these two assumptions tend towards opposite extremes and a compromise somewhere between the two must be adopted. The true assumption is that made in all redundant stressing, namely, that deflections and distortions of members are small compared with their length. One method suggested by the Stressing Panel consists in reducing the structure to the form of a composite girder to which orthodox methods may be applied. This applies if the structure may be considered as a long tube free from load along most of its length. Actually, however, an airship is continuously loaded and has not a great length compared to its diameter. In the case of an airship both ends are approximately true pyramids, hence the end frames remain plane. Also by symmetry the centre frame would be plane. It was also found that frames practically remain plane when the shape was truly polygonal. This indicates the suppression of a keel member. If the validity of this argument can be accepted it has the very great advantage that each bay may be treated separately. It was a similar line of reasoning that suggested the second method of stressing put forward by the Airship Stressing Panel. In this method each bay is treated separately, the frames being assumed as not deflecting out of their own plane.

"These methods are rather long and tedious to apply, but it is probable that any future methods will be developed from this second method and will be attempts at simplification and application to design office routine."

There is, of course, a great deal of literature on this subject, much of which is referred to in the bibliography, but which is too extensive and too detailed to be discussed here.

In designing the new British airships, care has been taken to make the joints between the main members in the form of pin-joints, thus avoiding secondary stresses of unknown amount due to rigid joints.

General Arrangement of a Rigid Airship

Before dealing with the constructional methods used in rigid airships it seems desirable to indicate the arrangement of all the components which form the airship, and for this purpose advantage has been taken of the material contained in a technical memorandum published by the United States National Advisory Committee for Aeronautics entitled the "American Airship Z.R. 3" by L. Dürr.

This airship was built by the Zeppelin factory in 1923-4 for the United States Navy, (figure No. 21).

Its principal dimensions are:—

Gas capacity...............2,472,000 cubic feet.
Length.....................656 feet.
Greatest diameter...........90.68 feet.

This airship bears the factory number LZ. 126, but was delivered to the United States as the Z.R. 3 and rechristened "Los Angeles." It was built as a commercial airship to carry twenty to thirty passengers. It has thirteen gas cells. The central and rear portions carry cars containing the engines while the forward portions carry the control car and the adjoining passenger car. The rest of the apparatus and load are inside the hull.

The ship is equipped with five motors of 400 h.p. each. It is calculated to be able to make a continuous flight of 110 hours with a pay load of 5 tons, corresponding to a distance in still air of 7,700 miles.

Hull

The hull is built on the usual Zeppelin principle. The cross section is a regular polygon with 24 sides, but with one angle on each side of the bottom straightened out. The lower part of the transverse frames is constructed so as to provide a keel frame, which extends throughout the whole length of the hull and contains all the apparatus required for the operation of the ship. The frames and longitudinal girders consist of longitudinal members and connecting strips of sheet duralumin rivetted together. The resulting lattice girders are generally triangular in section, but at a few points may be square. Longitudinal and transverse girders are fastened together by gussets and rivets.

The assembly is further stiffened by bracing wires in the plane of the transverse frame and in the panels formed by the longitudinal girders and the transverse frames. The transverse frames having bracing wires are called the main transverse frames, and those without bracing wires are called auxiliary or intermediate frames. The main transverse frames are braced by additional girders and kingposts, and divide the hull into a number of separate cells. The length of these cells is 10 metres at the rear, 15 metres in the centre and 12 metres in the front portion of the hull. The intermediate frames are generally about 5 metres apart.

The gas cells are made of goldbeater's skin attached to a light cotton fabric. Apart from gas tightness no special demands are made on the material of the gas cells since the lift stresses are transmitted to the frame of the airship by means of a special network of wires and string, and since the fabric is still further protected by safety valves against excessive loads due to expansion of the gas, (figure No. 22).

From the safety valves, which have a diameter of 50 centimetres, the escaping gas passes up through vertical shafts, and escapes into the air through hood-like openings near which are located the valves for manoeuvring purposes. The gas cells are protected from sudden changes of temperature and the action of the sun by the hull covering and the layer of air between them and this covering. The hull covering consists of strips of cotton cloth laced to the framework. The thickness of the cloth differs according to the amount of stress to be withstood. Special reinforcing strips are added in the vicinity of the propellers.

The outside surface is doped with a cellulose dope containing aluminum powder. The passenger car and the engine cars are braced outside, but when there are no special reasons for bracing any of the equipment outside the hull

Figure No. 16.—British Airship No. 1.

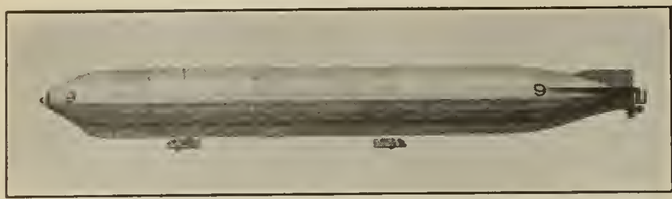

Figure No. 17.—British Rigid No. 9.

it is braced within the keel or corridor inside the hull. Heavy objects are located in the vicinity of the main transverse frames.

Power Plant

This consists of five independent power units in five separate engine cars. One of these is located under the rear portion of the hull while the other four are suspended in pairs by struts and cables on both sides of the middle portion of the hull. Access from the hull is by means of ladders and sliding doors.

The engines were made by the Maybach Engine Company and are of the twelve cylinder V water cooled type. They develop 400 h.p. at 1,400 r.p.m., thus enabling direct drive.

Propellers

Two-bladed wooden propellers are used.

Fuel Storage

The fuel is stored in the keel corridor in 70 tanks, which can be increased to 100 for specially long trips. The fuel tanks are cylindrical aluminum tanks with round ends, suspended by wires, usually in groups of three from the top girders of the keel on both sides of the walkway. In the vicinity of each engine there is a group of tanks for supplying that engine by gravity feed. These are replenished from the reserve tanks by means of wind driven pumps.

Ballast

The keel corridor also contains the ballast, store rooms, baggage, freight, etc. There are two kinds of ballast bags, one for landing ballast and the other for flight ballast. The difference is due to the fact that it must be possible to empty the former suddenly while the latter are emptied slowly. The landing ballast bags are located near the bow and stern, while the flight ballast bags are distributed throughout the keel corridor on both sides of the walkway. The former are trouser shaped with the legs downwards, and can be completely emptied in a very short time by letting the top part fall, thus inverting them. Both kinds of ballast bags are made of 3-ply rubber fabric. There are twelve landing ballast bags, each having a capacity of 66 gallons. The flight ballast bags have a capacity of 264 gallons each, and are emptied by means of valves so arranged as not to shower any of the cars.

Control Car

This contains all the apparatus for navigating the ship. A ladder leads to the keel corridor, and a door opens into the adjoining passenger car. The controls are divided between two wheels, one in the bow for the rudder and the other at the side for the elevator. For emergency use rudder controls are also installed in the lower vertical fin, to which position orders can be telegraphed from either the control car or the rear engine car.

Height regulation can be obtained by both static and dynamic forces. Since the static lift depends upon the weight of the airship and also upon the pressure, temperature and humidity of the air and of the gas, as well as on the quantity and character of the latter, it can be changed by releasing gas or ballast. Gas can be released either by purposely ascending till the safety valves open automatically or by opening the manoeuvring valves provided for landing. The cords for releasing ballast and gas terminate on ballast and gas boards above the elevator control wheel where they can be operated by handles, arranged under a diagram of the airship. The dynamic lift is varied by changing the trim of the airship either by releasing ballast or gas or operating the elevators.

Orders are transmitted to the engine cars by mechanical signals, and provision is made for communicating with the crews' quarters and with the anchoring and mooring points by telephone.

Methods of Construction

Hull Framing

The present description is confined to airships which have been evolved from the original Zeppelin methods of

Figure No. 18.—British Rigid 23X Class.

construction, and does not apply to the more recent airships now being built. From what has been given before it will be appreciated that the airship consists of a metal framework or skeleton braced together by wires, divided into compartments containing gas cells and usually having a keel or corridor built into the lower part of the structure.

The main transverse frames form a polygon usually with an uneven number of sides. These frames are built up of braced duralumin girders consisting of channels at the corners and duralumin strips forming the cross bracing between the channels. The sides of the polygon are often kingposted in the centre and braced from the top of the kingpost to the two ends of the side. Similarly at the bottom of the frame the keel member is built on to one of the sides and braced from the apex of the keel to adjacent corners of the polygon. In addition to these rigid girders the whole of the transverse frame is braced by wiring. It would be approximately true to say that every angle of the polygon is braced to every other angle.

Connecting the corners of the transverse frames and giving the outside shape to the ship there are a number of longitudinal frames. The panels formed between these longitudinal frames and the transverse frames are in themselves cross braced with wire, and intermediate between the main longitudinals there are auxiliary longitudinals spaced in the middle of the sides of the transverse

Figure No. 19.—Rigid Airship No. R.31.

Figure No. 20.—Rigid Airship R.34.

frame. Between the main transverse frames there may be one or more auxiliary transverse frames supporting the longitudinal frames, but these auxiliary transverse frames are not wire braced.

The photograph, (figure No. 23), gives a good idea of the arrangement of the transverse frames and longitudinals. It also shows some of the wire bracing.

A good view of the girder work is shown in the photograph, (figure No. 24), which shows some of the girders in the corridor of the British Airship R. 36, including the suspension of two of the gas tanks. The tail fins, rudders and elevators are framed with duralumin girders and covered with doped fabric.

The power cars and control car are all slung from the underside of the hull and are usually held in position by a combination of wire ropes and struts. In order to distribute the loads due to the lift from the gas, the gas cells are themselves supported by an elaborate system of netting, designed to distribute the lift as much as possible among members. Normally the gas cells would lift against the longitudinals in the top of the hull, but by suitable wiring it is possible to distribute these loads among the other longitudinals. It will be appreciated that in this method of construction the gas lift is carried as a side load on the longitudinal members.

Figure No. 21.—U.S. Navy Dirigible "Los Angeles."

An idea of the amount of bracing in the airship can be gathered from the photograph, (figure No. 25), which shows typical bracing as used in the British airship R. 38. A modification of the method of supporting the gas bags is sometimes used, in which a mesh wiring is used instead of the parallel wires shown in this diagram.

The outer cover is usually of cotton fabric, spread over the outside of the structure in strips, laced into position and doped. The wiring which retains the gas cells is so arranged that there is an air space left between the gas cells and the outer cover.

An interesting point in the design of airship structures arises over the use of a keel member, which forms a comparatively stiff portion of the ship running fore and aft. In the early Zeppelins this keel member consisted of a V shaped projection on the outside of the ship, which later became inverted and was put inside. When the British ships of the 23X class were designed this keel member was omitted, and terrible results were predicted, but which did not, in fact, materialize. In more recent British airships the keel was again introduced, following much the same design as contemporary Zeppelin airships.

Figure No. 26 shows the inside of the Graf Zeppelin. The keel is seen in the lower part of the picture, and also a longitudinal member in the centre, providing support for the frame bracing and access to the space between the fuel gas cells below and the hydrogen cells above.

It will be shown later that in the more recent British ships the keel has again been omitted, whereas in some projected American ships the number of keels has been increased to four.

Description of British Airship R. 101

It has already been stated that following the airship disasters previously referred to, airship construction practically came to a standstill, and in Great Britain an enquiry was held to determine the existing state of the knowledge relating to airship design and to decide under what conditions airships might reasonably be designed in the future. The result of this enquiry was to show that the existing state of knowledge was very incomplete, and undoubtedly a great deal of research work has since that time been done with a view to improving our knowledge of the subject.

There has, however, appeared so much criticism in books by Neon and by Spanner and in the press that engineers cannot help being interested in knowing exactly what there is in these criticisms. It is not proposed in this paper to make a case one way or the other, but the description given below of one of the new British airships will, it is thought, indicate that very considerable changes have been made in the design of the airship since the time of the R. 38, and that these changes have certainly been based upon some very sound scientific reasoning.

What the future holds for these airships remains to be seen, and it cannot be predicted, because with the best intention in the world it has not been possible to carry out all the full scale experiments that are necessary to obtain complete data and in addition the step taken in increasing the size to 5,000,000 cubic feet is in itself somewhat daring. Enough information, however, is available to warrant the statement that the design of these airships rests on a better scientific foundation than has ever been the case in the past.

Rigid airship R. 101, (figure No. 27), has a fineness ratio of 5.5 to 1 as compared with 8.3 to 1 for the R. 38. There has been some discussion upon a supposed difficulty of control with a short airship of this type, but extensive experiments have been carried out on the shape of the stabilizing fins, resulting in the choice of the triangular shaped fin of streamline section, which can be supported by internal bracing, and which shows a considerable improvement in efficiency over previous forms. It is estimated that the resistance of the bare hull of this airship will be but little more than 2 per cent of the resistance of a circular plate of the same diameter as the maximum diameter of the ship.

There are 15 main longitudinal girders and 15 intermediate girders whose function is merely to co-operate with the main girders in supporting the outer cover. The shape of the ship is a continuous curve without any parallel portion, and in order to more nearly approach the required shape, the longitudinal girders have been curved to an arc of a circle conforming practically to the theoretical shape of the ship.

The cross section of the hull is a polygon of 30 sides, the length of each side at the maximum diameter being approximately 13½ feet. The longitudinals are located entirely on the outside of the transverse frames, and the intermediate longitudinals are connected to the main hull in such a way that they can be forced outwards to take up slackness in the outer cover.

The airship has no keel, all the weights being stowed in the main tranverse frames. The design of the transverse frames used in this airship is very different from that previously employed, for in airships of the Zeppelin type the transverse frames were as described above, made up in the form of polygons cross braced by radial and chordal wires. With a wire braced transverse frame the deflation of one gas bag resulted in considerable side loads being put on the wiring, tending to cause distortion of the adjacent frames. In the R. 101 an attempt has been made to develop a type of transverse frame and gas bag wiring, which will overcome these difficulties. The single members of the conventional frame are replaced by stiff triangular braced structures strong enough to resist all transverse forces without any transverse bracing, (figure No. 28).

One effect of the decreased fineness ratio is that if all transverse frames were equally spaced the volume of each gas bag in the centre of the ship would represent an undue proportion of the total volume. The photograph, (figure No. 29), shows that the spacing of the transverse frames decreases towards the centre of the ship.

The R. 101 has no intermediate transverse frames. In previous airships these frames were required for the support of the longitudinal girders, but with the modified method of gas bag suspension the longitudinal girders are now relieved of side load, and these intermediate transverse frames are no longer required.

The bow of the ship has been extended beyond the theoretical shape in order to provide clearance for the mooring cone. The longitudinal members are brought out to meet at a point where a horizontal shaft is carried in bearings for the support of the mooring cone at the forward end.

Between the front face of the first gas bag and this mooring spindle there is a platform carrying winches for the mooring rope and the yaw ropes, also connections for the supply of gas, fuel, water, compressed air and electricity from the mooring mast.

A small lookout position on the top of the bow is also reached from this platform. Frame 1 is a flat radially braced frame of the Zeppelin pattern, which carries at the bottom a hinged platform, which can be let down from the ship for the entry of passengers from the mooring mast. Frame 2 is also of Zeppelin pattern. Frames 3 to 13 are all of the new ring pattern without radial bracing. Frame 4 carries two power cars. Frame 5 has access to the top of the ship by means of a stairway inside the frame.

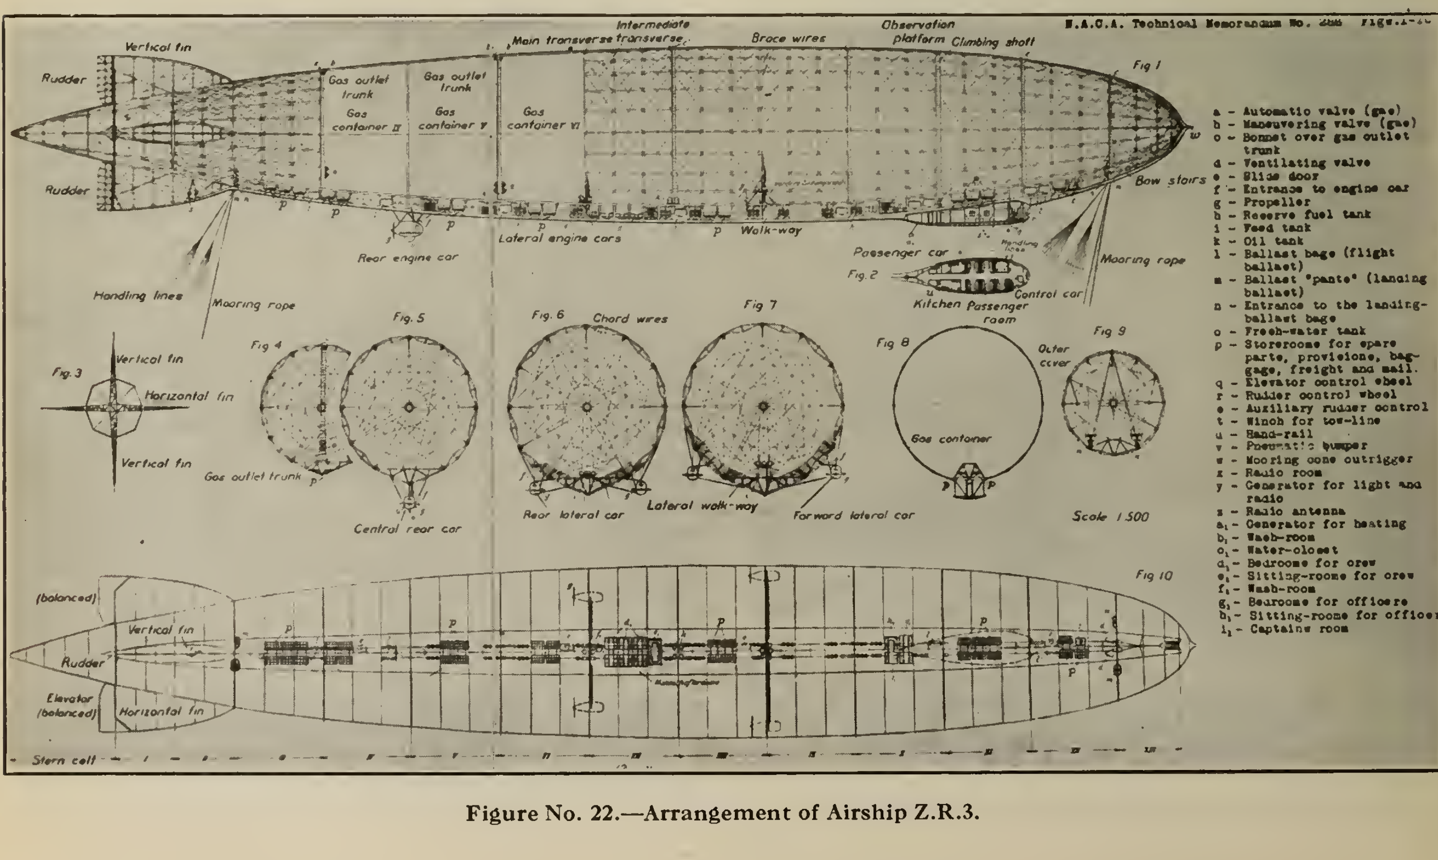

Figure No. 22.—Arrangement of Airship Z.R.3.

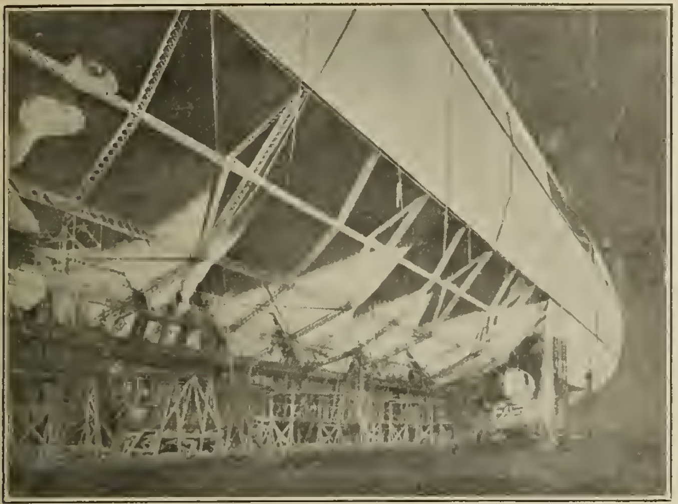

Figure No. 23.—British Rigid R.36.

Frames 6, 7 and 8 carry the passenger accommodation inside the hull. Frame 9 carries two power cars. Frame 11 carries a single power car on the centre line. Frames 14 and 15 are of special construction to carry the fins.

Details of Construction

The photograph, (figure No. 30), shows a portion in the main structure, and gives the nomenclature which will be used in the description of the various parts.

Considerable interest is attached to the construction of this airship because the manufacture of the parts of the ship was all carried out by contract. The Royal Airship Works at Cardington supplied Messrs. Boulton and Paul with a line diagram giving the geometrical properties of each part to be supplied and the loads to be carried by those parts. Messrs. Boulton and Paul designed and constructed the members in accordance with these requirements, making use of the experience gained in the design of heavier-than-air craft.

The main longitudinals are of triangular section about 45 feet in length employing three booms of stainless steel tubing to the section indicated in the photograph, (figure No. 31). These booms are spaced at 30-inch centres with struts of duralumin and diagonal bracing wires. These main longitudinals are made continuous with the frame longitudinal by means of joints with fitted bolts, and they are all curved to conform to the desired shape of the ship.

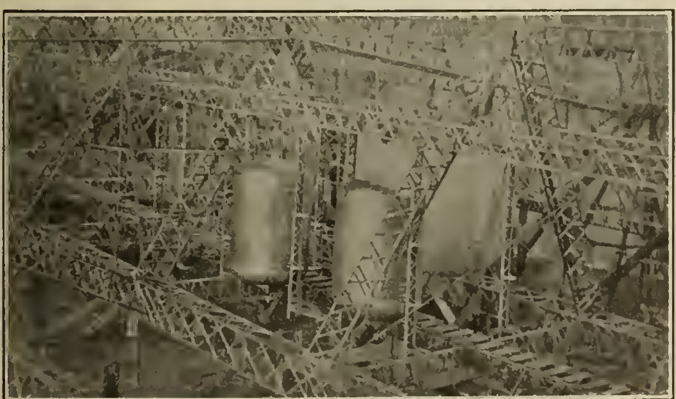

Figure No. 24.—Keel Construction, British Rigid R.36.

The *ridge girders* are constructed of stainless steel booms with webs formed from duralumin sheets. The booms in this case are all of the section shown in figure No. 32.

The *radial struts* are of similar design except that the boom tubes and the webs are each of duralumin.

The stainless steel strips used for the production of the booms and the longitudinals have the following composition:—

Carbon 0.16 to 0.22 per cent.
Silicon not exceeding 0.5 per cent.
Nickel not exceeding 1.0 per cent
Chromium 12½ to 14 per cent.

The tubes are formed on special draw benches with subsequent hardening and tempering by a continuous heat treatment process, and when completed have the following mechanical properties:—

Proof stress not less than 65 tons per square inch.

Ultimate strength between 88 and 95 tons per square inch, and to withstand a transverse close bend test around a radius of three times its own thickness without cracking. The proof stress is defined as that stress at which the stress strain diagram departs from the straight line of proportionally by 1 per cent of the gauge length.

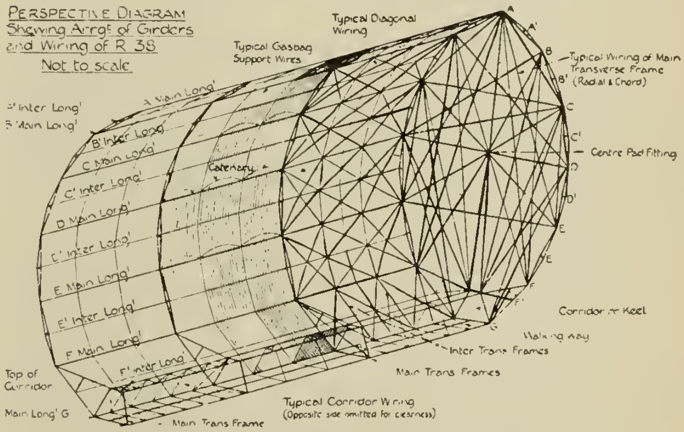

Figure No. 25.—Typical Bracing.

The stainless steel lipped tubes as used for the booms of the ridge girders are formed by rolling, with subsequent hardening and tempering; for the duralumin tubes of the same form the heat treatment is carried out prior to the drawing or rolling. Die castings of aluminum-silicon alloy and high tensile steel stampings are used for many of the connections. Typical joints are illustrated in the photographs, (figures Nos. 33, 34 and 35).

All members are erected in jigs before being shipped from the works of the contractor, and assembly has indicated that a very high degree of accuracy has been maintained throughout the whole of this work, as no fitting was required during erection.

The outer surface of the steel tubes is protected with a pigmented cellulose lacquer, and the duralumin is protected by the anodic treatment. Some criticism has been levelled at the combined use of duralumin and steel in the same structure, but it is stated that an analysis indicates that the loads imposed by changes of temperature consequent on the different coefficients of expansion of the two metals are only of a low order as compared with the failing strengths of the materials.

Very extensive tests on these new types of girders have been carried out, including a test of a complete

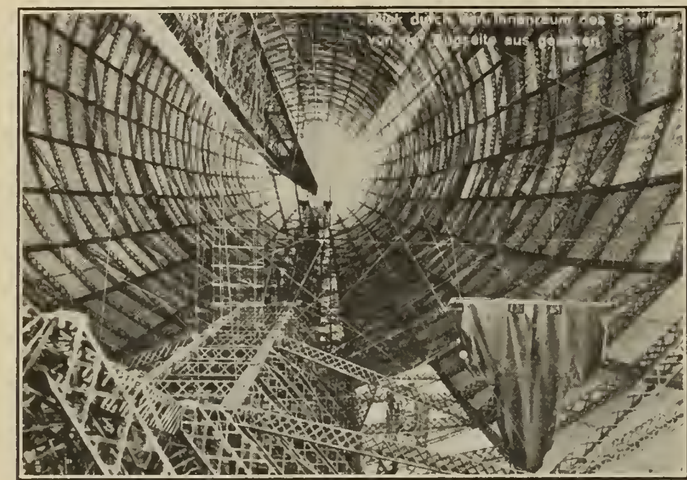

Figure No. 26.—Interior View of "Graf Zeppelin."

replica of the centre bay of the ship, consisting of two transverse frames and connecting longitudinals and shear wires. This complete bay was tested under static loads and with the gas cell inflated. The measured deflections were in very satisfactory agreement with those predetermined by calculation.

Power Plant of the R. 101

From a review of the history of previous airships the designers of the R. 101 considered that the use of gasoline had constituted the greatest fire risk in connection with their operation outside of the hazards incidental upon use during the war. For this reason it was decided that for the R. 101 a power plant using heavy fuel oil should be used instead of the usual gasoline engine.

The general arrangement of this airship has been explained before. There are five identical power units, of which the aftermost is placed on the centre line so as to give a good flow of air to the rudder. The remaining cars are in pairs some distance in front and behind the passenger accommodation.

The engines used are of the Beardmore Tornado type with a continuous rating of 585 h.p. and a maximum rating of 650 h.p. each. The oil burned is such that it has to be heated to the temperature of boiling water before it will give off any inflammable vapour at all. The engines have eight cylinders of $8\frac{1}{4}$-inch bore and 12-inch stroke arranged upright and in line. Some considerable difficulty has been experienced due to torsional resonance in the crankshaft, necessitating some changes in the dimension of the shaft, the fitting of a fly wheel at the end remote from the airscrew, and the employment of a spring coupling between the crankshaft and the propeller.

Figure No. 27.—R.101.

The engines are probably well known to some of the members of The Institute because in a somewhat heavier pattern they have been employed for some time in rail cars by the Canadian National Railway. Engine starting is by means of an auxiliary engine and a decompressor arrangement lifting the inlet valves of the main engines. When the main engine is running at about 100 r.p.m. the decompressor is shut off. The momentum of the airscrew carries the engine over full compression causing the injected charge to fire.

Variable Pitch Propellers

These propellers are designed to meet the special requirements of an airship. The blades can be turned so as to give thrust ahead or astern or into a neutral position where no thrust is being developed. If an engine is stopped the blades can be turned through about 90° so as to exert minimum drag. If the airship is going ahead the blades can be gradually turned until they form a windmill by which it may be possible to start the engines.

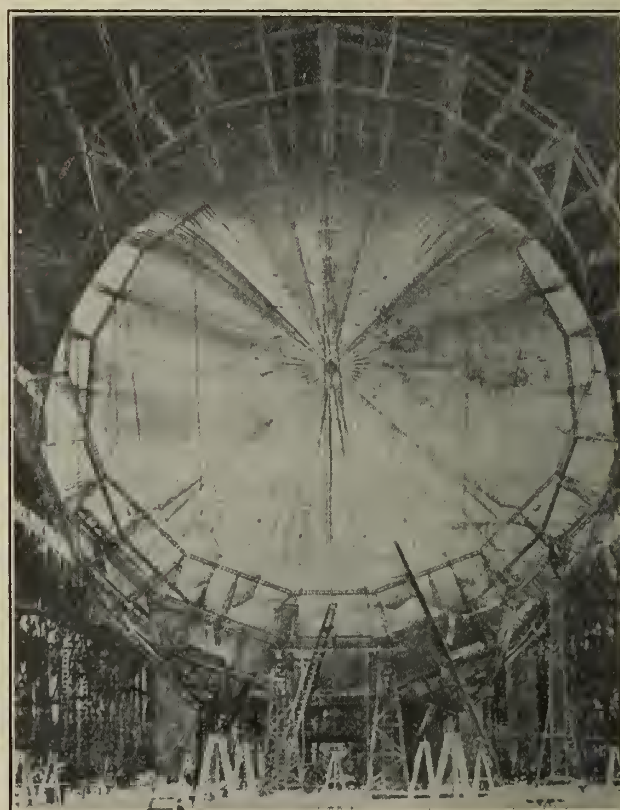

Figure No. 28.—R.101 Gas Bag Wiring.

Some trouble has been experienced with these propellers on test due to the crankshaft oscillations referred to above, and wooden airscrews of fixed pitch will be used as a temporary measure for the trial flights, and in order not to delay these until the completion of redesigned engines. One of these propellers will be designed for astern thrust, which is necessary for retarding the advance of the airship when approaching a mooring mast and under similar conditions. This decision will mean, however, that one power unit will not be available for forward propulsion.

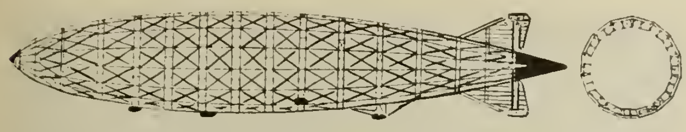

Figure No. 29.—Line Diagram, British Airship R.101.

Thrust Wires

In order to provide the proper support for the power cars when the airship is pitched and when the engines are developing full power, a bearing has been provided on the outer end of the crankshaft and a wire carried from this bearing to the structure of the airship. This thrust bearing cannot be lubricated by oil circulation, and, therefore, depends upon grease, an arrangement which for long flights certainly does not appear entirely satisfactory, (figure No. 36), but no doubt if trouble is to arise here it will become evident during the home trials and be eliminated.

Evaporative Cooling

The engine is cooled by evaporative cooling, the steam being carried away to condensers which may take the form of fabric ducts in the outer cover of the airship, but which at present are triangular shaped radiators on the side of the hull. The waste steam from the two centre engines is led to a radiator which can, if required, be drawn up into the ventilating system of the passenger quarters for heating purposes.

Auxiliary Engines

The auxiliary engines are not only used for starting the main engines, but are also required for driving electric generators and air compressors. Three of the engine cars carry generators and the remaining two cars air compressors. These auxiliary engines at present use gasoline from a tank which can be dropped in case of fire, but the use of even a small quantity of gasoline has been much criticized on account of the publicity which has been given to the use of heavy oil engines as a precaution against fire, the argument being that fire from a small quantity of gasoline is sufficient to cause destruction of the whole ship.

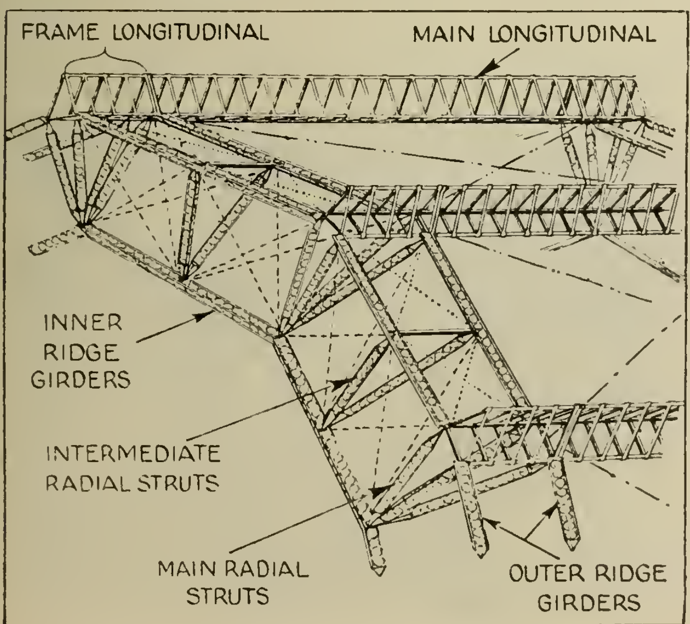

Figure No. 30.—Portion of Structure of R.101.

An arrangement of one of the power cars with the great portion of the outer casing removed is shown in the photograph, (figure No. 37).

Fabric Parts

The fitting of the outer cover is a departure from previous practice. In order to avoid the objections of doping this huge expanse of fabric when in position on the airship the material has been doped before being put into place, and is tautened on the ship by mechanical devices which allow a definite tension to be put on to each lacing point.

The control of pressure difference between the interior and the exterior of the gas cells and the outer cover is one of considerable importance. It is essential to arrange for a definite maximum rate of rise or fall for which the airship must be safe, and in the design of the R. 101 an attempt has been made to deal with vertical currents,

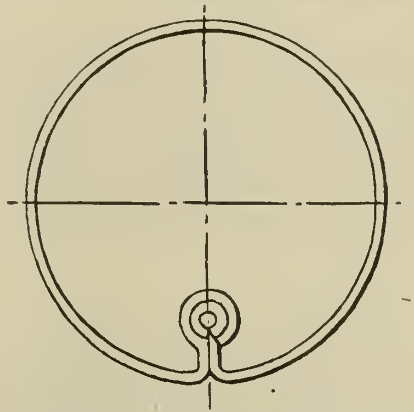

Figure No. 31.—Section Main Longitudinals R.101.

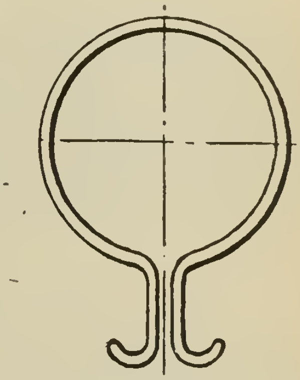

Figure No. 32.—Section Ridge Girders of R.101.

rising at the rate of 4,000 feet a minute and falling currents of approximately half this amount. If an airship is rising rapidly and the gas cells are not full, air must escape from the outer cover in order to allow the gas in the gas cells to expand. If the airship continues to rise past its pressure height a mixture of gas and air would have to pass through the outer cover.

So far as rapid ascent is concerned, therefore, the principal problem is to provide a sufficient opening to let out air at the maximum rate of rise under all conditions of flight. It is also necessary to provide for the inflow of air when the ship is descending. Simple holes in the cover are not sufficient because the pressure distribution on the outside of the ship consists of a high pressure region in the nose and tail, and a low pressure region over the remainder of the ship. The pressure distribution is in turn changed when the ship is pitched or yawed.

In the R. 101 air is admitted to the inside of the hull when the ship is descending by a series of inlet holes near the nose and tail in the regions of high pressure. These holes provide sufficient area for the general ventilation of the hull. They are not, however, sufficient to deal with the maximum rate of descent, and some additional holes with non-return valves are arranged at the bottom of the ship.

When the ship is rising air is let out of the hull by a series of slots arranged circumferentially in the cover in the neighbourhood of the centre where the hull is subjected to a reduced pressure under practically all conditions of flight. A flap is arranged so that the forward half of the

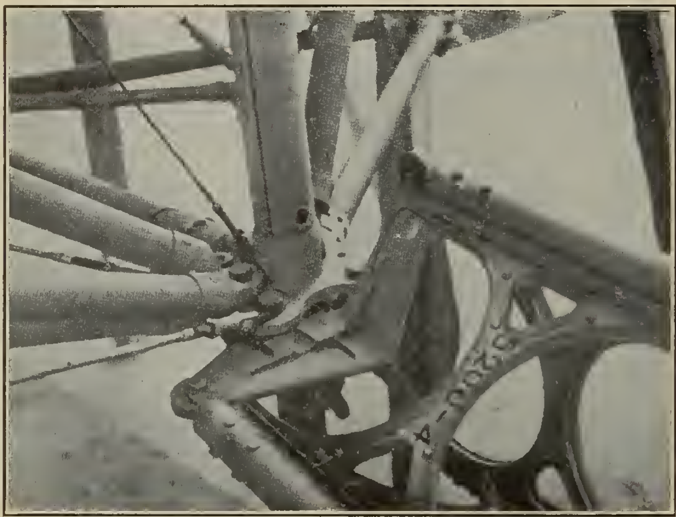

Figure No. 33.—Construction Details of R.101.

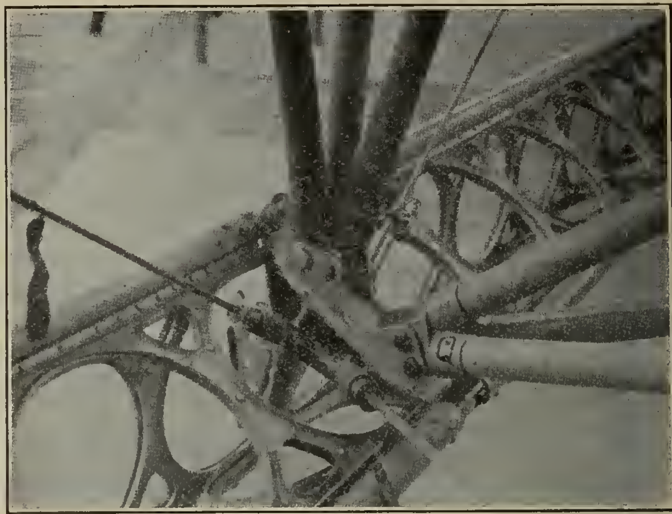

Figure No. 34.—Construction Details of R.101.

cover overlaps the back half, and the aft edge of the forward part of the cover is fitted with springs so that when there is an excess of internal pressure over external pressure the fabric can expand and provide an opening through which air can escape. These slots are, of course, completely closed when the ship is descending.

The position of these openings is indicated in the photograph, (figure No. 38).

Gas Valves

In previous airships automatic valves for limiting the internal pressure of the gas cells were provided in the bottom of the cells. When the gas cell is full these valves sit on cages connected to vertical trunks carrying away the hydrogen to the top of the ship, but as the gas cells become emptied these valves change in position.

In addition to the automatic valves mentioned above, previous airships also were provided with manoeuvring valves operated by hand, fitted in the top of the gas cells by means of which the crew could let out gas when required.

These valves are illustrated in the photographs, (figures Nos. 39 and 40).

The type of valve used in the R. 101 marks a considerable change from previous practice. It has been described by Colonel Richmond, Aeronautical Journal, 1929, as follows:—

"The valve and its method of operation are illustrated in figures Nos. 41, 42 and 43. The position chosen for the valve was on the side of the gasbag at mid-height, the valve being attached by a petticoat to the gasbag and also to the gasbag wiring. The proportion of disposable lift to gross lift in the airship is such that the pilot will never require to deflate the gasbags to such an extent that the free surface of the gas would be as high as the level of the valves. Thus the disadvantage of using valves which have to move with the free surface of the gasbag is avoided. Another advantage of this position over placing the valves at the bottom of the gasbags is that the pressure difference is greater at this height, and consequently a greater rate of discharge is obtained from a given aperture. Furthermore, when the valve is not required to open, the pressure is employed to exert a closing force, this level has the advantage of ensuring better seating of the valve.

"Two sizes of valve are employed, respectively 30 inches and 40 inches in diameter. In general, each gasbag is fitted with one valve on either side, the smaller diameter being employed in the smaller bags.

"A metal seating *A*, (figure No. 41), is fixed to a casting in the form of a wheel with four spokes. This is supported by the gasbag wiring. A fabric petticoat on the bag is bound around the rim. From the hub of the casting a tubular spindle *B* projects. Travelling on this spindle is the moving portion of the valve *C*, which is a large spun casing carrying a flexible fabric annulus which forms the seating. Fixed to the spindle is a stationary conical diaphragm *D*, within the moving casing and connected to the latter by fabric bellows *E*. Gas has direct access to the inside of the bellows and exerts a closing force on the flexible face, since the effective diameter of the bellows is greater than that of the seating. The valve is opened by the application of a small pressure to the chamber enclosed between the moving casing and the stationary diaphragm, this operating chamber being connected to the gas supply through the tubular spindle *B* and fabric cone *F*.

"The operating chamber has a direct leak to the atmosphere which enables the valve to close when there is no flow of gas into the chamber. Only a light closing spring is needed, owing to the fact that the jet of gas discharging exerts a closing force even when the valve is 10 inches away from its seat. No adjustment of this spring is required since small variations in its strength do not affect the work-

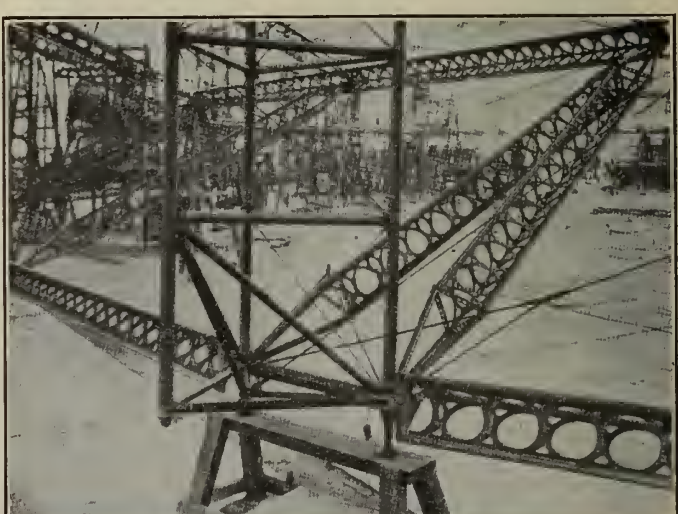

Figure No. 35.—Construction Details of R.101.

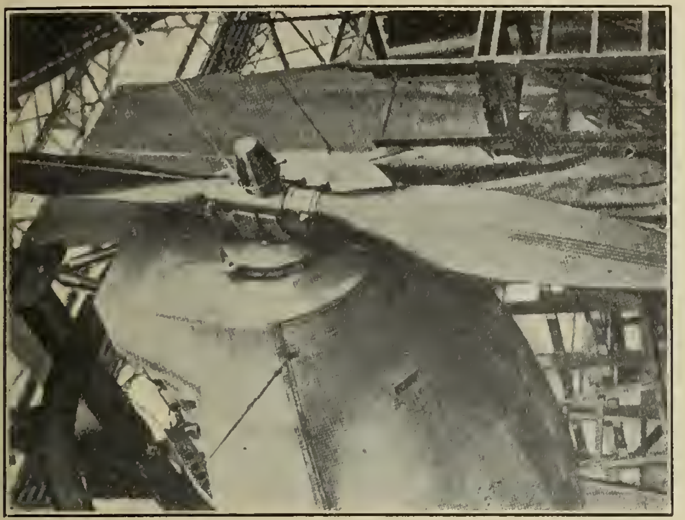

Figure No. 36.—Thrust Bearing, R.101.

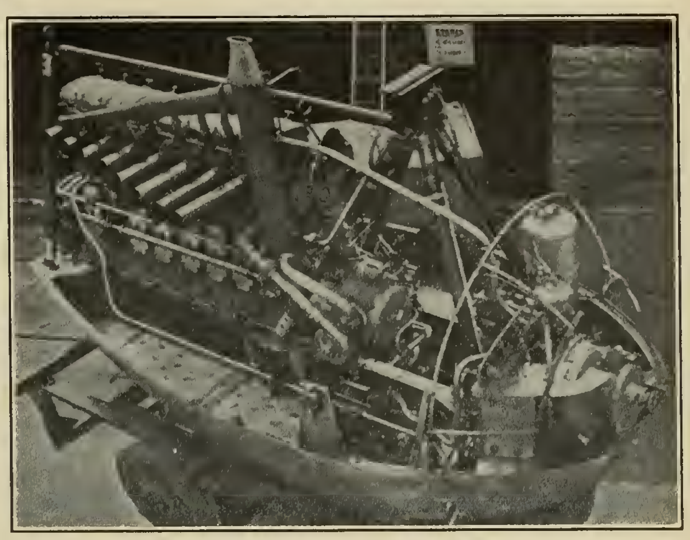

Figure No. 37.—Engine Car, R.101.

ing of the valve. The arrangement of the valve in the ship is shown in figure No. 42. One end of the U-tube or siphon pipe *G* is connected to the gasbag close to the valve, and the other end is connected to the operating chamber of the valve. The bottom of the *U*-tube is approximately level with the bottom of the gasbag, so that when the bag becomes full the gas spills round the tube and up into the operating chamber, thus opening the valve.

Owing to the permanent leak in the operating chamber a certain minimum rate of supply of gas through the U-tube is necessary to open the valve. It was found on test that by proper design of pipes the necessary velocity could be obtained with a pressure difference at the bottom of the bag of only two millimetres of water, at which the valve will open deliberately to its full extension. The rate of discharge of the 40-inch valve under these circumstances is 36,000 cubic feet per minute.

"There are two cross connections in the U-tube marked *H* and *J*. Connection *H* is a small spring loaded relay valve which can be operated from the control car. When this is open gas will enter the operating chamber of the main valve and open it, no matter what the degree of inflation of the gasbag may be, thus it serves the purpose of the so-called manoeuvring valves, which were fitted in past airships in addition to the automatic gas valves. The cross connection *J* is a fabric pipe which is normally tied off. If, however, the pilot anticipates a severe buffeting with rapid changes in height above the airship's ceiling, he can untie this connection, which means that the valves will then operate automatically when the free surface of the gas is level with this connection instead of when it reaches the bottom of the bag. Thus the generation of excessive pressures will be avoided. Since, normally, the airship will become light by the expenditure of fuel as the journey proceeds, it is anticipated that the normal procedure will be for the pilot to undo these connections after the first few hours of flight as a matter of routine."

Passenger Accommodation

For various reasons connected with the difficulties in producing an experimental airship of this size the passenger accommodation in the R. 101 has been reduced to accommodate only 50 passengers instead of 100 as originally comtemplated.

The accommodation is in two decks located between frames 6, 7 and 8.

The upper deck, having an area of 5,550 square feet exclusive of promenade, carries a lounge with promenades on each side, having glass windows in the outer cover, (figure No. 44). On this deck there is also a dining room and a number of two berth cabins. The lower deck, with an area of 1,730 square feet, accommodates the captain's control room, wireless room and kitchen.

The control car is immediately below and in communication with the captain's room. This car gives an excellent view in all directions except immediately upwards.

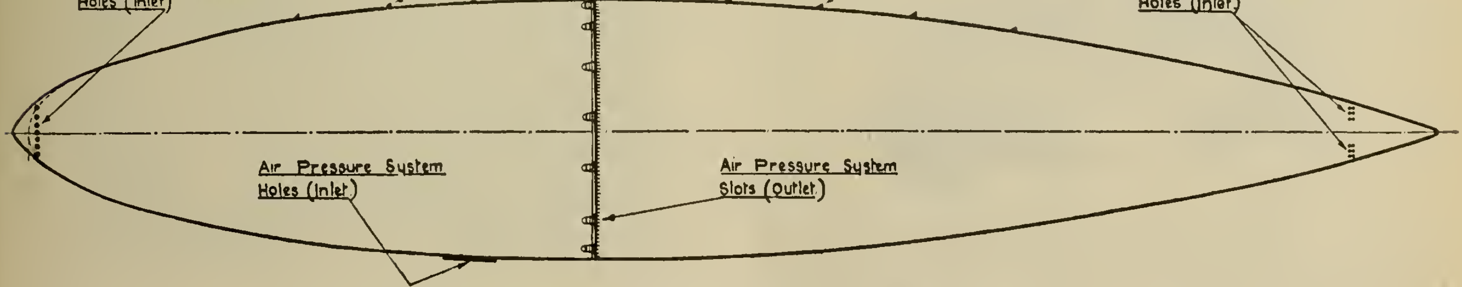

Figure No. 38.—Ventilation Outer Cover R.101.

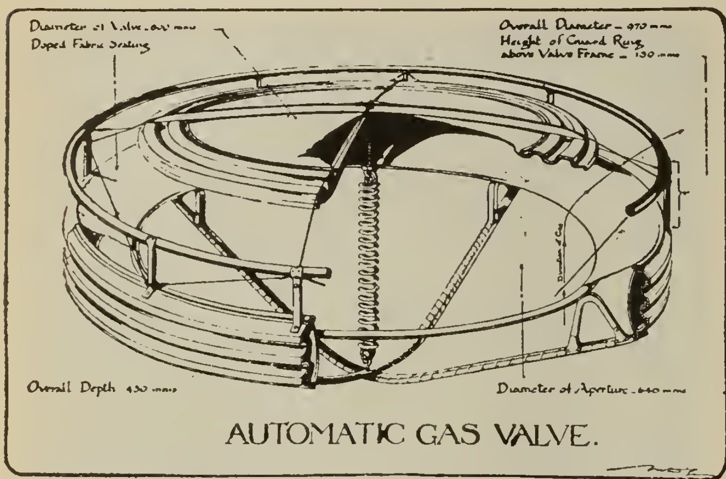

Figure No. 39.—Automatic Valve R.34 Class.

In order to determine the degree of comfort provided for the passengers, it would be necessary to take an extended trip in the airship, because the accommodation is entirely different from that provided in any other form of public transportation.

Other Airships

The R. 100

The R. 100 is a ship very similar to the R. 101; it is being constructed by the Airships Guarantee Co., a private company subsidized by the Government. In this ship the general principles mentioned in connection with the R. 101 are employed, but in this case the methods of construction are different.

In the R. 101 the booms for the frames and longitudinals were made of stainless steel, whereas in the R. 100 they are made from a special form of duralumin tube, which is the subject of a patent held by the Airship Guarantee Company.

These duralumin tubes are made up from sheet metal cut into strips and rolled in a spiral to form a round tube. The joint is connected by a spiral row of rivetting, and a special machine has been invented for carrying out the manufacture of these tubes, (figure No. 45).

The power units in the R. 100 are also different from those used in the R. 101, in that they are gasoline engines

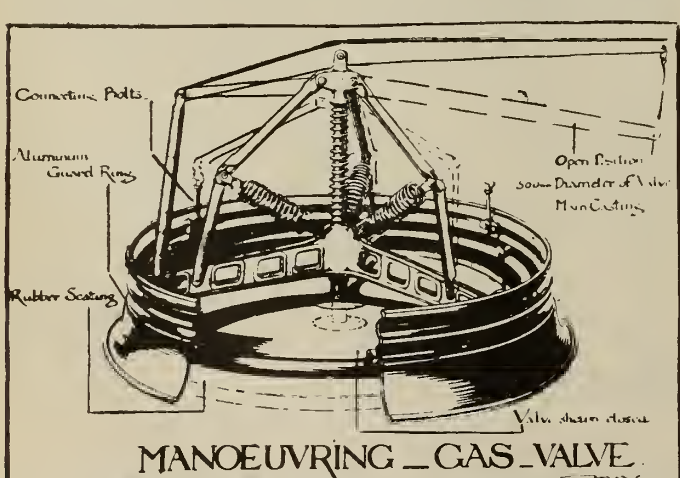

Figure No. 40.—Manoeuvring Gas Valve.

of the type which has been developed for heavier-than-air use. Very little published data are as yet available upon this airship.

Metalclad Airship

The first rigid airship to be constructed was made by Schwartz and consisted of an aluminum shell filled with lifting gas. The fact that this type of airship construction was not continued was due to a combination of circumstances, among which was the accident that occurred during the first flight, and the death of Schwartz before the completion of the ship.

The metalclad airship now being used in the United States follows the principles started by Schwartz, and consists of an "alclad" envelope, which itself serves not only as the structure of the ship, but also as the envelope for holding the lifting gas. This first ship called the Z.M.C. 2, (figure No. 46), is 149 feet 5 inches long and is 52

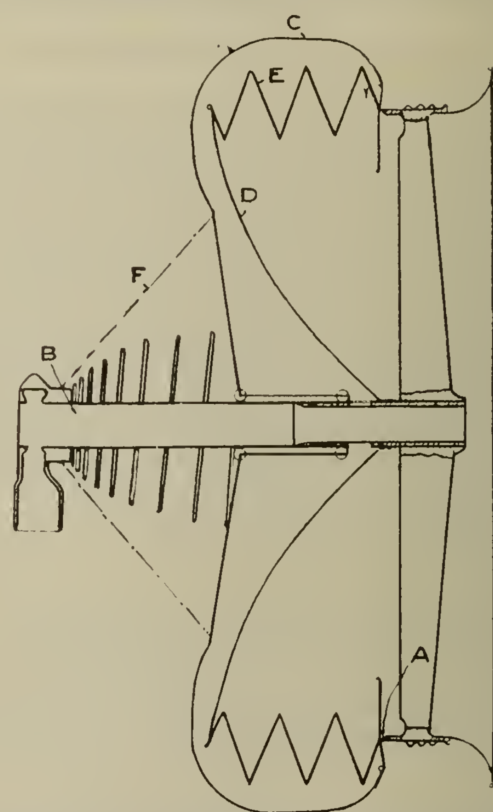

Figure No. 41.—Diagrammatic Arrangement of Gas Valve, R.101.

feet 8 inches in diameter with a fineness ratio of 2.83 to 1. It has a displacement of about 200,000 cubic feet.

The power is supplied by two Wright whirlwind, air cooled, radial engines of about 200 h.p. each. The thickness of the outer skin is 9½ thousandths of an inch.

This ship of small size is constructed more for the purpose of demonstrating the feasibility of this type of construction than for any idea of using it for commercial aviation. In order to construct a ship of this type it was necessary to invent a machine for carrying out the rivetting, which is now done by an exceedingly ingenious machine. This machine cuts off the wire into the length required for the rivets, punches the holes in the two plates, and fastens the rivets along three lines of rivetting in one operation with a minimum of labour. It is claimed that

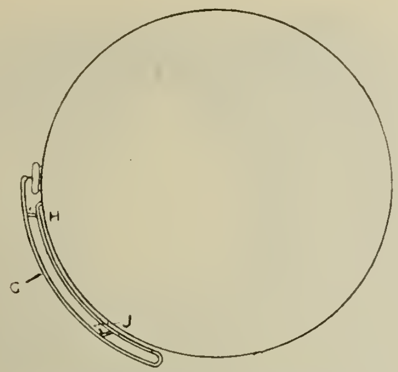

Figure No. 42.—Arrangement of Gas Valve Siphon Pipe.

this machine has successfully driven 3½ million rivets of 0.035 inch diameter with only one-third of one per cent defective rivets.

The airship is provided with internal ballonets for maintaining the gas pressure, and when filled with helium it is estimated it will have a gross lift of 12,242 lbs., of which the useful load is 3,442 lbs. The difficulties of inflating a ship of this kind were mentioned when dealing with the Schwartz airship.

It is understood that to inflate the Z.M.C. 2 the ship was first filled with carbon dioxide, which was in turn allowed to flow out from the bottom at the same time that the helium entered from the top of the ship. This airship has now been completed, and is undergoing trials, which will be watched with the keenest interest.

United States Airships

The United States Navy has placed contracts for two airships of approximately 6,000,000 cubic feet capacity,

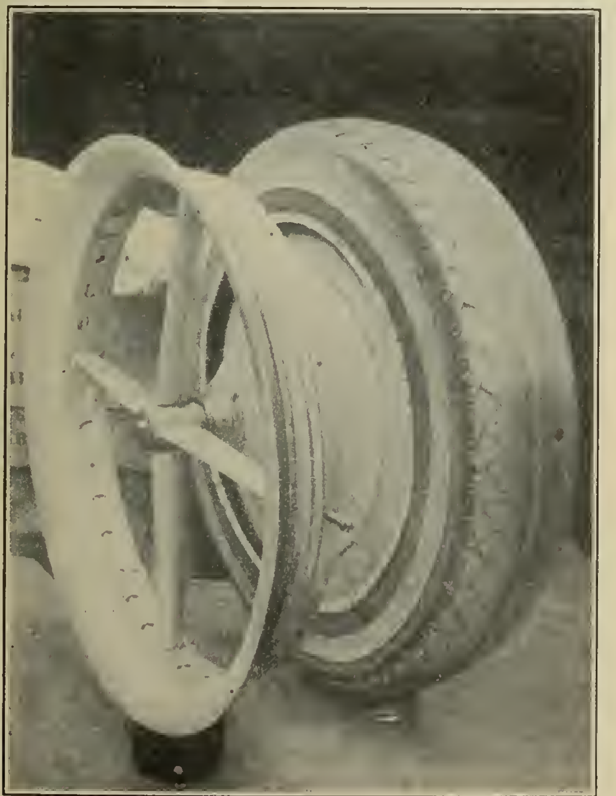

Figure No. 43.—Gas Valve R.101.

Figure No. 44.—Passenger Accommodation R.101.

but unfortunately details of these airships were not available at the time of writing this paper. An indication, however, of the trend of thought in the United States can be obtained from a recent paper by Karl Arnstein of the Goodyear Company, who was until recently connected with the Zeppelin Company.

In the transactions of the American Society of Mechanical Engineers Mr. Arnstein describes a proposed 7,000,000 cubic feet ship for commercial purposes, particularly for trans-Atlantic service. The dimensions mentioned are a length of about 800 feet with a diameter of about 132 feet, giving a fineness ratio of about 1 to 6, which is very much in keeping with the proportions of the British ships.

The type of transverse frame proposed for these large ships is the type now being used in the British ships, but in the large Goodyear ship it is interesting to note that it is proposed to use four longitudinal keels, (figure No. 47). The two side keels are intended for the accommodation of passengers and as promenade decks, and these keels are described in the paper as giving a great increase to the longitudinal strength of the ship, and forming a valuable support to the intermediate rings.

Conclusion

A consideration of the rather extensive campaign of criticism that has been raised against the airship led the author to investigate the history of steamships, and in this connection the following extracts from the Encyclopaedia Britannica are not without interest:—

"It was in 1815 that the first steamship began to ply between the British ports of Liverpool and Glasgow. In 1826 the 'United Kingdom,' a leviathan steamship, as she was considered at the time of her construction, was built for the London and Edinburgh trade."

"Isolated voyages by vessels fitted with steam engines had been made by the 'Savannah' from the United States in 1819 and by the first 'Royal William' from Canada in 1833."

Considerable competition arose over the ocean services, and there was a race between three companies to put ships into the ocean service.

"The London Company chartered the "Sirius," a 700-ton steamship, and despatched her from London on the 28th of March, 1833. She eventually left Cork on the 4th of April and reached New York on the 22nd, after a passage of seventeen days." Trouble over took all three

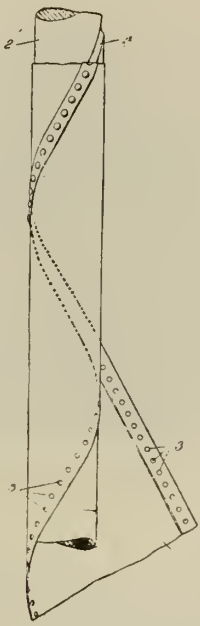

Figure No. 45.—Construction of Booms R.100.

of these early Atlantic Companies, and they soon ceased to exist. Perhaps the most serious factor against them was the success of Mr. Samuel Cunard in obtaining the Government contract for the conveyance of mails from Liverpool to Halifax and Boston.

The following extract indicates that all was not plain sailing.—

"The London Company put a second ship, the, 'President,' on their station. She was lost with all hands, no authentic information as to her end ever being obtained. Her mysterious fate settled the fortunes of her owners."

The next sentence, however, indicates that even disasters of this kind did not prevent development:—

"Steam navigation across the Atlantic was now an accomplished fact, but all the three pioneers had been borne down by the difficulties which attend the carrying out of new departures."

It is evident from the consideration of even a few quotations such as those given above that the development of steamships for ocean travel was not prevented by initial difficulties in the construction of the ship and in financing the Companies. It is interesting to consider what the future might have been if a century ago steamship construction had been stopped as a result of the difficulties that were being experienced.

Figure No. 46.—Metal Airship Z.M.C.2.

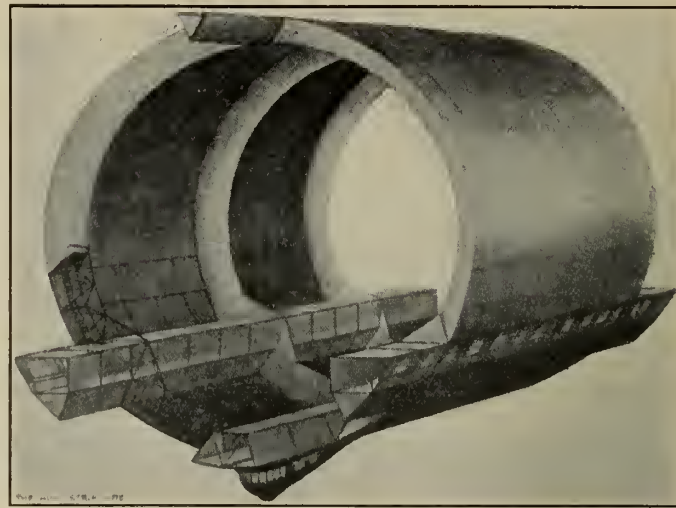

Figure No. 47.—Section of 7,000,000-Cubic Feet Airship.

If we could look forward another century, or even a much shorter time, is it not probable that we should see just as great developments in air navigation and in the airship itself as we can see by looking back on the development that has taken place in the past century in steamships?

We must always remember that rigid airship construction has all taken place within the memory of comparatively young men, and most of the members of this Institute will be able to recall the excitement caused by the initial flights of the Zeppelin airships. The enforced construction during the war period caused unnatural development of the ships in advance of the art of design; since the war more adequate time and talent have been available for research, with the result that rapid progress has been made both in the design and construction of ships of this type, and now it would appear that all that is necessary is a reasonable amount of encouragement and public interest during the period that airship builders and operators are overcoming their initial difficulties.

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XIII FEBRUARY 1930 No. 2

The Forty-fourth Annual General Meeting

This year the Ottawa Branch has again undertaken the sponsorship of the Annual General and General Professional Meeting. Those who were welcomed by the Branch at the Ottawa meetings in 1919 and 1924 will need no assurance that the Forty-Fourth Meeting, to be held this month, will be well worth attending. Both as regards technical and professional papers and social events, the programme will certainly maintain the well-deserved reputation of Ottawa for successful and thoroughly organized gatherings.

While these features are attractive and important, it should be noted that the Annual General Meeting is the one occasion in the Institute's year on which its work and the proposals of Council for future developments are open to review by the membership at large.

Keen debates have often taken place at our General Meetings, but this year the discussions should be of special interest, and the greater part of the first day of the meeting will probably be devoted to them. The reports of Council and of the various Committees which will then be presented touch on many debatable points, among which may be particularly mentioned those brought up by the Committee on Policy and by the Committee on the Relations of The Institute with the Provincial Associations of Professional Engineers. Both of these deal with problems affecting the future of The Institute as well as its present status and activity.

It was at the Annual General Meeting of 1922 that the general policy and development of The Institute last received special attention, and in that year the Committee on Policy, under the chairmanship of J. B. Challies, M.E.I.C., presented a report which was promptly acted upon, and which suggested many important features of the organization of The Institute as it is to-day. For example that report recommended the representation of the four zones by vice-presidents, and the election of members of Council by Branches instead of by zones as previously; in fact it dealt very successfully with the problems of organization and policy existing at that time. During the eight years which have since elapsed, The Institute has undoubtedly grown greatly in real strength and influence, a result largely due to the sound policy of Council and the steady maintenance of our standards of qualification for admission. Meanwhile the conditions under which engineering work is done in Canada have changed considerably. A much smaller proportion of our members than heretofore are now engaged in consulting work, and a greater number are in the employ of large organizations. More are occupied in highly specialized work, or in engineering work which has definite commercial affiliations, and at the same time there has been a marked development in the organization and activities of the Provincial Associations of Professional Engineers, bodies deriving authority for licensing or registration from their respective provincial legislatures.

The extraordinary industrial growth of Canada during this period gives every prospect of continuance, and with the country, The Institute is bound to continue its development. What are the lines along which this movement can best be directed, in view of the changing conditions as regards the professional activities of our members, and the establishment of the Professional Associations? It must be remembered that these bodies were inaugurated largely as a result of the work of an Institute committee, and in the opinion of Council it is for many reasons desirable that in the future, The Institute shall draw nearer to these organizations rather than take a divergent path.

Acting on this opinion, Council at its Plenary Meeting in October 1929 received and adopted the report of the Committee under S. G. Porter, M.E.I.C., which has for three years been studying this question. This report is one of the most important of those which will be presented at the Annual Meeting. It draws attention first to the lack of uniformity in the various professional engineering acts and in the powers and procedure of the several Associations. It points out further the anomalous situation existing in Canada as regards the diversity in the regulations for admission to the various professional bodies and to The Institute. It then recommends an endeavour to remove this anomaly by making a study of the present requirements of all these bodies, with a view to obtaining agreement between the Professional Associations and The Institute for the adoption of standard uniform regulations for admission to membership.

The report observes that any scheme of this kind must recognize fully the necessity for the effective continuation of the work of the individual Provincial Associations as regards professional licensing and registration. It then remarks that when standard uniform regulations for admission have been accepted by The Institute as well as by the Provincial Associations and have become effective, the next step would be for The Institute to regard membership in a Provincial Association as sufficient evidence of qualification for admission to The Institute. In due time, if supported by the Associations, this course would result in substantial identity of membership, The Institute having accepted the Associations' members; and eventually, with the absorption of those members of The Institute who do not belong to any Provincial Association, and vice-versa, complete identity would follow. The membership of The Institute would then consist entirely of the members of the several Associations. Its Council would be elected by the members of the Associations, and as a confederation of the Associations it would become in the truest sense the representative engineering organization of the country.

Such a scheme as that outlined above cannot of course be entered upon by Council without the support of the membership of The Institute, and for this reason will form an important, if not the chief, subject of discussion at the forthcoming meeting. As already mentioned, if this course is to be followed, it will be necessary to make a comparative study of the present requirements of the Associations and of The Institute to ascertain what changes in our regulations will be necessary. In such an enquiry it will also be needful to consult fully with the various Branch executive committees, many of which are in close touch with the local Professional Associations.

Another important question affecting the development and activities of The Institute will also be submitted, namely the necessity for an increase in the revenue of The Institute. This is a matter which was discussed briefly in the editorial column in the last number of the Engineering Journal, and the enquiry mentioned above is one of the purposes for which additional funds are needed. Evidently the solution of these problems will require the sympathetic cooperation, not only of our own membership, but also of the governing bodies of the various Provincial Associations of Professional Engineers.

OBITUARIES

John Goldsworth Culshaw, A.M.E.I.C.

Members of The Institute will learn with regret of the death of John Goldsworth Culshaw, A.M.E.I.C., which occurred on August 23rd, 1929.

Mr. Culshaw was born at Windle St. Helens, Lancashire, England, on August 31st, 1886, and received his education in the Old Country. He came to Canada in 1907, when he was engaged on construction with the Grand Trunk Railway, first as a rodman and later as instrumentman, field draughtsman, topographer and transitman. From April 1910 to May 1914, Mr. Culshaw was resident engineer in charge of construction with the Grand Trunk Pacific Railway, the latter year and a half being on mountain work. From May 1914 to May 1915 he was levelman and afterwards transitman on preliminary surveys for the Alberta and Great Waterways Railway. On June 10th, 1915, Mr. Culshaw joined the 11th Service Battalion South Lancashire Regiment, and after two and a half years service in France was demobilized with the rank of Lieutenant on April 12th, 1919, returning to Canada in August of that year. Following his return he was attached to the staff of the Commissioner of Irrigation as field draughtsman on reclamation work. In 1927 he was appointed resident engineer with the Canadian National Railways, western region, and at the time of his death he was resident engineer at Neidpath, Sask.

Mr. Culshaw joined The Institute as a Student on October 9th, 1909, and was transferred to the class of Associate Member on September 21st, 1920.

Edward Arnold Thomas, A.M.E.I.C.

Members will learn with regret of the death of Edward Arnold Thomas, A.M.E.I.C., which occurred suddenly on January 4th, 1930 at Saint John, N.B.

Mr. Thomas was born at Runcorn, England on June 21st, 1885, and was educated at grammar school at Bolton, Lancashire, and Silcoats College, Wakefield, Yorkshire, attending the Manchester Technical School in 1902-1903. In 1903-1904 Mr. Thomas was with the Ordnance Survey, Great Britain, and from 1905 to 1907 he was engineering assistant to the Water and Sewerage Department of the city of Saint John, N.B. During this period part of the present Loch Lomond waterway extension was built, and Mr. Thomas was employed on this work. In 1908 he was an instrumentman with the forest survey, and in August of the same year was appointed draughtsman with the Public Works Department of Canada at Saint John. In December 1908, he was named assistant engineer, and in 1911 was appointed to take charge of Courtenay Bay development under the district engineer, Saint John Harbour. From 1915 to 1920, Mr. Thomas served overseas with the Canaadian forces, leaving Saint John as a lieutenant in B. Company, 6th Mounted Rifles. He saw service in France and later was stationed in England, where his engineering abilities were utilized. On his return to Saint John in 1920 he was again placed in charge of the Courtenay Bay work, and studies were also made for development of ocean terminals there. In 1927 Mr. Thomas resigned to accept the position of senior on the staff of the Saint John Harbour Commission.

Mr. Thomas took a keen interest in the affairs of The Institute, being on the Executive Committee of the Saint John Branch in 1926, Vice-Chairman in 1927, and Chairman at the time of his death. He joined The Institute as an Associate Member on December 18th, 1923.

Arthur Edward Eastman, A.M.E.I.C.

It is with deep regret that we record the death of Arthur Edward Eastman, A.M.E.I.C., which occurred at Cardinal, Ontario, on June 18th, 1929.

Mr. Eastman was born at Petitcodiac, N.B., on December 26th, 1880.

Following his graduation from the University of New Brunswick in 1906, with the degree of B.A.I., Mr. Eastman was for two years rodman and leveller on the Ontario-St. Lawrence Canals, for the Department of Railways and Canals, and from 1908 to 1910, he was assistant resident engineer on the same work. In 1910-1911 he was a detailer in the draughting room of the Dominion Bridge Company, being engaged on general draughting. In 1911 Mr. Eastman again became connected with the Department of Railways and Canals as assistant resident engineer in charge of improvements to the Morrisburg and other canals. He was engaged on this work until 1916, when he was for a short time instrumentman on the Toronto harbour improvement for the Canadian Stewart Company. In 1917 Mr. Eastman returned to the Dominion Bridge Company for a short period of time. From 1917 to 1921 he was on the staff of the Canadian Steel Corporation at Ojibway, Ont., as inspector, draughtsman and was also doing general field and office work on steel plant construction. In 1921-24, Mr. Eastman was located at Ogdensburg, N.Y., and in 1924 he became general assistant engineer on hydro-electric construction for the St. Lawrence Valley Power Company of Potsdam, N.Y., and remained with that firm until 1926, when he joined the staff of the Central Maine Power Company of Augusta, Maine, as general assistant engineer on hydro-electric construction and remained with that firm until the time of his untimely death.

Mr. Eastman joined The Institute as an Associate Member on March 16th, 1915.

Joseph Aimé Godefroy Goulet, M.E.I.C.

It is with deep regret that we record the death of Joseph Aimé Godefroy Goulet, M.E.I.C., which occurred suddenly on December 16th, 1929 at Peterborough, Ont.

Mr. Goulet was born at St. Eustache, Que., on October 22nd, 1868, and received his education from McGill University and the Ecole Polytechnique, Montreal, graduating from the latter institution in 1890 with the degree of M.E.

Following graduation, Mr. Goulet was in charge of the testing department of the Deane Stream Pump Company at Holyoke, Mass., until 1891. In 1891-1892 he was engaged on the sounding of the Saguenay river and relocating buoys and giving alignment for same. In 1892 and 1893, he was located in Toronto, as mechanical engineer and superintendent of the Northey Manufacturing Company. In 1893-1894 Mr. Goulet was engaged in work for the Columbian Exposition at Chicago in the agricultural machinery department. In 1894-1896, he was superintendent of dredging and mechanical engineer in charge of designing and construction at the Government shipyard, Sorel, Que., and from 1896 to 1899 he was mechanical engineer and chief designer with the Northrup Loom Company of Canada at Valleyfield, Que. From 1899 to 1900, Mr. Goulet was mechanical engineer and chief designer with the Draper Corporation of Hopedale, Mass., U.S.A., and from 1900 to 1901 he was master mechanic with Isaac Mautner and Sohn, Vienna, Austria and Buda-Pesth, Hungaria. In 1901 Mr. Goulet returned to Canada and became designing draughtsman at the Montreal plant of the Canadian General Electric Company, and has remained on the Company's mechanical staff since that time being mechanical engineer at the time of his death.

JOSEPH AIMÉ GODEFROY GOULET, M.E.I.C.

Mr. Goulet joined the Canadian Society of Civil Engineers as an Associate Member on March 16th, 1899, and transferred to the class of Member on January 26th, 1920.

Henry Holgate, M.E.I.C.

In the death of Henry Holgate, M.E.I.C., which occurred at Montreal, Que., on January 21st, 1930, a well-known figure has passed from the engineering profession. Mr. Holgate was born at Milton, Ont., in 1863 and received his education at schools in Toronto. In 1878 he was apprenticed under the late Colonel F. W. Cumberland to the Northern Railway of Canada, later absorbed by the Grand Trunk Railway. From 1878 until 1891 he was connected with railway construction and maintenance, then until 1894 with bridge and structural engineering. In 1894 he entered the service of the Royal Electric Company at Montreal, and built and operated the Montreal Park and Island Railway. In 1898 Mr. Holgate went to Jamaica as manager of the West India Electric Company, and there built and operated the hydro-electric tramway system in Kingston. Returning to Montreal in 1901 he entered into partnership with R. A. Ross, D.SC., M.E.I.C., and for ten years the firm were engineers to many enterprises, and constructed a number of hydro-electric plants including the West Kootenay Power Company and the Canada Copper Company. This partnership was dissolved in 1911. While Mr. Holgate gave much attention to hydro-electric development, he followed a general practice. He investigated for the Dominion Government in 1906, matters regarding the Trent Valley canal, and was appointed by the Government as chairman of the Royal commission of enquiry into the collapse of the Quebec bridge in 1907, his report being issued in 1908. As one of a board of consulting engineers, he reported on the future development of Montreal harbour in 1909. He was president of the Cedar Rapids Power Company in 1911, afterwards becoming its consulting engineer. The last important work undertaken by Mr. Holgate was the exhaustive study of and report upon the proposed St. Lawrence deep waterway which he carried out in association with J. A. Jamieson, M.E.I.C., of Montreal, at the request of the Montreal Board of Trade.

Mr. Holgate was a member of the American Society of Civil Engineers, and the Engineers Club of Montreal, of which he was president, and was on the board of management of the Montreal General Hospital.

Mr. Holgate joined the Canadian Society of Civil Engineers as a Member on December 1st, 1887. He was a Councillor of the Society during the years 1906 and 1908, and was a vice-president in 1911 and 1912.

John Harrison Turner, M.E.I.C.

Members will learn with deep regret of the death of John Harrison Turner, M.E.I.C., which occurred at Lethbridge on December 11th, 1929 after a prolonged illness.

Mr. Turner was born at Liverpool, England in 1863. He studied engineering at University College and City and Guilds College, London, England, and in 1879-1883, was pupil of and assistant to the late Sir W. E. Garforth, developing and fitting up coal mines in England. Following this Mr. Turner was for a time surveyor and assistant manager of the Massarelos Foundry, at Oporto, Portugal, and later was engaged on the design and erection of pumping engines for the Kimberley Water works, South Africa. He was for a time engaged on the construction of wharf and buildings and the installation of plant for ice making, grain cleaning and pumping at Bushire, Persia, and following that erected buildings and installed the plant for a large lumber mill at Peterborough, England. From 1890 to 1904 Mr. Turner was resident engineer in charge of construction of four power stations, and was assistant superintendent and superintendent of the London Hydraulic Company, England. From 1904 to 1910 Mr. Turner was owner and manager of the Wiltshire Foundry, manufacturing oil and gas engines, agricultural machinery, water and sewage plants, and from 1910 to 1915, he was contracting on bridges, and sewage and water works in Alberta and Saskatchewan. In 1914 when war broke out Mr. Turner was contracting in Lethbridge, having completed the Ninth street overhead bridge. Contracting work being at a standstill, he accepted a position with the Dominion Government Reclamation Service in Calgary. In 1917 he moved to Coalhurst Alta., where he was engaged as mine surveyor at the North American Collieries. In 1919 he passed the examination for his mine surveyor's certificate. In 1922 he moved to Lethbridge, and since that time he has been engaged in mine surveying and as mine manager, having acted in the latter capacity at the old Taylor Mine, the Majestic Mine at Taber and also the Federal Mine at Lethbridge. During the last two or three years ill health has prevented him from following his profession. Mr. Turner was a member of the Canadian Institute of Mining and Metallurgy. He was elected a Member of The Institute on May 22nd, 1922.

Bartholomew Brosnan Kelliher, M.E.I.C.

In the death of Bartholomew Brosnan Kelliher, M.E.I.C., which occurred in a nursing home in London, England, on November 7th, 1929, The Institute has lost a most distinguished member.

Mr. Kelliher was born at Castle Island, Ireland, on December 26th, 1862, and was educated at the Kilmurry and Castle Island national schools and was later apprenticed to James Dillon, M.I.C.E., of Dublin. In 1884, Mr. Kelliher came to the United States and for a time was employed as draughtsman, topographer, transitman and assistant engineer with various railways. In 1890-1896 he was resident and assistant engineer with the Northern Pacific Railway and in 1896-1897 he was assistant engineer with the Union Pacific Railway. In 1897-1898, Mr. Kelliher was mining engineer with the Annaconda copper mines at Butte, Montana, but in 1898 he returned to railway engineering. Mr. Kelliher is of course best remembered as the builder of the Grand Trunk Pacific Railway. At the time that he undertook this work it was considered impossible to build a railroad through the Rocky Mountains with only a four-tenths of one per cent grade, yet Mr. Kelliher accomplished this, and as a result the Grand Trunk Pacific has the lowest mountain grade in the world. From 1906, Mr. Kelliher was chief engineer of the Grand Trunk Pacific Railway. In 1921 he was assistant to the president of the Denver and Rio Grande Western Railway Company at Denver, Colorado and in 1925 he returned to Ireland. Mr. Kelliher was elected a Member of the Canadian Society of Civil Engineers on April 19th, 1906.

Nathan Ernest Mules, S.E.I.C.

It is with much regret that the untimely death of Nathan Ernest Mules, S.E.I.C., which occurred at Montreal on December 20th, 1929 is recorded.

Mr. Mules was born at Baltimore, Maryland, U.S.A. on May 9th, 1904. He graduated from McGill University in 1927 with the degree of Ph.D., and in the same year became a part time demonstrator at the same university, and a candidate for the degree of B.Sc. In February 1928, while he was still engaged on this work, Mr. Mules' health broke down, and after that time he was unable to engage in anything but private tutoring.

Mr. Mules joined the Institute as a Student on November 25th, 1924.

John Bennett Briggs, A.M.E.I.C.

The death of John Bennett Briggs, A.M.E.I.C., which occurred at Clacton-on-Sea, England, on October 29th, 1929, is recorded with much regret. Mr. Briggs had been in failing health for some time.

Mr. Briggs was born at Arbroath, Scotland, on June 30th, 1874. He received his education at Arbroath High School and Dundee College (St. Andrews University) graduating from the latter institution with the degree of B.Sc. in 1895.

Mr. Briggs came to Canada in 1903, and located in Toronto. He was for a time with the Gutta Percha and Rubber Company. In 1904, he was with J. A. Jamieson, M.E.I.C., Montreal as draughtsman. In 1905 he was engaged on grain elevator work with the Dodge Company, Toronto, and was later employed by the Consumers Gas Company, as draughtsman in charge of extension work, etc. In 1909 he was again on the staff of Mr. J. A. Jamieson, later becoming connected with Messrs. Alex. Pringle and Son. In 1910-1912 Mr. Briggs was with John S. Metcalfe and Company on grain elevator work. He was later employed by Westinghouse Church Kerr and Company. Mr. Briggs was subsequently in private practice as a consulting engineer in Toronto. During the war he rendered valuable service in connection with munition work first in Canada and then in the United States.

Mr. Briggs was elected an Associate Member of The Institute on June 10th, 1913.

George John Nelson, A.M.E.I.C.

Deep regret is expressed in recording the death of George John Nelson, A.M.E.I.C., which occurred at Montreal Que. on January 21st, 1928. Mr. Nelson was born at Montreal, Que. on November 18th, 1876. He graduated from McGill University in 1900.

Following graduation, Mr. Nelson joined the staff of the Lachine Rapids Hydraulic and Land Company, which company was later purchased by the Montreal Light, Heat and Power Company. In 1905, Mr. Nelson became associated with Mr. R. S. Kelsch, M.E.I.C., in connection with the Kaministiquia Power Company's development at Fort William, Ont. Mr. Nelson's connection with Mr. Kelsch continued and in 1925 he took over the latter's practice. In 1928, Mr. Nelson became electrical engineer with the Fraser-Brace Engineering Company Ltd., Montreal.

Mr. Nelson joined the Canadian Society of Civil Engineers as a Student on March 16th, 1899, and was transferred to the class of Associate Member on October 11th, 1906.

PERSONALS

C. E. Hedley, S.E.I.C., has joined the staff of the Alcoa Power Company, Ltd., at Arvida, Que.

W. F. Guenther, S.E.I.C., who has, since 1924, been on the staff of the Hamilton Hydro-Electric Company, Hamilton, Ont., is now connected with the Standard Underground Cable Company of Canada, Ltd., at Hamilton. Mr. Guenther graduated from the University of Toronto in 1923 with the degree of B.A.Sc.

I. W. Boyd, S.E.I.C., who graduated from Queen's University in 1924 with the degree of B.Sc., obtaining the degree of M.Sc., in 1926, is now connected with Siscoe Gold Mines, Ltd., and is located at Amos, Que. Mr. Boyd was formerly on the staff of the Ingersoll-Rand Company at Phillipsburg, N. J. and later at Montreal, Que.

J. Jackson Crawford, A.M.E.I.C., a member of the staff of the Canadian Cellulose Company Ltd., at Cornwall, Ont., has been transferred to the Canada Paper Company at Windsor Mills, Que. Mr. Crawford is a graduate of the University of Toronto of the year 1922, and before becoming connected with the Canadian Cellulose Company he was chemist with Price Brothers and Company Ltd., at Kenogami, Que.

J. T. Rose, A.M.E.I.C., who has been with the Dominion Water Power and Reclamation Service since July 1914, has been appointed resident inspecting engineer for the Dominion Government. He is located at the City of Winnipeg power development on the Winnipeg river at Slave Falls, Man. Mr. Rose graduated from the University of Toronto with the degree of B.A.Sc. in 1915.

J. T. Thwaites, S.E.I.C., is now attached to the engineering department of the Canadian Westinghouse Company, Hamilton. In 1927 Mr. Thwaites was connected with Smart Turner Machine Company, Ltd., Hamilton, and in 1928, with the Wentworth Radio Supply Company, Ltd., Hamilton.

A. C. Knapp, S.E.I.C., who has been on the engineering staff of the Carborundum Company at Niagara Falls, N.Y., since graduating from Queen's University in 1927, has just returned to Niagara Falls after spending five months at Shawinigan Falls, Que., where he was in charge of the construction of a new furnace building for the Canadian Carborundum Company, Ltd.

W. H. Slinn, A.M.E.I.C., who was formerly engineer of special studies, Montreal division plant, Bell Telephone Company of Canada, Ltd., is now located at Hamilton where he is the company's Division Engineer. Before becoming connected with the Bell Telephone Company, Mr. Slinn, who graduated from Queen's University in 1916 with the degree of B.Sc., was assistant engineer on construction with E. G. M. Cape and Company.

J. R. Reid, A.M.E.I.C., gave up municipal engineering in April 1929 to become superintendent of construction for Foley Bros. Ltd., of Winnipeg, confining himself to highway construction on No. 1 Highway. In December 1929, Mr. Reid severed his connection with Foley Bros., Ltd. and reorganized a new company registered in Saskatchewan as the Western Engineering Company Ltd., with head office at Regina, Sask., of which Mr. Reid is president and managing director.

R. B. Winsor, Jr.E.I.C., has resigned his position on the engineering staff of the International Power and Paper Company of Newfoundland, Ltd., at Corner Brook, Nfld. and has joined the engineering staff of Canadian Industries Ltd., Montreal. Mr. Winsor graduated from McGill University with the degree of B.Sc. in May 1927, and immediately became construction engineer with W. I. Bishop Ltd., on paper mill construction for the Anglo-Canadian Pulp and Paper Mills Ltd., at Limoilou, Que.

Adhemar Laframboise, A.M.E.I.C., civic engineer of Lachine, Que., who has been in the service of that municipality since 1914 has resigned from that position. Mr. Laframboise graduated from the Ecole Polytechnique, Montreal, in 1911, and from August 1911 to March 1912 was structural engineer for the National Transcontinental Railway at Ottawa. From March 1912 to November 1913 he was employed as designer and draughtsman by the Dominion Bridge Company, at Lachine, Que.

Robert Ford, A.M.E.I.C., was appointed plant engineer of the Papineau factory of the Dominion Rubber Company, Montreal, at the beginning of the current year, having been, for several months, on the engineering staff of that company. Mr. Ford, who graduated from McGill University in 1922 with the degree of B.Sc. was resident engineer with the British Columbia Pulp and Paper Company Ltd., at Port Alice, B. C. prior to becoming connected with the Dominion Rubber Company.

Donald A. Killam, Jr.E.I.C., who was formerly connected with the International Power and Paper Company Corner Brook, Nfld., has joined the engineering staff of Canadian Industries, Ltd., at Montreal. Mr. Killam graduated from McGill University with honours in civil engineering in 1927. Shortly after graduation Mr. Killam was appointed to the staff of the Abitibi Fibre Company, Ltd., at Smooth Rocks Falls, Ont. In 1928 he was attached to the engineering department of the Canada Power and Paper Corporation at Montreal.

Kenneth Reid, Jr.E.I.C., has become assistant chief electrician of the Consolidated Mining and Smelting Company of Canada, Ltd., at Tadanac, B.C. Following graduation from McGill University in 1926 with the degree of B.Sc., Mr. Reid was for a time on the staff of the Canadian General Electric Company, Ltd., at Peterborough, Ont., and prior to accepting his present position, he was junior engineer in the electrical engineering department of the British Columbia Electric Railway Company at Vancouver, B.C.

R. S. L. Wilson, M.E.I.C., has been appointed Dean of the Faculty of Applied Science of the University of Alberta, Edmonton, Alta. Mr. Wilson graduated from McGill University in 1911 with the degree of B.Sc. and from 1912 to 1915 was in charge of purchasing, costs, subcontracts and latterly estimating with R. J. Lecky and Company, Ltd. engineers and contractors, Regina, Sask. From 1915 to 1919 Mr. Wilson was lecturer and demonstrator in mathematics and civil engineering at McGill University, and from 1919 to the present time he has been Professor of Civil and Municipal engineering at the University of Alberta.

P. M. Knowles, A.M.E.I.C., chief draughtsman, engineering department, Bell Telephone Company, Montreal, has been transferred to the Company's Toronto office. From 1916 to 1919, Mr. Knowles was on active service as a lieutenant in the Canadian Engineers, in 1917 and 1918 being officer commanding section of field company of army engineers in France on water supply, road making, bridging, construction of buildings, supervision of corps workshops. From 1919 to 1924, Mr. Knowles was draughtsman and inspector of works J. M. Miller, A.R.C.A., architect, and has held his present position since 1925.

Major R. A. Logan, A.M.E.I.C., who returned to this country during the latter part of 1929 after having been in Rhodesia, South Africa since 1927, where he was first located at N'Changa Nia N'Dola, Northern Rhodesia, as Manager, Aircraft Operating Company, African Aerial Survey, and later at Bulawayo, Southern Rhodesia, where he was manager of the African Expedition Aircraft Operating Company, Ltd., is now attached to the operations department of the Pan American Airways, Inc., and recently completed an aerial tour of the West Indies. Major Logan is a graduate of the Nova Scotia Technical College, from which he received a diploma in 1911.

Major F. R. Henshaw, A.M.E.I.C. is now at Headquarters, Military District No. 3, at Kingston, Ont. Major Henshaw graduated from the Royal Military College, Kingston in 1911, and from 1911 to 1913 attended the School of Military Engineering, at Chatham, England. In 1914 he was division officer for the Maritime Provinces, Military District No. 6, and in 1915 was chief instructor, Canadian Engineers Training Depot, in England. From 1916 to 1919, Major Henshaw served with various Canadian Engineer units in France and England. He was chief instructor at the School of Military Engineering at Halifax, N.S. and in January 1928 was attached to the Staff College at Quetta, India, returning to Canada in April 1928. Since that time Major Henshaw has been located at Ottawa with the Department of National Defence.

J. W. McCammon, A.M.E.I.C., has resigned from the Charles Walmsley Company (Canada) Ltd., Montreal, to become manager of the commercial department of the Beauharnois Power Company, Montreal. Mr. McCammon graduated from McGill University in 1912 with the degree of B.Sc., and later took an apprentice course with Canadian Westinghouse Company at Hamilton, Ont. Following this he was for one and a half years assistant to the mechanical and electrical engineer of Mackenzie Mann and Company on the Mount Royal Tunnel, Montreal, and later was for nine years manager of the pump and electrical departments of Canadian Fairbanks Morse Company, Montreal. Mr. McCammon enlisted in April 1915 with the 6th Siege Battery, was commissioned with the Royal Garrison Artillery in June 1917, transferred to Canadian Garrison Artillery with rank of lieutenant in October 1918 and demobilized in 1919.

W. S. Lee, M.E.I.C. has received the official nomination for president of the American Institute of Electrical Engineers. Mr. Lee has been a pioneer in high voltage power developments and transmission. He is a native of Lancaster, S.C., and was awarded the degree of civil engineer by the Citadel, the military college of South Carolina. Following his early engineering experience, he was appointed resident engineer at the Anderson (S.C.) Light and Power Company in 1897, resident engineer of the Columbus (Ga.) Power Company in 1898, and chief engineer of the latter in March 1902. One year later he was appointed chief engineer, and in October of that year vice-president and chief engineer of the Catawba Power Company, Charlotte, N.C. This company was a subsidiary of the Southern Power Company, and in 1905 he became chief engineer of the latter company. He later received the appointment of vice-president and chief engineer, which position he held for about fifteen years. He is at present vice-president and chief engineer of the Duke Power Company. Among Mr. Lee's other connections are the following: president of the W. S. Lee Engineering Corporation, president and chief engineer of the Piedmont and Northern Railway Company, vice-president and chief engineer and director Duke Power Company, Wateree Power Company, Western Carolina Power Company, Catawba Manufacturing and Electric Power Company, director, American Cyanamid Company, vice-chairman and trustee of the Duke Endowment. He is also engaged in practice as a consulting engineer with an office in New York City and Charlotte, N.C., and is at present engaged in that capacity in connection with the power development on the St. Lawrence river at Beauharnois, Que., of the Beauharnois Light, Heat and Power Company.

Colonel J. S. Dennis Retires from C. P. R.

Colonel John Stoughton Dennis, C.M.G., D.L.S., D.T.S., M.E.I.C., Chief Commissioner of Colonization and Development, of the Canadian Pacific Railway Company, retired on January 1st, 1930 after twenty-eight years' service with the company. But while Colonel Dennis has retired from his position as active head of the company's Colonization and Development, he will continue to act in an advisory capacity to the company's directors.

Colonel Dennis was born at Weston, Ont., in 1856. As a youth he studied surveying and soon secured the degrees of Dominion Land Surveyor and Dominion Topographical Surveyor. Going west as a very young man, he has played an important part in the development of the prairie provinces, and before the prairie provinces were formed, had risen to the position of Deputy Minister of Public Works, and chief engineer of the Northwest Territories, whose capital was then Regina. The important work he did as land commissioner for the Hudson Bay Company and in the developing of irrigation in the west, as well as the successful direction of the public works there, attracted the attention of the Canadian Pacific Railway Company, the officials of which induced him in 1903 to join the staff of the Canadian Pacific Railway Company as assistant to the second vice-president. In 1912 he was made assistant to the president which position he occupied until 1917 when he was given the appointment from which he has just retired. From 1915 to 1917 Colonel Dennis was head of the Canadian Mission in the United States and second in command of the British-Canadian Mission. In 1918 he was chairman of the Siberian Trade Commission, and was attached to the Intelligence Staff, and was in command of transportation and supplies, work enough for any ordinary three men. He was awarded the honour of

Col. J. S. Dennis, M.E.I.C.

the C.M.G. by His Majesty the King, and was also decorated by the Serbian and other governments for the part he played.

Colonel Dennis was elected a Member of the Canadian Society of Civil Engineers on November 21st, 1901; he was a member of Council in the years 1906 and 1911; he was elected a vice-president in 1907, and he became President in 1917.

Vice-President and Manager of National Bridge Company of Canada

E. S. Mattice, M.E.I.C., who for four years was manager and chief engineer of Steel Gates Company, Ltd., St. Catharines, Ont. in charge of the construction and erection of the steel gates of the new Welland Ship Canal, has been appointed vice-president and manager of the National Bridge Company of Canada, Ltd., and is located at Montreal, Que. Mr. Mattice was born at Cornwall, Ont. on December 15th, 1870 and received his education at Upper Canada College, Toronto, and McGill University, graduating from the latter institution in 1890 with the degree of B.A.Sc. Following graduation Mr. Mattice was on the staff of the Dominion Bridge Company Ltd., in 1891, with the Dominion Government on Cornwall canal from1891 to 1893, and with the Norton Iron Works Boston from 1893 to 1894. In 1894 Mr. Mattice again became connected with the Dominion Bridge Company, and from 1895 to 1910 was that Company's Montreal representative. In 1910-1911 he was assistant engineer with the Lewiston Land and Water Company at Lewiston, Idaho. In 1911 Mr. Mattice again returned to the Dominion Bridge Company, this time as contracting engineer. He organized the Structural Engineering Company in 1912, and was contracting engineer from 1918 to 1921. During this time he supervised the design of steel work for a number of large buildings in the city of Montreal including the Sun Life Assurance building, the Drummond building, the Montreal Street Railway building, the Technical school, the Bell Telephone Exchange buildings on Hospital and Ontario streets, and also Macdonald College at St. Anne de Bellevue, Que., the Technical school, Toronto, and the Yorkshire building, and Dominion Immigration building at Vancouver. Mr. Mattice was consulting engineer for Canadian Vickers Ltd., of steel work for the Montreal Harbour Commissioners' Elevator No. 3, he later was managing director of the Phoenix Bridge and Iron Works Ltd., and from 1923 to 1925 was chief engineer of Canadian Vickers Ltd., at Montreal.

E. S. Mattice, M.E.I.C.

ELECTIONS AND TRANSFERS

At the meeting of Council held on January 14th, 1930, the following elections and tranfers were effected:

Members

BILLINGS, Asa White Kenney, A.B., A.M., (Harvard Univ.), Vice-President, Brazilian Traction Light & Power Co. Ltd., Sao Paulo, Brazil.

MacLEOD, Hector John, B.Sc., (McGill Univ.), M.Sc., (Univ. of Alta.), M.A., Ph.D., (Harvard Univ.), professor of elect'l. engrg., University of Alberta, Edmonta, Alta.

PARKIN, John Hamilton, Diploma (Hon.), B.A.Sc., M.E., (Univ. of Toronto), asst. director in dept. of physics and engrg. physics, in charge of aeronautical research, National Research Council, Ottawa, Ont.

Associate Members

GLIDDON, William Gilbert Claude, B.Sc., M.Sc., (McGill Univ.), elect'l. engr., Canadian Hydro-Electric Corporation, Ottawa, Ont.

LILL, Cameron Dennis, engr. and mgr., Regina Branch, Manitoba Bridge and Iron Works, Regina, Sask.

Juniors

ARCHER, John Edward, B.A.Sc., (Univ. of Toronto), engrg. dept., Canadian General Electric Co. Ltd., Peterborough, Ont.

BANKS, Shewell Reginald, B.Eng., M.Eng., (Liverpool Univ.), design dept., Dominion Bridge Company, Ltd., Lachine, Que.

HUNT, John, B.Sc., (St. Andrews, Scot.), asst. designer, Canadian Vickers, Ltd., Montreal, Que.

LAIDLAW, Douglas Staunton, B.A.Sc., (Univ. of Toronto), dftsman., B.G. de Hueck & Co. Ltd., Montreal, Que.

PAULSEN, Rudolph Odin, B.Sc., (Univ. of Man), detailer, Winnipeg Hydro-Electric System, Winnipeg, Man.

Affiliate

GALILEE, John Anthoney Masey, in charge of technical advertising, Canadian Westinghouse Company, Hamilton, Ont.

Transferred from the class of Junior to that of Associate Member

ANDERSON, Dan, B.Sc., (McGill Univ.), elec'l. engr., Power Corporation of Canada, Montreal, Que.

JOHNSTON, Harry Lloyd, B.Sc., (McGill Univ.), plant engr., Canada Paper Company, Windsor Mills, Que.

LESLIE, Roy Campbell, B.A.Sc., M.A.Sc., (Univ. of Toronto), design office, Canadian Bridge Co. Ltd., Walkerville, Ont.

MUIRHEAD, Stuart Robert, B.A.Sc., (Univ. of Toronto), engr., Sask. Govt. Telephones, Regina, Sask.

Transferred from the class of Student to that of Associate Member

HOWES, Frederick Stanley, B.Sc., M.Sc., (McGill Univ.), Ph.D., (Univ. of London), lecturer and lab. demonstrator, dept. of elect'l. engrg., McGill University, Montreal, Que.

Transferred from the class of Student to that of Junior

BINNS, George Frederick, B.Sc., (McGill Univ.), asst. factory engr., Imperial Tobacco Co. of Canada, Ltd., Montreal, Que.

BRUMELL, John Hunter, production engr., Canadian Ingersoll-Rand shops, Sherbrooke, Que.

GRANT, Alexander George, B.A.Sc., (Univ. of Toronto), engr. on constrn. of Hamilton Terminal, Canada Steamship Lines, Russell Construction Co. Ltd., Toronto, Ont.

KEEFLER, Ralph Holley, B.A.Sc., (Univ. of Toronto), general commercial engr., Bell Telephone Company of Canada, Montreal, Que.

Students Admitted

DICKSON, William Leslie, B.Sc., (N.S.T.C.), 231 Bonnaccord Street, Moncton, N.B.

DUTTON, William Lawrason, (Undergrad., Univ. of Toronto), East House, University of Toronto, Toronto, Ont.

HALL, William, (Undergrad., Univ. of B.C.), 1256 Denman Street, Victoria, B.C.

MILLER, William Frederick, (Undergrad., Queen's Univ.), 31 Commercial Street, North Bay, Ont.

PETERS, Henry F., (Undergrad., Univ. of Man.), 132 Colony Street, Winnipeg, Man.

PHILLIPS, Ernest Albert, (Undergrad., Univ. of Toronto), South House, University of Toronto, Toronto, Ont.

SOUTHAM, William Watson, (Undergrad., McGill Univ.), 3434 McTavish Street, Montreal, Que.

BOOK REVIEWS

Select Methods of Metallurgical Analysis

By W. A. Naish and J. E. Clennel. Chapman & Hall, Ltd., London, 1929. Buckram, 6 x 9¾ in., 495 pp., front., illus., figs., tables, $9.00.

This book, dealing as it does with analytical methods, must necessarily discuss matters about which a good deal has been written already. The methods described are those calculated to give accurate results with the expenditure of a reasonable amount of time. The chapters on the metals themselves make this book more complete than the ordinary work of its class, and enable the reader to make an intelligent application of the methods of analysis of complicated products. The presentation of alternate methods of analysis is another good feature of the book, as also is the extensive and complete bibliography attached to each division. The methods outlined give every evidence of including the well tried methods of the past, and also keep the chemist up to date with the latest proved methods for accurate analysis. The amount of detail given in many of the methods is much greater than that commonly employed, and most of us will realize the value of such detail.

To sum up the matter, this book is essentially of a practical nature, and can be recommended as a real contribution to the analytical chemist's library.

HAROLD J. ROAST,
President and General Manager,
National Bronze Company,
Montreal.

The Radio Manual

By George E. Sterling, edited by Robert S. Kruse. D. Van Nostrand Company, New York, 1928, leatherette, 5½ x 8 in., 666 pp., illus., figs., tables, $6.00.

The first paragraph of the preface of this book states that "this work has been prepared to serve as a guide and text book to those who expect to enter the radio profession as an engineer, inspector, commercial or amateur operator." This is a fairly accurate indication of its scope.

The author has not discussed theory except in elementary terms, and only the simplest of mathematical expressions are used. In dealing with the fundamentals, the author has endeavoured to present the subject in simple form in the hope that any one previously unacquainted with the subject might be able to obtain a working knowledge. Apart from the portions covering first principles, the book might be accurately described as a treatise covering current American radio practice. It contains detailed descriptions of typical installations in all fields of radio, and in this respect it should prove very useful, both to the student and the operative engineer. It should also be useful to the specialist for the general information contained therein regarding the branches of the radio field other than his own specialty.

It contains little of the historical background of radio, except in the chapter on amateur short wave apparatus, in which there is a brief outline of the history of the development in the United States. Not much is said as to the progress and development made in other countries.

The author, nevertheless, covers the whole of the radio field exceedingly well in a descriptive manner and gives a comprehensive view of the present state of radio.

J. H. THOMPSON, A.M.E.I.C.,
Canadian Marconi Company,
Montreal.

Basic Principles of Concrete Making

By Franklin R. McMillan, with an introduction by F. E. Schmitt. McGraw-Hill Book Company, New York, 1929, buckram, 6 x 9 in., 99 pages, illus., figs., tables, $2.00.

This book fills a want that has long been felt amongst the students of concrete. It is often said, and truly so, that necessity is the mother of invention. This book was born out of the necessity for putting the whole subject of concrete-making in such simple and lucid form that much of the mist surrounding this subject at the present would be dispelled. The author has succeeded in doing this. Mr. McMillan's little book of one hundred pages, divided into nine chapters, sets forth the fundamental principles underlying the best methods for the production of uniform and durable concrete for whatever service it may be put to. The purpose of the book is not to lay down methods, rules or specifications: it is an exposition of the laws governing the fundamentals on which all methods, rules and specifications should be based in order to obtain uniformity in structures and the anticipated results. As the author says in the preface, "the text is not written for the man at the mixer or the concrete finisher." It is written for the man in responsible charge of the work, in order to give him a thorough understanding of the basic principles involved so that he may set down the necessary instructions or specifications for the work at hand through the personnel of his own organization.

Chapter 1 treats of the philosophy of concrete mixtures. For too long the subject of mixtures has been approached from the wrong end, through fixed proportions, such as 1-2-4 or 1-2½-5 mixtures. The author in a very graphic and original way explains concrete mixtures on the basis of the water-cement paste, the active element of concrete. Now that the water-cement ratio law of Abrams has been thoroughly established it seems to be the next logical step to base the mixture on the water-cement paste, for the concrete cannot be better than the water-cement paste that holds the particles of sand and stone together.

Chapter 1, in the words of the author "is in effect a summary of the entire text stripped of explanation, proof or illustration." Chapter 2 treats of the combined and uncombined water. The combined water is that which through the curing of concrete has become water of constitution or which has chemically reacted with the cement to form new compounds. The uncombined water is the excess that has had to be used to give the concrete the necessary plasticity to render the concrete placeable. Figure 1 in this chapter illustrates very clearly the effects of combined and uncombined water. Chapters 3 to 9 respectively treat of the compressive strength, water-tightness and other properties, combining aggregates with cement paste, design of concrete mixtures, selection of curing period and water-cement ratio, selection of aggregates, importance of proper construction methods. All through these chapters much stress is laid on the quality of the water-cement paste and other salient points in the art of making uniform and durable concrete, such as water-cement ratio, size and grading and type of aggregates, effect of curing and age, necessity of using plastic consistency, cause of segregation and its effects, methods of placing and treatment, effect of temperature, time of mixing, transporting concrete and importance of proper placing, etc.

Many of the principles mentioned in this volume have been enunciated before here and there in concrete literature, but this is the first book to put them all in such clear and concise manner and with such effectiveness. It is a text which can be recommended and should be thoroughly mastered by all those in responsible charge of concrete construction. If the principles contained therein were to be practised, the dawn of a new concrete age would soon arrive.

B. VIENS, M.E.I.C.,
Director, Testing Laboratories,
Dept. of Public Works, Ottawa.

Transmission Networks and Wave Filters

By T. E. Shea. D. Van Nostrand Company, New York, 1929, buckram, 6 x 9 in., 470 pp., figs., tables, $6.50.

This book is an extremely important contribution to the subject of wave filters, the subject of transmission networks being apparently inserted merely as an introduction to the mathematical theory of filters.

The simplest use of such a filter is to convert a distorted alternating current into a pure sine wave by filtering out the harmonics. The theory of filters was first developed by Mr. G. A. Campbell, one of the Bell Laboratories engineers, who in 1915 showed how to make high pass, low pass and band pass filters, Mr. Campbell's work being based on that of Oliver Heaviside, who must be recognized as the founder of transmission engineering. Mr. Campbell's work on filters was developed further by O. J. Zobel and K. S. Johnson at the Bell Laboratories in New York and by K. W. Wagner in Europe. Filters are of great importance in connection with telephone repeaters, radio, carrier current transmission over wire lines, picture transmission over telephone lines, talking moving pictures, and, in fact, all modern developments in the communication art owe much to their use.

This book covers somewhat similar ground to K. S. Johnson's "Transmission Circuits for Telephone Communication," but is more comprehensive, and devotes more space to the subject of filters and less to the theory of networks. There is also a chapter on the resolution of steady state and transient waves into their sine wave components, by means of Fourier analysis.

The book was evidently written for those with some previous knowledge of telephone transmission, in fact, we are told in the preface that it was written for the "out-of-hour courses" at the Bell Laboratories. For those who are unacquainted with transmission theory, we would recommend that before taking up Mr. Shea's work they should read some such book as "The Propagation of Electric Currents in Telephone and Telegraph Conductors," by A. J. Fleming, although much may be learned about filter design from this book without going thoroughly into telephone transmission.

The book will, no doubt, be heartily welcomed by all those who desire a knowledge of electric wave filters as they will find in this volume a great deal of information previously unavailable.

W. B. CARTMEL, M.E.I.C.,
Engineering Department,
Northern Electric Co. Ltd.,
Montreal.

Work of the Ontario Metal Industries Research Association

Industrialists in all parts of the Dominion of Canada will watch with great interest the development of a significant new undertaking sponsored jointly by the metal industries of the province of Ontario and the Ontario Research Foundation.

This is a co-operative movement for the carrying on of a comprehensive plan of research through the organization of the Ontario Metal Industries Research Association which is to act as the link between the Foundaton and the manufacturers.

Active direction of the new organization is completely in the hands of the industries themselves, with an executive composed of forty-six representative individuals from as many different firms acting as the general board which will supervise the work. R. W. Gifford of the Massey-Harris Company, Ltd., Toronto, has been selected as chairman; J. J. Ashworth of the Canadian General Electric Company, Ltd., as honorary treasurer and R. Skelton of the Ontario Research Foundation is secretary. Offices of the association are at 47 Queen's Park, Toronto.

Briefly, the plan of operation is that the Foundation under the chairmanship of Sir Joseph Flavelle and with Dr. H. B. Speakman as director, will provide laboratories, staff and facilities. Overhead and general expenditures of the experimental work are to be borne by the metal industries, through the new organization.

The metal industries of Ontario, therefore, have complete research facilities placed at their disposal without the necessity of shouldering capital costs and their share of the undertaking, basically, consists simply of running expenses.

A thoroughly modern Chemical and Metallurgical Research Building is now nearing completion which is to house the special laboratories for this research and O. W. Ellis, M.Sc., well-known metallurgical engineer, will direct the work of the metallurgical division. After studying at Birmingham University, he was chief metallurgist at the Royal Ordnance Factories, Woolwich, England, later coming to Canada as assistant professor of metallurgical engineering at the University of Toronto. Since that date, he has been associated with the Mellon Institute of Industrial Research in Pittsburgh and the Research Department of the Westinghouse Electric and Manufacturing Company in the same city. As a consultant, he has had wide experience in dealing with the special problems confronting the metal industries in Canada.

Special stress has been laid, in the organization of the O.M.I.R.A. on the practical application of this metallurgical research to plant practice.

"This whole project," says an official announcement just issued, "is based on the view that each company, large or small, is concerned with the business of establishing plant practice on the best possible basis because nothing less permits a legitimate profit on operations or can insure a continuance of business success. Funds raised constitute an investment and a guarantee that whatever the group may accomplish will be available to the individual. As results are obtained, the Foundation will stand ready to assist in their application to your particular business. This latter is a most important consideration."

Already an extensive program of investigation has been mapped out and preliminary work actively commenced. The research will be carried out along the following particular lines:

(1) Macroscopic and microscopic examination and photography of metals, alloys and, if necessary, other solid materials.
(2) Determination of melting points and critical points in steels and other alloys and, under certain conditions, the checking of thermocouples.
(3) Chemical analysis of metallurgical materials.

(4) Mechanical testing of materials in tension, compression, etc., and also the conduct of hardness tests and the calibration of hardness-testing machines.

(5) General investigation of metallurgical processes, such as founding, forging and rolling, with a view to possible improvement.

(6) Investigation of causes of failures in metal parts in service.

(7) Checking of methods of heat treatment of metals and alloys.

(8) Search for information already published in regard to metallurgical processes and the creation of a very complete metallurgical library for the use of members, — for the elimination of unnecessary work and to provide accurate information.

Even a casual glance at the proposed studies, obviously, is sufficient to demonstrate that the new co-operative movement can be of direct and practical assistance to every metal industry in the territory which it is now preparing to serve.

Actual membership covers wide range of manufacturing activity and firms connected with practically every phase of the metal industries in Ontario are all represented. The gist of the scheme lies in the fact that, with research an admitted necessity for present-day industrial progress of every sort, many firms are handicapped for financial reasons due to the heavy burdens it would be necessary for them to shoulder in order to carry on the required work individually. By this means, they can take advantage of complete facilities at an expenditure which is only nominal.

In addition to the officers mentioned above, the newly-elected Council of the Ontario Metal Industries Research Association includes:

J. L. Agnew—The International Nickel Co., of Canada, Ltd.
H. J. Bassett—Galt Malleable Iron Co. Ltd.
Thos. F. Bingham—Otis Fensom Elevator Co. Ltd.
W. J. Blair—Canada Cycle and Motor Co. Ltd.
H. B. Bowen—Canadian Pacific Railway Co.
J. B. Carswell—Burlington Steel Co. Ltd.
H. Champ—Hi-Speed Tools, Limited.
C. V. Corless—Consulting Metallurgist.
A. G. Davis—International Harvester of Canada, Ltd.
L. F. Fitzpatrick—Flexible Shaft Co. Ltd.
T. R. C. Flint—Toronto Hydro Electric System.
W. C. Franz—Algoma Steel Corporation Ltd.
J. G. Fraser—Northern Bolt, Screw and Wire Co. Ltd.
A. R. Goldie—Babcock-Wilcox and Goldie-McCulloch, Ltd.
E. H. Gurney—Gurney Foundry Co., Ltd.
C. B. Hamilton, Jr.—The Hamilton Gear and Machine Co. Ltd.
R. M. Hamilton—Canada Machinery Corpn. Ltd.
H. U. Hart—Canadian Westinghouse Co. Ltd.
R. T. Herdegen—Dominion Forge and Stamping Co. Ltd.
C. J. Ingles—Toronto Hardware Manufacturing Co. Ltd.
C. S. Mackenzie—Ontario Steel Products Co. Ltd.
G. S. Mallett—Anaconda American Brass, Ltd.
H. Malley—Sawyer-Massey, Ltd.
P. F. Mellinger—Canadian Acme Screw & Gear, Ltd.
W. H. Moyse—General Motors of Canada, Ltd.
R. J. Needham—Canadian National Railway.
J. G. Notman—The Welland Vale Mfg., Co. Ltd.
W. O. Oliver—The Steel Co., of Canada, Ltd.
A. P. Page—Frost Steel and Wire Co., Ltd.
N. F. Peterson—Canadian Acme Screw and Gear Ltd.
A. Ross Robertson—Dominion Bridge Co. Ltd.
D. Roden—Roden Brothers, Ltd.
C. W. Sherman—Dominion Foundries and Steel, Ltd.
A. H. Tallman—Tallman Brass and Metal Co. Ltd.
F. Tissington—Tools and Hardware, Ltd.
W. G. Turnbull—The Turnbull Elevator Co., Ltd.
M. F. Verity—Massey-Harris Co. Ltd.
G. N. Wedlake—Cockshutt Plow Co. Ltd.

Widespread general interest in the effort is due to the practicability of applying the same principle to almost any other type of industry in Ontario and the fact that the Ontario Research Foundation is prepared to cooperate, in a similar way, with other manufacturing groups.

International Illumination Congress

(To be held in Great Britain in September 1931).

During recent years there has grown up a general recognition of the value of international conferences, which serve many good purposes, in facilitating unity of action on matters of common interest, in assisting standardization, and especially in promoting exchange of experience, personal intercourse and friendly relations between experts in different countries.

This tendency has been especially evident in connection with illumination. Illuminating Engineering Societies exist in Great Britain and the United States, Germany, Austria, Holland and Japan; and everywhere there are developing organizations which aim at bringing about better lighting.

Experts on such a rapidly developing subject as lighting naturally desire to exchange views and learn of activities elsewhere and this wish has led to continuous growth in the extension of the movement towards international treatment of the subject, which had its origin in the International Photometric Commission, founded in 1901. The expediency of broadening the scope of this body so that all illuminants and all aspects of lighting might be represented was soon recognised. In 1913 effect was given to this desire by the reconstitution of the Commission on a wider basis as the International Commission on Illumination, to which are linked National Committees in all the chief countries of the world. The outbreak of war naturally imposed a check on its development, but subsequently meetings in Paris (1921), Geneva (1924), Bellagio (1927) and New York (1928) revealed continuous progress. The International Illumination Congress and the Session of the Commission held in the United States last year probably formed the most important conference on lighting matters ever held. It was marked by great enthusiasm, being attended by 500 delegates from the following countries:—Austria, Belgium, France, Germany, Great Britain, Holland, Italy, Japan, Sweden, Switzerland and the United States.

It has been decided that the next International Illumination Congress is to be held in Great Britain in 1931. All interested in the cause of better lighting are uniting to render this Congress an outstanding success. In this country the machinery for the study of illumination is perhaps more perfectly organised than in many other places, and the aid of all the leading scientific and technical bodies interested and of organizations concerned with gas and electric lighting is being secured. The National Illumination Committee of Great Britain, in cooperation with the Illuminating Engineering Society, will be responsible for this important event. Several Committees are already at work on the arrangements, fuller particulars of which will be announced in due course.

The International Illumination Congress, which will take place during the period September 3rd to 13th, 1931, will be combined with a Voyage d'Etude of places of interest in England and Scotland so that other cities beside London will share in the work of the Congress. Papers dealing with the most varied aspects of lighting will be presented and these will be grouped so as to ensure that topics of special local interest will be dealt with at each centre. The Congress will be followed by the technical meetings of the International Commission on Illumination, which will be held in Cambridge during September 13th-19th.

The Honorary General Secretary of the Congress is Colonel C. H. Silvester Evans (C/o The Illuminating Engineering Society, 32, Victoria Street, London, S.W. 1) to whom all communications should be addressed.

The Guide Book "Along Quebec Highways"

The most complete tourist guide-book of the Province of Quebec that has ever been published, has just been issued by the Department of Highways.

The publication of this guide-book had been looked forward to with considerable interest for the last few months. It consists of a volume of nearly 900 pages, in which are described all the cities and towns, villages and parishes situated along the provincial highways. It contains most valuable historical, municipal, industrial, commercial and descriptive data.

The opening chapters are devoted to a general description of the province of Quebec. They deal with the geographical position of the province, its history, climatic conditions, physical aspect, mineral wealth, forests and fisheries, agriculture, manufacturing industries, economic situation, good roads system and population.

Then follows a complete and detailed description of each of the fifty main highways of the province, to which has been added the famous tour of the Isle of Orléans.

Each of the chapters devoted to a particular highway, first gives a general description of the road itself, of the country it traverses, a complete list of the cities, towns, villages and parishes on that road, with their respective populations, the nature of the pavement of the road, the distance from both its terminal points, as well as the distance between each municipality. In each case a map accompanies that description.

The guide-book then gives a detailed description of each of the cities, towns, parishes and villages.

It contains 325 illustrations representing the most interesting places in the province. Besides, it has 76 full-page road maps, 32 plans showing the points of entry and egress of the principal towns, and a general map of the highways of the province. The book contains altogether 435 drawings and photographic reproductions, forming 293 pages of illustrations.

To complete the work there is an alphabetical list of all the localities mentioned in the guide-book, with their population, the county, the number of the highway along which each locality is situated; general information regarding traffic regulations, road signs and symbols, Canadian and United States Customs laws; a summary of the fish and game laws; a list of distances between the principal points in the province and the leading cities and towns in the United States.

The book has been most carefully printed, and the illustrations are clear and distinct. It is elegantly bound in a fine solid rigid cover.

The French edition only has so far been issued. The English edition is now under way and should be completed within the next couple of months or so.

On account of the high cost of production, the Department of Highways cannot undertake to make a general free distribution of this guide-book. It has, therefore, set a nominal price of $2.00 a copy for the book, postage free. This amount does not nearly represent the cost of preparation and printing. Motorists cannot dispense with the information contained in the guide-book, and all those who wish to be well posted on Quebec matters will find it a most valuable book.

Ice, Snow and Frazil*

Thanks are due to the officers of the World Power Conference who, at very short notice, have made it possible to exhibit a number of moving pictures made by Canada's Trade and Commerce Department.

The pictures have a bearing on work which was accomplished 25 years ago and which, at that time, was discussed before the Canadian Electrical Association. They also relate to demonstrations made for The Engineering Institute of Canada ten years ago.

Neither of the above organizations, however, discussed the special phase of the ice question with which the pictures deal nor was there mention of the vital part which *agitation* plays in the creation or formation of frazil ice at hydraulic works.

For many years it was very generally believed that if a stream were free from waterfalls and turbulent rapids no frazil would be formed in it and, consequently, no ice difficulties would be encountered at hydraulic works located upon such streams, The wind, however, often disturbs the surface of an otherwise smooth body of water and prevents a sheet of surface ice from forming upon it; under such conditions myriads of ice spicules float along, multiply by acting as nuclei, agglomerate into mushy masses and stick to every cold thing that they touch. Strange though it may seem the writer has seen waterwheels 72 inches in diameter affected by frazil although those wheels were supplied with water from a forebay through which the water moved so slowly that its surface was as smooth as a mirror. The gates of those wheels were often frozen to the penstocks or wheel-cases while the gates were in the ¼ open position, that is while the water passing through them was much disturbed or agitated.

Still water—quiet water—may have its temperature lowered below the freezing point without turning into ice. The scientists tell us that water at 32° F. has a "tendency to crystallize but finds difficulty in making a beginning; *agitate* it," they say, "or introduce any colder thing than itself into it, and ice-formation immediately begins." Intakes, racks or screens, sharp bends in pipes or penstocks, valves, sluices and the gates and water-distributors in hydraulic power plants all tend to *agitate* water as the latter passes along and, if those metallic parts of the plants are *cold*, if their temperature is ever so little below 32° F., when the temperature of water is at its critical point, crystallization immediately takes place.

The ice that is formed under the above conditions is called *frazil* in Canada and it is often misnamed "anchor ice" because of its resemblance to the latter. Frazil is soft or mushy so long as it is immersed in water and is not subjected to the cooling action of the air, or, of anything else with a temperature below 32° F. Frazil resembles "lolly"—the mushy ice encountered in salt water harbours in cold climates.

The pictures illustrate in a novel and striking manner the speedy way in which particles of frazil are created by *agitation*, the way they multiply, the way they stick to everything colder than themselves, and, finally, and best of all, how easy it is to prevent them from sticking to anything by the employment of an exceedingly small amount of heat.

Twenty-five years ago, after successfully using the steam from a thirty horse power boiler to prevent a 3,000 horse power hydro-electric plant, which used 1,667 cubic feet of water per second, from being shut down by frazil, it was very hard to find anyone who would believe what had been done. Hydraulic engineers showed that it would require the heat-equivalent of nearly fifty 3,000 h.p. stations to raise the temperature of the water at one such station 1° F.—without melting any ice at all. These men of course missed the point entirely. The writer's experience was that ice would not cling to anything if the temperature of that thing were maintained above 32° F.—the freezing point of water.

Dr. H. T. Barnes, M.E.I.C., of McGill University, Montreal, in 1904 with a differential electrical thermometer, showed that the temperature of the water, in the St. Lawrence river, only varied a few thousandths of a degree at the times when the air's temperature changed from 40° F. above zero to 30° F., below zero. Maintaining the temperature of the immersed metal parts of a hydraulic plant at a temperature of a thousandth of a degree above the freezing point of water, and thus preventing ice from adhering to them, proved to be an easy task. Even though it were necessary to heat water or to melt ice in order to prevent ice from interfering with a power plant's operation it is interesting to note that the whole stream need not be heated. One hundred and forty four million (144,000,000) times as much water passed down a Canadian stream last winter as was turned into ice at a given point on it. However, as is said above, neither need water be heated nor ice melted at a power plant. A little heat in the hydraulic apparatus acts like a lubricator and the freezing water flows on past the plant as water glides off the back of a duck.

Some plant in Scandinavia employ electric rack or screen heating and they were described in papers at the World Power Conference in 1924. Last year at The Engineering Institute of Canada's annual convention, complete details of the Shawinigan Water and Power Company's electric rack heating were presented. Methods of construction and power consumption were fully described. None of the designers of any of those installations knew that patents for electrically heated racks were granted to the writer in the year 1906! "How old the new."

Particles of snow falling into water when the latter is ready to turn into ice act as nuclei and start ice-formation which proceeds cumulatively at a great rate of speed.

Winter operation of hydraulic plants, now that ice handling is better understood, is not the very difficult and hazardous thing it was 25 years ago.

Electric heating, frequently a most uneconomical proceeding, may, at times, be warranted for heating racks in order to combat ice troubles on account of the fact that its need and employment is only an occasional, and not a continuous one.

*This is a report of an extemporaneous address given by John Murphy, F.A.I.E.E., M.I.E.S., M.E.I.C., of Ottawa, at the World Power Conference in Tokyo, Japan, in November last. Mr. Murphy was a delegate at this conference representing; The Engineering Institute of Canada, Canadian Engineering Standards Association, and Member Canadian National Committee W.P.C., representing the Department of Railways and Canals and the Board of Railway Commissioners for Canada.

BRANCH NEWS

Border Cities Branch

R. C. Leslie, Jr.E.I.C., Secretary-Treasurer.
Harold J. A. Chambers, S.E.I.C., Branch News Editor.

The regular meeting of the Border Cities Branch was held on January 10th. The speakers of the evening were S. I. Krieger, German mathematician and J. H. Walker, superintendent of central heating for the Detroit Edison Company.

Prof. Krieger's address consisted of outlining methods for making or checking very rapidly, several arithmetical computations and then illustrating these methods. Included in these arithmetical gymnastics were the "magic square," the rules of 3, 7, 9, 11 and 101,—the rule of 101 being discovered by Prof. Krieger, the multiplying of two numbers of 20 figures mentally, the time taken being only that necessary for writing down the answer, and the obtaining of the day of the week for any date from the year 900 to the year 2000.

Mr. Krieger also illustrated a method of computing logarithms using the formula $M = L + X\ (434 - 2X)$ where L is the logarithm of the first figure of any number, X is the quotient obtained by dividing this first figure into the remaining figures of the number and where M is the mantissa of the desired logarithm.

i.e. to find the logarithm of 512,—

$$L = \log. 5 = 0.69897$$
$$X = \frac{12}{5} = 2.4$$
$$M = 0.69897 = 2.4\ (434 - 4.8) = 0.69897 + 0.01030 = 0.70927.$$

Therefore, since the characteristic of 500 is 2, the log. 512 = 2.70927.

Defining that by central heating he meant not the European idea of replacing fire-places, etc. by a central heating unit in the basement of a building, but the heating of a large number of buildings from one central plant, Mr. Walker in his address outlined the development of central heating since its introduction by Holly in 1870, and then by the use of lantern slides illustrated the progress made in central heating by the Detroit Edison Company in the business section of Detroit.

The speaker stated, that after several unsuccessful attempts at central heating by the use of hot water, in 1900, steam satisfactorily replaced hot water as a medium for the distribution of heat.

He also stated that central heating has several advantages over separate heating units. Firstly, the space usually taken up by boilers and coal storage in the large modern buildings is now utilized for other purposes, since this space, as in the case of basements of departmental stores, is also often valuable. Secondly, the nuisance of handling fuel and ashes in the building is obviated, and thirdly, intangible assets such as the elimination of smoke and soot from around the building as well as doing away with the hauling of coal, are obtained.

With reference to efficiency, the speaker stated that the Detroit Edison plants had roughly, an efficiency of production of 80 per cent, an efficiency of distribution of 85 per cent and an efficiency of use of around 90 per cent, giving an approximate total efficiency of 60 per cent against an efficiency of 50 per cent for individual heating units.

The fields for central heating as outlined by Mr. Walker were business, residential and industrial buildings. To date, he stated, that office buildings were the chief market for central heating companies being more economically heated than residences. Residences entail a greater ratio of pipe to heat used, and this field is consequently open to the use of gas and oil. The industrial building field is only beginning to develop.

There are in North America, the speaker stated, 161 plants with a total capitalization of $237,000,000.00 and earnings around $56,000,-000.00.

Regarding fuel, Mr. Walker stated that pulverized coal was now used in many plants, but that in Detroit lump coal was used. This was because, firstly, some of their plants were constructed prior to the development of the Cottrell treaters; secondly, because of the need to be able to burn any grade of fuel; thirdly, in the city the undesirability of shooting ash dust into the air, and fourthly, the possibility of selling the ashes.

The Detroit Edison, Mr. Walker stated, were pioneers in the use of the *W* type of boiler and depended more upon the over-all efficiency of heat distribution than upon the efficiency of the boilers alone.

He also dwelt briefly on the chemistry of the water used. The Detroit Edison Company use the Zeolite method of treatment.

The method of charging for the heat supplied in Detroit, he stated, is either by a flat rate or on a basis of condensation.

At the conclusion of the addresses a hearty vote of thanks was conveyed to both speakers, on behalf of the members, by O. Rolfson, A.M.E.I.C., chairman of the Branch.

Calgary Branch

W. H. Broughton, A.M.E.I.C., Secretary-Treasurer.
H. R. Carscallen, A.M.E.I.C., Branch News Editor.

The Calgary Branch held its third annual ball on November 22nd at the Palliser hotel and it was a wonderful success. This is now a fixed annual function in the affairs of the Branch and has progressed to such an extent that it has become one of the outstanding social events of the city. This has not come about without a great amount of hard work and the committee in charge has certainly earned the thanks of the entire Branch in this respect. It is believed that the annual ball has done much towards bringing The Institute to the attention of the general public and in that way is performing a real service in the affairs of the Calgary Branch.

In the decorations The Institute was prominently featured by a large reproduction of its emblem in the form of a shield suitably illuminated with coloured lights and mounted on one wall, while a large sign with E.I.C. in Neon lighting was displayed in another part of the ballroom. Purple and gold streamers from these principal pieces added to their effectiveness. Swaying balloons and vari-coloured streamers completed the decorations while two large spotlights supplemented the normal lighting of the ballroom. The sub-committee in charge of decorations, Messrs. W. St. J. Miller, A.M.E.I.C., F. G. Cross, A.M.E.I.C., G. H. Morton, A.M.E.I.C., and R. Mackay, A.M.E.I.C., deserve great credit for the results obtained.

The patrons and patronesses were as follows:—

Brig.-Gen. C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., President of The Institute. His Honour Lt.-Gov. W. G. Egbert and Mrs. Egbert. His Worship, Mayor F. E. Osborne and Mrs. Osborne. Mrs. F. J. Robertson and Mrs. W. St.J. Miller, wives of the chairman and vice-chairman respectively, performed the duties of hostesses in a very acceptable manner.

The Petroleum Industry of Alberta

B. L. Thorne, M.E.I.C., engineer, Coal Mines Branch of the Department of Natural Resources, C.P.R., spoke to the Calgary Branch on the petroleum industry of Alberta at a meeting held in the Board of Trade rooms on December 5th.

Mr. Thorne had obtained the loan of a moving picture film on this subject from the Canadian Pacific Railway Company. The film, he explained, was prepared by the Associated Screen News for the Department of Colonization and Development, C.P.R. The speaker described the film in a short talk, after which it was shown on the screen.

The picture started with a map of the various oil fields on the continent, extending from the Gulf of Mexico to Alberta. Then followed a short historical account of oil development work in Alberta, featuring the "Grand Old Man" of the Alberta field, Mr. A. W. Dingman who had charge of the old "Discovery" well, the first producer in the Turner Valley oil field.

It was brought out by the speaker that a great deal of geological prospecting has been carried out in the foothills area during the last few years, particularly in the last two years. Studies of the geological structures by means of shallow drilling had been carried out not only in the Turner valley but also on the prairies, in the Ghost river, Highwood and Pincher areas, also in structures west of Turner valley.

The film included a number of scenes in and around Turner valley illustrating the tools used, also general characteristics and different methods in use in the oil development work. The different types of rigs used, viz., standard, rotary and diamond drill were illustrated.

A portion of the film pictured the method of recovery of samples from the wells and their examination with the microscope, this latter work being carried on in a very thorough manner by the supervisory engineer of the Dominion Government and his staff located in Calgary.

Pictures were shown of the "Wonder Well" of the valley, Royalite No. 4, the extent of freezing on pipes conveying gas from the producing wells as depicted by the coating of ice on conveyors, the gas scrubbing plant of the Royalite Oil Company in Turner valley, etc. The film also showed sections of geological horizons encountered, diamond drills and their samples and a diagrammatic representation of the drilling of a well and its production from a gas horizon.

The picture showed the disposal of the gas residue from wells after extraction of its gasoline content, part of it being transported to and used in towns and cities in Alberta, while the portion which cannot be used in this way is burned. A night film was shown of various flames of waste gas burning in the Turner valley.

A map of the province followed, on which was shown all of the prospective fields according to present information.

Refining operations at local refineries were then depicted, also the laboratory methods used to ensure that none but sweet, clean gas shall reach the public.

The film ended with a few views showing the dispersion of the gasoline by train and truck to the distributing stations and to the consumer.

Mr. Thorne in his introductory remarks brought out some very interesting information regarding the development in the Turner valley oil field. This went to show that recent activity has centered in the south end of the valley, south of Sheep creek. The production from the Turner valley field for January 1929 was 38,506 barrels, of which only 3,279 barrels came from wells south of Sheep creek. In November, 1929, the total production was 99,379 barrels, of which 52,892 barrels were produced south of Sheep creek. At the beginning of 1929 there were only twelve active wells south of the creek, which number has now increased to fifty. A few of these are producing and the remainder are either drilling or rigging in preparation to start drilling operations.

An animated discussion followed the showing of the moving picture film, after which Mr. Thorne was tendered a very hearty vote of thanks for his interesting lecture.

A general meeting was held in the Board of Trade rooms, Calgary, on December 19th, 1929.

Certain proposed amendments to the Branch by-laws were discussed after which S. G. Porter, M.E.I.C., gave a report on the proceedings at the Plenary Meeting of Council held in Montreal in October.

Mr. Porter explained that he was present at the Plenary Meeting not as a member of Council but as chairman of the Committee on Relations with the Provincial Association of Professional Engineers which was meeting in Montreal at the same time.

Mr. Porter outlined briefly the history of the movement for affiliation and the progress made to date as embodied in the report of his committee to Council. He now thought substantial progress had been made and it was likely that affiliation will come into effect very much more quickly than appeared to be possible during the earlier years of the movement. The speaker stated that he had retired from the chairmanship of the committee after five years of rather strenuous work, to leave its consummation in other hands.

There was considerable discussion, taken part in by various members present, during which Mr. Porter answered a number of questions.

J. H. Ross, A.M.E.I.C., member of Council for the Branch, gave a short report on other phases of the business transacted at the Plenary Meeting and told of the hearty appreciation of the work done by Mr. Porter as expressed by Council and recorded in its minutes.

The chairman then introduced Mr. F. N. Rhodes, head of the electrical department at the Provincial Institute of Technology and Art, to address the members present on "Static Electricity."

Static Electricity

The speaker stated that he had of necessity to considerably curtail his address because of time taken by the large amount of business transacted earlier in the evening.

Mr. Rhodes explained that although the name given to his paper on the notice of meeting was "Static Electricity" this was really a misnomer, as the subject was concerned with the *flow* of atmospheric currents which were not necessarily of static origin.

He drew attention to the importance of the subject to all engineers concerned with the maintenance of aerial lines for power or communication, also its bearing on wind and storms to aviation and to those interested in rainfall.

The excellent work in investigating and establishing data by Scott, L. A. Bauer, Swam and others was commended, it being explained that this was one of the scientific objects of the Polar expeditions.

Figures were given showing the large amount of electric power continuously flowing from air to earth and in the reverse direction, other than lightning, and the various theories explaining these were reviewed.

The action of clouds as electric generators was then discussed, and their final discharge in the form of lightning.

The reasons for static surges on transmission lines were fourfold, the speaker claimed, first direct to the line; second electro-magnetic induction fron adjacent discharge; third, the shifting of a cloud binding an electro-static charge, and fourth the collecting of convective current from dust and moisture.

The discussion following the reading of the paper was evidence of the appreciation of those present.

General Meeting

A general meeting of the Branch was held in the Board of Trade rooms, Calgary, on January 9th, 1930, to discuss the question of a general increase in dues to members as proposed by Council. Unfortunately only seventeen members were present.

The secretary read the report of the Finance Committee of The Institute in which was set out the necessity for the increase in dues, after which the chairman called on J. H. Ross, A.M.E.I.C., councillor for the Branch, to open the discussion.

Mr. Ross summarized the old scale and compared it with the new scale as proposed by Council, which is to be considered at the Annual General Meeting to be held on Ottawa in February, 1930, and discussed in detail the reasons why a larger income is desirable by Headquarters. He thought the figures submitted showed that Headquarters expended their funds to good advantage and that some of the smaller Branches were justified in asking for a larger return in rebates, but that possibly some of the larger Branches, including Calgary, might do with less than they are now getting.

The Hamilton Branch scheme was also reviewed by Mr. Ross, who thought that we should vote for whatever scheme is put forward by the members assembled at the Annual General Meeting.

A discussion being called for by the chairman, Mr. F. K. Beach gave a masterly exposition of the reasons why he thought no increase in dues necessary at the present time. Mr. Beach explained that he had prepared the case against general increases well knowing that the case in favour would be prepared and presented by the councillor for the Branch, as he felt that members should have both sides before them in reaching a decision.

Mr. R. S. Trowsdale offered the suggestion that Associate Members should automatically become Members at some specified age, (say 40) and so provide additional revenue. The secretary pointed out that under the present scale Calgary would suffer a loss of about $30 if it increased its corporate membership from 97 to 100, and he would favour some scheme which would remove this anomaly.

Before the meeting closed it was announced that a dinner meeting was to be put on jointly by the Professional Engineers Association of Alberta and the Calgary Branch of The Engineering Institute of Canada in the Elizabethan room, Hudson's Bay building, Calgary, on January 18th. The chairman thought this a good opportunity for promoting closer relations between the two bodies and urged that as many members as possible make it a point to attend this dinner.

Victoria Branch News

K. M. Chadwick, M.E.I.C., Secretary-Treasurer.

The annual meeting of the Victoria Branch was held on December 5th, 1929, at which the following officers were elected for the coming year:

Chairman	H. F. Bourne, A.M.E.I.C.
Vice-Chairman	A. L. Carruthers, M.E.I.C.
Executive Committee	F. C. Green, M.E.I.C.
	O. W. Smith, M.E.I.C.
	J. P. Forde, M.E.I.C.
	I. C. Barltrop, A.M.E.I.C.
Secretary-Treasurer	K. M. Chadwick, M.E.I.C.

Following the election of officers, Mr. Bourne the new chairman took the chair, and R. F. Davy, A.M.E.I.C., addressed the meeting, his subject being "Engineering Achievement in Canada during the past Century."

The annual report and financial statement of this Branch will appear among the Branch Annual Reports to be presented at the Annual Meeting of The Institute and published in a subsequent issue of The Journal.

Halifax Branch News

R. R. Murray, A.M.E.I.C., Secretary-Treasurer.
W. J. DeWolfe, A.M.E.I.C., Branch News Editor.

The annual meeting of the Halifax Branch was held at the Halifax hotel on the evening of December 19th, at 6.30 p.m. The meeting was of the supper meeting nature, and the chairman, H. F. Bennett, A.M.E.I.C., presided. Seated on his right was Professor F. H. Sexton, Principal of the Nova Scotia Technical College, who was the principal guest. It had been expected that the general secretary, R. J. Durley, M.E.I.C., would be present but he was not able to do so.

Chairman Bennett called the meeting to order immediately after supper and extended a cordial welcome to out of town members who were present and also to J. B. Hayes, A.M.E.I.C., B.Sc., Nova Scotia Technical College, who has recently taken over the managership of the Nova Scotia Light and Power Company, in the stead of the care of Mr. J. F. Lumsden, lately deceased.

The attendance was about forty.

The minutes of the November meeting were read and approved.

The regular business of the meeting was suspended whilst Professor Sexton read the report of the local joint committee on the co-ordination of The Institute with the various Professional Associations in Canada.

The report in general strongly favoured the formation of one large body to carry on the social, ethical and legal activities of engineers throughout Canada, and in detail enumerated many reasons why such a body is desirable. A resolution approving of the report was moved by F. A. Bowman, M.E.I.C., and seconded by C. H. Wright, M.E.I.C. Mr. Bowman felt that the time is ripe for our Branch to give a formal lead to other branches in Canada, whilst Mr. Wright said that the idea back of the resolution is to approve of one general organization and also that as this province had always been in the van in matters of a progressive nature we should put our shoulder to the wheel in our own best interests.

Mr. Wright took occasion to compliment Colonel F. W. W. Doane, M.E.I.C., as being the prime worker in the matter in hand, also Professor F. R. Faulkner, M.E.I.C., and the committee for their earnest and painstaking work. Major H. W. L. Doane, M.E.I.C., added a few remarks to those already made, he having made more extended remarks as already recorded at the November meeting. The report of the committee was adopted unanimously and it was decided to send a copy of it and the resolution to all the Professional Associations and Institute Branches, and all the members of the Council of The Engineering Institute.

The Branch committee appointed to consider the advisability of combining with the Provincial Professional Association to hold a joint banquet, reported that a banquet had been arranged to be held on the evening of January 16th next, at the Halifax hotel. The programme will consist of an orchestra, a quartette, one principal speaker, and a toast to each of the local engineering societies. The cover charge to each member is a nominal one and the balance of cost will be absorbed by the two societies. The report was adopted.

The report of the Branch Executive was ready by R. R. Murray, A.M.E.I.C., secretary-treasurer, and gave a detailed account of the activities of the Branch during the year, commenting very favourably on the general good attendance at meetings; on the increasing interest of members and the general good quality of the addresses delivered, amongst which were that by Col. C. H. L. Jones, M.E.I.C., on the Mersey Newsprint development at Liverpool, N.S. and that by Mr. Otto Schierbeck, on Re-forestation in Nova Scotia, also to the success of the Students' meeting in October.

The report of the secretary-treasurer, giving a detailed statement of receipts and expenditures for the year, showed the Branch to be in a healthy condition financially. Some few members have allowed themselves to fall behind in dues but it is hoped to have a clean sheet shortly.

The report of the Membership Committee was ready by Prof. W. P. Copp, M.E.I.C. The report evidenced an earnest effort to enroll new members and to interest all members in the work of the Branch.

The Paper's Committee's report was read by Col. F. W. W. Doane, M.E.I.C., and referred particularly to the papers read at each meeting. It also contained suggestions for addresses on a long, varied and most interesting list of subjects including:—The Refining of Sugar, Cold Storage, Harbour Commission and others of a like interesting nature.

The Publicity Committee's report outlined the efforts made during the year to bring to the eye of the public the activities of the Branch and offered the suggestion that engineers are all too modest in not claiming for their profession that need of recognition which is their due and that such should not be the case; that in too many enterprises the engineer, who was the central figure, was entirely left out of the picture whilst the glory of accomplishment too often accrued to those less conspicuously engaged in the undertakings. It was good to note that at the hydro plant, which will serve the Mersey mill, there has been erected a tablet on which are inscribed all the names of the engineering staff who made the power development possible.

Prof. W. F. McKnight, A.M.E.I.C., councillor, gave the meeting a survey of the Council's work and stated that a more detailed report will come to each member in the columns of the "Journal" at a later date.

The scrutineers appointed to consider the election ballots reported the following as having been chosen as the Executive for 1930:—

Chairman........................W. P. Copp, M.E.I.C.
Executive........................H. C. Burchell, M.E.I.C.
C. B. McDougald, A.M.E.I.C.
J. L. Allan, M.E.I.C.
C. St.J. Wilson, A.M.E.I.C.
H. F. Bennett, A.M.E.I.C.
W. H. Noonan, A.M.E.I.C.
L. M. Allison, A.M.E.I.C.
J. J. Sears, A.M.E.I.C.
L. M. Matheson
G. S. Stairs, M.E.I.C.
J. D. Fraser, Jr.E.I.C.

Chairman Bennett now delivered a very interesting and informative address on his retirement from the chair. He had received the greatest possible co-operation of the executive during the year; been aided in his work by the various committees who laboured faithfully; been assisted very materially by members generally by their increasing interest and attendance at meetings. He referred in very sincere and feeling terms to the loss sustained by the Branch through the deaths of two of our outstanding members, viz., Prof. D. W. Munn, of the Technical College staff, and Mr. J. F. Lumsden, manager of the Nova Scotia Light and Power Company.

He made a reference to the growing recognition by the public of the value and necessity of the engineer in the management and upbuilding of industry; to the efforts being made at headquarters to render greater service to the membership and finally quoted President Beatty, of the Canadian Pacific Railway, to the effect that the engineer is absolutely essential to the proper government of a country.

Chairman H. F. Bennett, A.M.E.I.C., expressed the hope that his successor in office, Prof. Copp, may have the same happy co-operation during the coming year.

Prof. W. P. Copp, M.E.I.C., on assuming office, thanked the members for the honour done him and in a short, well delivered address assured all of his intention to work hard for the Branch welfare during 1930 and to do all in his power for the advancement of the profession.

Professors F. R. Faulkner, M.E.I.C., and H. C. Burchell, M.E.I.C., were re-appointed as auditors. W. A. Winfield, M.E.I.C., was appointed Branch representative on the General Nominating Committee of The Institute.

The thanks of the Branch were voted to Moirs', Limited, for boxes of chocolates presented to each member and to the Northern Electric Company for serviceable desk diaries for 1930.

It was stated that there is strong likelihood of a Maritime Professional Meeting being held in Saint John, N.B., next summer and the Branch will co-operate to make it a success.

It was announced that J. A. Wilson, A.M.E.I.C., controller of Civil Aviation Department of National Defence, will address the January meeting on the subject:—Aviation.

J. B. Hayes, A.M.E.I.C., newly appointed manager of the Nova Scotia Light and Power Company, voiced his pleasure at being once more on his native heath and amongst his friends of the engineering profession and complimented the Branch on its increased activity and usefulness during his absence. And thus was concluded another successful annual meeting, all present joining in the singing of "Oh, Canada," and "God Save the King."

Joint Dinner

The annual meeting of the Association of Professional Engineers of Nova Scotia was held on the afternoon of January 16th, at the Technical College, in Halifax.

President Thos. J. Locke, district engineer, Department of Public Works of Canada, was in the chair and called the meeting to order at 2.30 p.m. After a word of welcome to the out of town members the report of council for 1929 was read and adopted. The report was a very concise resumé of the work done during the year.

The report of the Joint Co-operation Committee—a copy of which has already reached each association in Canada— was read and a resolution adopted, unanimously, that we endorse the movement towards closer union of the principal engineering societies in Canada.

The financial report was read and showed the association to be in a safe condition, financially.

The registrar's report was also approved by the meeting.

Following these, and some committee reports, the meeting was given over to a series of five-minute talks on a number of questions of import to members.

(1) Proper zoning of the province for the better enforcement and administration of the Engineering Profession Act.
(2) Has registration of engineers in Nova Scotia been successful?
(3) Do infringements of our act occur without the knowledge of the council?
(4) The closer co-operation of The Engineering Institute of Canada and the Associations of Professional Engineers.
(5) 1930—The beginning of the graduate engineers requirements for admission.
(6) Prompt payment of fees.
(7) Should there be a summer meeting as well as the annual meeting?

There was a good discussion on all these points and some valuable information gleaned.

The report of the scrutineers showed the following officers as having been elected for the year 1930.

President—R. J. Bethune, A.M.E.I.C., divisional engineer, Guysboro Railway.

Vice-President—R. W. McColough, chief engineer, Department of Highways, Nova Scotia.

Past-President—Thomas J. Locke, district engineer, Public Works of Canada.

Councillors.

H. F. Bennett, A.M.E.I.C...........term expires January 1931.
W. F. McKnight, M.E.I.C.......... " " " "
Two to be appointed to fill vacancies caused by the death of J. F. Lumsden, M.E.I.C., and the selection of R. J. Bethune as president.
H. W. Johnston..................Term expires January 1932.
K. G. Chisholm.................. " " " "
Ira P. MacNab, M.E.I.C........... " " " "
W. P. Copp, M.E.I.C.............. " " " "
Seven members to be appointed by the Lt.-Governor-in-Council.

Auditors

W. J. DeWolfe, A.M.E.I.C. and H. F. Laurence, M.E.I.C.

The meeting was concluded by the installation of officers and a short address by the new president.

At 7.00 p.m. the engineers and their guests, to the number of about 90, sat down to a banquet which was held in the St. Julien room of the Halifax hotel.

This was a joint banquet conducted by The Engineering Institute of Canada and Association of Professional Engineers of Nova Scotia. The first half of banquet was presided over by Prof. W. P. Copp, M.E.I.C., chairman of the Halifax Branch, and the second half by R. J. Bethune, A.M.E.I.C., president of the Association.

During the dinner several choruses were rendered by members whilst the Joe Mills Orchestra dispersed enjoyable music.

A comic sketch, introducing sleight of hand magic, was engineered by Mr. Phil Moore, Mr. A. R. Cobb and Mr. Patterson, and was very much appreciated.

At the conclusion of dinner a number of toasts were honoured.

Prof. F. R. Faulkner, M.E.I.C., in happy vein stated that the Association is really the offspring of The Institute, and gave an interesting description of its development since 1920, when it was organized.

Mr. T. J. Locke was earnest in his thanks for the kind words said of the Association and delivered a good address on the present position of engineers and the very bright outlook for the future.

The Northern Electric Company's quartette, consisting of four of the city's leading male singers, rendered a number of solos and quartettes which were of a high artistic order and which were heartily applauded.

Prof. H. W. McKiel, M.E.I.C., president of the New Brunswick Association of Professional Engineers, delivered a short address bringing the greetings of that body. The theme of the address was the closer co-operation of the two engineering bodies in Canada and he stressed the point that such action is much needed and must come soon.

President Bethune then took charge of the gathering and introduced Dr. H. F. Munro, Superintendent of Education for Nova Scotia, who delivered a forceful address on "The Coming Naval Disarmament Conference." Dr. Munro, who claimed to be an engineer inasmuch as he is doing constructive work in building up a high grade system of education in Nova Scotia, said at the beginning that there are four principal angles to the question of disarmament:—disarmament itself, diplomacy, statesmanship and economics.

He emphasized the point that, if Great Britain and the United States would unite to say yes on the matter, the question of diplomacy and economics would be settled at once.

He said that each world nation has its own diplomatic policy, due to geography and other conditions which exist.

Great Britain's policy rests on maritime freedom and neutralization of the smaller states in Europe.

The U.S. policy is founded on splendid isolation as indicated by the terms of the Monroe Doctrine.

Dr. Munro gave some interesting figures to show the cost of armament to nations to-day and stated that Great Britain is spending more than $14.00 per capita annually and the United States nearly $5.00 per capita. Such being the case, he asked why do these nations not scrap their navies and he answered that there is no international court to ensure protection to them from those who may not follow their lead.

The address of more than an hour gave an altogether interesting and informative resumé of the various attempts, from time to time, to limit the hazards of war and of the various diplomatic chess moves made by each nation to protect its own interests, especially in a maritime manner.

He took his hearers back to the victory of Trafalgar and showed how the British navy had developed into, what the late President Roosevelt once characterized as "the greatest civilizing agency in the world's history." A sincere vote of thanks was tendered Dr. Munro at the conclusion of his address.

Dr. F. H. Sexton, President of the Nova Scotia Technical College, in proposing the toast to the E.I.C., said an engineer is too literal minded and is so taken up with his work that he has not developed an imagination, a thing Prof. Sexton thought very necessary and desirable. He told a story to emphasize this need for imagination and then proceeded to pay tribute to the E.I.C. for its part in the development of the engineering profession and the part played by it in fostering the Professional Associations and helping them to be successful organizations.

H. F. Bennett, A.M.E.I.C., immediate past chairman, in response to the toast, thanked Dr. Sexton for his kindly references to The Institute and expressed The Institute's appreciation of all the felicitations addressed to it by other speakers. He brought out the fact that engineers are surely coming into their own, in the near future, and gave as an illustration of it that at two hydro power sites in Nova Scotia to-day tablets have been erected which contain the names of the engineers who had developed and constructed them.

Mr. Bennett's remarks were accorded a hearty reception.

Favours were received from the Canadian General Electric Company, The British Empire Steel Corporation, Canadian Westinghouse Company and the Canada Cement Company. The thanks of the members were voted to each donor.

A touching reference was made by Prof. Copp to the fact that two of our most respect members, Prof. D. W. Munn and Mr. J. F. Lumsden, had died during the year and letters of condolence were ordered sent to their families.

A vote of thanks was tendered the joint committee for the excellent conduct of the banquet, the entertainment provided and the excellent nature of the decorations.

The bond of unity so desired in engineering bodies could not have been better shown than in the manner, spirit and cordiality of all in this unique gathering.

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.

Geophysical Methods Applied to Foundations

The Lethbridge Branch held its regular meeting on December 14th, when J. E. Duncan of the geological staff of the Canadian Western Natural Gas, Light, Heat and Power Company gave a talk on "Geophysical Methods Applied to Foundations."

Mr. Duncan outlined various methods used in geophysical work, and gave references to various texts on the subject.

The use of electrical and electro magnetic methods and their correlation with geological information was discussed.

Special Meeting, January 4th

A special meeting of corporate members was held on January 4th, to attend to various business matters. The usual excellent dinner provided by the Marquis hotel preceded the business session.

The principal item on the agenda was the report of Councillor G. S. Brown, A.M.E.I.C., who represented the Branch at the Plenary Council meeting in October. Two hours of report and discussion showed the interest the members took in the general affairs of The Institute. Following this, thorough discussion was had of certain proposed amendments submitted by Headquarters and the Hamilton Branch.

A special committee's report on proposed changes in the Branch by-laws was submitted and after due consideration was adopted by the meeting and referred to Council for its approval.

Joint Meeting

On January 11th, the district annual meeting of the Alberta Professional Engineers Association was held at the Marquis hotel, with R. B. Baxter of the Calgary Power Company, President of the Association, in charge.

In his remarks at the close of the dinner, Mr. Baxter outlined the year's progress in the Association's affairs, particularly in regard to the unifying of the Association with The Engineering Institute of Canada, and also in regard to certain amendments which it is proposed to make to the present act.

The principal speaker of the evening was Horace L. Seymour, Town Planning Commissioner of the Province of Alberta, who spoke on "A Year of Town Planning in Alberta."

Since the creation of the Town Planning Commission in March, 1929, great progress has been made, said Mr. Seymour, and already four cities and thirteen towns have appointed local town planning commissions to study their problems and make recommendations to the municipal governments.

The provincial commission's activities have also been extended to the rural parts of the province, and farmers are able to benefit by its services in laying out their groups of farm buildings. School districts present their problems for consideration. Main highway development is also considered in regard to building lines, suitability of public service buildings and above all the bill-board. This last institution which has grown to be the curse of the highways in the United States is now under regulation in this province.

Mr. Seymour discussed the technical matters involved in making a survey of a community for planning purposes, and illustrated his remarks by references to what has already been accomplished in certain towns in the province.

Attending the meeting were several city officials and councillors and several of the most influential business men of the city. They took an interested and spirited part in the discussion which followed, and it is expected that town planning will become a live issue here shortly.

The Lethbridge Branch of The Engineering Institute, which was well represented at the meeting, is proud of being in many cases a forum where engineering matters of local importance are discussed by engineers from all parts of the province and the business men of the city are taking advantage of this fact. The securing of Mr. Seymour for this address was due to the efforts of the local Branch which is certainly doing its part in the building up of the community.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

"The Construction, Operation and Maintenance of Unit Cars," was the subject of an illustrated address delivered by T. H. Dickson, B.A., B.Sc., A.M.E.I.C., at a supper meeting of the Branch held in the Y.M.C.A. on December 12th. M. J. Murphy, A.M.E.I.C., chairman of the Branch, presided. Immediately following the supper two very enjoyable vocal selections were rendered by Mr. R. B. Metzler.

The Construction, Operation and Maintenance of Unit Cars

A unit car, Mr. Dickson stated, might be defined as any self-propelled rail car, which operates in regular train service either alone or coupled to one or more trailer cars. A number of causes have contributed to the development of this type of equipment, among which might be mentioned, losses in operation of most branch lines with steam train operation; increased cost of ton mile operation; failure of freight, passenger and express revenue to increase in proportion to the increase in operation costs, and finally decrease in passenger revenue due to increasing competition from busses and private autos.

Various types of unit cars have been tried with varying success.

The "gas-mechanical" is really an automobile with flanged wheels. It consists of an auto engine with gear drive to one or more axles. This type requires little attention and is quite economical. Unless carefully handled, however, there is liable to be objectionable jolting when changing gears or accelerating.

With the object of producing a smoother running car, the "gas-electric" was developed. It differs from the "gas-mechanical" in that the mechanical connection between the engine and driving wheels is replaced by an electrical drive made up by coupling a d.c. generator to the engine. Current from this generator, carried through the necessary control equipment, is supplied to motors geared to the axles. While the addition of the electric drive was an immense improvement, it made the car much more expensive and also increased the cost of maintenance.

The "storage battery car," in its limited field has been quite successful. The cleanliness and quietness of this car make it attractive, but it has serious disadvantages. The speed is limited and the mileage is also limited, and as a car usually operates over a run where its battery capacity is all needed to make the trip in fair weather, there is little reserve of power for bad weather. Furthermore, the cost of battery replacement is quite high.

"Distillate electric cars" have been tried, but the saving in cost of fuel has been nearly balanced by the increased cost of maintenance, as the engines have more valve trouble, require more frequent decarbonizing and require very accurate setting of the carburetors.

The "oil-electric" or Diesel engine with electric drive, is the most recent development, and has been found highly economical and satisfactory, especially for long runs and heavy service. The non-stop record from Vancouver to Montreal is held by this type of car, the 2,937 miles having been covered in 67 hours.

Diverting from the subject of unit cars, Mr. Dickson described in detail the massive, high speed oil-electric locomotive, which has a tractive force of twice that of the most powerful steam passenger locomotive in operation in Canada.

A vote of thanks, moved by A. S. Gunn, A.M.E.I.C., seconded by F. B. Fripp, A.M.E.I.C., was tendered the speaker by the presiding chairman.

Peterborough Branch

S. O. Shields, Jr.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

Annual Dinner

The annual dinner of the Peterborough Branch was held on Tuesday, November 19th, 1929, at the Empress hotel, Peterborough.

Among the guests were included Brigadier-General C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., president of The Institute; R. J. Durley, M.E.I.C., general secretary of The Institute; E. T. Sterne, president of the Association of Professional Engineers of Ontario; A. J. Grant, M.E.I.C., chief engineer Welland Ship canal; C. E. Sisson, M.E.I.C., works engineer, Davenport Works, Canadian General Electric Co., Toronto; Rev. W. McDonald, secretary of the Peterborough Ministerial Association; and Dr. C. B. Waite, representing the Peterborough Medical Association.

R. C. Flitton, A.M.E.I.C., president of the local Branch, proved a capable master of ceremonies. Following the banquet, he introduced the programme by a brief address, in which he reviewed the aims of The Engineering Institute, and the possibilities it holds for the profession.

"This occasion marks the tenth anniversary of the inauguration of the Peterborough Branch of The Institute," he declared. Continuing, he commented on the sincerely-felt absence of the late Professor Gillespie, a special friend of the local Branch.

In proposing the toast to The Institute, W. M. Cruthers, A.M.E.I.C, said, "The Engineering Institute of Canada is unique among the other national organizations, in that it includes in its members, engineers practising all branches of the profession." He said further that The Institute was assisting greatly in the engineering development of Canada, having Branches stretching from Halifax to Victoria.

Brigadier-General Mitchell, responding, complimented the local Branch on the evening's gathering. "Your Branch is unique for many reasons. But to mention only a few; it has more younger members in proportion to its total strength than any other Branch in the province, and lists more graduates of S.P.S., University of Toronto.

"Peterborough, as the centre of eastern Ontario, has a diversity of engineering carried on here. There are railways and canals which benefit directly from your Branch."

He recalled a visit paid here by himself in 1922, and complimented Peterborough on producing three eminent Past-Presidents of The Institute in recent years. Comparing conditions in the country to those existing seven years ago, he noted a decided change for the better. "We had great cause to be thankful for many things then, but have much greater cause now after five years of general prosperity. We can look down from the top of the hill at the way we have come, and we must admit that we are in far better shape now.

"Let us see that we take our part in helping this country, not only as engineers but also as citizens—so that it will become not only a better place to live in, but something that we can hand on with pride to posterity."

The general secretary of The Institute, R. J. Durley, spoke of the service given engineers by the information bureau conducted by The Institute. He also stressed the value of organization, and dealt with the relationship between The Engineering Institute and the Association of Professional Engineers of Ontario. He said that both were aiming at the same purpose—increasing the scope of engineering, and expressed the hope that the future would bring them even closer together.

E. T. Sterne, president of the Association of Professional Engineers of Ontario, said, "I come as a non-member to pay tribute to The Engineering Institute." He said that the organization which he represented felt that while the two were working on common ground, it was necessary to avoid duplication. He said that each had separate duties to perform, but that they had a unity of thought.

P. P. Westbye, M.E.I.C., proposed the toast to "The Branches." In so doing, he referred briefly to the mission and benefits of the Branch as a unit promoting the interests of The Engineering Institute of Canada as well as the individual members.

The representative of the Niagara Peninsula Branch, A. J. Grant, M.E.I.C., chief engineer on the new Welland ship canal, expressed his pleasure at being present among his old friends of the local Branch, and thanked them for nominating him to the office of president of The Institute. "No man can be alone in any great work and he cannot succeed without the assistance and help of loyal men with him," said Mr. Grant, speaking of his experiences as an engineer.

C. E. Sisson, M.E.I.C., former member of the local Branch, conveyed the greetings from the Toronto Branch.

The toast to "The Sister Professions" was ably proposed by H. R. Sills Jr.E.I.C., and was responded to by Rev. W. McDonald for the Ministerial Association, and Dr. C. B. Waite for the Medical Association, the other professional representatives not being present.

The programme was enlivened at intervals by musical and humorous items by Messrs. Hunter, Bishop and Taylor and other Students and Junior members of the Branch. A skit featuring the radio broadcast of the "Voice of the Muskeg" at a meeting of an imaginary new branch of The Institute at Fort Churchill, proved an entertaining item.

Recent Developments in Hydraulic Turbines

At a regular meeting of the Branch held on Thursday, December 12, 1929, under the chairmanship of A. E. Caddy, M.E.I.C., H. S. Van Patter, A.M.E.I.C., hydraulic engineer of the Dominion Engineering Works, Montreal, gave an address on the above subject.

Some 300,000 h.p. per annum of water turbines are installed in Canada, and owing to the fact that the head seldom exceeds 300 feet, the great majority are of the reaction type. The speaker stated that the cost of the turbine itself was a comparatively small percentage of the total cost of a hydro-electric plant ranging from 3 to 6 per cent.

The two general types of reaction turbines, the Francis and the propeller type were described, and their different characteristics explained. The demand for higher speeds had led to the development of the propeller type runner, which has advantages in manufacture and operation but has a higher thrust and overspeed.

A comparison was made between two typical installations, the Cedars Rapids plant with Francis type and Great Falls Manitoba Power, with propeller type machines. The possibility of efficient operation of the propeller type turbines at low heads is a great advantage in some cases.

Some initial difficulties with pitting of the throat ring and draft tube liner have been overcome by slight design changes, and there seems no reason why the propeller type, properly designed cannot be used for still higher heads.

The subject of regulation was briefly touched on, and a chart on the Great Falls plant showed a maximum variation of about three twentieths of a cycle.

Other designs such as the Kaplan, Escher Wyss, Nagier and Moody were mentioned and a description given of the Kaplan movable blade propeller type turbine which is being built in Europe in sizes up to 35,000 h.p. at 35-foot head.

The address was well illustrated by slides and was concluded by an interesting demonstration by means of a model, of the Dominion Engineering Works hand operated, movable blade type runner, which has advantages in obtaining the maximum output under seasonal variations in head.

Details of construction and manufacturing facilities of Dominion Engineering Works were described and illustrated.

A hearty vote of thanks was proposed by R. C. Flitton, A.M.E.I.C.

The Construction of a Modern Locomotive

A particularly interesting and informative address on the modern locomotive was given by Mr. W. A. Newman, chief mechanical engineer of the Canadian Pacific Railway, at a regular meeting of the Peterborough Branch held on January 9th, 1930, under the chairmanship of M. V. Powell, Jr.E.I.C.

Introducing his subject by contrasting the traffic requirements of today with those of ten years ago, the speaker pointed out the increased demand of some 50 per cent on the locomotive, due to the change from wooden to steel cars, and the increase in number of cars per train from 8 to 10, 12, or 14.

Quicker schedules are necessary and bus and aeroplane competition has to be met. Similar conditions exist in freight service.

Mr. Newman then proceeded to indicate the various methods of attaining greater output from the locomotive, showing first a chart depicting the gradual increase in number of wheels, from the 4-4-0 up to the 4-12-2 type.

The problem is essentially one of greater boiler capacity, but the increase in number of axles is limited by track curvature. The weight on the drivers must be four times the tractive effort at the rim and the weight per axle has been raised from 35,000 lbs. 25 years ago to a maximum of 75,000 lbs. today. Owing to balancing difficulties affecting the track, a limit of 63,000 lbs. per axle in good practice has been set by the C.P.R. Hence, only refinement in design is available to increase the "sustained capacity" of the locomotive.

The speaker then described some of these developments such as the improved arrangement of boiler tubes, superheater (which has given 25 per cent economy), feed water heater (15 per cent), mechanical stokers, unit construction, and the use of alloy steels. As examples of "unit construction," the C.P.R. uses a single nickel steel casting, weighing 105,000 lbs. rough and 65,000 lbs. machined, for the complete frame and cylinders, and the tender base is also a one-piece alloy steel casting.

This design allows a substantial saving in weight, which can be put into additional boiler capacity.

The use of alloy steels for forgings, castings, boiler plate, etc., is a comparatively recent development, pioneered by the C.P.R. in 1926 and based on their higher elastic limit and ability to stand abuse.

Approximately 28 per cent increase in boiler pressure has been rendered possible by nickel steel plate, and the C.P.R. is now operating locomotives at 280 lbs. per sq. inch, this being the highest in regular service.

Mr. Newman described and illustrated by slides, some of the latest C.P.R. passenger and freight engines and details of their design and construction. He concluded by outlining the possibilities for still further development, such as higher pressures (for example the Schmidt system), use of multi-cylinders, the turbo-locomotive, and the electric and Diesel electric locomotive.

A moving picture film showed the details of construction of a large locomotive in the Angus shops of the C.P.R. at Montreal.

At the close of his address, the interest aroused was amply demonstrated by the large number of questions answered by Mr. Newman. The vote of thanks was proposed by P. P. Westbye, M.E.I.C., and heartily endorsed.

Saint John Branch

E. J. Owens, A.M.E.I.C., Secretary-Treasurer.

On November 21st the members of this Branch had the pleasure of listening to a very interesting paper by R. A. Lawther of the Saint John River Power Company. Mr. Lawther is the engineer in charge of the erection of the transmission line from Grand Falls to Dalhousie.

Mr. Lawther took for his subject the construction of the above transmission line. This line is 112 miles in length and is located near the highway of the International Railway. It occupies a separate right-of-way of its own 100 feet wide. Power is to be transmitted over this line at a pressure of 132,000 volts. The initial load to be transmitted is 40,000 h.p., while the ultimate capacity of the line is 60,000 h.p. The line consists of a single circuit carried on steel towers 60 feet high and has two ground wires.

Mr. Lawther presented a paper on this subject at the Maritime Professional Meeting in Moncton last summer, which was published in September issue of the Engineering Journal. In reading his paper he used a good many slides to illustrate it.

At the conclusion of the paper a hearty vote of thanks was tendered the speaker on motion of S. R. Weston, M.E.I.C., seconded by J. N. Lamb, Jr.E.I.C.

The tremendous increase in output over a period of eight years from 1921 to 1929, and another large increase anticipated in 1930, warranted the expenditure of approximately $800,000 by the New Brunswick Power Company, Ltd. in the construction of an additional unit to their plant. Such was a statement made last evening by J. D. Garey, A.M.E.I.C., chief engineer of the company, in an illustrated lecture on the new plant, delivered before a large meeting of the Saint John Branch of The Engineering Institute of Canada, held in the company's offices at the corner of Dock and Union streets. The lecture, which depicted by means of lantern slides the construction of the new plant in Smythe street and the extension of the intake pipes 145 feet out to the harbour line, was interestedly followed by the members of The Institute, following which refreshments were served by the company, assisted by the office staff, after which an inspection of the plant was made under the guidance of Mr. Garey and W. H. Swift Jr., manager of the company.

During the lecture Mr. Garey showed a chart giving the increases enjoyed by the company since 1921. He explained as the pictures showing the foundation and construction work of the plant at various stages were flashed across the screen, that the recently completed unit was one of four to be erected by the company, the others to be added as the increased output required them. He gave as his reason for the increase the policy of the company which held out to the citizens "assured service."

At one stage of his lecture he said that he had been asked to announce that the Federal Light and Traction Company were not thinking of disposing of the plant, as rumors had it, but were going to continue to give "assured service" as in the past, and were also prepared to take care of any growth to be experienced as time went on.

One point stressed by Mr. Garey was the precaution taken by the company in the building of their new plant to eliminate the smoke nuisance, through the installation of special equipment. He explained that the plant comprised a power capacity for 7,500 kv.a.

At the conclusion of the lecture, a hearty vote of thanks moved by Geoffrey Stead, M.E.I.C., was extended to Mr. Garey by the chairman, E. A. Thomas. F. P. Vaughan, M.E.I.C., moved a vote of thanks to the New Brunswick Power Company for the courtesies extended to The Institute. This was seconded by A. A. Turnbull, A.M.E.I.C. Mr. Swift in his reply to the motion, extended an invitation to the members to make an inspection of the plant.

As the men entered the plant the first thing to meet their gaze was the 10,000 h.p. generator, while on the same landing was stationed the various meters, showing a 7,500 h.p. load at 10 o'clock at night. On the next landing below the men were shown the pulverized fuel system, whereby the accurate weight of coal was taken mechanically, following which it was crushed in two large pulverizers and then shot up through large pipes into the furnace, where it was sprayed over the great blazing pit by forced draft.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer.

December Meeting

The December meeting of the Saskatchewan Branch was held at the Kitchener hotel, Regina, on Wednesday, December 18th, about forty-five members and guests being in attendance. The meeting was preceded by a dinner, Chairman H. R. Mackenzie, A.M.E.I.C., presiding.

Engineers' Legislation

The Legislation Committee reported satisfactory progress on the engineers' bill which is to be presented to the forthcoming session of the provincial legislature which is expected to meet early in January. Considerable interest centres in this bill due to the fact that on two former occasions bills were introduced into the legislature, each meeting with defeat, also that at the present time Saskatchewan is one of the two provinces which have no legislation incorporating the engineers although they were the first province to seek such legislation following the preparation of a model draft bill by The Institute in 1919. The Legislation Committee of this Branch is being augmented by representatives from the electrical and mining engineers of the province and from other engineers not members of The Institute, and this committee will co-operate with the government in the preparation and introduction of the bill.

Civil Service Enquiry Commission

The following resolution was passed by the Branch:—

"Resolved that this Branch of The Engineering Institute of Canada lend encouragement to the engineering services in the employ of the government of the province of Saskatchewan in their presentation of a classification and salary schedule to the Civil Service Enquiry Commission, and to this end that the matter be left in the hands of the Executive Committee for such action as may be necessary."

The Einstein Theory

On the occasion of this meeting, R. N. Blackburn, M.E.I.C., delivered a very interesting address on the Einstein Theory illustrated by a number of diagrams.

Sault Ste. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer.

The annual meeting was held on January 3rd, 1930, at 8 p.m. in the Y.W.C.A. rooms, Queen street east. J. H. Jenkinson, A.M.E.I.C., chairman, called the meeting to order and after the minutes had been read, the Nominating Committee reported the result of the election. The executive for 1930 is as follows:

Chairman	C. H. E. Rounthwaite, A.M.E.I.C.
Vice-Chairman	A. H. Russell, A.M.E.I.C.
Secretary-Treasurer	A. A. Rose, A.M.E.I.C.
Executive resident:	
(2 years)	J. W. LeB. Ross, M.E.I.C.
(1 year)	R. A. Campbell, A.M.E.I.C.
Executive non-resident:	
(2 years)	J. M. Silliman, A.M.E.I.C.
(1 year)	J. G. Dickenson, A.M.E.I.C.
Ex-officio	J. H. Jenkinson, A.M.E.I.C. A. E. Pickering, M.E.I.C.

Mr. J. H. Jenkinson, the retiring chairman, in a short address expressed his appreciation for the help of the members and executive during the past year. He pointed out the difficulty of getting local papers and wished the new executive every success for 1930.

Mr. C. H. E. Rounthwaite, A.M.E.I.C., chairman-elect, took the chair and expressed his thanks for the honour conferred on him by his being elected chairman. He hoped that 1930 would be a most successful year and urged that all do whatever they could to that end.

The secretary-treasurer's report was read and adopted. It showed the Branch to be in a healthy financial condition.

L. R. Brown, A.M.E.I.C., and A. E. Pickering, M.E.I.C., were appointed auditors for 1930.

On behalf of the Branch, Mr. J. H. Jenkinson presented Mr. A. H. Russell, A.M.E.I.C., the retiring secretary, with a desk set as a token of their appreciation of the faithful service he had rendered the Branch. During his four years as secretary-treasurer Mr. Russell has been most untiring in his service to The Engineering Institute. Mr. Russell then thanked the members for their remembrance and expressed his appreciation for the co-operation of the various executives during his term of office and his belief that the good work would continue.

Toronto Branch

J. J. Spence, A.M.E.I.C., Secretary-Treasurer.
Archie B. Crealock, A.M.E.I.C., Branch News Editor.

On the evening of Thursday, December 19th, 1929, the members of the Toronto Branch were presented with a paper prepared by R. R. Deans, vice-president of the Canadian Inspection and Testing Company, Limited. Unfortunately Mr. Deans was not able to present his paper in person and it was delivered by Mr. R. W. Hurlburt of that company.

The paper delivered was a very interesting one and described in detail the subject of "The Value of Accurate Testing and Inspection." The speaker in his paper brought out how the life of a structure is dependent not only on good design but also on the quality of the materials used and the workmanship; and how the testing and inspecting engineer was responsible for seeing that the material was up to standard and that the workmanship was carried out in the right manner. The speaker then elaborated on the duties of the testing engineer showing how varied was his work, not only having to deal with the common place materials of construction but also with the new materials which are making their way into our constructional activities. The method of testing the various materials was then explained. Taking the rolling of steel the speaker explained how when an order is placed in an inspector's hand, he studies the contract and specifications and all the elements that may affect the carrying out of the work and the complete check at all times during the process of manufacture, the physical and chemical tests that are made and the visual inspection of the material before shipment. The speaker also explained some recent tests of rail steel rolled from the so-called hot top or big end up ingot and how they found that this method of pouring steel in hot top moulds produces sounder and more uniform steel and that in spite of the extra expense due to the fact that there are royalties to contend with that on high class steels it is now becoming almost universal to use the big end up ingot. The speaker then described the inspection of steel castings at the foundry and illustrated by actual experience some of the difficulties that had to be overcome. Following this the method of inspection in the fabricating shops was dealt with and then the field inspection of the erection. The difficulties incidental to both bridge and building work were dealt with and the differences between the two explained.

In describing the inspection of concrete the speaker showed how the methods had changed greatly during the past few years especially from the standpoint of the Inspection Company. A description of the present-day inspection was given showing how all the materials were tested and how a complete check is made from the proportioning of the materials to the taking of cylinder tests to show the strength of the concrete that has been placed.

In concluding his address the speaker showed examples covering brick tests which were of interest to the members present. The address was illustrated with lantern slides showing the result of a number of tests made by the speaker. The meeting concluded by a hearty vote of thanks being tendered to both Mr. Hurlburt and Mr. Deans and expressing regret at the inability of Mr. Deans to be present to personally present his paper.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

MECHANICAL ENGINEER, graduate, Canadian or English preferred, to enter mechanical department of large metallurgical concern operating in province of Quebec. Work will be along lines mechanical maintenance and plant extension. Young graduates with two or three years experience preferred. Apply to Box No. 454-V.

DRAUGHTSMAN wanted by a large company in the province of Quebec, skilled in mechanical and structural design. Single man with two or three years experience out of college preferred. Apply to Box No. 456-V.

ELECTRICAL ENGINEER—Graduate with two or three years experience. Westinghouse or General Electric test floor experience desirable. Opening is along lines of maintenance and construction work with large metallurgical plant in the Province of Quebec. Permanent connection with bright future for right applicant. Apply to Box No. 472-V.

STRUCTURAL DRAUGHTSMEN, experienced in detailing steel for industrial plants, city buildings or bridges, for a bridge company located in Winnipeg. Give age, experience, whether married or single, and other particulars to Box No. 474-V.

DRAUGHTSMEN—Two first-class draughtsmen, experience must include water tube boilers, air heaters and economizers. Apply, giving full particulars as to nationality, age, if married, and salary expected, to Box No. 481-V.

DRAUGHTSMAN, familiar with timber construction and gold milling practice. Apply, giving particulars of experience, salary expected and date available, to Box 484-V.

HYDRO-ELECTRIC ENGINEER, graduate, experienced in operation of hydro-electric power developments, to take charge as operating engineer, with supervision of five systems. State age, if single or married, university and year of graduation, general experience with design experience, if any, and salary expected and when available. Apply to Box No. 485-V.

DRAUGHTSMAN, experienced on materials handling equipment, location Ontario. Apply to Box No. 486-V.

DRAUGHTSMAN with experience in electrical layout work for position with engineering company in Montreal. Apply to Box No. 488-V.

Situations Vacant

TECHNICAL ASSISTANT for large firm in Montreal, engineering training desirable, with knowledge of French and stenography. Apply to Box No. 489-V.

MECHANICAL ENGINEER, about 35 years of age, with experience in pulp and paper mill maintenance, and to take charge of small construction work in connection with mill. Location Western Province. Apply to Box No. 492-V.

CHEMICAL ENGINEER. Large newsprint company in St. Maurice Valley desires recent graduate in chemical, electrical or mining engineering, who would like to make a permanent connection with the industry. Good living conditions. Apply to Box No. 495-V.

ELECTRICAL ENGINEERS. Wanted, two young electrical engineers with about two years experience since graduation, for three to four months survey of large distribution and transmission system in province of Quebec. Work may result in permanent employment. State experience and salary expected. Apply to Box No. 496-V.

SALES ENGINEERS. Two experienced industrial paint salesmen wanted by a large paint manufacturing company; one for Toronto City, one for London and Border Cities. Applicants should state fully experience, names of three references. Apply Box No. 497-V.

DESIGNING ENGINEER, capable of handling details problems or general layout work in a large newsprint mill centrally located. Only men with at least five years' experience in this line need apply. State fully experience and salary expected. Apply to Box No. 498-V.

TOWN MANAGER—A new mill town in northern Quebec requires a young civil engineer as town manager. French-Canadian with fluent knowledge of French and English essential. Previous experience in municipal work preferable. State full particulars in application. Apply to Box No. 500-V.

CIVIL ENGINEER, to act as principal assistant to chief engineer on large work. Must have had extensive experience on large contracts, particularly harbour works. Must be capable of designing wharves and docks. Executive ability most essential. Apply, giving full particulars as to experience, salary expected and earliest date available, to Box No. 501-V.

Situations Vacant

DESIGNING DRAUGHTSMAN, wanted by a large pulp and paper mill, ideally situated. The work will comprise general drawings and details for building construction and alterations. Applicant should be able to design reinforced concrete and structural steel. State age, education, experience, salary desired, and other particulars. Apply to Box No. 503-V.

MECHANICAL DRAUGHTSMAN, wanted immediately for general draughting. Preferably one with two or more years experience in draughting room of some large industrial concern. Permanent position with excellent opportunity for advancement. Location, Montreal. Apply to Box No. 504-V.

Situations Wanted

ELECTRICAL ENGINEER, graduate '24, M.Sc., E.E. Six years experience in construction and design and hydro stations and sub-stations. Was for two years in charge of engineering design, including large outdoor sub-stations, switchboards, etc. Two and a half years in South and Central America. At present employed; desires change to position offering scope for initiative and advancement. Married; age 30; location immaterial. Apply to Box No. 7-W.

RETIRED LIEUT.-COMMANDER, Canadian, aged 32, A.M.E.I.C. Specialized in engineering from executive rank. Two years and six months chief engineer marine 31,500 s.h.p. Desires position with manufacturing or business concern in Montreal-management. Apply to Box No. 106-W.

CIVIL ENGINEER, graduate '26, with fair knowledge of French. Experience as instrumentman on surveys, maintenance engineer on railway construction, and resident engineer on railway construction. Available at once. Apply to Box No. 149-W.

ELECTRICAL ENGINEER, B.Sc., E.E., A.M.E.I.C., Canadian, age 29, single, graduate Canadian university 1924. Have been with large power company in U.S.A. since graduation, ten months on sub-stations, remainder of time on design, construction and operation of overhead and underground distribution and transmission system. At present employed by same company. Would like to return to Canada. Available on reasonable notice. Apply to Box 236-W.

CIVIL ENGINEER, with office in Toronto and extensive connection, is in a position to act as agent for contractors' equipment, building materials or allied lines, or would consider position as sales engineer with large manufacturer or distributor. Apply to Box No. 311-W.

CONSTRUCTION ENGINEER, with twenty years' experience in general construction work and design of docks, wharves, steel, reinforced concrete and timber, buildings for industrial plants, office buildings, housing developments, substations, garages, etc. Apply to Box No. 319-W.

Situations Wanted

INDUSTRIAL ENGINEER, thirty-five years of age, graduate of a well-known university, twelve years' experience in design, construction, maintenance and changes in production methods in industrial plants, including several years in pulp and paper industry in complete charge in large mills of all engineering, maintenance and development work; still engaged; desires to establish new connection. Apply to Box No. 320-W.

CHEMICAL ENGINEER, McGill graduate, nine years commercial and technical experience, with good knowledge of chemical manufacturing methods and industrial economics, desires position in which stability is prime consideration. Qualified by training and personality to act as assistant to executive who must relieve himself of details requiring efficient and tactful handling or to undertake industrial and chemical development or research. At present employed. Apply to Box No. 321-W.

CIVIL ENGINEER, university graduate, with extensive experience of winter surveys, desires position. Available immediately. Location immaterial, northwestern Ontario preferred. Apply to Box 322-W.

CIVIL ENGINEER, graduate three and a half years standing, desires spare time work in evenings and Saturday afternoons. Neat draughtsman. Typing. Apply to Box No. 323-W.

CIVIL ENGINEER, A.M.E.I.C., twenty years experience field and office, in railway, highway, concrete construction, water conservation, etc., desires position with prospects of permanency. At present employed but available on short notice. Will go anywhere if terms satisfactory. Apply to Box No. 327-W.

ELECTRICAL ENGINEER, age 31, two years test course, the British Thompson, Houston Co. Ltd. Four years experience on erection, construction, maintenance and repairs of electrical apparatus. Diploma E.E. Bristol University '23. Seeks an opening with a public utility or power company. Apply to Box No. 328-W.

CIVIL ENGINEER, B.A.Sc., A.M.E.I.C., M.P.E.O., age 37, desires a permanent position as chief draughtsman or plant engineer, preferably in Toronto or district. Seventeen years experience with consulting engineers on industrial, structural and railway work, hydro-electric plants and pulp and paper mills. Some mechanical and electrical experience. Apply to Box No. 332-W.

ELECTRICAL ENGINEER, graduate Queen's University '28, with experience in steel tower transmission line construction, railway construction, contour surveying, and eighteen months testing experience with the General Electric Company at Schenectady, would like to secure employment in Canada. Apply to Box No. 333-W.

ELECTRICAL ENGINEER, B.Sc., age 25, three summers experience as assistant city engineer, one and a half years on the survey, layout, construction and inspection of a hydro-electric power line. At present employed, but desires a position with a power or public utility company. Apply to Box No. 335-W.

CIVIL ENGINEER, A.M.E.I.C., Reg. Pro. Eng. Ont. and N.B., age 47, married, twenty years experience in this country; twelve years in Scotland as construction and municipal engineer, specializing in roadway, water and sewer works, desires similar position, available forthwith. Just completed sewer and waterworks schemes for town in Maritime Province. Have also been engaged as engineer and superintendent with contractors on steam shovel excavation, concrete and caisson works for large buildings in Toronto, etc. Apply to Box No. 336-W.

CIVIL ENGINEER, graduate '29, desires engineering position with possibilities of advancement. Work in hydro-electric, construction, municipal, railroad, or mining preferred. Past experience consists chiefly of survey work. Location in western provinces preferred. Apply to Box No. 338-W.

CIVIL ENGINEER, B.Sc., fifteen years experience, including surveying, construction, mining and tunnelling. Available at once. Will go anywhere, but prefer Eastern Canada. Apply to Box No. 346-W.

MECHANICAL ENGINEER, Jr.E.I.C., Irish, age 28, graduate '27, seeks connection in British Columbia, varied outdoor and indoor experience. During vacation and since graduation in mechanical, electrical and civil engineering. Versatile, intelligent, and quick to learn. Fast and accurate with slide rule transit T-square or electrical equipment. Prefer maintenance or research work or any opening with opportunity for advancement. Apply to Box No. 349-W.

CIVIL ENGINEER, grad. '29, eleven months on construction, three months on road location, five months in draughting office, desires position on construction or would like to enter draughting office with possibilities in steel and reinforced concrete design. At present employed. Aplyy to Box No. 352-W.

SUPERINTENDENT, competent electrical superintendent, wishes position with large industrial or power supply company. New construction programme preferred. Experienced in engineering, designing and electrical construction of power houses, sub-stations and industrial control work. Available on short notice. Apply to Box No. 353-W.

Preliminary Notice

of Applications for Admission and for Transfer

January 23rd, 1930

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in March 1930.

R. J. Durley, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for a least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BARNETT—HENRY EDGAR, of 213 Park Place, Peterborough, Ont., Born at London, England, Jan. 3rd, 1908; Educ., B.Sc. (Eng.), 1928, M.Sc. (Eng.), 1930, Univ. of London; at present in test dept., Canadian General Electric Co. Ltd., Peterborough, Ont.
References: L. DeW. Magie, W. M. Cruthers, A. B. Gates, B. L. Barns, V. S. Foster, W. E. Ross.

CRASE—GEORGE H., of Toronto, Ont., Born at Butte, Montana, U.S.A., Sept. 27th, 1892; Educ., B.C.E., Univ. of Mich., 1915. Night school of Economics, Univ. of Pittsburgh, 1917; 1915-16, dftsman., 1917, dftsman., Pittsburg Des Moines Steel Co.; 1918-24, with Canadian Des Moines Steel Co., Chatham, Ont., as contracting engr. and district sales mgr. i/c of Canadian work—design, estimating and contracting for struct'l. steel, steel plate, and water works; 1924 to date, with Horton Steel Works, Ltd., Bridgeburg, Ont., as district sales mgr., i/c of Ontario sales—design, estimating and contracting for steel plate work.

FOR TRANSFER FROM THE CLASS OF JUNIOR TO A HIGHER CLASS

CHAUSSEE—PIERRE MAURICE, of Montreal, Que., Born at Letellier, Man., Aug. 1st, 1896; Educ., 1912-13-14, Montreal Technical Institute; 1914, with Northern Electric Co.; 1914-16, elect'l dept., Dominion Guarantee Co. Ltd.; 1916-17, ticker service system, Montreal Quotation Company; 1917-20, with Electrical Commission of Montreal; 1920-27, chief dftsman., and 1927 to date, engr. of elect'l. dept., Montreal Water Board.
References: C. J. Desbaillets, F. Y. Dorrance, G. E. Templeman, J. F. Brett, J. A. Jette, A. Leroux.

DOWNES—MICHAEL AUGUSTINE, of 3985 Laval Avenue, Montreal, Que., Born at Montreal, August 4th, 1889; Educ., B.Sc., McGill Univ. 1912; 1912-13, dfting., Dominion Bridge Company; 1913-15, struct'l. designing, Ross & Macdonald; 1915-17, asst. engr., sewer dept., City of Montreal; 1917-18, asst. engr., mains and services, gas distribution, Montreal Light, Heat & Power Cons.; 1918-20, 1921-23, asst. supt., McGill Observatory; 1920-21, asst. engr., General Combustion Co. of Canada; 1923 to date, asst. engr., Technical Service, City of Montreal.
References: G. R. MacLeod, J. G. Caron, W. T. Jamieson, W. Dickson, J. Weir.

HADLEY—WILLIAM FRASER, of 17 Main Street, Hull, Que., Born at Chatham, Ont., May 29th, 1894; Educ., Diploma (Hons.), R.M.C., 1914; 1914-15, Univ. of Toronto; 1915-17, Lieut., 1917-19, Capt., R.C.E.; 1915-16, asst. to director of work and bldgs., Dept. Militia and Defence, i/c of camps and barracks, Ottawa area; 1916-19, asst. director of signalling, Dept. Militia and Defence, i/c of all signalling, military telephones, telegraphs etc., in Canada; 1920 to date, manager of Scott Estate, Hull, Que., supervised various surveys on Ottawa River for lawsuits (1920-25), and at present looking after all estate building and construction.
References: C. R. Coutlee, G. G. Gale, F. H. Emra, A. C. Caldwell, L. B. Rochester.

HILL—GEORGE RIXON, of Virden, Man., Born at Peterborough, Ont., Dec. 4th, 1888; 1906-09, rodman on land and rly. surveys; 1910-14, instr'man. and dftsman. on constrn. and location surveys, C.P.R.; Season 1914, engr. on prelim. and constrn. road surveys, Manitoba Good Roads Board; 1915 to date, municipal engr. i/c of road constrn. in Western Manitoba under the district engr. of the Good Roads Board—employed jointly by six rural municipalities, i/c of design and constrn. of reinforced concrete culverts and treated timber bridges up to 24 ft. spans; i/c of design, location and constrn. of roads not built under the provisions of the Manitoba Good Roads Act.
References: W. A. James, A. McGillivray, A. J. Taunton, E. W. M. James, W. A. Mather.

MITCHELL—FRANK LESLIE, of Iroquois Falls, Ont., Born at Jamaica, B.W.I., June 21st, 1894; Educ., B.Sc., McGill Univ., 1921; 1914 (summer), survey for Ontario Hydro Electric, Chippawa Power development; 1920 (summer), chemist in raw sugar manufacture control; 1914-19, overseas; Lieut., Can. Inf. and Can. Engrs.; 1921-22, tester in control and asst. chemical engr., 1922-23, chem. engr. i/c physical control dept., 1923-24, asst. sulphite supt., 1924-28, sulphite supt., and Jan. 1929 to date, asst. mgr. of operations, Abitibi Power & Paper Company, Iroquois Falls, Ont. (May 1927 to Jan. 1929, in executive charge of development, Abitibi Fibre Company.)
References: H. J. Buncke, A. A. MacDiarmid, W. G. Mitchell, L. E. Kendall, W. B. Crombie.

POWELL—MORLEY VINCENT, of 370 London Street, Peterborough, Ont., Born at Peterborough, Oct. 11th, 1895; Educ., B.A.Sc., Univ. of Toronto, 1922; 1922-23, demonstrating in hydraulic and thermodynamic lab., Univ. of Toronto; 1923 to date, mech'l. design of elect'l. generators and motors, at Peterborough plant of the Canadian General Electric Co. Ltd.
References: L. DeW. Magie, F Bowness, B. L. Barns, B. Ottewell, A. B. Gates, W. E. Ross, W. M. Cruthers.

TOOKER—GUY LANGRISHE, of Vancouver, B.C., Born at Tenby, South Wales, Sept. 18th, 1884; Educ., 1899-1902, Prince of Wales College, Charlottetown, P.E.I.; 1902-04, ap'ticed to The Locomotive & Machine Co., Montreal; 1904-08, rodman, topog'r., leveller and transitman, Transcont. Rly. (Quebec); 1908-10, transitman on surveys of harbour and townsite, G. T. R. Rly. (Prince Rupert;) 1910-11, with Ritchie, Agnew & Co., Civil Engrs. and Surveyors, as asst. engr. on surveys and constrn. of water and sewerage systems for City of Prince Rupert; 1911-12, i/c of parties making surveys for the proposed future water supply and hydro-electric development for same city; 1912-13, with Prince Rupert Hydro-Electric Company, as asst. engr. i/c of parties making complete topographical, drainage area and transmission line surveys for proposed developments of the Kh-ta-da and Falls Rivers, and later supervising constrn. of rock-filled crib dam across the Falls River; 1913-15, right of way surveys, G. T. P. Rly.; 1915-19, overseas, C. E. F.; 1919-20, leveller on prelim. and location surveys, Vancouver Is., C. N. R.; 1922 (May-Nov.), dftsman. on right of way surveys of main line; 1922-24, and May 1925 to Feb. 1926, with Noel Humphrys & Co., Civil Engrs., and Surveyors, as instr'man. and asst. to Mr. Humphrys on land and subdivision surveys, also prelim. and location surveys for logging rlys.; Oct. 1924 to May 1925, and 1926 (Mar.-June), C. N. R. right of way dept., asst. surveyor on land ties and general survey work; 1926-29, instr'man. on layout and constrn. of concrete sidewalks and pavements, and from June 1929 to date, asst. engr. on design and constrn. of Macadamized roads throughout the Greater Vancouver area, for engrg. dept., City Hall, Vancouver, B.C.
References: D. O. Lewis, W. P. Wilgar, W. B. Young, R. Rome, D. McMillan.

FOR TRANSFER FROM THE CLASS OF STUDENT TO A HIGHER CLASS

BLACKMORE—CYRIL LESLIE, of Deer Lake, Nfld., Born at Tilt Cove, Nfld., June 14th, 1898; Educ., B.Sc., McGill Univ., 1927; 1920-21, constrn. work at Laurentide Power; 1921-23, elect'l. constrn. work on new units, Shawinigan Water & Power Company; 1924 (4 mos.), elect'l. constrn. work on new machines, International Paper Co., Three Rivers, 1927-29, elect'l. constrn. and gen. course in paper making, and at present elect'l. engr. in charge of installn. of apparatus in power house extension for same company at Deer Lake, Nfld.
References: H. C. Brown, H. K. Wyman, C. V. Christie, E. Brown, R. L. Weldon, H. E. Bates.

JOHNSON—WILLIAM JAMES, of Lachine, Que., Born at Slocan, B.C., April 7th, 1901; Educ., B.Sc., McGill Univ., 1923; 1923-25, in dfting room, and from 1925 to date, res. engr. on constrn. of grain elevators, for John S. Metcalf Co. Ltd., Montreal.
References: H. Rolph, L. Coke-Hill, E. Brown, E. G. M. Cape, J. B. Stirling, W. B. McLean.

JONES—J. H. MOWBRAY, of Liverpool, N.S., Born at Sault Ste Marie, Ont., Aug. 24th, 1905; Educ., B.A. Sc., Univ. of Toronto, 1927; 1924, forestry dept., 1925, hydraulic dept., and 1927-28, asst. to cost engr., Spanish River Pulp and Paper Mills; 1928, engr. and dftsman., Abitibi Power & Paper Co. Ltd., Sault Ste Marie Divn.; 1928, asst. to chief engr., 1929, acting res. engr., and at present res. engr., Mersey Paper Co. Ltd., Liverpool, N.S.
References: G. H. Kohl, C. H. L. Jones, J. L. Lang, G. F. Hardy, J. D. Jones, F. Smallwood, J. W. LeB. Ross.

MATSON—BRUCE COOK, of 444 Gladstone Avenue, Toronto, Ont., Born at Toronto, July 22nd, 1902; Educ., B.A. Sc. (Hon.), Univ. of Toronto, 1924; Summer work: 1921, lab. asst., City of Toronto Testing Lab.; 1922-23, dfting., G. W. Rayner, M.E.I.C., Toronto; 1924, i/c party, surveying and drilling, Hanover Cement Co., Beachville, Ont.; 1924-25, asst. engr., Bloor Street subway, Toronto, for the Foundation Company; 1925-26, plant engr., Iroquois Sand & Gravel Co., Agincourt, Ont.; 1925-26, also sales engr., John Maloney Ltd., Toronto; 1926-29, plant engr. and sales mgr., The Beachville White Lime Co., and Hydrated White Lime Co., Beachville; 1927-29, mgr., Innerkip Lime & Stone Co., Woodstock & Guelph, Ont.; At present, engr., Innerkip Lime & Stone Co., Woodstock, and sales engr., Maloney Supply Co , Toronto.

TREASURER

F. P. SHEARWOOD, Montreal, Que.

SECRETARY

R. J. DURLEY, Montreal, Que.

OFFICERS OF BRANCHES

HALIFAX
Chairman, H. F. BENNETT
Vice-Chair., W. J. DeWOLFE
Sec.-Treas., R. R. MURRAY, 87 Cambridge St., Halifax, N.S.
Executive, H. W. MAHON, D. S. WICKWIRE, W. B. MacKAY, G.T.MEDFORTH, H. C. BURCHELL, C. B. McDOUGAL, J. L. ALLAN, W. P. COPP, C. St.J. WILSON
(Ex-Officio) W. F. McKNIGHT

CAPE BRETON
Chairman, A. L. HAY
Vice-Chair., A. P. THEUERKAUF
Sec.-Treas., S. C. MIFFLEN, Dom. Coal Co. Ltd., Glace Bay, N.S.
Executive, C. M. SMYTHE, J. P. COTTER, J. A. FRASER, T. C. BARRINGTON, M. DWYER.

SAINT JOHN
Vice-Chair., W. J. JOHNSTON
Sec.-Treas., E. J. OWENS, P.O. Box 820, Saint John, N.B.
Executive, A. A. TURNBULL, J. N. FLOOD, C. C. LANGSTROTH

MONCTON
Chairman, M. J. MURPHY
Vice-Chair., L. H. ROBINSON
Sec.-Treas., V. C. BLACKETT, Eng. Dept., C.N.R., Moncton, N.B.
Executive, J. R. FREEMAN, T. L. LANDERS, J. G. MACKINNON, G. E. SMITH, C. S. G. ROGERS, F. WILLIAMS
(Ex-Officio) F. O. CONDON, H. J. CRUDGE

SAGUENAY
Chairman, R. E. PARKS
Vice-Chair., S. J. FISHER
Sec.-Treas., R. LANCTOT, Box 151, Arvida, Que.
Executive, H. R. WAKE, G. E. LAMOTHE, J. A. KNIGHT, G. O. VOGAN

QUEBEC
Hon. Chair., A. R. DECARY
Chairman, A. B. NORMANDIN
Vice-Chair., S. L. deCARTERET
Sec.-Treas., P. METHE, Ecole Technique, Blvd. Langelier, Quebec, Que.
Executive, H. CIMON, T. J. F. KING, L. C. DUPUIS, A. LARIVIERE
(Ex-Officio) W. G. MITCHELL

ST. MAURICE VALLEY
Chairman, ELLWOOD WILSON
Sec.-Treas., R. MORRISSETTE, City Engr., Cap de la Madeleine, Que.
Executive, H. DESSAULLES, B. GRANDMONT, A. A. WICKENDEN

MONTREAL
Chairman, D. C. TENNANT
Vice-Chair., A. DUPERRON
Sec.-Treas., C. K. McLEOD, 1440 St. Catherine St., W., Montreal, Que.
Executive, A. COUSINEAU, P. E. JARMAN, W. McG. GARDNER, J.A. LALONDE, N. L. MORGAN, F. NEWELL
(Ex-Officio) F. A. COMBE, FRASER S. KEITH, G. R. MacLEOD, O. O. LEFEBVRE, F.P.SHEARWOOD, P. B. MOTLEY, J.A. McCRORY, JULIAN C. SMITH, J.L. BUSFIELD

OTTAWA
Chairman, F. H. PETERS
Sec.-Treas., F. C. C. LYNCH, Nat. Resources Intelligence Service, Dept. of the Interior, Ottawa, Ont.
Executive, G. A. BROWNE, V. M. MEEK, L. L. BOLTON, W. L. CASSELS, W. F. M. BRYCE
(Ex-Officio) N. CAUCHON, C. CAMSELL

PETERBOROUGH
Chairman, R. C. FLITTON
Secretary, S. O. SHIELDS, 2 Chester St., Claraday, Ont.
Treasurer, A. B. GATES
Executive, A. L. KILLALEY, B. OTTEWELL, W. E. ROSS, E. R. SHIRLEY, H. R. SILLS
(Ex-Officio) R. L. DOBBIN, W. M. CRUTHERS

KINGSTON
Chairman, D. M. JEMMETT
Vice-Chair., A. JACKSON
Sec.-Treas., L. F. GRANT, Royal Military College, Kingston, Ont.
Executive, A. G. MacLACHLAN, F. R. HENSHAW, L. M. ARKLEY
(Ex-Officio) W. L. MALCOLM

TORONTO
Chairman, T. TAYLOR
Vice-Chair., J. J. TRAILL
Sec.-Treas., J. J. SPENCE, Eng. Bldg., University of Toronto, Toronto, Ont.
Executive, H. W. MASON, A. B. CREALOCK, G. H. DAVIS, C. S. L. HERTZBERG, C.B. HAMILTON, J.R.COCKBURN
(Ex-Officio) L. W. WYNNE-ROBERTS, T. R. LOUDON, J. G. R. WAINWRIGHT, R. B. YOUNG

HAMILTON
Chairman, H. A. LUMSDEN
Vice-Chair., A. H. MUNSON
Sec.-Treas., W. F. McLAREN, Can. Westinghouse Co., Ltd., Hamilton, Ont.
Executive, J. B. CARSWELL, H. S. PHILIPS, F. P. ADAMS, W. D. BLACK
(Ex-Officio) W. L. McFAUL, E. H. DARLING

LONDON
Chairman, W. G. URE
Vice-Chair., W. R. SMITH
Sec.-Treas., F. C. BALL, City Engr's Dept., London, Ont.
Executive, D. M. BRIGHT, J. FERGUSON, E.V. BUCHANAN, R.W. GARRETT, G. E. MARTIN
(Ex-Officio) W. P. NEAR, W. M. VEITCH

NIAGARA PENINSULA
Chairman, E. G. CAMERON
Vice-Chair., WALTER JACKSON
Sec.-Treas., R. W. DOWNIE, Welland Ship Canal, Thorold, Ont.
Executive, N. BATES, F. L. HAVILAND, H. M. KING, E. P. MURPHY, W. R. MANOCK, J. E. SEARS, C. W. WEST, J. K. WYMAN
(Ex-Officio) A. J. GRANT, C. H. SCHEMAN, M. B. ATKINSON

BORDER CITIES
Chairman, ORVILLE ROLFSON
Vice-Chair., R. J. DESMARAIS
Sec.-Treas., R. C. LESLIE, 1618 Giles Blvd., Windsor, Ont.
Executive, C. G. R. ARMSTRONG, F. STEVENS, H. J. COULTER
(Ex-Officio) A. E. WEST, L. M. ALLAN

SAULT STE. MARIE
Chairman, C. H. E. ROUNTHWAITE
Vice-Chair., A. H. RUSSELL
Sec.-Treas., A. A. ROSE, 34 The Drive, Sault Ste. Marie
Executive, J. W. LeB. ROSS, J. M. SILLIMAN, R. A. CAMPBELL, J. G. DICKENSON
(Ex-Officio) J. H. JENKINSON, A. E. PICKERING

LAKEHEAD
Chairman, C. B. SYMES
Vice-Chair., D. G. CALVERT
Sec.-Treas., GEO. P. BROPHY, P.O. Box 86, Port Arthur, Ont.
Executive, D. C. CHISHOLM, J. C. MEADER, W. H. SOUBA, G. R. DUNCAN
(Ex-Officio) H. S. HANCOCK, H. Y. HARCOURT

WINNIPEG
Chairman, F. H. MARTIN
Sec.-Treas., E. W. M. JAMES, 255 Balfour Ave., Winnipeg, Man.
Executive, R. N. COKE, T. C. MAIN, G. S. ROXBURGH
(Ex-Officio) J. N. FINLAYSON, C. H. ATTWOOD

SASKATCHEWAN
Chairman, H. R. MacKENZIE
Vice-Chair., W. G. WORCESTER
Sec.-Treas., R. W. E. LOUCKS, Surveys Br., Land Titles Office, Regina, Sask.
Executive, D. W. HOUSTON, A. P. LINTON, P. C. PERRY
(Ex-Officio) D. A. R. McCANNEL, C. J. MacKENZIE, A. M. MacGILLIVRAY

LETHBRIDGE
Chairman, J. B. deHART
Vice-Chair., C. S. CLENDENING
Sec.-Treas., Wm. MELDRUM, Galt Mines, C.P.R., Lethbridge, Alta.
Executive, R. LIVINGSTONE, P. M. SAUDER, J. T. WATSON
(Ex-Officio) N. H. BRADLEY, G. N. HOUSTON

EDMONTON
Chairman, R. W. ROSS
Vice-Chair., J. GARRETT
Sec.-Treas., H. R. WEBB, C. E. Dept., University of Alberta, Edmonton, Alta.
Executive, H. GREENE, A. W. HADDOW, C. A. ROBB, E. STANSFIELD
(Ex-Officio) V. PEARSON, E. STANSFIELD

CALGARY
Chairman, F. J. ROBERTSON
Vice-Chair., W. St.J. MILLER
Sec.-Treas., W. H. BROUGHTON, Inst. of Technology and Art, Calgary, Alta.
Executive, F. M. STEEL, F. J. HEUPERMAN, R. C. HARRIS
(Ex-Officio) T. LEES

VANCOUVER
Chairman, A. D. CREER
Vice-Chair., H. B. MUCKLESTON
Sec.-Treas., J. C. OLIVER, 930 Birks Bldg., Vancouver, B.C.
Executive, C. E. WEBB, A. C. R. YUILL, F. LEE, F. P. V. COWLEY, P. H. BUCHAN, A. C. WOOTTON
(Ex-Officio) A. K. ROBERTSON

VICTORIA
Chairman, F. G. ALDOUS
Vice-Chair., H. F. BOURNE
Sec.-Treas., K. M. CHADWICK, 25 Brown Bldg., Victoria, B.C.
Executive, A. L. CARRUTHERS, F. C. GREEN, L. W. TOMS
(Ex-Officio) F. M. PRESTON

THE

ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

Published monthly at 2050 Mansfield Street, Montreal, by The Engineering Institute of Canada, Incorporated in 1887 as The Canadian Society of Civil Engineers.

Entered at the Post Office, Montreal, as Second Class Matter.

The Institute as a body is not responsible either for the statements made or for the opinions expressed in the following pages.

Volume XIII Montreal, March 1930 Number 3

Radio Communication as An Aid to Aviation in Canada

Major W. Arthur Steel, M.C., A.M.E.I.C.,
The Royal Canadian Corps of Signals.

Paper presented before the Annual General Meeting of The Engineering Institute of Canada, Ottawa, Ont., February 13th, 1930.

During the war science produced many new and important inventions but it is doubtful if any of them have served a more useful purpose, in the succeeding years of peace, than the two outstanding developments of aviation and radio communication. It is not the intention here to touch on the subject of aircraft development during the war. That has already been fully covered by other writers, but it should be remembered that the radio industry as well as aircraft, owes its rapid expansion to the war. The demands of the armies of all countries forced the introduction and development of the thermionic valve, or vacuum tube as it is sometimes called in America, and resulted in the development for military purposes of light and efficient portable sets with astonishingly long ranges. Many of these sets were developed especially for use in military aircraft and it is not surprising to learn, therefore, that the first combined use of these two developments in Canada was in connection with the aviation activities of the Department of National Defence.

When the Dominion Forestry Department and the Air Board first undertook experiments on the use of aeroplanes for forest patrol work, it soon became evident that some form of communication between the aircraft and their base station was essential. Radio alone could supply this demand. In 1920 experiments were begun in Alberta and so great was their success that a steady development has been taking place from year to year until today the three western provinces of Manitoba, Saskatchewan and Alberta are covered by a system of radio stations serving the aircraft engaged on forestry duty. In Ontario a similar development has taken place and an extensive service is in operation there under the control of the Ontario Forestry Department.

During the past few years aircraft in Canada have expanded their field of operations and passengers, express and air mails are now being carried, on a commercial scale, to many distant parts of the country. This service has produced new demands for communication and an earnest attempt is being made to step into the breach and supply the demand. This service requires a very widespread ground system for the collection and distribution of meteorological information, as well as for ground traffic. In addition, since night flying and regular schedules are essential, the service demands a system of Aids to Aerial Navigation comprising both radio and light beacons. How these demands are being met in Canada will be described in detail in a later part of this paper.

Very recently aircraft have been put to a further extensive use in connection with aerial exploration work in the Northwest Territories, Northern Quebec and other outlying parts of Canada. The newspapers have very recently been full of reports about one party of explorers whose planes were lost in the vicinity of Victoria Island in the eastern Arctic. All of this information was brought out to civilization by means of radio, but the planes used by this party were not themselves radio equipped. The result was that the friends of the lost fliers spent many anxious weeks before the party finally reached a Hudson's Bay post which was in touch with the outside by means of radiotelegraphy. This at once brings up the question, what steps are to be taken to safeguard this very essential exploration work, first, — by providing communication in case of other similar unavoidable accidents or forced landings, second,—by establishing aids to aerial navigation in the Northwest Territories.

It would, therefore, seem advisable to treat this extensive subject under the following headings:

(a) Civil government air operations.
(b) Civil aviation and air mail routes.
(c) Northern explorations.
(d) Military aviation.

Each subject will be roughly divided into two parts, the first covering the work already underway, and the second, contemplated future developments.

In connection with the subject of civil aviation and air mail routes, a short résumé has been included of the work being done in other countries of the world, in order to emphasize the reasons for the choice of the system that has been decided upon for Canada.

Two maps are attached covering parts (a) and (b) above. In addition, numerous photographs have been reproduced showing graphically details of the types of

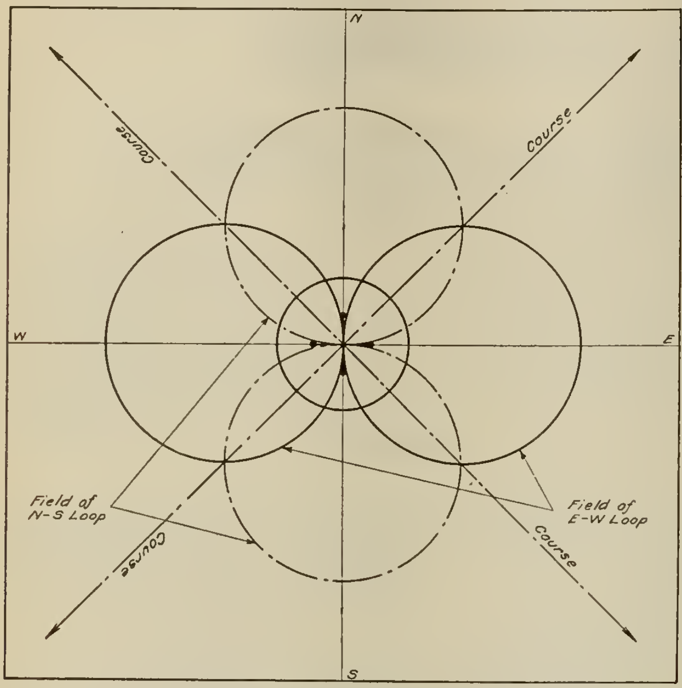

Figure No. 1.—Diagram showing Theoretical Field Strength Pattern of Two Crossed Coils or Loops when Energized with Equal Power at Same Radio Frequency.

equipment in use and the nature of the country in which this work is being carried out.

Civil Government Air Operations

Under this heading are grouped all aircraft operations, whether federal or provincial, which are being carried out for civil government departments. This work is almost entirely in connection with forestry patrols, although a certain amount of smuggling preventive flying is either planned or already underway. The greater part of this civil government flying is under the control of the Royal Canadian Air Force, however, the Ontario Forestry Department maintain a large fleet of aircraft and have an extensive flying and radio service throughout northern Ontario. These two systems will be described separately and in the order given.

Federal Government Operations

The Royal Canadian Air Force does not maintain a Signal Service of its own but has entrusted its communication problems to the Royal Canadian Corps of Signals. This scheme has been in operation now for over seven years with satisfactory results. The operation of the system may be briefly outlined as follows—The Engineering and Stores sections of the Royal Canadian Signals are responsible for the provision and operation of all signal and radio equipment, and for the design and construction of base radio stations and special aircraft radio apparatus. Operational stores for these radio services are also supplied through the Royal Canadian Signals Stores Branch. All officers and men required for the operation of these communication services are obtained through the Signal Service and are given a thorough course of training at the Royal Canadian Signals Depot before being posted to flying stations.

Wherever the Air Force are co-operating with the Forestry Service, the same general system of communication is adopted. In general the units of both the Flying Service and the Forest Protection Service are located together at strategic points throughout the area to be protected. At each of these places permanent ground radio stations are established, so that the headquarters of the services and all of the individual patrol stations, are constantly in touch with one another. These radio stations are used both by the Royal Canadian Air Force and by the forestry officials.

The aircraft employed on the work are divided into two classes:—

(a) Detection or patrol aircraft.
(b) Suppression aircraft.

The detection machines are equipped with radio transmitting sets, capable of both telegraph and telephone transmission, and they are therefore constantly in touch with their base stations while on patrol. No attempt has been made up to date to equip the planes with receiving apparatus, due to the necessity of reducing to a minimum the weight to be carried on these small machines. The suppression aircraft are not usually fitted with radio equipment.

The procedure at each individual station may be briefly summarized as follows:—

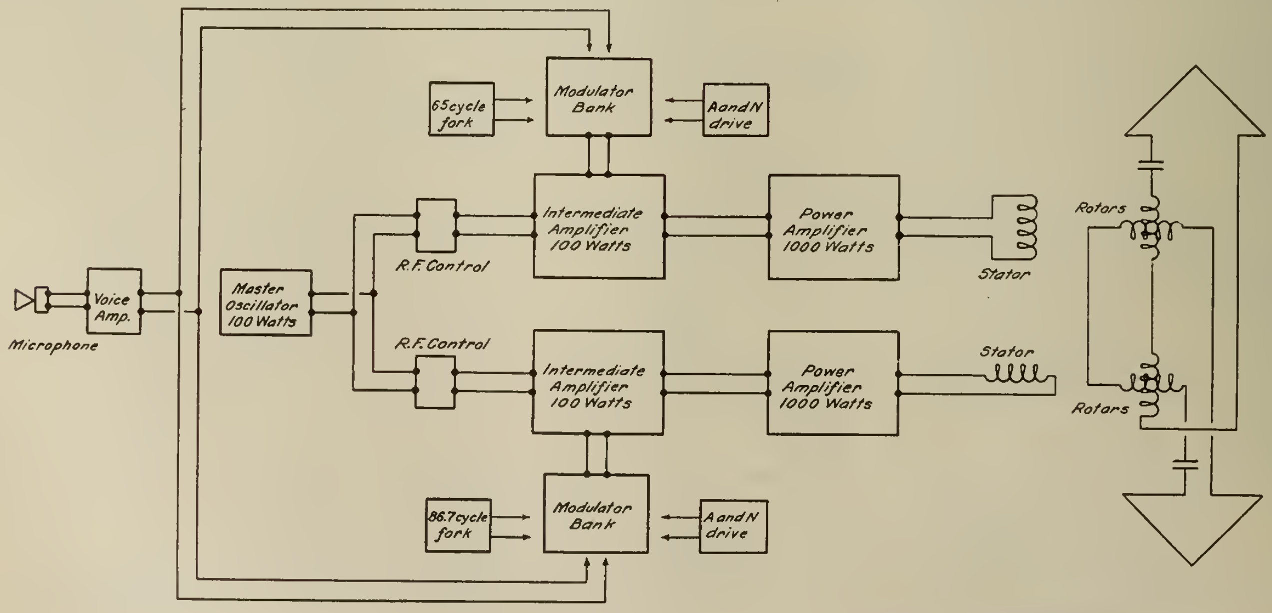

Figure No. 2.—Schematic Diagram of Arrangements of Parts of Canadian Radio Beacon.

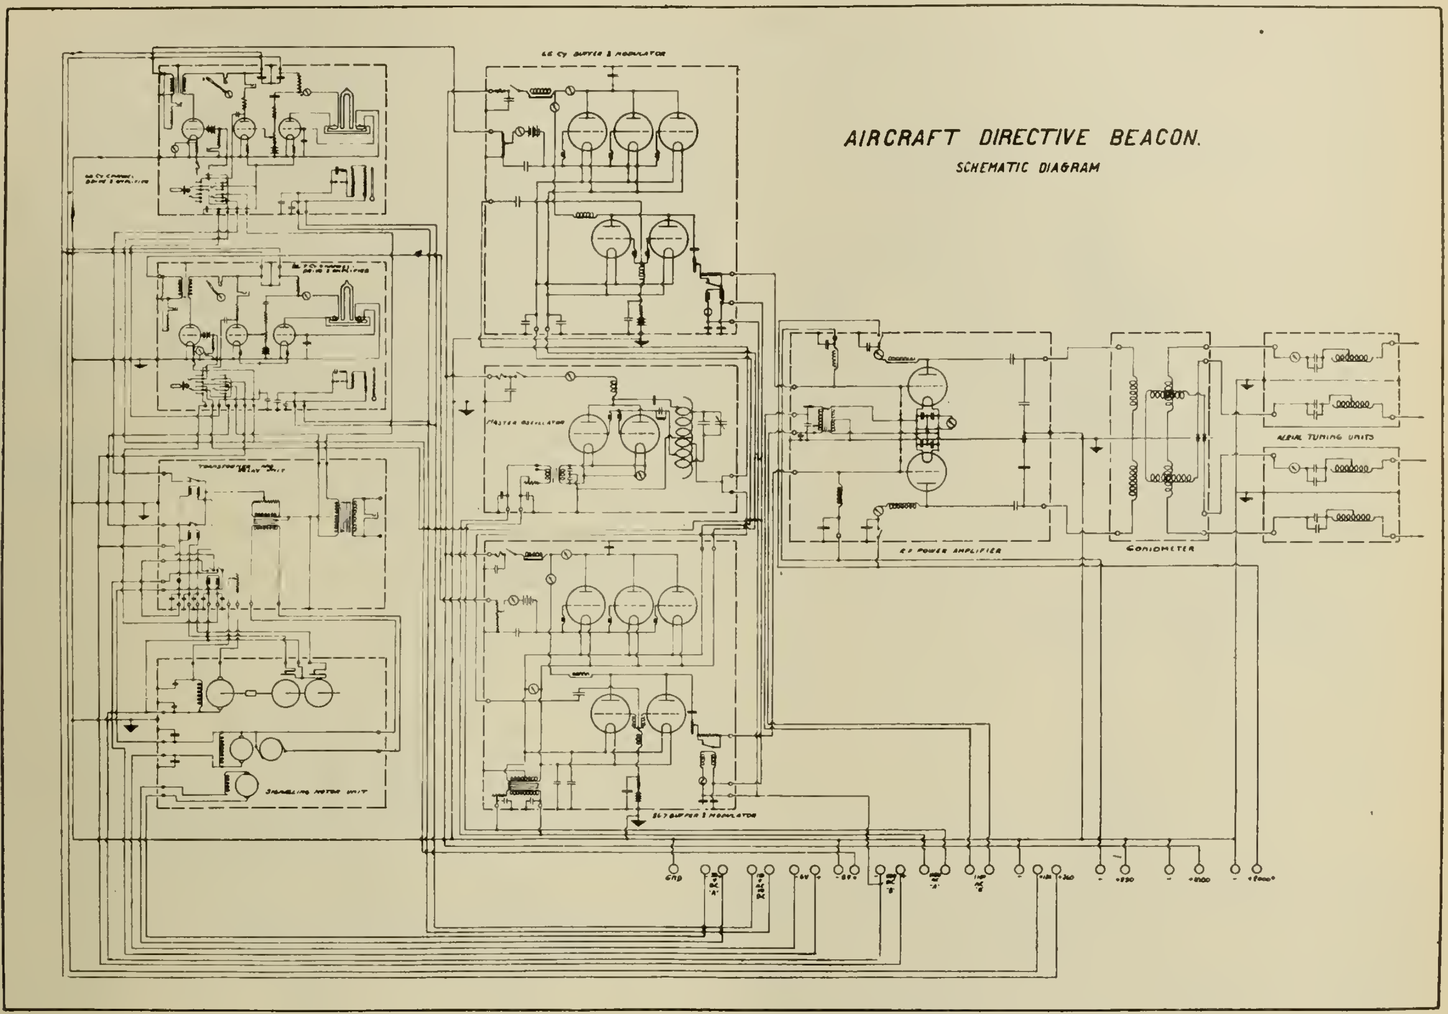

Figure No. 3.—Schematic Wiring Diagram of Aircraft Directive Beacon.

The area covered by the station is carefully divided into areas or patrols, and the general route to be followed on each patrol is marked on the area map. These maps are mounted on the walls of the operating room, and small distinguishing flags are used for the various pilots and patrols. At each report from a pilot his particular flag is moved to the new location given so that a glance at the map will show the station officials the approximate location of all planes in the air at any time. Pilots usually report every 15 or 20 minutes and, when more than one machine is in the air at once, the times for calling are arranged so as to avoid interference. The system not only provides information on conditions on the ground, but helps to insure the safety of pilots as well. It is for this reason that the pilots are instructed to give their exact location every time they come on to report. Should a man fail to report at his proper time, and there is reason to suspect that he has encountered trouble and has been forced to make a landing, the station officials know within a few minutes flying, where to look for him. Under ordinary circumstances a pilot should be able to come on and give his location, even during the time he is gliding down and searching for a suitable spot to make a forced landing. In actual practice this has very frequently happened. The receiving set on the ground station is manned from the time the first plane leaves until the last plane returns to the station. This is to insure that should any such emergency arise it will be possible for the pilots to operate their sets and give information or ask for assistance at any time. Should such an emergency arise, and it is necessary for one pilot to come on at the exact time that another patrol should be making its report, the pilots are instructed to use telegraphy rather than telephony, since telegraph signals are easily copied through strong speech or other jamming.

When information of special importance has to be transmitted, or in the case of names of places likely to be misunderstood, all pilots are instructed to give the information by voice first, but to repeat it immediately afterwards using the telegraph key. This insures the gist of the information getting through, no matter what the static is like, since the telegraph signals are much stronger than the speech. Names of places, proper names and figures are the only things which are liable to be misread or misunderstood. The repetition of map locations by telegraphy is intended to insure that mistakes will not occur.

During the summer season each base transmits by radio to headquarters a daily synopsis of the weather conditions during the previous twenty-four hours, together with the probable fire hazard as nearly as it can be judged. From this information and from radio reports received from patrolling aircraft, Forestry officials at Headquarters decide upon the area to be patrolled on the following day. Upon receipt of this information the officer commanding the Air Force sends out by radio his orders for the desired patrols.

In addition to this work the administration of both the flying and forestry detachments, the ordering of

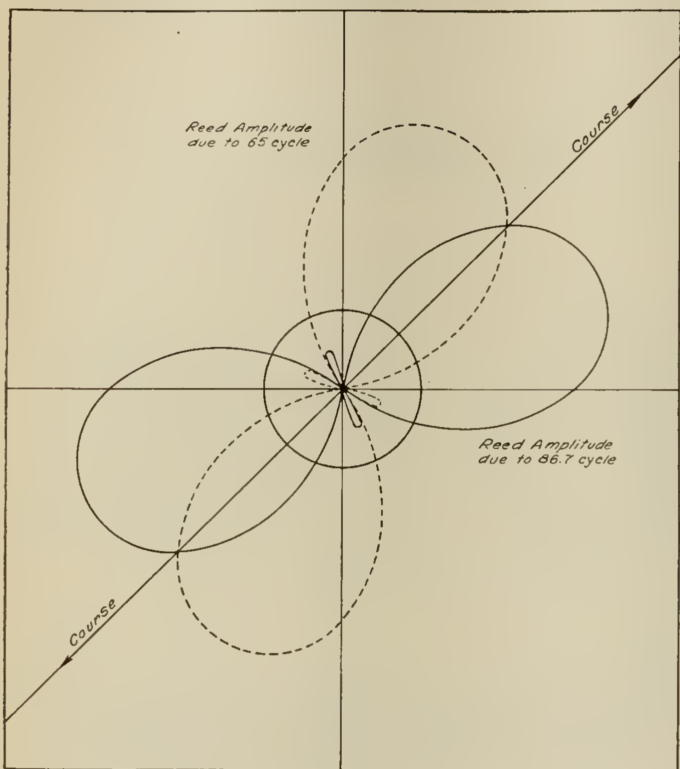

Figure No.4

provisions and technical stores, and the general communication required by detached units, is all performed by the ground stations. In certain localities where telegraph or telephone communication is already available, a large percentage of the general routine work mentioned above is handed over to the Commercial Service in order to speed up the operation of the radio system. However all matters pertaining to operations, and urgent messages of any nature, are handled by radio.

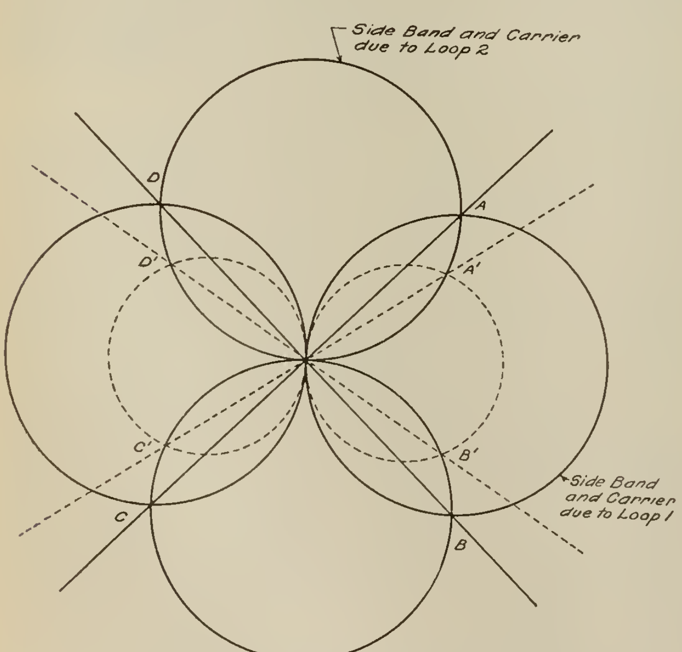

Figure No. 5.

Types of Equipment in Use

Ground Stations

As a result of the experience gained during the past few years the Signal Service has designed two standard types of ground stations for use on forestry work. The type of apparatus installed on any station depends upon the distance, but in general, a 100-watt set is used for distances up to 150 miles and a 500-watt set where longer ranges have to be covered. In the design of all this apparatus particular attention has been paid to the question of reliability, and, as far as possible, equipment and parts procurable in Canada have been used. The problems of repairs and replacements have therefore been reduced to a minimum. As previously mentioned these sets are only used for ground communication and not for ground to air work.

The 100-watt sets are fully automatic in operation and do not employ a station battery. A small automatic

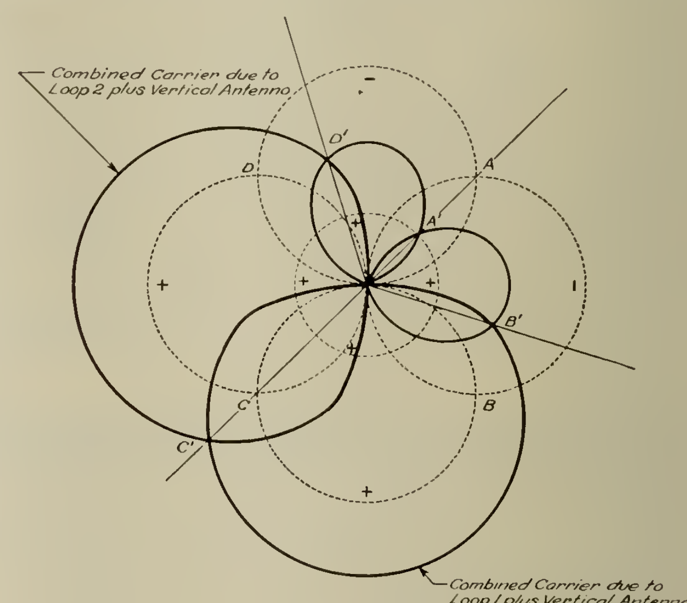

Figure No. 6.

gas engine is used, controlled directly from the operating table. The parts of the set are so arranged that it is very easily transported, and can be moved by plane if necessary. It can be erected by a crew of two men and may be installed in any type of building in any locality.

The larger sets are capable of putting from 500 to 1,000 watts into the antenna. The equipment is so arranged that the power output may be adjusted to suit the distance to be covered and the atmospheric conditions prevailing at the time. The stations are self contained in every way. The source of power is a 3-k.w. coal oil engine-generator set, with a 125-volt high capacity station storage battery for purposes of voltage regulation, and as a stand-by in case of emergency. The battery normally supplies the lighting for both the radio station and the camp. In case of a breakdown to the engine the battery can carry the essential load for about one week. Due to the capacity of the set, and the use of a station storage battery, special buildings are required wherever these larger sets are used.

Aircraft Radio Equipment

The use of radio equipment in aircraft is quite a problem. The set must be light, easy to operate and as nearly as possible foolproof, since once the aircraft leaves the ground the pilot is unable to carry out adjustments or repairs

without landing. As previously stated, no attempt has been made as yet to provide reception in the plane. Since the pilot cannot, therefore, be certain that his messages are being received, particular attention has been paid to the provision of suitable meters to enable him to determine when his set is working normally.

The aircraft sets now in use have been specially designed and built by Signals for this service. In order to minimize installation troubles in different types of aircraft, the number of parts have been kept to a minimum and the total overall weight is lower than that of any other aircraft radio apparatus now on the market. The experience of the past three years would indicate that the operational troubles from this apparatus were very few indeed. The following list of equipment includes all parts necessary for a complete installation in any plane:—

(1) Transmitter, containing all valves, wavelength controls and power switches.
(2) A 1,500-volt generator mounted on one of the wings and driven by a small windmill.
(3) The aerial reel for manipulating the trailing wire antenna used with the transmitter.
(4) The telegraph key, microphone and coiled spring suspensions for the transmitter.
(5) A small leak-proof storage battery for lighting the filaments of the valves in the set.

The total weight of this apparatus is 70 pounds.

Since the pilot has to be made responsible for the operation of the radio telephone set in the air, all of the equipment just described must be installed in the cockpit, together with the flying and engine controls. This requires some manipulation as great care has to be taken to see that those parts in which valves are mounted are protected from jars and bumps, which are unavoidable during the period that the plane is taxiing on the ground. It was recognized from the start that the average pilot, being in general unfamiliar with both the theory and operation of radio sets, would in all probability be unable to make the necessary adjustments for wavelength and resonance while in the air. Therefore the technical personnel would be called upon to test and adjust everything on the ground before the plane went up. Once in the air it would then only be necessary for the pilot to let out his aerial and throw over his transmitting switch in order to put the equipment into operation. To facilitate this test work, the stations were provided with complete equipment to duplicate on the ground the conditions met with when the aeroplane was in flight. The provision of this test apparatus proved to be a very wise precaution, as highly satisfactory results have been obtained in operation.

One of the main difficulties to be overcome in connection with radio-telephony from the air is the elimination of outside noises, due to the operation of the engine and the rush of the air. A very complete test on different types of microphones was made during the installation of this system, and, while several microphones gave excellent modulation, there was only one type which was free from the effect of extraneous noises. This type is known as the anti-noise microphone, and is manufactured by the Magnavox Company of Oakland, California. In this device, the diaphragm is connected to the microphone button by means of a brass link about half an inch long. The combination is then mounted in the frame in such a way that the outside noises can strike with equal strength on the two sides of the diaphragm and are, therefore, balanced out. The speech, however, being impressed on one side only, is transmitted without loss to the microphone button. Excellent results have been obtained with this instrument, and so perfect is the noise elimination that, when static is not present, the circuit compares favourably with a long-distance telephone line.

Operation of the Radio Systems

The attached map shows the locations of the various stations engaged on forestry work in Canada. It will be noted that there are three separate subdivisions in the west, in addition to the system operated by the Ontario government in northern Ontario.

These subdivisions are operating in conjunction with the three mid-western provinces and are referred to as the Manitoba, Saskatchewan and Alberta systems. While operating independently within themselves, the three systems are tied in together through the medium of the ground radio stations.

The best indication of the usefulness of any system of communication can be gathered from reports of the work done and the traffic handled. The following tables are included merely as an indication of the extent of the operations up to date.

Experiences in the Air

On the 22nd of July one of the summer bases was ordered to carry out a patrol over a certain area on the following day. At 9.45 a.m. the next morning a detection plane left the base on patrol. Half an hour later at 10.15 a.m. a radio message was received from the pilot reporting a fire of some ten acres in area and giving full information as to location, landing facilities, etc At 10.35 a.m., twenty minutes after the receipt of this report, a suppression machine left the base carrying two fire rangers, fire fighting equipment and food to the scene of the fire. A landing

1929 (to Oct.)	1,139,953			

was effected in the vicinity of the fire and actual fighting commenced before the detection plane had returned to the base. Under the old system where the detection planes were not equipped with radio the fire would not have been reported to the base until the detection plane had completed the patrol and returned to its base; probably three hours after the fire had been sighted.

On another occasion during a period of severe fire hazard a detection machine was out on patrol reporting at frequent intervals on the condition of fires on which crews were already working and at the same time keeping a sharp lookout for new smokes. During the course of the patrol the pilot reported one fire out and a new fire burning in good timber in the same vicinity, but at a point about twenty miles distant. Full information was given as to size, location, approximate rate at which spreading, and accessibility by air. Within an hour and a half from the time the radio report was received a suppression plane with two fire rangers and equipment had landed within 300 feet of the fire. The plane then left for the fire reported as being out, a landing was effected and extra men and equip-

Figure No. 13.—Cormorant Lake Air Base, Northern Manitoba, showing the Radio Station.

ment brought from there to the new fire. Many such cases occur each season where delays amounting to several hours and occasionally a day or more are eliminated by the use of radio. Apart from the time element which is perhaps one of the most vital factors in fire suppression, radio reports giving information on the condition of fires burning and the progress of fire fighting crews are of great assistance to the chief ranger in the handling of the whole fire fighting organization in his district.

As an example of the rapidity with which information is handled the following example is given: During a patrol from Cormorant lake the pilot was copied in Winnipeg all the way south as far as Lake Winnipegosis. At 12.15 p.m. he reported a class B fire, that is, one between 10 and 20 acres in extent. The pilot gave the location and all necessary details,—these were received in Winnipeg at 12.30 p.m., whereupon the pilot landed. A telegram was sent from Winnipegosis at 12.40 and received in Winnipeg at 3.30 p.m. Thus the radio effected a saving of three hours in connection with this particular fire.

In April 1929, aircraft *YR* from Lac du Bonnet station was patrolling in the Dogskin river area. Reports had been coming in steadily since the plane left at 9.50 a.m., but at 4.30 in the afternoon the engine suddenly developed magneto trouble and the pilot had to make a very rapid landing. However he had just time to come on, report his position, state that the magneto was not working and ask that a new one be sent out at once. As the weather was cold and snow was still covering the ground in that area, there was no time to be lost, if the pilot was to be rescued from a bad night in the woods. A Fairchild cabin machine was run out, a new magneto loaded on board and in half an hour was on its way to the location given by the pilot in his last message. Suffice it to say that both machines were back at their base by the time darkness had set in.

Winter Operation and Commercial Traffic

For the past few years most of the stations in the Manitoba and Saskatchewan areas have been kept open during the winter for the convenience of the traders, trappers and local inhabitants. Arrangements have been made for these stations to handle commercial traffic, clearing to the telegraph companies either through Cormorant lake to The Pas, or direct to Winnipeg. The use made of these stations has been very encouraging, and, while the business taken in does not begin to cover the cost of operating the stations, it is felt that the value of this service in opening up and developing the country cannot be measured in dollars and cents. In 1928, the commercial traffic handled amounted to 1,317 messages with a total value of $2,625.21.

Future Developments

Future developments in this service will depend to some extent on the re-organization following the taking over of the natural resources by the provinces. If the present system of forest patrols is maintained, an expansion of the area to be protected will be followed at once by an increase in the number of ground radio stations required. The most important extensions at present outstanding are at Cold lake near the Saskatchewan-Alberta boundary, and in the Reindeer lake district. It is also probable that some new stations may be erected shortly in the area east of lake Winnipeg, between Norway house and Island lake. Additional service is required in the Peace river district north and west of Grand Prairie, but it is not known whether this will be proceeded with in 1930.

Steps are now being taken to inaugurate in 1930 an aerial preventive service in the Gulf of St. Lawrence. A base station will be established on Anticosti island and radio equipped flying boats will operate in the gulf in conjunction with the revenue boats of the Preventive Service. This service should prove highly successful.

The Ontario Government Radio System

The province of Ontario maintains its own flying service for the protection of the provincial forest areas. In connection with this service an extensive and highly efficient radio system has been developed. At the beginning, ground stations only were installed but, as the system developed, air to ground communication was introduced with great success. It is understood that in the near future all the planes will be in radio contact with their base stations during patrols.

From Sioux Lookout, the headquarters of the flying and forestry services in the western part of the province, to Remy lake and Timagami on the eastern side, there are a total of eighteen stations. The map does not show all of these on account of the small scale used, but the stations shown serve to emphasize the extent of the area covered.

These stations all work in the wavelength band from 50 to 200 meters. For purposes of control and to minimize interference, they are operated in three groups corresponding to the Hudson, Cochrane and North Bay districts as shown below:—

Hudson Group
Sioux Lookout (Two stations)
Wingiskus Lake
Gold Pines
Red Lake
Goose Island
Swain's Lake
Jackson Manion
Cat Lake
Crow River
Fort Hope
Savant Lake
Caribou Lake
Armstrong

Cochrane Group.
Stimson
Little Abitibi

North Bay Group.
Maple Mountain
Elk Lake
Timagami.

In the Hudson district, a total of thirteen stations were operated, including two, one at Gold Pines and another at Sioux Lookout, which were used very largely for commercial work. In the Cochrane district, two stations

Figure No. 14.—A Typical Bit of the Area to be patrolled in the Foothills of the Rockies. Radio is Essential Here as Landings are Difficult.

Figure No. 15—Not a Forced Landing, Just an Ordinary One in Hudson's Straits. Note the Radio Generator on Starboard Side of Fuselage.

were operated and in the North Bay district three. This was one more than in the previous season.

From the point of view of operation there is considerable difference between the eastern and western stations. In the Hudson Inspectorate communication is largely required between district and ranger headquarters, this service being necessary because of the lack of land line communication of any kind throughout the area in question. For the same reason, the demand for a commercial service has also arisen.

In the two small eastern units, however, the use of radio is more definitely restricted to a specialized type of communication, in particular to communication with lookout towers. There is at present very little call for a commercial service for the eastern areas since land lines had been constructed throughout this territory prior to the establishment of the department's present organization.

In addition to the land stations described above, which are classified as "permanent" as distinguished from portable, the Ontario Forestry radio service have designed and constructed two other types of radio apparatus which it is expected will be of value in the work of the branch. These are (*a*) a portable set, (*b*) an aircraft set.

Before mentioning the portable sets it should be noted that the permanent sets weigh six hundred pounds and can be broken down into units of about two hundred pounds or less for purposes of transportation. The portable sets, however, have been especially designed for light weight and intermittent service. Two types have been developed (1) a battery operated set, (2) a gas-engine-generator set. Because of its relative simplicity, the battery set was completed first and was given an actual test on fire fighting operations during the present season. The set was found to have ample power and maintained schedules without failure. The gas-engine-generator set was completed and while it has not been actually tried on a fire fighting operation, has been given an equivalent test as regards distance and general working conditions. The set operated with entire satisfaction.

In considering these two types, it might be noted that the complete weight of either set is less than one hundred pounds, the battery driven set being the lighter of the two. In point of initial cost, the power driven set is at a disadvantage while in point of upkeep, the battery set suffers. On the whole, it would appear that the power driven outfit will be more generally desirable.

The aircraft set, which was designed and tested during the past season, differs from all other equipment in use in Ontario in that it provides for one way communication only. Considerable difficulty was encountered in obtaining material for the construction of this apparatus, owing to its special nature and to the general rapid development of the radio industry. The equipment did not therefore receive a working test until near the close of the season. The test was successful, but it is now considered that it would be desirable to lighten the apparatus and supply two-way communication.

These stations were intended primarily for government traffic but, as in the case of the Saskatchewan and Manitoba systems, commercial and private messages are accepted at a very reasonable rate, for the convenience of the inhabitants of the area.

Traffic figures for 1929 are not yet available, but the following information taken from the 1928 report, will serve to show the extensive use beng made of this service both by the Ontario government and the settlers and traders in the district.

Table No. 4.—Traffic Report—Ontario Government Radio System.

Year	Words Handled		Totals
	Government	Commercial	
1927	35,072	23,167	58,239
1928	52,289	181,566	233,855

On account of the growth in the number of stations operated during the past year it is expected that these figures will show a considerable increase for 1929.

Civil Aviation and Air Mail Routes

Commercial aviation, dependent as it is upon air mail, express and passenger carrying for its basic source of revenue, relies for its success, in large measure, upon closely maintained flying schedules by day and night. The one big hazard not yet completely overcome is the weather. Reliable engines, the use of multiple engines on the planes, numerous and well lighted flying fields and well constructed aircraft have all helped to stabilize the service, yet air traffic is often halted when meteorological conditions make the pilot uncertain that he can see landmarks or find his landing fields.

It is to reduce these uncertainties that the Directorate of Civil Aviation of the Department of National Defence has undertaken to install an extensive system of aids to

Figure No. 16.—Wakeham Bay Radio Station, Hudson's Straits Expedition.

aerial navigation throughout Canada. It is the intention of the government to provide throughout the country aids to air navigation in a manner similar to the aids to ship navigation maintained by the Department of Marine. It will then be necessary for commercial aviation companies to equip their planes with the necessary apparatus to make use of these radio aids, in the same way that shipping concerns must equip their boats with both instruments and operators. These aids include lighting of the airways for night flying, special meteorological service and radio aids. Only the radio will be dealt with here.

The possibilities of radio as an aid to air navigation include:—

(1) Communication between air and ground.
(2) Navigation over given routes.
(3) Landing in heavy fog or cloud.

From the point of view of most pilots, communication is considered to be the most essential. The pilot is anxious to receive while en route, information on weather conditions ahead and conditions at possible landing fields. The second step in the conquest of the weather hazard is the provision of a reliable system of course navigation that will permit a machine to be flown on a given route regardless of fog, mist or snow. It is not as yet possible to use radio to land a machine in fog but promising experiments along this line are underway.

Before proceeding with the details of the proposed Canadian system, the following description is given of the schemes at present in operation in Europe and in the United States.

European Systems

In Europe all planes flying on regular routes are equipped with radio-telephone transmitters and receiving sets. Two-way contact is maintained by voice between ground and air, and weather information and landing instructions are given to the pilot in this way. In addition the governments maintain a number of radio direction finding stations in connection with each of the principal airports. Upon request by radio from an aeroplane, two or more of these direction finding stations determine the direction of travel of radio waves from the plane. These bearings are combined at the base station and the position of the aeroplane calculated and transmitted by radiotelephone to the pilot. This system demands that the base station, and all the direction finding stations, shall be in constant communication, preferably by wire. An individual position can be calculated and transmitted to the plane in about a minute and a half, on the average. The big difficulty lies in the fact that, if several planes are calling for their positions at the same time, the last one may have to wait anything up to 10 minutes for this information. At busy airports this is a frequent occurrence. A further difficulty of this system is the necessity for carrying a transmitter, which means an added weight of approximately 100 pounds.

For the independent flyer, and to a certain extent for regular commercial services, a system of direction finding may be operated on the plane. Coils or loops are mounted in the wings and fuselage and the plane is swung around until the signals indicate that the axis of the machine is pointing towards the known ground transmitting station. By steering a course in the indicated direction the aeroplane can be. certain of reaching the desired point, the accuracy of the indicated direction increasing as the objective is approached. This is the well known system employed on marine vessels and on lighter-than-air craft. It is not as useful, however, on aeroplanes. On account of the noise and the electrical disturbances due to the engine ignition system, the errors are very much greater. This system is in use successfully to a certain extent, but requires very expert handling. This method of navigation has the inherent limitation that it does not prevent winddrift from shifting the aeroplane off its course: the scheme does eventually bring the machine to its destination, although by a circuitous route if there is any side wind.

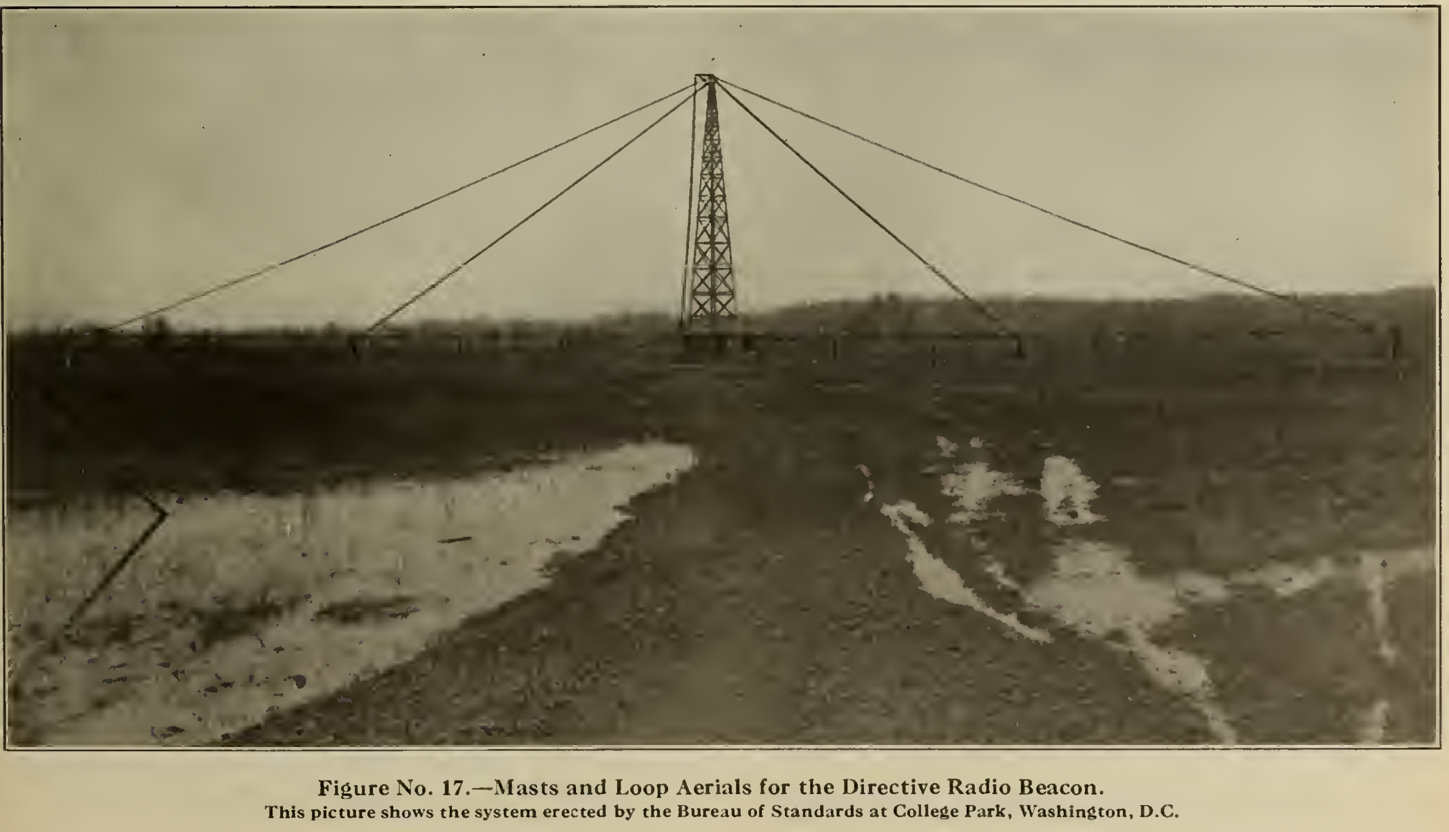

Figure No. 17.—Masts and Loop Aerials for the Directive Radio Beacon.
This picture shows the system erected by the Bureau of Standards at College Park, Washington, D.C.

Figure No. 18.—Canadian Radio Beacon Transmitter—Front View of Panels, Doors Closed. These Beacons were manufactured by the Canadian Marconi Company, Montreal.

A third method of furnishing navigational aid to aircraft is the rotating radio beacon. This is a radio transmitting station located at an airport, or at some known point on a route or junction of several routes, and provided with a rotating loop as an antenna. The loop rotates once in 60 seconds so that each one tenth second represents 0.6 degrees of rotation. The loop aerial causes a beam of radio waves to be sent out, and the rotation of the loop causes this beam to sweep continuously around the circle. A special signal indicates when the beam is pointing due north. A pilot, listening for this beacon signal in his receiving set, can determine his direction by the time elapsing between the north signal and the instant when the beam is heard with maximum or minimum intensity. The elapsed time is determined by means of a stop-watch whose dial is calibrated directly in degrees. This system only requires a receiving set in the plane and, by means of a number of these stations suitably located, the pilot could obtain his position to a fair degree of accuracy. The big disadvantage lies in the necessity for the pilot, or an observer, to continually check his direction if he is flying in bad weather or fog, or at night.

American Radio Beacon System

In the United States the Aeronautical Branch of the Department of Commerce, with the assistance of the Bureau of Standards, has developed a system of aids to air navigation to be operated in conjunction with the many air routes being developed in that country. They have recognized that the pilot's main requirements were to know weather conditions ahead of him, and to be able to fly on a direct course without the necessity of seeing landmarks or lights on the ground. The scheme involves a simple receiving set with fixed antenna on the plane, and radio telephone stations and radio beacon stations situated at suitable locations on the ground. With this system the pilot receives by radio telephone, information on weather conditions and other matters, and also the radio beacon signals to guide him along his course. All of the complicated and expensive apparatus is on the ground at the transmitting end and is maintained by the government.

The experimental work carried out on this system up to date shows that all practical requirements can be met by placing the beacons and the radio telephone stations at main airports approximately 250 miles apart. It has also been shown that the use of speech to transmit weather and other information, to the pilot while in flight, is thoroughly practicable.

The following description of these beacon stations has been taken from articles published by Dr. Dellinger, head of the Radio Branch of the Bureau of Standards, in Aeronautical Engineering, and in the Proceedings of the Institute of Radio Engineers.

"The radio beacon is a special type of radio transmitting station. Instead of having a single antenna like an ordinary radio station, it has two large loop antennae placed at right angles to one another. The two loops are energized simultaneously at exactly the same radio frequency. Each loop emits a signal which is strongest along a line which is the extension in either sense, of the plane of the loop. In a direction at right angles to the plane of the loop the signal strength is zero. The diagram of figure No. 1 shows the theoretical field strength pattern of two crossed coils or loops when energized with equal power at the same radio frequency.

It will be observed that if an aeroplane was flying along either of the dotted lines, that is, midway between the two beams of radio waves, it would receive signals of equal intensity from each of the beams. If the machine gets off of this line, it will receive a stronger signal from one loop than from the other. Interlocked cams are used to transmit a signal over each loop, the letter A (- —) being transmitted over one loop and the letter N (— -) over the other. The cams are so adjusted that if the outputs from both loops are fed equally into a common receiving system, only a long dash will be heard. Therefore if an aeroplane is flying along either of the dotted lines of figure No. 1 only a long dash will be heard. This provides an additional means of enabling the observer to decide when the signals are of equal strength, or in other words, when he is exactly on the prescribed course."

This system suffers from the same defect as the rotating loop beacon, namely that the pilot must be listening to the signals during the entire flight in order to keep the plane on its proper course. This is very fatiguing especially if static or interference is strong, as it very frequently is during bad weather when the system is most needed.

From what has already been said it is quite evident that some form of visual indicator for use in the plane is essential if the aircraft radio beacon is to be a success. This problem was attacked by both the American Signal Corps and the Bureau of Standards. Valuable work has been done by both organizations, but quite recently the Bureau of Standards has completed a system known as the double modulation beacon, together with a vibrating reed visual indicator. This system has shown great promise, and in view of the fact that a modification of this scheme has been adopted for use in Canada, a short account of the method of operation will be given.

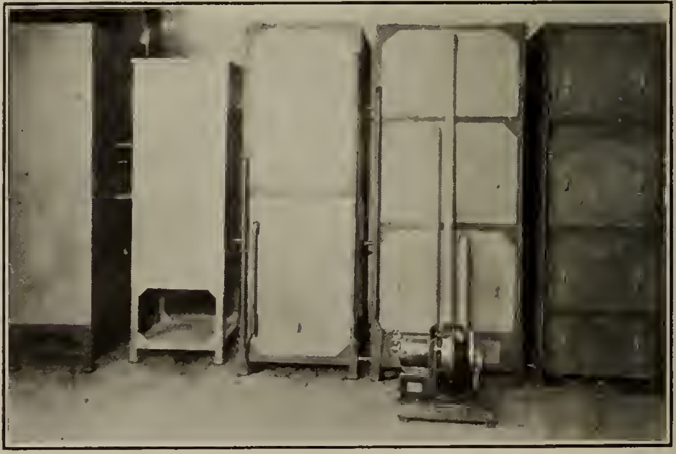

Figure No. 19.—Canadian Radio Beacon Transmitter—Back View of Shielded Cabinets showing the Blower Unit for Cooling the Intermediate Amplifier and Modulator Units.

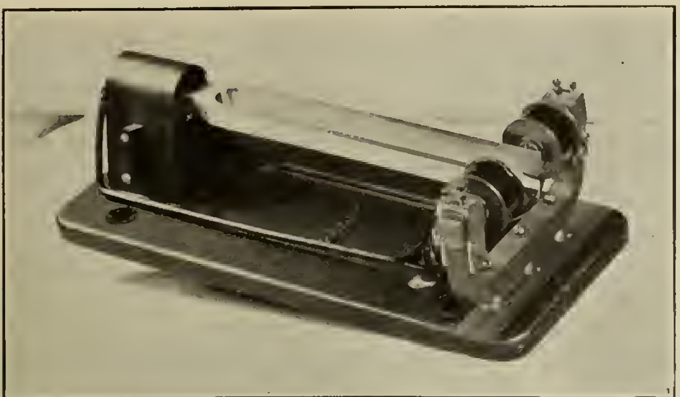

Figure No. 20.—One Tuning Fork with Electric Drive for Canadian Radio Beacon Transmitter.

In this system both loops are fed with power at the same radio frequency, but different modulation frequencies are employed for each loop. Low audio frequencies were chosen for two reasons,—first—so that a simple vibrating steel reed could be used as an indicator, and secondly, to keep to a minimum the width of the side bands transmitted. In other words, this would reduce the amount of interference which the system would cause to neighbouring services. On the plane a simple non-oscillating receiver is employed and the output of this set is fed to the indicator, which consists of small electromagnets between which two vibrating polarized steel reeds are mounted. These two reeds are tuned mechanically one to each of the two frequencies of the loop modulation voltages. In operation these reeds vibrate with equal amplitude when the plane is on its course, since the receiving set picks up equal signals from each loop. When off course, the pilot can estimate the amount of the deviation by the relative reed amplitudes. One of the main advantages of this system is that the apparatus is immune to ordinary static and magneto interference owing to the sharp mechanical tuning of the reeds.

Canadian Radio Beacon System

So much for the principle of operation, the following details of construction, together with the diagrams and photographs, illustrate the equipment designed and built in Canada by the Canadian Marconi Company in collaboration with the engineers of the Royal Canadian Corps of Signals. Figure No. 2 is a schematic diagram of the arrangements of the parts of the beacon, while figure No. 3 is a schematic wiring diagram of the set itself. The photographs are self-explanatory. The photos of the aerial system at College Park, Maryland, and the visual indicator for the aeroplane were supplied through the courtesy of Dr. Dellinger, head of the Radio Department, Bureau of Standards, Washington, D.C.

Beginning at the left of the diagram of figure No. 2 it will be noted that the transmitter consists of a master oscillator of 100 watts output feeding two intermediate amplifiers each of 100 watts. Each of the intermediate amplifiers control a power amplifier of one kilowatt rating. The output from these last stages is fed through a four coil goniometer into the two loop antennae. Tuning is provided in each leg of each loop so that an exact balance of the aerial system may be secured. The modulation frequencies are introduced into the two intermediate amplifiers, and it is in this part of the circuit that the modifications have been introduced into the Canadian apparatus. It will be observed that the two audio frequencies of 65 and 86.7 cycles are obtained from two valve driven tuning forks, the temperatures of which are held constant by means of thermostats, at 90° F. Two UX. 210 valves are used as an output amplifier for the tuning fork, the energy from this amplifier being fed into the intermediate amplifier through a bank of UX. 845 modulation valves. Means are provided to control the depth of modulation produced by the tuning fork signals. In order to provide for planes not equipped for visual indication, apparatus has been provided to convert the beacon to the aural, or A and N type. A small 500-cycle generator, together with a motor-driven set of interlocked cams, may be switched into the circuit in place of the forks and the output of the two loops, modulated with a 500-cycle signal, may be keyed as in the original American system. This modification will provide for service to visiting American aircraft equipped for the visual system, or for any of our own planes that may be flying beyond the range of operation of the visual indicator. No change is required on the aircraft receiver, as head telephones are already provided to receive the meteorological broadcast.

It has been pointed out that both telephone communication from the ground and beacon signals are required by the pilot flying on a modern air route. In the American system this is provided by a second transmitter at the airport operating on a second frequency within the range of the aircraft receiver. There are two disadvantages to this scheme. First—the cost of the second transmitter with its power plant and associated equipment. Second—the necessity for the pilot to tune his set while in the air from one frequency to another, with the accompanying possibility of mistakes being made.

To overcome these difficulties a further modification has been added to the Canadian beacons. A microphone and speech input amplifier have been included in the transmitter, together with the necessary switching, so that voice modulation of the output of each loop can be secured. In order to transmit weather reports or other information to the pilot, it is only necessary for the operator at the station to throw the switch from either of the beacon positions to "voice" and to speak over the microphone provided. No change is required in the tuning of the aeroplane receiver, and the pilot can adjust the strength of the speech by means of the volume control provided on the remote control device.

The aircraft receiver is of the high gain type employing three stages of screen grid radio frequency amplification ahead of a detector and two-valve audio amplifier. This amount of amplification is required to operate the visual indicator, since it has been found necessary to use a vertical rod type aerial on the plane to minimize "night errors," or variations in apparent direction due to reflections

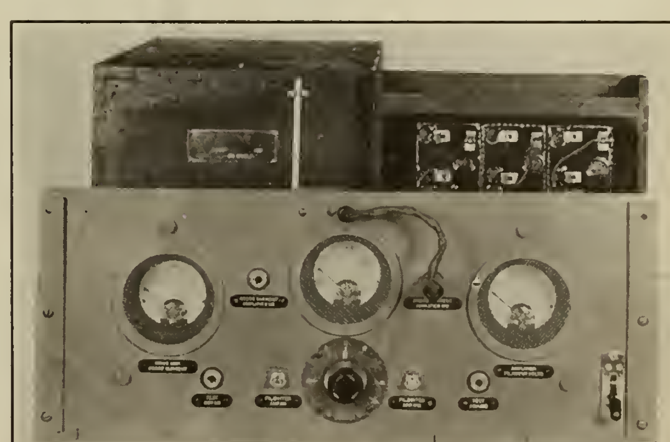

Figure No. 21.—Canadian Radio Beacon Transmitter—Front View of One Tuning Fork Panel, showing the Controls.

from the heavyside layer. This antenna consists of a streamlined metal clad rod, mounted on the fuselage of the machine and extending seven feet above the upper surface of the plane body. It is held in place by guys to the two wing tips and to the tail. The actual receiver is mounted in any convenient place in the tail of the aeroplane and the on and off switch, telephone jack and volume control are mounted in a small box on the instrument board. The visual indicator is also mounted on the instrument board in some spot where it can easily be seen. The effect of the electro-magnets on the compass has been completely eliminated by proper screening of the indicator box.

In order to obtain the maximum benefit from this receiver complete shielding of the ignition system should be employed The high and low tension wires, the spark plugs and the magneto distributor blocks should all be shielded Special shielded ignition harness has been developed by several United States firms, chief among whom is the Belden Company of Chicago . In this harness the distributor blocks are covered by metallic shields and the spark plugs are of a special type in which the shield is an integral part of the spark plug It is possible, however, to operate the receiver with a fair amount of success even without any shielding. The beacon signals are not greatly affected by the magneto disturbance but the speech will be interfered with to some extent.

The goniometer, coupling the power amplifiers to the crossed coil antennae, is used to enable the two courses mapped out by the beacon to be oriented in any direction required. The goniometer consists of four coils, two stator coils at 90 degrees to each other and two rotor coils also crossed at 90 degrees. The stator coils are connected to the plates of the power amplifiers, while the rotor coils are connected each in series with one loop antenna. The currents in the loop antennae, due to the driving voltage from each stator coil, create a resultant field in a direction such as would be produced by an imaginary antenna rotating with the goniometer rotor. Since there are two stator coils at 90 degrees, there are two such phantom antennae rotating as the two rotor coils turn together, thus allowing the equisignal zones or courses in space to be swung into any required direction.

There is a further advantage to be gained from this system. By suitable adjustments of the goniometer coils and the transmitter, two different effects may be secured. First—two of the right angle courses may be eliminated, leaving only one direction along which aircraft may fly. Second—the four courses may be retained but the angle between the two directions may be varied over quite wide limits. This is often necessary at airports where a number of radiating courses are in existence. A practical example of this is found at the air mail fields at Hadley, New Jersey, and Bellefonte, Pa. At Bellefonte, two courses at 165° are used, while at Hadley there are three courses in simultaneous use leading to Hartford, Conn., Bellefonte, Pa., and Washington, D.C. These various possibilities are illustrated diagrammatically in figures Nos. 4, 5 and 6.

The directive beacon, while it guides the pilot along the course, gives no information about the particular point on the course at which he is located at any given instant. To provide for this requirement, marker beacons are being used on the United States airways. These are small non-directive transmitting sets placed at intervals of about 25 miles. The power is usually of the order of

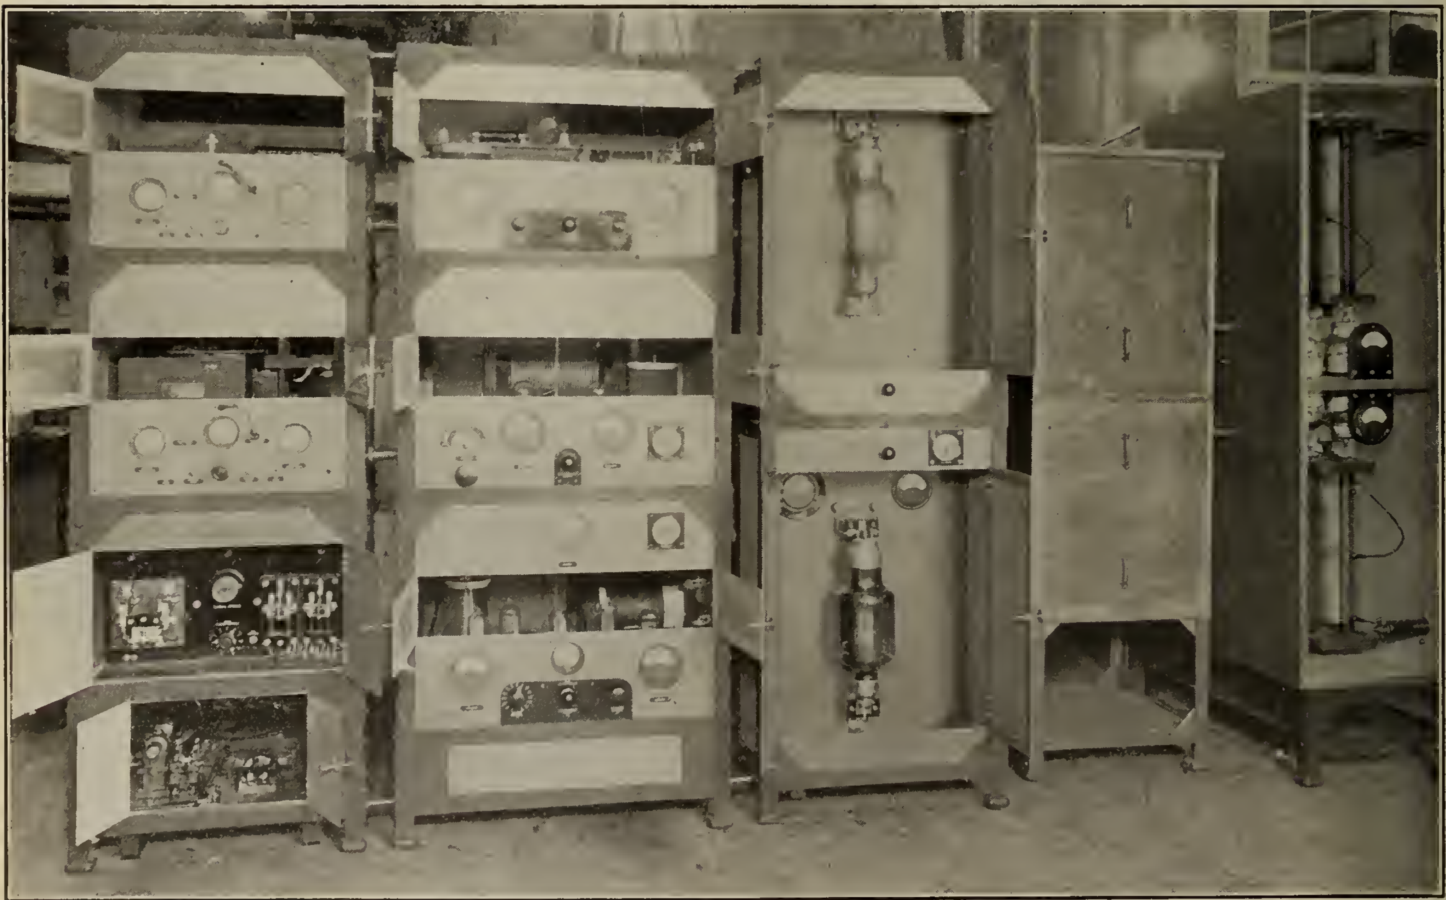

Figure No. 22.—Canadian Radio Beacon Transmitter—Front View, on Left is Tuning Fork and A and N Drive—on Right is the Loop Tuning Apparatus.

10 watts and the range to the aeroplane not over 2 or 3 miles. The output of these beacons is modulated at 120 cycles and the visual indicator is fitted with a third reed mounted alongside the other two. This reed will indicate when the plane is passing over a marker beacon, since the frequency of the carrier wave from the small transmitter is exactly the same as that used at each of the main beacons on the route. In all probability this scheme will be incorporated in the Canadian Air Mail system at some future date.

Canadian Air Mail System

The Canadian Transcontinental Air Mail system, upon which the Government is establishing complete aids to navigation, is laid out as follows. In summer the mail is taken from the steamers at Rimouski and transferred to aeroplanes flying to Montreal via Quebec and the St. Lawrence river. In winter the mail is picked up at Saint John, N.B., and taken by plane to Moncton where it is transferred to the transcontinental planes of Canadian Airways Ltd. It is then flown to Quebec via Fredericton, Edmundston and Riviere du Loup. At Quebec it is transferred to the Montreal plane and delivered to St. Hubert aerodrome. From St. Hubert the mail goes via Toronto and London to Windsor and Detroit, at which point it is handed over to the United States Transcontinental Air Mail Service which takes it as far as Minneapolis. Here it is again transferred to Canadian machines which take it to Stephenson field, Winnipeg. From Winnipeg the Western Canada Airways operate air mail planes to Calgary via Regina, Moose Jaw and Medicine Hat. At Calgary it is transferred to fast express trains for the trip through the mountains to Vancouver. In addition to this service there is an air mail route from Regina to Edmonton via Saskatoon and North Battleford. This circuit is operated in connection with the direct Winnipeg-Calgary route. It has not yet been decided which air route will be followed through the Rockies to Vancouver and, therefore, the final selection of the main transcontinental route cannot be made.

However, radio aids to air navigation are being installed on two sections of the system, namely, from Montreal to Windsor, and from Winnipeg to Calgary and Edmonton.

Map No. 2 attached will explain clearly what is being done. On the eastern half of the route a special radio-telegraph station has been erected at St. Hubert, and the Marine Department stations at Saint John, Father Point, Quebec, Kingston and Toronto are co-operating with St. Hubert in the collection and dissemination of weather information. Reports are prepared and transmitted from Saint John, Father Point, Quebec and St. Hubert before the planes leave the various stations. In this way the pilots know the weather conditions ahead of them on the route they are to follow. In addition to these reports received before departure, the Canadian Airways planes are now carrying a receiving set and an operator and, while in flight, are receiving special weather broadcasts by radio telegraphy from the stations on the different routes.

In order to permit the aerodromes to keep closely in touch with one another, a teletype line has been installed with teletype instruments at St. Hubert, Kingston, Toronto, Hamilton, London and Windsor. The meteorological department in Toronto have arranged for special observers at each of these places and weather reports may be obtained from any station at any time during the day. In addition to these special reports, a number of routine weather reports are transmitted from each station to all other stations every day. These reports give full meteorological information so that every station on the teletype system has on hand at all times a complete fyle of weather reports covering all stations on the system. This information is available for pilots or others contemplating flights over any part of the route. At St. Hubert the operator copies the regular radio weather broadcasts from Arlington, Virginia, and a weather map of the eastern half of North America is made up daily. This map is available on the station hours before the map sent out by the meteorological office in Toronto can arrive by mail.

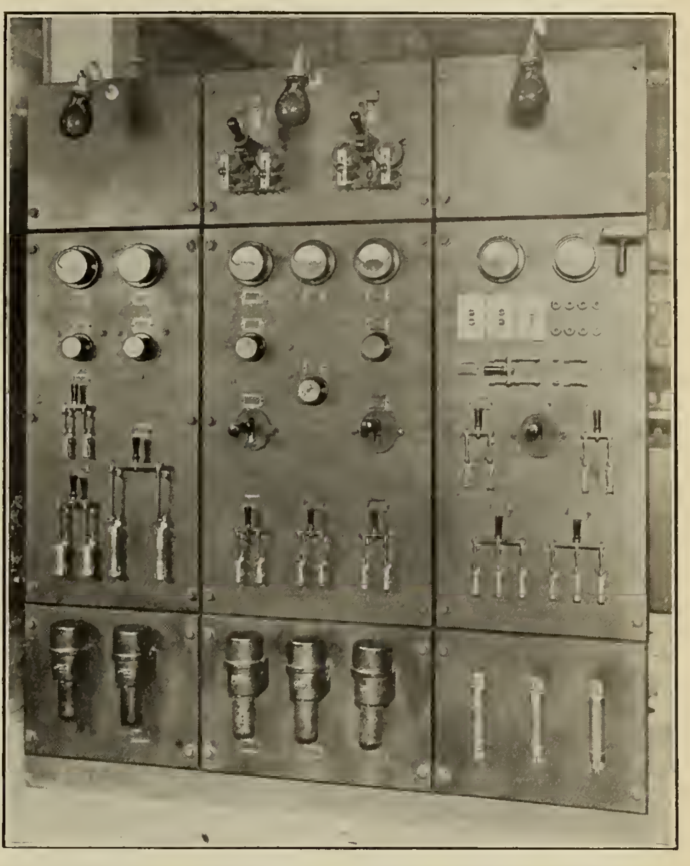

Figure No. 23.—Canadian Radio Beacon Transmitter—Power Control Panel.

On the eastern end of this route the planes are flying in daylight, but from Hamilton to Windsor and Detroit there is considerable night flying especially in the fall, winter and spring. For this reason, lighting has been installed on the route and a radio beacon will be erected at London during the coming year. It will then be possible for all planes flying between Montreal and Windsor to obtain full weather information at any time, and in addition, be able to fly by beacon over that part of the line where night flying is required.

On the western end of the system, between Winnipeg, Calgary and Edmonton, beacon stations are being installed at Forrest, Man.; Regina, Sask.; Maple Creek, Sask.; and Calgary, Alta. It is quite probable that radio beacons will also be erected at Saskatoon and Edmonton. In general these stations are being placed at 250-mile intervals, since the dependable range of the aircraft visual indicator system is 125 miles. It will be observed from the map that at Broadview, Morse and Medicine Hat the direction of the mail route changes somewhat and the beams from the beacon stations intersect at these places. It is proposed to erect marker beacons at these points and to use a third reed in the visual indicator as previously described. Until such time as these special stations can be erected, "on

Figure No. 24.—Visual Indicator with Third Reed for Marker Beacon Transmitter.

course" lights have been installed to indicate to the pilot that he must change direction.

A teletype line has been installed from Winnipeg to Calgary with instruments at Forrest, Regina, Maple Creek, Medicine Hat and Calgary. There will also be a line from Regina to Edmonton via Saskatoon. It is expected that the Winnipeg-Calgary route will be night flying entirely, but for the time being at any rate, the Regina-Edmonton service will be a daylight service only.

Observers will be provided by the meteorological department at each of the flying fields and the same routine followed as in the case of the eastern mail route. A weather report, collected over the teletype system from all other stations on the chain, will be broadcast by voice once every hour from each of the beacon stations. This can be easily arranged since they are equipped to operate as broadcasting stations as well as radio beacons. The routine to be followed on each station will be somewhat as follows. During the time when machines are in the air, the beacon signals will be shut off exactly on the hour and the weather report transmitted for the information of the pilots. At this time special messages dealing with navigational matters, or orders for the pilots from owners of machines using the route, will be broadcast. At the present time it is necessary to shut down the beacon while this broadcast is taking place but experiments are now under way to make it possible to operate both at the same time. It is hoped that this improvement will shortly be available for all ground stations and aircraft receivers.

Before leaving this part of the subject, the writer would again emphasize the fact that all aids to air navigation, comprising meteorological service, teletype line, radio beacons, lighting and emergency flying fields are all provided and maintained by the government. Air mail contractors and private or commercial aviation companies wishing to make use of these aids may do so simply by equipping their machines with a suitable receiving set with a visual indicator and head telephones. The cost of the aeroplane installation and its maintenance will, of course, have to be met by the owner of the plane, but the government radio engineers are always available to advise owners with regard to the type of apparatus required and the best methods of installation for their machines.

Northern Explorations

A glance at the map of Canada will show anyone the vast areas still to be opened up and developed. It is said that before any country can develop and be made attractive for settlers, facilities for transportation and communication must be provided. The aeroplane with its great speed and range of operation is an ideal means of transportation when one considers the geography of northern Canada. In summer the greater part of the area is covered with numerous lakes which make ideal landing grounds for seaplanes or flying boats. In the winter, the use of skis still further extends the field of operation of the aircraft. However, it has been amply demonstrated during the past that communication is of vital importance to the operation of air services, and it is for this reason that this subject has been introduced here. The interest taken by the public in the combined questions of radio, aircraft and exploration is shown by the space devoted to them in the daily papers. Attention need only be called to the extensive search for the McAlpine party, lost in the Dease straits area, and to the more recent Christmas air mail armada that made the round trip from Edmonton down the MacKenzie valley to Aklavik in the MacKenzie delta. Without communication these enterprises would be made very difficult if not impossible.

The question of developing communication in the north country is one which concerns the government very closely, in fact it might be said that the government is responsible for the provision of this very essential utility. It remains then to decide what form this communication should take in order to provide the greatest benefit, not alone for the many companies operating aircraft in that area, but for the inhabitants of the country as a whole. A great deal has been written about the wonders of short wave radio. In fact it is quite commonly considered as the panacea for all the ills of ordinary radio-telegraphy. Unfortunately this is very far from being the case, even with the more permanent stations used for point-to-point communication. Short wave radio apparatus is more intricate and requires greater precision of adjustment than the better known long wave equipment. Operators must be more carefully trained and have more experience on account of the greater tendency for signals to swing and fade, and, in addition, they must be thoroughly acquainted with the vagaries of reflection, skip-distance and night-effect in order to be able to choose the proper wavelength to use for each period of the day and season of the year. Even among radio engineers these matters are not yet reduced to standard practice, since different effects are found in different parts of the world. The application of short waves to aircraft communication is still very much in the experimental stage, and it would be very unwise to depend upon that alone in laying down a basic scheme of communications for aircrafts operating in the Northwest Territories.

Turning then to the more standard medium wave apparatus for aircraft, it may be definitely stated that a good dependable telegraph range of 250 to 300 miles can be obtained with apparatus which may be conveniently carried on the type of aircraft generally used for this exploration work. The use of telegraphy and the carrying of an operator are strongly recommended for this work for the following reasons:

(1) The ranges obtainable by telephony are too small for the weight that has to be carried.

(2) Telegraphy can be easily read through static and interference that would make speech unintelligible.

(3) Aircraft radio apparatus is delicate, since both weight and space must be kept to the absolute minimum, and must be given skilled attention if results are to be obtained.

(4) Because communication is so important to the safety of aircraft and personnel it is just as important that they should carry an operator as an engine mechanic.

Since the size of the crew to be carried is such an important item on exploration work, it is suggested that radio operators might be taken and trained as engine mechanics, since it is easier and quicker to train a man on engines than to make him first an operator and then give him all the technical skill required by a good radio man. Again, it might be pointed out that all men cannot be made into expert telegraph operators, but your radio operator has received, during his training, such an insight into technical matters that he is already well on the way to becoming a good mechanic. It should also be mentioned that modern pilots are usually first class aircraft mechanics and the mechanic in the plane is more an assistant to the pilot than an air engineer.

Map No. 3 shows the radio stations that exist at present in the north country. The approximate distances between stations have also been shown. The stations of the Marine Department are all of high power, those of the Department of National Defence of medium power, but the privately owned stations are of very low power and short range. If all the stations shown were even of medium power rating, and were equipped with modern valve receivers for aircraft reception, all the stations on the chain would be able to intercommunicate with one another, either direct or with not more than one relay. (The medium power stations of the Department of National Defence have a dependable range of 600 miles).

Turning now to the aircraft side of the problem it will be seen that, if the recommendations already made with regard to aircraft radio apparatus should be adopted, any machine flying in the area west of the Hudson's bay could be in touch with some base station at all times. In order to take in both shores of Hudson's Bay it would be necessary to erect two medium power stations, one at Moose Factory, and the other at some point on the eastern shore of the bay, such as Whale river. For satisfactory operation unified control is essential which points to the inclusion of the present privately owned stations in the network. To be of use for this purpose, the power of the stations in question would have to be increased. This system, if installed, would make flying in the north comparatively safe and could be put into operation now with apparatus already on the market. As and when short wave for aircraft becomes commercially feasible, this improvement could be added to the existing system.

No mention has yet been made of the much discussed question of emergency communication when the aeroplane has been forced to land. It is the opinion of the writer, after many years experience in aircraft radio work for the Department of National Defence, that this subject is very much over-emphasized. What is of more importance is that a careful system of communication should be worked out between aircraft and ground stations. Frequent reports should be made and at each call the position of the plane should be given. This can easily be done, without undue waste of time, if an operator is carried and telegraphy used, since repetition would seldom be necessary as is the case when voice is used. If a plane is forced to land under these conditions its position is known by the ground station within a comparatively few minutes flying time.

As an excellent example of the way this system works out in practice, the writer has taken the liberty of attaching as an appendix, an extract from the log of the Wakeham bay station of the Hudson's strait expedition. It will be remembered that this expedition spent 18 months in the Hudson's strait area exploring, by means of aircraft, the drift of the ice. All machines were radio equipped, and operated on the principle advocated by the writer.

When a machine has to make a forced landing it is very often damaged and the likelihood of the radio being put out of commission is at least as great as that of any other part of the machine. However, if an emergency power plant is needed, there are available on the market small gasoline engines under 30 pounds in weight and sufficiently powerful to supply all the energy required by the radio apparatus. In the latest type of engine, bed-plate and coupling are arranged so that the wind-driven generator can quickly be coupled to the power unit. If a trained operator is carried this re-arrangement offers no technical difficulties. It is pointed out however, that the range of a given aircraft transmitter on the ground is seldom greater than 40 per cent of its range when in the air. This is due to the high percentage of energy absorbed by the rocks, earth and vegetation.

For this system to be fully useful it would, of course, be necessary to insure that all aircraft flying into the north country would carry both an operator and the approved type of equipment. This would simply be placing the communication requirements for the operation of aircraft on the same basis as that in force for many years on ships.

Military Aviation

Flying for military purposes is not as extensively carried on in Canada as in other countries of the world. The main military flying base is located at Camp Borden, where most of the training work of the Royal Canadian Air Force is concentrated. In addition to the Camp Borden activities there is a limited amount of aircraft co-operation at the naval bases at Halifax and Esquimalt, and at certain militia summer camps throughout Canada.

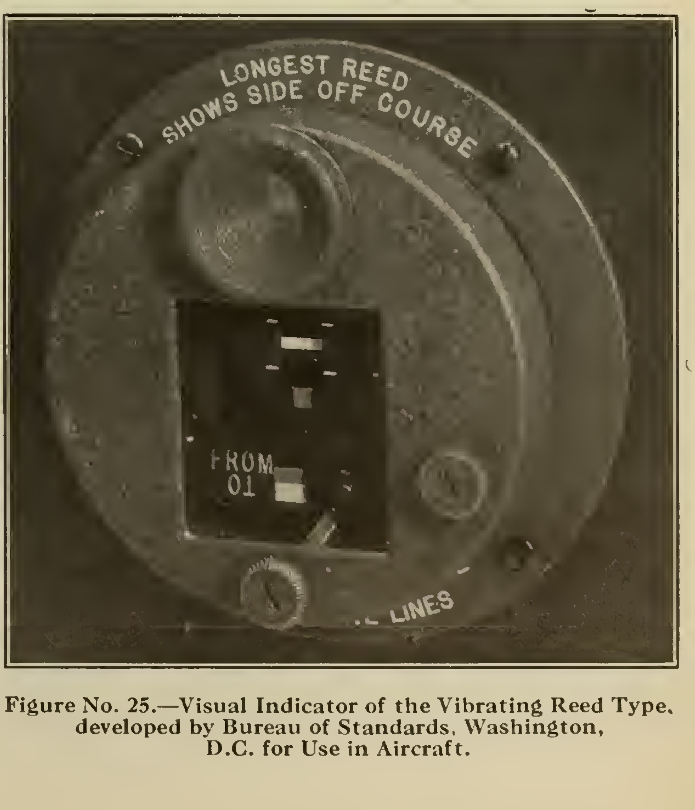

Figure No. 25.—Visual Indicator of the Vibrating Reed Type, developed by Bureau of Standards, Washington, D.C. for Use in Aircraft.

The radio communication work carried on for this service is naturally limited. Two ground stations are in operation, one at Ottawa and the other at Camp Borden. These are used to connect the Air Force headquarters with the training base. Considerable traffic is handled over this circuit.

Two types of aircraft sets are in use. For short range communication from air to ground, and for telephone communication between different machines in a flight, special sets have been developed by the Royal Air Force in England. These sets operate in the wavelength band from 50 to 120 meters and are intended solely for telephone transmission. For long range air to ground service, a special set known as the CT21 set has been developed in Canada. This set is a combined telegraph and telephone transmitter and may be operated by means of an electrical remote control so that the transmitter may be located anywhere in the aeroplane. As previously mentioned, this type of set is also used in the civil flying operations of the Department, for which work it was originally developed.

During the summer months aircraft are assigned for duty at the militia camps at Niagara, Ont.; Camp Hughes, Man.; Sarcee, Alta.; and Petawawa, Ont. These planes are equipped with radio apparatus and a portable ground station, with the necessary Signals Corps operators, is sent along to provide whatever communication may be required. Both artillery observation and army co-operation and reconnaissance schemes have been successfully carried out. The general policy of the Department, with regard to communication for our fighting aircraft, is to follow the lead given by the Air Ministry in Great Britain.

Conclusion

In conclusion the writer wishes to acknowledge valuable assistance given in the compilation of the data, photographs, diagrams and maps contained in this paper to the officers and men of the engineering staff of the Assistant Director of Signals Office, Ottawa; to the Canadian Marconi Company, Montreal; to Dr. Dellinger of the American Bureau of Standards, Washington, and to the Photographic Department of the Royal Canadian Air Force.

Appendix

The following extract from the aircraft radio log of the Wakeham bay station, Hudson's strait expedition, for the period January 8th to January 17th, 1928, constitutes an excellent example of the type of service rendered by the aeroplane radio equipment during 18 months the party were in the north.

On January 8th Squadron Leader Lawrence with his mechanic and native guide left in aircraft GCAHI for a flight from Wakeham bay to Nottingham island.

The information recorded here was sent by voice from the planes and was recorded by the operators at the base. The distance from Sugluk inlet to Wakeham bay was about 160 miles.

January 8th, 1928

1027 a.m. Machine off.

1125 a.m. "Lawrence speaking—now off Cape Weggs—Ice is level and light, only a few floes on which machine could be landed."

1142 a.m. "A few miles off Sugluk inlet—visibility is just fair."

1258 p.m. "Still on westerly course—visibility fair."

1310 p.m. "Weather is getting bad—coming back to Hall's place (Sugluk)—everything O.K."

1340 p.m. "Now over Sugluk—reeling in to land."

January 9th, 1928

1211 p.m. "Fokker HI going back to Wakeham bay—Weather bad to west."

1233 p.m. "Weather bad—landing at Little Sugluk" (40 miles east of Sugluk inlet).

1240 p.m. "Reeling in at Mr. Grassett's place—weather bad—come and have a look for us day after tomorrow if we are not back."

January 10th - 15th, 1928

Note: Weather unfit for flying.

January 16th, 1928

1055 a.m. Flying Officer Carr-Harris with mechanic and guide took off from Wakeham bay in aircraft GCAHE for Sugluk to look for Squadron Leader Lawrence.

1218 p.m. "Bucking a strong wind—we may not be able to get back tonight—listen in this afternoon however."

1237 p.m. "Can now see buildings at Little Sugluk."

1245 p.m. "Hello Nottingham and Wakeham bay—Can see HI now on ice in front of Post—she looks alright—they are making place for me to land—stand by all day."

January 17th, 1928

1203 p.m. "HI—Lawrence speaking—leaving Sugluk along with HE—weather not too good."

1206 p.m. "HE calling—left little Sugluk few minutes ago with HI—all O.K.—visibility fair."

1225 p.m. "HI—weather is thick—I really do not know where I am but Squadron Leader Lawrence is flying a compass course—HE is right behind us flying at 5,000 feet" (evidently the mechanic speaking).

1234 p.m. "Now opposite Outer island."

1240 p.m. "Thick fog ahead—we are between King George sound and Wales island."

1300 p.m. "HE—now nearing Fisher bay—it was very thick a while age—planes both together—please have good ground signals out."

1310 p.m. "Reeling in—coming in the bay."

It is easy to imagine the satisfaction felt at the base station when they knew exactly what was going on—why the machines did not return to their base at night and when to expect further word from the pilots. Is it any wonder that after a few experiences of this nature that pilots object strenuously to being sent out on patrol without their radio apparatus?

Aerial Surveying as Applied to Engineering Problems

A. M. Narraway, B.Sc., D.L.S., M.E.I.C.,
Chief Aerial Surveys Engineer, Department of the Interior, Ottawa.

Paper presented before the Annual General Meeting of The Engineering Institute of Canada at Ottawa, Ont., February 13th, 1930.

Aerial surveying may be defined as being the practical application of aircraft and of the aerial photograph to the investigation and development of the country's natural resources.

Ever since man first inhabited the earth he has been trying to improve his powers of penetration into the unknown in order that he might increase his knowledge of the potential natural resources of his domain and turn that knowledge to his benefit. To the engineer especially the increase of this knowledge is most essential, and to this end he has bent every effort and has used every available instrument which offered promise of success. But due to the natural obstacles, such as trees, hills, and swamps, which retarded his progress and restricted his vision, his search for this increased knowledge was a long, tedious, uphill fight with a corresponding high cost. There was apparently no royal road to follow.

However, when the Wright Brothers, scarcely a generation ago finally succeeded in manipulating a plane a few hundred feet into the air a new field was opened to the engineer, to the geologist, the surveyor, and to all those interested in the development of the natural resources of the country. The search after increased knowledge was quickened and the frontiers were pushed back and practically eliminated; for at last man would follow the birds to the air and visualize the hitherto inaccessible country from aloft, and could increase his speed from fifty to one hundred times over that hitherto attained. By taking a camera with him he did not have to trust to memory for what he had seen—and notes written from memory are not the most satisfactory—for the ability of the camera to make instantaneous exposures and to fix a clear image on a sensitized plate or film, enabled him to obtain a record, not only of the scenes he had viewed, but also of many which he might have missed, a record that for detail and accuracy could not be approached by the most elaborate of notes or the most graphic description.

For the last seven or eight years an intensive programme of aerial mapping has been carried out in Canada, and it is probable that most engineers know in a general way something about this work. In this paper, therefore, it is not my intention to do more than touch on this phase of aerial surveying, important though it is, but rather to attempt to show the engineers of this country that in the aeroplane and the aerial photograph they have at hand a new method of surveying which can be adapted to many engineering purposes. The engineer is only interested in maps in a general way. A map must in the nature of things generalize, while the engineer must have, for his considered judgment, detailed and accurate information. In the past he has had to rely upon ground surveys and plans for this information, often at heavy expense and a great waste of time, and it is proposed to show that a very large part of the data heretofore obtained by reconnaissance and survey can be taken directly from the aerial photograph under expert stereoscopic examination. The aerial photograph will not eliminate ground surveys, but rather will control and direct them in obtaining the essential information regarding a project with the minimum expenditure of time and money.

In this paper no claims or statements will be made that are not based on experience. The methods and results referred to have been applied to and obtained from some of the largest projects carried out in Canada during the last three years. The science of aerial engineering is only in its infancy with but a short history, and the engineers of Canada must, like our surveyors, become air minded if

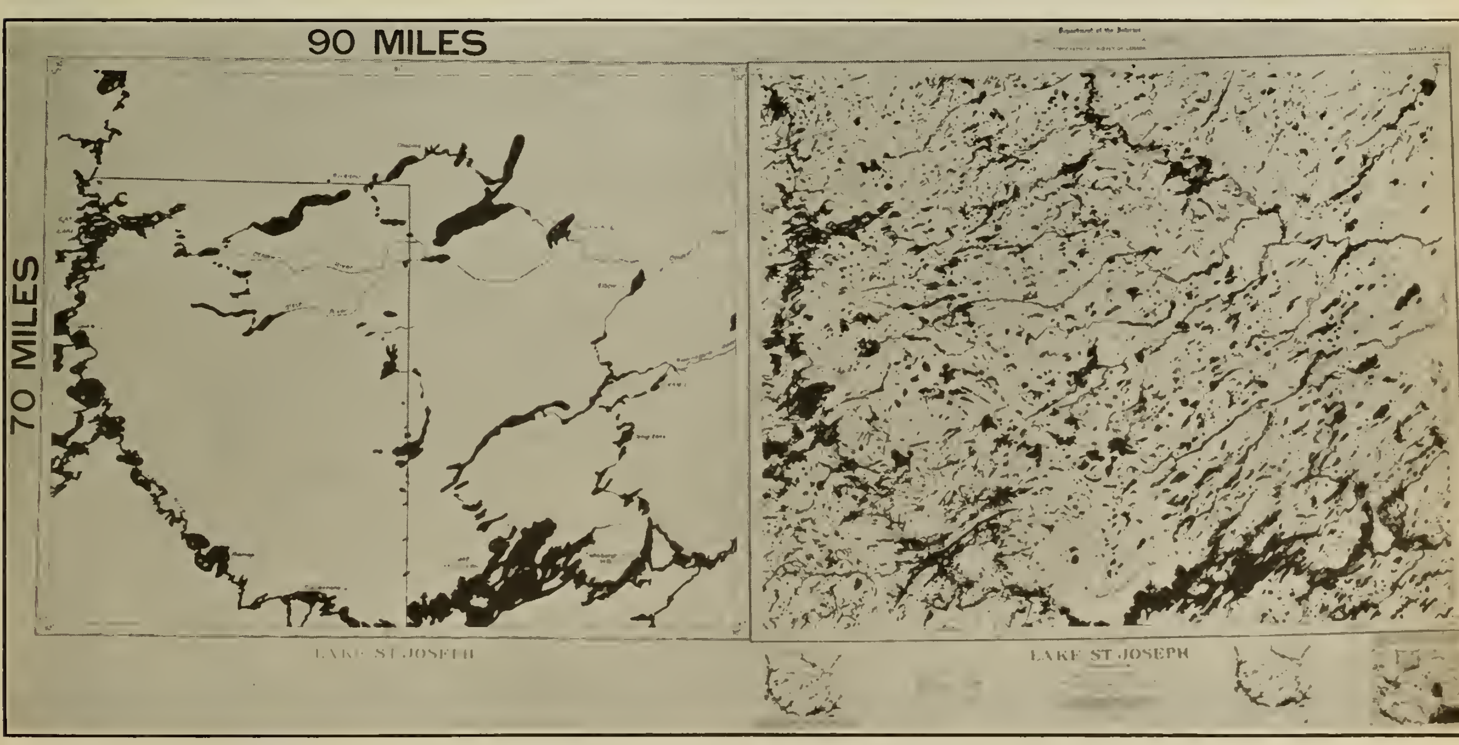

Figure No. 1.—Comparative Mapping.

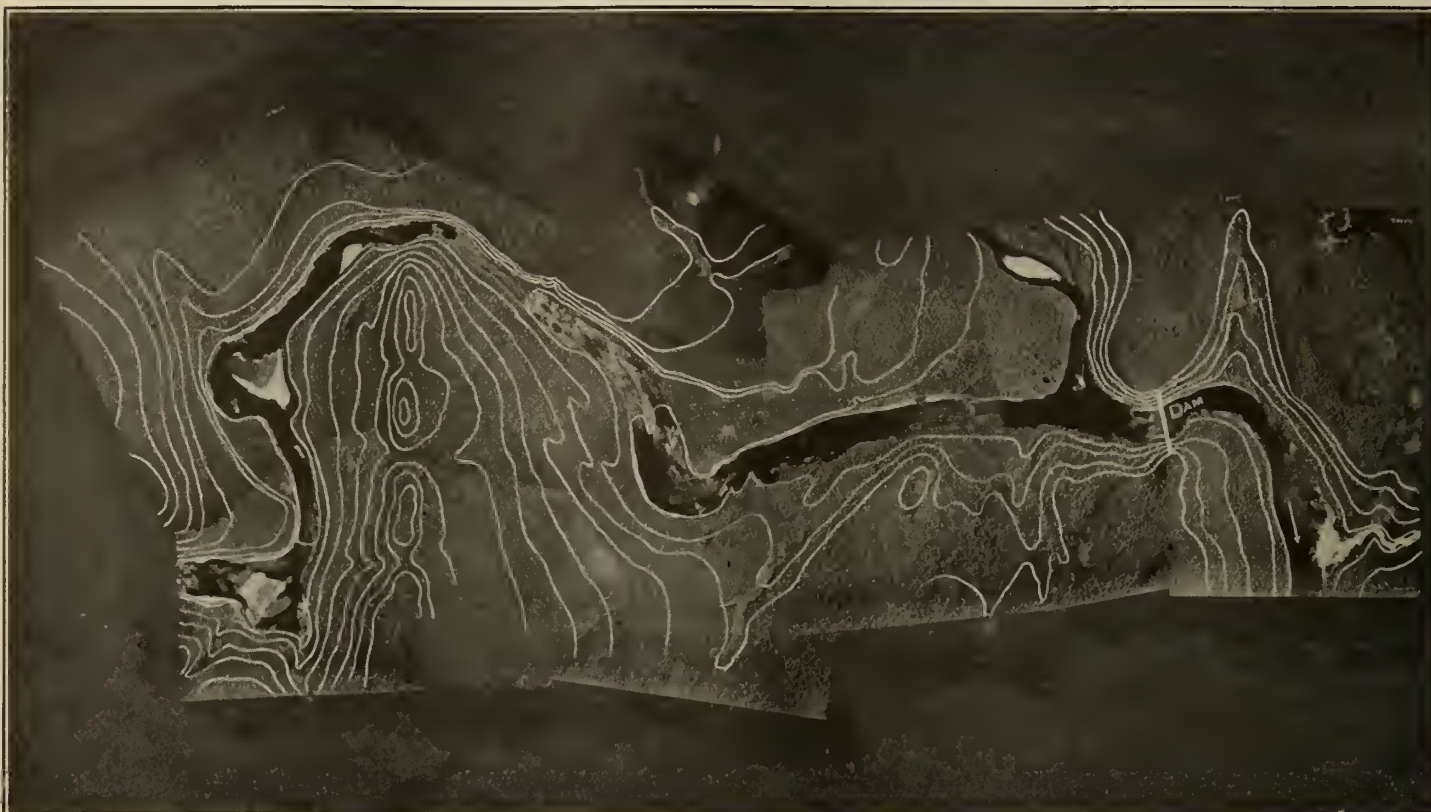

Figure No. 2.—Specimen of Mosaic of River showing Stereoscopic Form Lines.

they are to bear their proper part in the development of our country.

An examination of the progress made in developing aerial surveys during the past few years would appear to indicate that some engineers have been depending very largely on pilots and other air officials for their understanding of this new science. It is certainly a pilot's duty to see that a suitable plane is provided and that it is efficiently and economically operated, but it cannot be expected that the pilot will be a geologist, a water-power, forest, railroad, or other engineer, or all combined. This, for obvious reasons, he cannot be, nor can aerial surveys be condemned or criticized for any failure in this respect. Fortunately there appears to be a marked change taking place, and more attention is being given to the use and the study of the individual photographs, rather than depending on mosaics.

The interpretation of features shown on the individual photographs is one of the key factors of aerial surveys. In presenting an aerial photograph to an engineer he gets not a map, but an exact image of the country which awaits his interpretation.

To aid the engineer in this interpretation a stereoscope has been developed to enable him to examine the aerial photographs stereoscopically. With this instrument the relief shows up prominently and truthfully, and there are revealed to the engineer the hills and valleys, the flats and gentle slopes, the trees, rivers, and other topographical features of interest. The country is seen by him just as it is, thus enabling him to put down form lines on the photographs which can be later transferred to a plan. A closer study under the stereoscope indicates precisely where field measurements should be made in order that the form lines may be converted into true contours.

Thus we can readily visualize an engineer seated comfortably in his office examining a pair of photographs of some area of interest perhaps hundreds of miles away. He puts them under the stereoscope and instantly he is no longer in his office. He is in the air, poised over some water power development area, or the prospective route of a railroad or transmission line. There are the hills, valleys, trees and swamps. Nature has revealed her secrets to him and he gets a clear conception of the factors upon which the solution of his problem depends. Whether or not he can make use of the information he sees before him will depend to a large extent on his previous training on such work and on his ability to interpret. Now he wishes to move on. He removes his eye from the stereoscope and he is back in his office. He changes the photographs under the stereoscope and back he goes to an air position in the field only to discover that in effect he has moved, as though by magic, half a mile further on with no apparent break in the continuity. He discovers something else as well, for he realizes that even if he were in a plane over the spot he could not get as effective a view, for the stereoscope has really put him into two positions simultaneously—the right eye is in effect over the centre of the area of one photograph, and the left eye is over the centre of the adjacent area. In other words the same object is viewed from two different positions.

We see from this short description of the use of the stereoscope that immense possibilities are opened up before us. We can delete uninteresting country at a glance and can give as much time as we wish to the critical places. We can balance one alternative solution against another without actually going on the ground. In connection with the study of a large water power investigation in Canada there were at least five possible schemes, any one of which might have been adopted. The stereoscopic study of the photographs enabled all but one to be eliminated without any field work. The saving in field expenditure in this case can very readily be appreciated.

Practical Applications of Aerial Surveys Mapping

The first practical application of the aerial surveys in Canada was in connection with the mapping of mineralized areas in northern Canada.

Figure No. 3.—Specimen of Individual Photograph with Stereoscopic Form Lines.

Figure No. 4.—Aerial Stereoscope in Use.

Here we had areas of immense potential value, but very incomplete maps. Due to large numbers of lakes with intricate shore lines and a maze of islands, also to the character of the country between lakes, mapping by ordinary ground methods was practically precluded except at an exceedingly heavy expenditure. A few aerial photographs were taken over the area and all topographical features of importance stood out prominently. Methods of plotting these photographs were eventually developed and a new field was opened to the mapper. The work was rapidly extended to other fields, and it was evident that at last there was no frontier line beyond which the mapper could not go.

One of the immediate results of this wide extension of mapping was the development of a national topographic mapping system of Canada which ranks with the best in the world, and incidentally it is interesting to note that the methods for developing this mapping work were strictly

Figure No. 5.—Lower Manitou Falls, English River; Study of Falls and Timber Types.

Figure No. 6.—Chaudiere Falls, showing Flood Conditions on the Ottawa River.

Canadian. The success which has attended the development of this work in Canada is well known by engineers and need not be further discussed in this paper.

Water Power Engineering

The development of hydro-electric power in this country has been one of the most remarkable features of the last decade and promises to be of even greater importance in the future. In this field aerial engineering has had a very marked success in preliminary reconnaissance and investigation, in the preparation of final plans of storage reservoirs and pondages, in the selection and detailed study of dam sites and in draughting the general lay-out of construction. Once photographs are available along a river they are in use from the first inception of a project until the construction has finally been completed.

As an illustration let us assume that there is a proposal for developing the power resources of a river. A profile has been carried up the stream showing the head and there is adequate information with respect to the water available. Aerial photographs are then taken of the stream and its principal tributaries, or better still of the whole watershed. With these in hand the aerial engineer is prepared to produce a plan or map of the stream indicating the character of the adjacent terrain by contours or rather form lines. These form lines may not be strictly accurate as to absolute elevation, but they will adequately indicate the nature of the country for some distance back from the river. Possible dam sites will be clearly shown, together with notes on the nature of the soil and occurrence or otherwise of rock exposures. With these and the profile it is possible to study the river, in detail, to determine its possibilities for storage and pondage and to select tentatively the dam sites which appear most promising. If a consulting geologist is called to report on dam sites he will require the photographs to help him interpret the underlying formations. He may even want to fly over the district himself to help solve some of his problems. The dam sites having been selected, detailed large scale plans can be prepared of the sites themselves and the limits of flooded areas determined by a comparatively few field measurements at critical points which will serve as a control for the contour as determined in the stereoscope. If storage is being developed a contoured plan can be prepared from the photographs quickly and at a tithe of the cost of a ground survey and with greater accuracy. The transmission lines can be located as treated in detail elsewhere. Construction roads or railways can be located in their best positions, and a very excellent idea obtained of the amount of timber suitable for construction purposes which can be found adjacent to the sites. Extensive deposits of gravel, if any exist, can also be spotted from the photographs. All this can be done, at a price, by ground methods, but no ground survey will give the feeling of assurance when the final plans are being drawn that no possible contingency has been overlooked, and that the development as proposed is the best possible under the circumstances.

If a watershed is completely photographed there may be many possibilities of stream diversion either from one watershed to another or from tributary to tributary. In Canada, where streams have generally been modified or changed by glacial action, these are of frequent occurrence. When a stream is being intensively developed the conservation and use of the available water to the best advantage is of the utmost importance and it is believed that any money spent in the aerial photography and intensive investigations of a watershed as a whole would be amply repaid.

Transmission Line Location

Aerial photographs have been used on more than one occasion for the location of transmission lines, and perhaps in no field of engineering have aerial methods met with more success than in transmission line work. The conditions of a good transmission line location are comparatively simple, requiring as they do only a reasonably straight line which avoids as far as possible extremely rough country and in particular hills and gullies where footings for towers are unduly expensive, or locations in settled country where the right of way would be too costly or valuable improvements and buildings would be affected. Even so it has been found that several trial lines are usually required before a suitable location is found, and even then there may be still many angles requiring full anchor towers to carry the line. The use of aerial photographs enables the aerial engineer to project upon the photographs a line which will fulfill these requirements as completely as the local conditions will permit before putting a party in the field, and the field work narrows itself down to running and levelling only one line rather than several. Moreover he is assured that the line is being built on the best possible location, which if the line has been located by ground methods is never at all certain.

Another important consideration is the rapidity with which a final location can be determined by aerial methods. Once the line is located in the photographs it is possible to start construction with the assurance that no unforeseen difficulties will be encountered, and as many location parties as may be required can proceed with the ground location knowing that the work of each party will join the adjacent work without angles or gaps.

The technique of the aerial location is generally speaking similar to a ground location. The photographs lying between the terminal points of the line are first studied stereoscopically and the general route of the line determined. In general there will be certain definite places where the line, to avoid obstacles such as large lakes, or towns, must pass. The most favourable points for the crossing of rivers and railway lines are also determined, and between those more or less fixed points trial lines are projected. Each possible route is studied in detail and

Figure No. 7.—Timber Typing, each Square of Grid Represents Ten Acres.

compared with the other routes and the final location will be a compromise between the straightest and shortest line and the deflections which must be made to avoid obstacles.

The actual positions of the towers are not usually determined as they depend upon the profile of the ground and the sag curve laid out for the line in question. As a matter of fact, however, the aerial engineer must always keep in mind that his line is a succession of towers, and must scrutinize each hill top and valley bank, each angular point and river crossing, to make sure that a tower can economically be built there. In other words tower locations are only made at important points, leaving the intermediate towers to be located from the profile.

The location having been made the photographs are plotted in the usual way and a plan prepared giving the bearings and distances between angular points, which is given to the field engineer for the ground location. He is also supplied with a set of photographs with the line indicated thereon and he is expected to check his location by its relation to topographical features shown on the photographs. This will ensure that his ground line is actually following the photographic location. Form lines giving the general shape of the country are also shown on the plans and if necessary the best routes for the location of roads are indicated.

The advantages of the aerial method, besides the saving in time, lie chiefly in the fact that the location has been made after the fullest consideration of all the physical features of the terrain, which makes it possible to lay out a line with few angles and a corresponding saving in construction and maintenance. In settled country it is of course a very decided advantage to be in a position to make arrangements for purchasing right of way before the inhabitants of a district have been warned by the activities of survey parties that some such work is contemplated.

The practice of locating a line on a mosaic prepared from aerial photographs which has, no doubt, been tried, may offer some advantages over a ground location, but is in no way comparable with the results that can be obtained by a careful stereoscopic examination of the individual photographs. The main item of cost in any aerial work is the cost of the photographs themselves, and it is false economy to use only a part of the information, which may under expert interpretation be obtained from them.

Forestry

The second application in the development of aerial surveys in Canada was in connection with the protection and development of the forest wealth. It was stated recently in an editorial by one of our local papers that "Forest fires destroy more real Canadian wealth than a score of stock market crashes." Of course various agencies including aerial fire patrols are brought into service to protect the forests, but a vital part is played by aerial surveys in this protection. In the first place the maps produced from the aerial photographs show the natural topographical features and hence a base map is furnished upon which timbered areas may be indicated, but aerial surveys go

Figure No. 8.—Paugan Falls Power Developments, Gatineau River.

Figure No. 9.—The Canadian "Soo".

much farther, for the photograph, because of its completeness of detail and the intimate study it permits, enables the forest engineer to visualize his resources and the various factors upon which the protection of these resources depend.

Canada's forest resources are extensive, and every effort is being made to investigate them and to study carefully the best means of penetration and development. The aerial photograph showing these forests is invaluable to the forester and through its medium he is able to obtain an increased knowledge of available raw material with a dispatch, a certainty, and a finality not otherwise obtainable. It is evidence of this kind, showing in detail the location and general character of the timber, its extent and accessibility, that enables the forester to restrict the ground activities to areas of productive value, and to develop projects which have in view the establishment of pulp and paper plants and other phases of forest industry.

From the aerial photograph what is known as a "type map" is prepared. The useful or merchantable timber is indicated by one colour; another colour designates the young stands; another, the burns, and other colours delineate the swamps and water areas, and embody other information of importance. Such a type map enables the forester to concentrate his fire-protection operations upon areas of concentrated timber values. It shows the swamps, rivers, lakes, and other means of checking fires; in fact, it is only upon the basis of complete information of this character that a fire-protection system can be made effective. The type map may also afford the forester useful information relating to means and methods of utilization.

One of the most important applications of the aerial photograph is in connection with the location of logging roads. This is done by placing the vertical aerial photographs under the stereoscope and examining the relief of the country in relationship to the stands of timber, due attention being paid to swamps and other topographical features of interest. An expert interpreter is able to place the roads in the most efficient location to give the best grades, and at the same time to serve the largest number of trees. There is always present the assurance that the best location has been made as alternative locations can be compared at any time..

Railway and Road Location

In railway locations the aerial engineer does not profess to be able to take the place of a locating party, but he is able to select the most feasible route or routes from the photographs. Generally an experienced man can tell pretty closely if changes in elevation are such as to make a railway out of the question. His examination of the photographs will save cutting useless trial lines and ensure that the best possible location has been found. In rough and difficult country a preliminary reconnaissance by plane, followed by aerial photographs of the most practical looking route, is generally the best method of finding a satisfactory location.

Road location is much the same problem as railway work, but the wider range of permissible grades make it generally possible to find a suitable location on the photograph without any preliminary survey and to confine the field work entirely to the final location line.

Geodetic Surveying

One of the most interesting developments of the past year has been the application of aerial surveys to geodetic work. In the first instance an experiment was made in using the aeroplane for a general reconnaissance to select a route for triangulation and later to locate the points most suitable for triangulation stations. This proved so successful the planes were used throughout the remainder of the season for the transportation of tower building and observing parties. In fact the major portion of the transport work of one survey party was done by air with a marked saving both in time and expenditure. This saving was all the more impressive since the whole of the flying was carried out by an aerial photographic detachment in weather which was unsuitable for photography and which otherwise would have been lost time.

Other Applications of Aerial Engineering

Further applications of the aerial photograph could be discussed in detail and one might readily refer to its application to the mining and prospecting fields. As rock exposures are visible in the photograph even in a bush country the geologist's footsteps are guided at least to this extent. The structure is frequently shown up very prominently in a way quite impossible to meet with in any other way. It is sufficient to say that some of the largest mining and prospecting companies maintained large fleets of aircraft last year in various parts of Canada, even to the Arctic, for this express purpose.

One could refer to the application of the aerial photograph to soil surveys, for again the bird's eye viewpoint discloses boundaries of soil types much as it does with timber types; or one could describe under-water investigations, as the camera does penetrate the water to considerable distances below the surface.

The application is, in each case, similar to that of water power engineering in that success depends upon the training of the expert and his ability to interpret what he sees. Cases of doubt are settled by a check on the ground. As stated at the commencement aerial surveys are dependent upon interpretation of photographs with checking on the ground at doubtful or critical points.

For illustrative purposes, the aerial photograph would seem to have an exceptionally large part to play in the engineering field. Probably in no other way can the characteristics of an area or a project be more intelligently shown.

In conclusion it may be said that aerial surveys are but on the threshold of development and that engineers generally will find that this new science, which is more rapidly gaining impetus in its growth, will assist them materially in solving some of their serious engineering problems. Commercial air companies are becoming equipped with up to date aeroplanes and efficient personnel. As their business expands the efficiency will increase and the costs will be materially lowered. Canada can look with pride upon her accomplishment and her leadership in this new field, and can look forward with confidence to its future development.

Report of Council for the Year 1929

On the occasion of the Forty-fourth Annual General Meeting of The Institute it may be observed that the activity in Canadian engineering work noted in previous reports has continued during the past year. Conditions as regards employment have accordingly been favourable, and many important Canadian projects, contemplated or in progress, have been available for consideration at the meetings of the Institute and its Branches. The wide range of subjects treated at these meetings is noteworthy, and in many cases the gatherings have afforded an opportunity of bringing the engineer's achievements to the attention of the general public, a most valuable feature of The Institute's work. This diversity of topics is indicative of the variety of occupation of our members, and in this connection, it is interesting to note that during the last four years The Engineering Journal has published in full one hundred and fifty-three papers, classified as to subject matter as follows:

Civil engineering and construction, with surveying	38
Mechanical engineering, including heat power and aviation	33
Electrical engineering	32
Mining, metallurgical and chemical work	21
Various, including economics, education, etc	29

The attached reports of the various Committees of The Institute are presented for discussion, and Council desires to point out that two of these deal with matters of such importance to the future of The Institute as to call for special mention.

The report of the Committee on the Relation of The Institute with the Provincial Associations of Professional Engineers, which is now submitted to the membership, was presented and adopted at the Plenary Meeting of Council in October last, and contemplates a definite policy of co-operation with the associations, primarily with a view of obtaining uniformity in the requirements for admission as between The Institute and the organizations in question. Such uniformity would remove the present anomalous conditions under which an engineer who is a member in good standing of one of these bodies is not necessarily eligible for admission to The Institute, and vice versa. In the opinion of Council, every effort should be made on behalf of The Institute to obtain agreement upon a uniform standard of qualification acceptable to all the professional bodies.

The Committee on Policy, which was appointed following a resolution of the Annual Meeting at Hamilton in February 1929, has presented a report which, while not a final one, makes a number of important recommendations. The most urgent of these, dealing with the need of additional funds, supports the proposals of the Finance Committee and the Council, all of whom are impressed with the present limitation of the activities of The Institute caused by lack of funds. Council has accordingly taken action in this matter by repeating its proposed amendment to Section 34 of the By-laws, which by increasing the annual contributions of Members, Associate Members and Juniors, would provide a substantial addition to The Institute's revenue, and would form the first step towards placing The Institute on the same footing as regards resources as some of its sister societies.

In addition to the amendment to Section 34, Council is proposing three others, including a suggested change in Section 75, dealing with the procedure in amending By-laws, and designed to avoid the possibility of sending out to ballot so many conflicting proposals to amend By-laws as to render it unlikely that anyone of them can obtain the necessary two-thirds majority.

Last year there was initiated a considerable extension of our Employment Service, which, aided by the E-I-C News, has proved very successful. The results obtained indicate that still further development could be carried out with great advantage to our membership, but this is at present impossible for financial reasons.

During the past year Council has received with regret intimation of the deaths of several eminent members of The Institute, among whom may be mentioned Willis Chipman, Peter Gillespie, James Freeman Lumsden, Arthur Wells Robinson and Emil Andrew Wallberg. Their loss is greatly deplored.

From time to time Council has been called upon for expressions of opinion on behalf of The Institute in connection with inquiries of public or professional interest. Among these may be noted the investigations of the Royal Commissions on radio broadcasting and on the salaries of technical employees in the Civil Service, and discussions on the customs regulations regarding engineering and technical books, and with regard to proposed standard forms of construction contracts. In the case of the first two, the importance of the questions involved led Council to appoint special committees; their reports, each of which involved a good deal of work, were duly submitted to the proper authorities.

The Institute was represented at the World Enginering Congress held in Japan in November by four of its members, headed by Past-President J. M. R. Fairbairn, M.E.I.C., and will be represented at the Fiftieth Anniversary Celebrations of the American Society of Mechanical Engineers in April 1930 by President C. H. Mitchell, C.B., C.M.G., C.E., D.ENG., M.E.I.C., and President-elect A. J. Grant, M.E.I.C.

Two Institute meetings were held during the year, namely the Annual General and General Professional Meeting in Hamilton on February 13th, 14th and 15th, and the Maritime Professional Meeting held in Moncton on July 30th and 31st. These were both well attended and successful gatherings.

Branch activities have been well maintained, and it is gratifying to note that the President has been able to visit personally nearly all the Branch centres from Halifax to Victoria. Visits of this kind do much to aid in developing that Dominion-wide outlook which characterizes the work of the Institute.

During the year Council has again taken action to reduce the amount of unpaid arrears of annual fees, and has also noted the considerable number of Students and Juniors who are over the age limit for their respective classes. It is expected that the measures adopted in this connection will result in marked improvement in these respects.

The Third Plenary Meeting of Council was held on October 7th, 8th and 9th, thirty-six members being in attendance, and it was gratifying to note the presence of no less than six Past-Presidents of The Institute. The counsel and experience of these senior members were of great value in dealing with the important questions of general policy which were under consideration. A report of the proceedings was published in The Engineering Journal for November, pages 594 to 598, and in the opinion of Council its perusal will aid members materially in discussing and voting on the questions now before The Institute for decision.

It is believed that the principal needs of The Institute to-day are additional funds and more general participation by our members in the activities of The Institute and its Branches. This applies particularly to the contribution of papers on engineering subjects with which a member's work and experience renders him familiar. It is only by the co-operation of our members at large that it is possible to fulfil one of the principal objects of The Institute, namely, the acquirement and interchange of professional knowledge

Meetings

Annual General Meeting

The Forty-third Annual General and General Professional Meeting was held at Headquarters in accordance with the By-laws on Thursday, January 24th, 1929, at 8.00 p.m., President Julian C. Smith, M.E.I.C., in the chair. After the approval of the minutes of the Forty-second meeting and the appointment of the scrutineers and auditors, the meeting was adjourned, to reconvene on Wednesday, February 13th at 10 a.m. at the Royal Connaught hotel, Hamilton, Ontario.

At the adjourned meeting, President Julian C. Smith, M.E.I.C., took the chair on the morning of February 13th, and the report of Council for 1928, the reports of the various committees, and the Branch reports were approved and adopted.

The Nominating Committee for 1929 was appointed.

The presentation of the medals and prizes of The Institute then took place, and this ceremony was followed by discussion on the various amendments proposed to the By-laws which continued during the afternoon session. The principal result of this discussion was the appointment of a Committee on Policy to review the activities of The Institute in collaboration with the Branches.

President Smith then delivered his valedictory address, after which the scrutineers' report was submitted, and the officers for 1929 were declared elected.

The newly-elected President, Brigadier-General C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., was then conducted to the chair, and the business proceedings terminated with votes of thanks to the retiring President, the scrutineers and the Hamilton Branch.

General Professional Meeting

Three technical sessions were held on the 14th and 15th, at which fourteen professional papers were presented and discussed. Advantage was taken of the facilities afforded by the industrial development in and near Hamilton to arrange a series of interesting visits to engineering works, a very complete programme of social events was carried out, and the closing event was the annual dinner of The Institute, at which the members were addressed by Sir Robert Falconer and Sir William Hearst.

Maritime Professional Meeting

A very successful Professional Meeting was held at Moncton, on July 30th and 31st, and the members of the Moncton Branch, as hosts, arranged an admirable programme of professional and social events. Four technical papers were presented and discussed, and at the dinner which concluded the meeting, addresses were delivered by the Hon. Dr. P. J. Veniot, Postmaster-General of Canada, and Brig. Gen. C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., President of The Institute.

Roll of The Institute

During the year 1929, one hundred and seventy-six candidates were elected to various grades of The Institute. These are classified as follows: thirteen Members, thirty-six Associate Members, Twenty-four Juniors, ninety-eight Students, and five Affiliates. The elections during the year 1928 totalled three hundred and thirty-nine.

Transfers from one grade to another were as follows: Associate Members to Member, eleven; Junior to Associate Member, twenty-seven; Student to Associate Member, seven; Student to Junior, forty-two, a total of eighty-seven.

A summary of these elections is given below. The names of those elected or transferred are published each month immediately following the election, and are then added to the membership list.

Elections

	Members	Associate Members	Juniors	Students	Affiliates

Total: 87	11	27	7	42

Removals from the Roll

There have been removed from the membership roll, during the year nineteen hundred and twenty-nine, by resignation and for non-payment of dues, twenty-six Members, one hundred and forty-four Associate Members, twenty-two Juniors, fifty Students, and four Affiliates, a total of two hundred and forty-six.

Thirty-four reinstatements were effected, and six Life Memberships were granted.

Deceased Members

During the year 1929 the death of thirty of The Institute's members have been reported as follows:

Members

Bell, James Anthony
Chipman, Willis
Dawes, Albert
Gent, Rufus Taylor
Gillespie, Peter
Hegan, James Black
Herd, Walter
Hyslop, James
Lumsden, James Freeman
Macdonald, Charles
McDougall, John Jeremiah
Robinson, Arthur Wells
Walkem, Hugh Blake
Wallberg, Emil Andrew
Wragge, Edmund

Associate Members

Boisseau, Louis Jos. Gustave
de Coriolis, Gustave (Baron)
Gage, Charles Edwin
Heroux, Jos. Philippe
Jackson, Alan Mair
Johnson, Lancelot Llewellyn
Massey, Arthur William Kay
Meader, Joseph Cave
Munn, David Walter
Pope, Charles Arthur
Robb, Roland Wentworth Tupper
Ure, Frederick John

Junior

Smith, Robert Macfie

Student

Lewis, Frank Adrian

Affiliate

Quigley, Harry Stephen

Total Membership

The membership of The Institute at present totals four thousand six hundred and eighty-three. The corresponding number for nineteen hundred and twenty-eight was four thousand, eight hundred and twelve.

R. J. Durley, M.E.I.C., *Secretary.*

Finance Committee

The President and Council:

Your Committee in submitting the financial statement for the year 1929, would point out that during the past three years progressive development has been taking place in the activities of The Institute and its committees, with a corresponding increase in the cost of operation, but there has been no similar increase in the income available to defray working expenses and maintain the work of the Branches.

In framing the budget for 1929, your Committee drew attention to this matter, but Council was naturally unwilling to curtail the services rendered to our members, and during the year it was further found necessary to incur certain expenditure not provided for in the budget; for example the expenses connected with the work of The Institute's Committee on the Relations of The Institute to the Professional Associations, and in preparing a report for submission to the Royal Commission on the salaries of technical employees in the Civil Service.

While the income of The Institute during 1929 somewhat exceeded anticipation, it will be seen from the attached financial statement that taking the year's operations as a whole, a deficit has resulted. Expenditure on items covered by the budget has been in accordance with the appropriations, and the deficit is due to such necessary items as are mentioned above.

Your Committee earnestly hopes that Council's proposal to increase the annual fees of Corporate Members and Juniors will receive the approval of the membership. It should be noted that our present income and expenditure per member is much lower than in any similar organization known to your Committee. If the proposal for increased fees is not approved, it will be necessary to restrict the present activities of The Institute.

In accordance with Council's instructions the accounts of members in arrears have been closely followed up, and the amount collected during 1929 is larger than was anticipated; thus the amount of revenue available under this head during 1930 will probably be somewhat reduced.

Respectfully submitted,

G. R. MacLeod, M.E.I.C., *Chairman.*

STATEMENT OF ASSETS AND LIABILITIES AS AT 31st DECEMBER, 1929

Assets

Property		$ 89,041.64
Furniture:		
Balance as at 1st January, 1929	$ 6,180.24	
Less: 10% depreciation	618.02

Nominating Committee—1930

The following nominations to the Nominating Committee for the year 1930 have been made by the various Branches and have been noted by Council, and are herewith presented to be announced at the Annual Meeting in accordance with the By-laws:

Chairman: A. Duperron, M.E.I.C.

Branch	*Representative*
Halifax Branch	W. A. Winfield, M.E.I.C.
Cape Breton Branch	J. R. Morrison, A.M.E.I.C.
Saint John Branch	J. L. Feeney, A.M.E.I.C.
Moncton Branch	T. L. S. Landers, M.E.I.C.
Saguenay Branch	N. D. Paine, A.M.E.I.C.
Quebec Branch	Philippe Méthé, A.M.E.I.C.
St. Maurice Valley Branch	A. A. Wickenden, A.M.E.I.C.
Montreal Branch	H. G. Thompson, A.M.E.I.C.
Ottawa Branch	D. W. McLachlan, M.E.I.C.
Peterborough Branch	W. M. Cruthers, A.M.E.I.C.
Kingston Branch	D. S. Ellis, A.M.E.I.C.
Toronto Branch	G. A. McCarthy, M.E.I.C.
Hamilton Branch	H. S. Philips, M.E.I.C.
London Branch	F. C. Ball, A.M.E.I.C.
Niagara Peninsula Branch	C. G. Moon, A.M.E.I.C.
Border Cities Branch	F. H. Kester, M.E.I.C.
Sault Ste. Marie Branch	J. L. Lang, M.E.I.C.
Lakehead Branch	F. C. Graham, A.M.E.I.C.
Winnipeg Branch	J. W. Sanger, A.M.E.I.C.
Saskatchewan Branch	H. R. MacKenzie, A.M.E.I.C.
Lethbridge Branch	N. H. Bradley, A.M.E.I.C.
Edmonton Branch	R. S. L. Wilson, M.E.I.C.
Calgary Branch	F. M. Steel, M.E.I.C.
Vancouver Branch	W. B. Greig, A.M.E.I.C.
Victoria Branch	F. L. Macpherson, M.E.I.C.

Publication Committee

The President and Council:

Your Publication Committee was left with very few duties by the absence of Transactions, but two papers which were referred to us by Headquarters were reviewed and recommendations made as to treatment. This was the sum total of our activities, other work on the general questions of publications having been allocated to other committees.

Respectfully submitted,
P. L. Pratley, M.E.I.C., *Chairman.*

Legislation Committee

The President and Council:

As a result of the ballot of the membership taken in May 1929, two of the amendments to the By-laws then proposed by Council failed to carry. One of these, when it was discussed at the Annual General Meeting, elicited a number of alternative suggestions, two of which, in accordance with the requirements of Section 75 of the By-laws, went out to ballot together with the original proposal. None of the three proposals secured the necessary two-third majority to become effective, and your Committee, recognizing that such a division of votes is liable to occur in connection with some much more important question, felt bound to recommend a further modification of Section 75, intended to avoid the occurrence of such a difficulty in future.

The amendment to Section 34 which Council proposed in 1929 regarding an increase in the annual fees of members also failed to carry, the vote being almost evenly divided. Your Committee felt that this proposal was of such importance to the future welfare of The Institute that it should be renewed this year, and has made a recommendation accordingly.

Your Committee has also considered, in accordance with Council's instructions, and has recommended, amendments to Section 13, dealing with a change in the term of office for Councillors, and Section 37, dealing with arrears of annual fees. All of these amendments have the approval of Council for submission to the Annual General Meeting, and were printed for the information of members on page 650 of the Journal for December 1929, accompanied by brief explanatory notes regarding them.

No questions of importance regarding legislation were referred to your Committee during the past year.

Respectfully submitted,
O. O. Lefebvre, M.E.I.C., *Chairman.*

Board of Examiners and Education

The President and Council:

The results of the examinations held during 1929 for admission to The Institute are as follows:—

	Examined	Passed	Failed
For admission as Junior (Schedule B)	2	1	1
For admission as Associate Member (Schedule C):			
Electrical Engineering	3	1	2
Structural Engineering	4	1	3
Civil Engineering	4	None	4
	13	3	10

The revised syllabus of examinations and specimen examination papers has been issued, and copies have been forwarded to the councils of the various provincial Associations of Professional Engineers for their information and comment.

Your Board would draw attention to the large proportion of candidates who have failed to pass The Institute's examinations. The examiners' reports indicate that in most cases this is due to lack of training in fundamental subjects, such as mathematics, physics and strength of materials, a lack which, with most men, can only be supplied by study under competent direction. It is felt that our present standards are a minimum and should not be changed. Past Boards have established the standards, issued typical examination papers, lists of text-books and done all in their power to make the path of the candidate plain and straight. Even with these helps the showing is not better but if possible worse.

Your Board deplores this condition and feels that something is wrong. We feel that in some cases the trouble is with the preparation of the candidate. We feel that Council, through its Branches, has a responsibility and duty to help these candidates.

We consider that it might be possible for prospective candidates to consult the nearest Branch secretary and discuss with him his academic qualifications or lack thereof, and through the secretary be put in touch with those members of the Branch who could and would be willing to give assistance in that part of the schedule which could not be given at either night or technical schools.

We feel that such work, done to help those young engineers who have not had the advantage of a university training, would be a real contribution to the profession.

Respectfully submitted,
C. M. McKergow, M.E.I.C., *Chairman.*

Committee on Engineering Education

The President and Council:

Engineering education as a subject for discussion seems to be somewhat in the same category as the weather, as commented on by Mark Twain when he said "Everybody talks about it but nobody ever does anything." Writers and speakers have worn the subject threadbare, mostly in discussing generalities or in attempting to prove how one curriculum offers advantages over some other curriculum.

Your Committee inspired the idea and sponsored the allocation of the Past-Presidents' Prize for the current year, in the hope that the response would give a cross-section viewpoint of the members of The Institute throughout the Dominion. The results was disappointing in that only seven papers were submitted, all of which were of a more or less general nature.

Your Committee has studied the problem of engineering education in its relation to the engineering profession and the bearing that the present method of teaching has upon the status of engineering as a profession, and has come to this definite conclusion—that the reason the engineer does not occupy the position as a professional man that is accorded to other professions lies largely in our present curricula and the fact that a cultural background is not provided. It is not to be insinuated for a moment that the system in vogue in Canada does not produce engineers of the very highest calibre, nor that the men at the heads and on the staffs of our engineering schools and colleges do not compare favourably with engineering professors in any other part of the world, but the fault lies mainly in the fact that every year a large number of men are turned out as graduates in some branch or other of engineering, believing themselves to be graduate engineers, when they are in reality science graduates. The present course, with slight modifications, may be considered as almost ideal for giving a man splendid training to fit him to take a high position in the industrial, commercial, or engineering world. A man following an engineering career, however, should be given an additional two years in his engineering course, or alternatively a much higher standard of admission to study. The two years being added would be partly in the university and partly in engineering practice. It is now many years since the leaders of the medical profession decreed that the medical course should be extended, and the tendency since then has been to increase the length of time necessary rather than to diminish it. In law we have the same situation.

One great weakness of the engineering training is that the engineer is not taught to properly articulate, either in writing or orally, and this should be considered as essential to the engineer as it is to the lawyer or to the minister. Greater attention might be given to the study of economics in the four years of the science course.

The question of student activities which was referred to your Committee has been discussed and the conclusion reached that the engineering student has received insufficient attention from The Institute to arouse his interest in its activities. This has resulted in large numbers of students graduating from universities with practically no knowledge of The Institute and to whom its development is of little concern. If the student body is not cultivated, the interest in The Institute on the part of the young men cannot be sustained. Your Committee, therefore, urgently recommends the adoption of a policy which will result in creating a student branch of The Institute or some Institute affiliation with the students in every engineering university centre in the Dominion, and that this be followed up as an Institute activity which is of vital concern to its future welfare.

It is the belief of your Committee that The Engineering Institute should take a more dominant and aggressive position in relation to the subject of engineering education, and form a more intimate contact with the universities, whereby the advice of the older and most successful engineers would be available to the universities through an Institute committee. Further, The Institute might act as a special agency between the university and industry. The Institute should also consider technical training from the junior aspect and its bearing upon industry and upon the profession. The definite suggestions of your Committee, therefore, are:—

(1) The formation of a more intimate bond between The Institute and engineering universities throughout Canada, in order that The Institute may be in a position to advise on engineering education through its older and most successful members.

(2) That steps be taken whereby The Institute becomes the definite agency—the active connecting medium—between engineering universities and industry.

(3) That a study be made by a committee on technical education in its relation to industry and to the engineering profession.

(4) That immediate steps be taken by conference with university heads with a view to adopting a six year course for engineers, or a much higher matriculation standard.

(5) That the universities be urged to give consideration to giving additional time on the curriculum to public speaking and literature.

(6) That immediate steps be taken leading to the formation of student branches of The Institute or student affiliations in every engineering university in the Dominion.

Respectfully submitted,

FRASER S. KEITH, M.E.I.C., *Chairman.*

Canadian National Committee of the International Electrotechnical Commission and the Committee on International Co-operation

The President and Council:

Only one meeting of the Canadian National Committee of the International Electrotechnical Commission has taken place during the year, this having been held at Ottawa on April 10th, 1929, at which a general discussion was held on the organization and policy and on the method of financing operations.

Documents which have been received from the different Secretariats have been distributed throughout the year for comment by the members of the Committee and the result of these comments forwarded to the appropriate Secretariats.

A meeting of the International Electrotechnical Commission was held in Japan in October 1929 and was attended by Mr. John Murphy, M.E.I.C., chairman of the Canadian National Committee. The next plenary meeting of the I.E.C. will be held in Stockholm in June 1930.

At Tokyo, during the recent World Engineering Congress and the Sectional Meeting of the World Power Conference, there were many happenings of considerable interest to the members of The Engineering Institute of Canada.

Canadian participation in those meetings, insofar as the presentation of papers and personal attendance were concerned, was very meagre—altogether too meagre, in the writer's opinion, when the magnitude and importance of Canada's engineering developments and the standing of her engineers is kept in mind. Delegates to those meetings, as well as the officers in charge of them gazed upon the thousands of delegates from thirties and the 800 papers listed on the programmes and asked, (a) "How many delegates are here from your country," and, (b) "How many papers were prepared in your country?" Canada's answers to those questions could be given "without detaining the questioners."

Co-operation, international co-operation, was the keynote of the proceedings in Tokyo. The Japanese Imperial family and the Prime Minister and the members of his government encouraged and personally assisted the Japanese engineers in many ways to make the meetings successful.

The meetings were held in the temporary Parliament buildings and the opening and closing ceremonies were carried out with much pomp and ceremony. In the writer's opinion the best of the closing addresses was made by our Past-President Dr. J. M. R. Fairbairn, M.E.I.C. The large American delegation in attendance with the personal and official approval of that eminent engineer the Hon. Herbert Hoover, President of the United States of America, was the most prominent one at the Tokyo meetings. Next in importance and in point of numbers was the British delegation. Practically all the proceedings were carried out in English.

The Japanese engineers also held special meetings at which architectural, civil, chemical, electrical, mechanical and mining engineers from other countries were each given a chance to see what was being done in their own spheres of action in Japan. The Japanese electrical engineers have prepared standard specifications, printed in English, which might be used as models in any country. Their chairman was asked to tell how the immense amount of work, which those specifications represented, had been carried out? He replied:—"We—200 of us—worked three hours every evening from 6 to 9 o'clock until the work was finished." Such enthusiasm is not usually encountered in Canada.

To the electricians at the Tokyo meetings two very sad messages came; one contained news of the death of Mr. John W. Lieb of New York, an associate of Edison from his pioneering days, and, one of the world's most capable and best known electrical engineers.

The other message was from Milan, Italy, where Mr. Guido Semenza died suddenly on November 7th as the outcome of a protracted illness. Mr. Semenza was one of the most lovable men in the world. He was the Junior Past-President of the International Electrotechnical Commission; he had acted in a consulting capacity for important undertakings all over the world.

Since the earthquake and fire in 1923 the destroyed portions of Tokyo and Yokohama have been rebuilt and are now perfect models of beautiful modern cities. The courage and the progressive spirit of the Japanese is astonishing. Their hospitality was almost overwhelming.

Respectfully submitted,
John Murphy, M.E.I.C., *Chairman.*

Gzowski Medal Committee

The President and Council:

Your Committee, having carefully studied all of the papers eligible for consideration for the award of the Gzowski Medal for this year, has concluded that no one of them is of a sufficiently high order of merit to have earned for its author the award of this esteemed medal.

The Committee therefore recommends that no award of this medal be made for this medal year.

The Committee, however, respectfully directs your attention to the fact that in its opinion most of the papers covered by its study are of real value to The Institute, in that they have afforded the membership an opportunity of broadening the scope of their knowledge of Canadian engineering practices and works of interest, which otherwise would not have been available. Your Committee feels, therefore, that The Institute is much indebted to the authors of these very excellent papers.

Respectfully submitted,
W. C. Adams, M.E.I.C., *Chairman.*

Leonard Medal Committee

Your Committee has found great difficulty in reporting because of the large number of excellent papers before it for consideration, but no one of these was of such outstanding merit as to warrant the award of the medal.

Respectfully submitted,
F. W. Gray, M.E.I.C., *Chairman.*

Plummer Medal Committee

The President and Council:

Your Committee has examined the various papers which came under the Plummer Medal classification for the season 1928-1929 and it is the majority opinion of the Committee that the Plummer Medal for the period should be awarded to Mr. A. S. Wall, M.E.I.C., for his paper entitled "Arc Welding in Structural Fabrication," published in The Engineering Journal in July 1929.

It is the opinion of the Committee that Mr. Wall's paper deals with a metallurgical subject and it represents a considerable amount of original work by the author; it is well presented, and it deals with a subject of increasing importance.

Your Committee has, therefore, much pleasure in recommending the award of the "Plummer Medal" to Mr. Wall.

Respectfully submitted,
J. R. Donald, M.E.I.C., *Chairman.*

Honour Roll and War Trophies Committee

The President and Council:

During the year 1929 the list of names for the Memorial covering those who served with units not included in the Canadian Expeditionary Force, was forwarded to the War Office in London for checking. This list has lately been returned, and when a few further verifications are made the list for the Memorial will be complete.

The work on the Record is being proceeded with.

Respectfully submitted,
Charles J. Armstrong, M.E.I.C.. *Chairman.*

Report of The E.I.C. Members of the Main Committee of the Canadian Engineering Standards Association

The President and Council:

The Institute nominees on the Main Committee of the C.E.S.A. are now as follows:—

F. B. Brown, M.E.I.C., retires March 1930.

P. L. Pratley, M.E.I.C., retires March 1931.

C. J. Mackenzie, M.E.I.C., retires March 1932.

Mr. Pratley has succeeded Professor C. M. McKergow, M.E.I.C.

The Main Committee of the Association is still operating as the Associate Committee on Engineering Standards of the National Research Council, and it is expected that the Association will be assigned quarters in the new Research building, contract for which has recently been let.

General support from industrial interests has again been forthcoming during the past year and up to December 31st, 1929, the sum of $5,420 has been received as subscriptions. The sustaining memberships have been put on a more stable basis and the securing of support from industry is under the direction of a Financial Committee which has recently been organized by the C.E.S.A. executive. The members of this Committee are as follows:

Mr. P. F. Sise, M.E.I.C., (chairman), Northern Electric Co. Ltd.
Mr. G. H. Duggan, M.E.I.C., president, Dominion Bridge Co. Ltd.
Mr. D. C. Durland, president, Canadian General Electric Co. Ltd.
Mr. R. H. McMaster, president, Steel Company of Canada, Ltd.
Mr. P. J. Myler, president, Canadian Westinghouse Co. Ltd.

The co-operation from the press and technical publications has been a feature of the year's work and many publications have given quite extensive reviews of the specifications issued by the Association during the past year. The Association wishes to again record its appreciation of the helpful co-operation which has been given by the members of the different working committees and from the different representatives of the industries.

The sale of specifications has shown a marked increase and it is evident that their practical value is becoming recognized. One of the features has been the requests received from different technical libraries for complete sets.

The third year book of the Association was issued during the year and widely distributed, and the quarterly bulletin continues to serve a very useful purpose.

Publications Issued During 1929

C2-1929. Standards for Single-Phase Distribution Transformers. This is a revised edition of C2-1920 which was entitled "Standard Requirements for Distribution Type Transformers." This revision takes into account the experience gained by the operation of the specification since it was first published and it is believed that it more closely meets the present situation and will clear up much of the misunderstanding which has prevailed in connection with this type of apparatus.

A6-1929. Standard Specification for Steel Highway Bridges. This is the second edition of the specification which was first issued in 1922 and the chief feature is the raising of the unit stress for axial tension from 16,000 to 18,000 lbs. per square inch, which has necessitated revision in corresponding stresses. All references to eyebars have been deleted; specifications for materials have been brought up to date and a specification for silicon structural steel has been added. The specification for bridge paint and all references thereto have been deleted until a more satisfactory understanding can be reached with the paint manufacturers.

A23-1929. Standard Specification for Concrete and Reinforced Concrete. This is one of the most important specifications that has been issued by the Association since its incorporation. Special acknowledgment is given to the work which was done by the late Professor Gillespie, who was chairman of the committee which prepared this specification. The specification is divided into three parts, the first intended primarily for the use of the contractor, and the second for the guidance of designers. The third part comprises specifications for materials and methods of testing, supplemented by drawings, a glossary, and a list of algebraic symbols. Several of the specifications already issued by the Association have been reprinted in the appendices. This publication has been very favourably received and many reviews have appeared in technical publications. Enquiries for copies have been received from all parts of the world

G24-1929. Standard Specification for Sampling for Check Analysis of Steel Billets, Bars and Shapes. It is felt that this specification will clear up much misunderstanding between manufacturers and mill inspectors. Detailed information is given as to the best methods of sampling and a diagram showing proper location of drill holes for sampling has been included.

G25-1929. Standard Specification for Carbon Steel Billets and Bars of Forging Quality. It is hoped that this specification will clear up much misunderstanding as to the terms used in the buying and selling of this particular quality of steel, and the specification has been framed in as simple a manner as possible and contains only those requirements which are considered absolutely necessary to clear up any doubt as to the properties of the material concerned. The specification is essentially general in its purport and is not intended to cover any specialized requirement.

G26-1929. Commercial-Quality Hot-Rolled Bar Steels.
G27-1929. Commercial Cold-Finished Bar Steels and Cold-Finished Shafting. These specifications have been issued in one volume to replace specification No. G8-1923 which was issued under the general title of Commercial Bar Steels. Experience since the issuance of the first edition has indicated the advisability of issuing this specification in two parts, on the basis of the process of manufacture. Specification G27 makes it clear that cold-finished material covers shafting, as there has been considerable misunderstanding on this point.

G28-1929. Standard Specification for Carbon Steel Castings. This specification has been prepared by the committee after a most intensive study of the situation. It includes a special section dealing with heat-treatment of castings subject to heavy duty, such as rotating parts of machines, housings, etc., and an endeavour has been made to give the most up-to-date information. The committee has recommended that hollow drill tests be taken on all important castings, for the reason that they give a good indication of the quality of the annealing. The adoption of this specification is strongly urged on designing engineers, purchasing agents, inspectors and foundrymen, whose close co-operation is necessary to ensure castings which will give reliable service.

B29-1929. Established List of Machine Screws. This is the first of a series of standards or established lists which it is proposed to issue under the general title of "Established Lists of Dimensional Standards." It is proposed to issue these different lists in pamphlet form which can be conveniently filed in a binder which has been prepared by the Association and thus enable them to be conveniently used by draughtsmen, designing engineers, or purchasing agents. The chief feature of the Established List of Machine Screws is the reduction in the number of varieties from 43 to 21. Eleven different diameters of screws are listed with a fine and a coarse thread in all sizes but one, medium fit being adopted throughout, and it is felt that this will give a range which should meet every practical requirement and the adoption of the list is strongly recommended by the Association.

Work in Progress

Civil Engineering and Construction

Specifications for Concrete and Reinforced Concrete and a revised edition of the specification for Steel Highway Bridges have been issued during the year.

The specification for Steel Structures for Buildings is now being revised and it is hoped to have it issued early in 1930. This will constitute the second edition and its chief feature will be the raising of the working unit stress.

A revised edition of the specification for Reinforcing Materials for Concrete is now in preparation and it is proposed to issue it in three separate booklets, one covering each type of reinforcement. This will be issued early in 1930.

A committee has been organized to consider the question of preparing specifications for Wood Piles and Wood Pile Driving, and arrangements have been made for the first meeting of this committee early in the new year.

Mechanical Engineering

The Established List of Machine Screws was issued during the year and it is now proposed to proceed with the preparation of similar lists relating to cap screws, set screws, binder screws, plough bolts, etc.

Electrical Engineering

In the preparation of the second edition of the Canadian Electrical Code, great difficulty has been experienced in getting unanimity of opinion, but the Code is now in final proof form and it is expected to have it issued early in January 1930. A great deal of new material has been added and quite radical revisions have been made and it is expected that the second edition will be about 50 per cent larger than the first edition. During the year the Code has been adopted by the Workmen's Compensation Board of Alberta, and it is hoped that official adoption by the province will be obtained in the near future.

With reference to Part II of the Code, covering specifications for electrical apparatus, a panel has now been formed and it is expected to send out shortly a draft specification for preliminary review by this panel.

With reference to Part III, covering outside wiring rules, a representative panel has been organized and this panel held its first meeting in May, 1929. The work has been divided and assigned to four sub-panels as follows:

(1) Overhead systems.
(2) Underground systems.
(3) Inductive co-ordination.
(4) Grounding and conductive co-ordination.

In addition, a correlating sub-panel, consisting of the chairmen of the sub-panels, the chairman of the panel itself, and the C.E.S.A. secretary has been organized to assist in carrying out the work. Several meetings of this sub-panel have been held and the sub-panels are now at work.

The Committee on Transformers is now working on a specification covering Power Transformers, having recently completed the revised edition of the specification for Distribution Transformers. The specification for Power Transformers has now reached the second draft and is before the committee for comment.

A committee was organized during the year to consider the question of specifications for transformer and switch oils, and one meeting has been held at which it was decided to collect data on specifications which are now in use and addressing these to the members of the committee for review and comment.

Ferrous Metals

As noted in "Publications issued during 1929," five specifications covering Sampling for Check Analysis of Steel Billets, Bars and Shapes; Carbon Steel Billets and Bars of Forging Quality; Commercial-Quality Hot-Rolled Bar Steels and Commercial Cold-Finished Bar Steels and Cold-Finished Shafting; and Carbon Steel Castings, have been issued during the year and it is felt that these publications will be of great service to those interested in the manufacturing or purchasing of steel.

Co-operation with standardizing bodies in other countries has been continued. The latest country to organize a standardizing body has been Roumania, and national bodies are now organized in twenty-two different countries throughout the world.

Respectfully submitted,
F. B. Brown, M.E.I.C.
P. L. Pratley, M.E.I.C.
C. J. MacKenzie, M.E.I.C.

Awards of Students' and Juniors' Prizes

The reports of the examiners appointed in the various zones to judge the papers submitted for the Prizes for Students and Juniors were approved by Council at its meeting on January 14th, 1930, and make the following awards:—

H. N. Ruttan Prize—Western Provinces: No award; one paper received.

John Galbraith Prize—Province of Ontario: To M. V. Powell, Jr.E.I.C., for his paper on "Fabricated Steel Construction for Large Electric Generators."

Phelps Johnson Prize—Province of Quebec (English): To. E. Gray-Donald, Jr.E.I.C., for his paper on "Distribution Transformers."

Ernest Marceau Prize—Province of Quebec (French): No award; no papers received.

Martin Murphy Prize—Maritime Provinces: No award; no papers received.

Past-Presidents' Prize Committee

The President and Council:

Your committee charged with the duty of judging the papers on Engineering Education submitted in competition for the Past-Presidents' Prize has carefully reviewed the seven papers sent in.

Four of these were of a creditable nature but none was of such outstanding excellence as to warrant your committee in recommending it for this important prize. It is, therefore, suggested that no award be made for the papers presented this year, but that a further opportunity be granted members for winning the prize on the subject of Engineering Education, with specific limitations as to the effect of the present system of engineering education upon the status of the engineering profession.

Respectfully submitted,
Fraser S. Keith, M.E.I.C., *Chairman.*

Service Bureau Committee

The President and Council:

One of the principal functions of this Committee is to further the development of The Institute's Employment Bureau, whose activities naturally deal with employers seeking men as well as with men seeking positions. In carrying on the work of the Bureau your Committee's policy has been not to confine its operations to members of The Institute, although these, of course, take up the greater part of the time of the staff. In fact, during the past year, some thirty per cent of the total number of applicants for positions have been non-members of The Institute and a considerable number of these have secured employment, a result which has aided our relations with employers and has led to a considerable number of applications for admission to The Institute.

The Institute's Bureau, like other similar organizations, finds that only a small proportion of the persons benefitting by its operations inform us as to their success in obtaining positions, and it is probable that those who do send in information are not more than twenty-five per cent of the total. During the past six months, for example, we have heard directly from 52 applicants who have been placed, which indicates that during this period at least 200 positions have been filled through the activities of the Bureau. From the above it will be seen that it is only possible to estimate the number of men who have secured appointments.

For the 17 months that have elapsed since enlargement of The Institute's Employment Service, our records are:—

Members' advertisements published in the E. I. C. News	183
Replies received	392
Members' records forwarded to prospective employers	382
Vacant positions registered	486
Replies received to advertisements of vacant positions	1699
Men notified of vacancies	347

In addition to the correspondence connected with this work, a large number of personal interviews take place, usually averaging from thirty to forty per week. A considerable number of these interviews have been with young technical men from the British Isles and from the continent of Europe, many of whom have obtained positions without undue delay and have been grateful for the assistance received. As a rule, they have been of a very desirable type and when their acquaintanceship in Canada is sufficient to enable them to obtain the necessary number of sponsors, will be desirable additions to the membership of The Institute.

Your Committee would draw attention to the comparatively small number of our members who register with the Bureau and place their professional records on file. Up to date, only 345 members have done this. The work of the Bureau would be greatly aided if we had on file the professional records of the members, for use when the Bureau is notified of vacancies. Unless a member registers, the latest information available regarding him is usually that contained in his application for admission or transfer.

Your Committee feels that the results obtained from the Bureau's work during the past year have been extremely encouraging, and indicate that the operations of the Bureau might be greatly developed. The activities of the Employment Bureau, like those of other departments of The Institute, are limited by lack of funds. More of the time of our staff should be available for the Bureau's work, it should be possible to maintain closer personal touch with prospective employers and large engineering firms, and such measures, with possibly the appointment of suitable part-time representatives with local offices at such points as Halifax, Toronto, Winnipeg and Vancouver would, in your Committee's opinion, enable our service to be further extended and improved, with corresponding advantages to our membership.

Respectfully submitted,

T. R. Loudon, M.E.I.C., *Chairman.*

Library and House Committee

The President and Council:

Following the policy of previous years, the funds available for the library have been largely devoted to the purchase and binding of technical periodicals, the sets of which are of permanent value. Book purchases have been practically confined to standard text-books specially requested by members, but a considerable number of review copies have been presented by publishers and duly acknowledged in The Engineering Journal. The number of library accessions during 1929 was 714, including books, periodicals, government and other reports and society transactions.

The information service has been extensively used, 854 requests (written or verbal) having been received, while twenty bibliographies and a large number of photostat copies of articles have been prepared and forwarded to members. Your Committee believes that if the facilities for obtaining information were more clearly realized by members, a considerable increase in the activities of this department would result.

The Institute premises have been kept in good order and the necessary minor repairs, painting, etc. executed. No extensive repairs or alterations took place during the year.

Respectfully submitted,

W. C. Adams, M.E.I.C., *Chairman.*

Committee on Publicity

The President and Council:

Following the appointment of your Committee at the Plenary Meeting of Council last fall, a meeting of the Committee was held and consideration given to the subject entrusted to this Committee by Council. In a letter to Council dated November 13th, 1928, five suggestions were made, as follows:—

(1) That the Council establish either a permanent Publicity Committee of the Council, or attach the duties of such a committee to the present Publications Committee.

(2) That Council sponsor the establishment of a Publicity Committee in each Branch of The Institute.

(3) That each Branch be written, asking for a summary of their publicity activities, and to submit any suggestions they may have to offer whereby Council can be of assistance to them in that connection.

(4) That the Council keep up a continuous effort to give greater publicity to engineering affairs through the local Branches.

(5) That the Publicity Committee, after hearing from the Branches on the subject, be authorized to make a further report, after having advantage of the information from every Branch of The Institute, and thus be in a favourable position to make constructive suggestions.

At a meeting of Council held on November 16th the letter was considered, and it was agreed that the Committee be continued with a view to carrying out the third and fifth suggestions, no action being taken with regard to the second and fourth.

During the months intervening your Committee has made a study of the publicity situation, after having communicated with all Branches to find what their activities were in this connection. A summary of the replies of the Branches is as follows:—

Halifax—Publicity not actively followed previous to 1929. A committee recently appointed. Newspaper contact established. Looking for more Branch publicity.

Saint John—Publicity covered by separate committee. Friendly relations with newspapers. Always have good account of meetings. Invite to annual dinner. Papers always send representatives to meetings.

Moncton—Supper meetings. Special invitations to men likely to be interested in the address. Write-up of meetings handed to the press.

Saguenay—No attempt at publicity. Lectures open to public.

St. Maurice Valley—Always secure reports of meetings published in the local press.

Montreal—Have publicity committee. Send notices to the press. Chairman telephones various papers who usually send representatives.

Ottawa—Has evidently reduced the question of branch publicity to an exact science, and introduced most of the successful publicity methods in keeping the activities of the Branch and its members before the public. Maintain a committee of two on publicity, which is a sub-committee of the Proceedings Committee. This committee, should either local paper fail to send a reporter, prepares an account of meeting ready for type-setting. This committee suggests more Canadian press despatches from Headquarters to appear in local press throughout Canada.

Peterborough—General public invited to lectures and meetings. Sometimes more outsiders than members present at meetings. Favourable relations with local press. Reporter generally present to cover meetings. Front page write-up. Send complimentary tickets to press for dinners. Suggests that an endeavour be made to build up a systematic cordial relationship or working arrangement with the press.

Kingston—Consider doing all publicity possible. Invite general public when papers of general interest are presented. The press supplied with abstract of address. Generally reproduced. Have endeavoured to take stand on questions of local interest but failed, due to lack of unanimity. Appreciate suggestions from other Branches.

Hamilton—Has engineering advisory committee to act with Chamber of Commerce. Branch news editor endeavours to get articles for local papers. Invitations occasionally sent to city council and members of Chamber of Commerce to attend meetings.

London—Reporters of local papers invited to all meetings and are given information of interest. Auxiliary mailing list containing names of men who might be interested.

Niagara Peninsula—Members conduct visiting newspaper men to local engineering projects. Branch meetings open to those who wish to attend. Have large complimentary mailing list. One meeting a year places The Institute before the public. Secretary feels greater results possible. Suggest short articles "What the engineer means to our present civilization," for distribution to Branches for local publication. Suggest author of such articles be paid.

Border Cities—Publicity committee established. Secures write-up of meetings before and after—sometimes nearly an entire column. Member of Branch acts on directorate of Chamber of Commerce. Invite representative citizens to meetings. Endeavour to secure prominent outside speakers.

Sault Ste. Marie—Secretary prepares reports of meetings and accounts of important lectures. Local papers always publish.

Winnipeg—Secretary makes notes at meetings, and following meetings prepares reports which are usually published verbatim by the press.

Saskatchewan—Secretary keeps in touch with local press, who receive notices of meetings and write-up following. Suggest news of importance sent to Headquarters by wire, to be transmitted to Canadian press.

Lethbridge—Branch invites leading business men to meetings. Has many affiliates not connected with engineering. Public invited to meetings, particularly when outside speakers are secured. Full reports of Branch meetings appear in local press. One member of Branch writes copy.

Edmonton—Admit not using effective publicity. Secretary to get write-up in local papers. Wants suggestions from committee.

Calgary—Appreciate advantage of publicity. Newspapers receive and usually publish notices of meetings. Generally get satisfactory publicity. Members invited to represent Engineering Institute at other professional annual gatherings. Endeavour to obtain summaries of addresses from speakers in advance for press.

Vancouver—Little to report. Notify press of meetings. No suggestions to offer.

Victoria—No suggestions to offer. Publicity consists of notices of lectures in local press and report after.

Four Branches did not reply to either of two communications.

From the above it is seen that publicity activities of the Branches run all the way from zero to practically 100 per cent, with much left to be desired in most Branches. Generally speaking, the question of publicity is left for the most part to the Branch secretary. It is the belief of this Committee that the Branch secretary already has duties sufficient or more than sufficient as a contribution from one member, and that he should not be asked to assume the responsibility of looking after this important phase of Branch activity. It is obvious then, that every Branch should have its own publicity committee, composed of men who will take their appointment seriously and who will not only form a friendly contact with the local paper or papers, and get the activities of the Branch before the public, but who will be ever on the alert to keep the local press supplied with articles from the Engineering Journal which would be of interest to the public.

It is apparent to your Committee that the object of securing greater recognition of the engineers by the public will not be attained by even the most studied effort in this direction by all the Branches, but must have in addition an inspiration from a central committee. To follow the matter to a logical conclusion it would therefore appear necessary that any central or Headquarters committee on publicity should have at its disposal funds to carry out a publicity programme.

The major item in this connection would be to pay for the services of a man devoting part or full time—preferably the latter—to preparing articles and despatches and making arrangements to have these appear in the press throughout Canada. The Committee's duties would be to draw up a general plan, and the publicist engaged would carry out this plan under the direction of the General Secretary. Your Committee, therefore, would recommend for the serious consideration of Council, the following:—

(1) The establishment of a permanent publicity committee whose duty would be to present a definite publicity campaign both through Headquarters and through the Branches.

(2) That a publicity committee of at least two be established in every Branch.

(3) That provision be made in the budget for the engagement of the services of a man familiar with newspaper publicity and capable of carrying out a campaign calculated to bring the engineer more prominently to the notice of the public.

Reference was made by the Committee on Policy to this Committee of attaining a greater appreciation of the profession by the public, and we submit that this can only be accomplished by keeping the public better informed as to what the engineer is doing and has done, and emphasizing at all times the importance of his achievement in municipal, provincial, and national development.

The above report was presented to the Plenary Meeting of Council on October 8th, and by them referred to the Finance Committee, who reported that at present, funds are not available for carrying out its recommendations.

Respectfully submitted,

FRASER S. KEITH, M.E.I.C., *Chairman.*

Committee on Policy

The President and Council:

Your Committee on Policy was appointed in April 1929 following a resolution of the Annual General Meeting at Hamilton, it being understood that its work would be carried on in as close collaboration as possible with the various Branches of The Institute.

Your Committee accordingly transmitted to the various Branches of The Institute a number of questions bearing on the constitution, organization and working of The Institute, and, after holding seven meetings, presented an interim report at the Plenary Meeting of Council on October 9th, 1929, submitting at the same time the various expressions of opinion which had been received from the Branches. This resulted in a lengthy discussion by Council, and it is hoped that further expressions of opinion will take place during discussion at the Annual General Meeting of 1930; these no doubt will be available for the guidance of your Committee in preparing its final report.

The questions forwarded to the Branches were as follows:

(1) Review of aims and objects of Institute as set forth in Section 1 of the By-laws. Do they need any change or amendments?
(2) Present classes of membership. Are any changes desirable in nomenclature or in qualifications for admission?
(3) Are criticisms of the present publications of The Institute supported by the majority of our members, and if so, what changes are desirable?
(4) Organization of Council and Officers. Is a two-year terms for councillors desirable?
(5) Activities of The Institute and its Branches. What can be done to give better service to our members?
(6) Encouragement of the Student class. Formation of Student sections. Financial and other assistance for these.
(7) Finance. Desirability of change in rebate system as proposed by Lethbridge Branch.
(8) Finance. Need of additional revenue.
(9) General policy of The Institute. Should we aim at maintaining our present high standards for admission, or consider the admission to corporate membership of persons less fully qualified than at present?

The following notes form a brief record of the discussion of these various points at the Plenary Meeting of Council

(1) Modification in statement of aims and objects of The Institute. In this matter your Committee recommended no change, and this opinion was concurred in by the Branches, although it was suggested that it might be possible to give a broader interpretation of the objects as set forth in Section 1 of the By-laws.

(2) Changes in nomenclature and qualifications for various classes of membership. In regard to this matter the opinions of the Branches generally expressed satisfaction with the present arrangement, although four Branches would recommend the replacement of the present name "Member" by the term "Fellow" and the present term "Associate Member" by "Member," this being a change suggested by the report made at the Plenary Meeting of 1928 by Mr. Shearwood's Committee on Grades of Membership. Your Committee, however, did not feel justified in making any definite recommendations regarding this matter, as it was felt that it should be left in abeyance pending developments arising from the report of Mr. S. G. Porter's Committee on the Relations of The Institute with the Professional Associations. It is evident that any arrangement entered into with these Associations for uniformity in requirements for admission to The Institute (as contemplated by Mr. Porter's Committee), might require possible modification of our present classes of membership both as regards nomenclature and qualifications. It may be remarked that there are really two separate points which arise in this connection:

(a) Is it desirable to modify our classes of membership and our requirements for admission to them so as to give a wider corporate membership than is at present the case, and
(b) Will it be necessary to change the number and nomenclature of our present classes of membership to facilitate closer relationship with the various Professional Associations?

Council concurred in the Committee's view, and did not think it wise to make any definite recommendation at this time.

(3) Publications of The Institute. In its interim report presented at the Plenary Meeting, your Committee recommended that the Journal should be continued in its present size, and that any suggestions as to improvements should receive careful consideration. It was not considered desirable to undertake the publication of Transactions but your Committee did advise the continuation of the publication of the E-I-C News.

At the Plenary Meeting Council devoted considerable time to this important question. The views of a number of Branches were presented and were largely concerned with detailed criticism and Council referred the question with the criticisms received to a special committee under the chairmanship of Dean C. J. MacKenzie, M.E.I.C., of Saskatoon, which committee after due deliberation reported as follows:

"In the opinion of the Committee there must always be a certain amount of compromise in the publications of a society with interests so varied as those of The Engineering Institute of Canada.

"Three questions have been considered: (1) Are Transactions desirable? The meeting has already gone on record regarding this point. Transactions are not only desirable, but absolutely necessary if The Institute is to maintain its position as a scientific body.

(2) Is the Journal necessary in addition to the Transactions? The answer is yes. A monthly journal is essential as the means of informing our members as to the activities of The Institute and its Branches.

(3) Is the E-I-C News necessary in addition to the Journal and the Transactions? The answer is emphatically yes. Believing that these three things are desirable and necessary the Committee makes the following recommendations:

(1) That The Engineering Journal be continued.
(2) That the E-I-C News be continued.
(3) That an effort be made to publish Transactions of a high grade.
(4) That a committee under the chairmanship of Mr. W. C. Adams, M.E.I.C., with power to select two other members, be appointed to investigate the whole situation.

"The Committee also suggests that Mr. Adams' committee consider the possibility of getting the Journal published by an outside publisher which in the opinion of the committee would relieve Headquarters of a good deal of work, and would possibly result in a considerable monetary saving which might be applied to the publication of Transactions."

The small committee suggested by the above report was duly appointed by Council under the chairmanship of Mr. W. C. Adams, but has not yet reported in detail, although it submitted an interim report to Council on December 3rd, stating that it is inadvisable to turn over the publication of the Journal to any existing publishing house. Mr. Adams' committee is continuing its work and will no doubt present its final report to Council at a later date.

(4) Regarding the organization of the Council and Officers, your Committee draw attention to the desirability

of obtaining greater continuity in the membership of Council by arranging for a minimum term of two years. Effect has been given to this recommendation by Council in the amendment proposed to Section 13 of the By-laws, and the suggestion met with a considerable degree of support from the Branches.

(5) In regard to question No. 5, dealing with the activities of the Institute and its Branches, your Committee has made no special recommendations, but the discussion at the Plenary Meeting and the opinions expressed by Branch executive committees embodied several suggestions, among others the possibility of arranging for visits to Branches by the President and Secretary during the winter rather than during the summer; the desirability of developing further arrangements for visiting speakers, particularly in connection with the smaller Branches; broadening the scope of The Institute's employment and information services, and action by Council to secure better salaries for members.

At the Plenary Meeting the discussion emphasized the facts that Branch activities are principally dependent on the initiative of the Branches themselves, and that the great need of The Institute is a much greater degree of co-operation by members in contributing papers of high quality for presentation at the meetings of The Institute and its Branches.

(6) In regard to question No. 6, the encouragement of the Student class, the Branch executive committees are all impressed with the importance of this, but it is realized that the formation of Student sections is not possible or desirable at all Branches. Much may be done if prominent members of The Institute can be brought into touch with the graduating classes at the universities.

(7) Your Committee has not been able to make any definite recommendation as regards the proposal coming from the Lethbridge Branch to change the present system of payment of rebates to the Branches. The consensus of Branch opinions did not seem favourable to this proposition, and your Committee did not recommend immediate action, since the whole question of funds available for Branch activities depends upon the decision to be given by the members on the proposed increase in annual fees. Should this increase be approved this year, funds will be available in 1931 for additional resources for the Branches.

(8) With reference to the need of additional revenue for The Institute, your Committee throughout its studies has been impressed with the fact that many developments in The Institute's work which are eminently desirable cannot be carried out for lack of funds. This subject will no doubt be covered by the report of the Finance Committee, and your Committee heartily supports the proposed amendment to Section 34 of the By-laws which will come before the Annual Meeting for discussion.

(9) In its interim report your Committee did not make any recommendation regarding the general policy of The Institute, as it was felt that the future development of The Institute depends on the course of events following the work of Mr. Porter's Committee on the Relations of The Institute with the various Professional Associations. When The Institute develops its proposal for uniformity in standards of admission, and if this course leads to close relations or confederation with the Professional Associations, the future line of development of The Institute will be more definite. Your Committee feels, however, that serious consideration should be given at this time to the fact that The Institute's membership is practically stationary at a time when the country is prosperous and engineering work is rapidly developing. In your Committee's opinion this is largely due to the fact that engineers feel bound to join the Professional Associations and in many cases for financial reasons are unable to become or remain members of The Institute as well. This question should receive careful consideration by the membership of The Institute in discussing the proposals of Mr. Porter's Committee.

Your Committee would deprecate any change in the regulations for admission to The Institute which would admit to corporate membership persons less fully qualified than at present, and would support such suggestions as will fully maintain our professional status.

Respectfully submitted,

O. O. Lefebvre, M.E.I.C, *Chairman.*

Committee on Relations of The Engineering Institute of Canada with the Provincial Associations of Professional Engineers

The President and Council:

Your Committee on the Relations of The Engineering Institute with the various provincial associations of professional engineers met at The Institute's Headquarters on October 5th, 1929, and adopted the following progress report and recommendations for your consideration.

Your committee was appointed at the Plenary Meeting of council in October 1927 and consists of the following members:—

G. R. MacLeod,	Montreal, Que.	D. L. McLean,	Winnipeg, Man.
A. R. Decary,	Quebec, Que.	W. M. Scott,	Winnipeg, Man.
F. R. Faulkner,	Halifax, N.S.	L. A. Thornton,	Regina, Sask.
H. W. L. Doane,	Halifax, N.S.	H. R. MacKenzie,	Regina, Sask.
H. W. McKeil,	Sackville, N.B.	S. G. Porter,	Calgary, Alta.
A. Gray,	Saint John, N.B.	R. J. Gibb,	Edmonton, Alta.
H. J. Lamb,	Toronto, Ont.	G. A. Walkem,	Vancouver, B.C.
A. D. LePan,	Toronto, Ont.	P. Philip,	Victoria, B.C.

The members in attendance at the meeting of the committee on October 5th, 1929, when this report was adopted were:—

S. G. Porter, chairman.
G. R. MacLeod
F. R. Faulkner
H. W. L. Doane
H. W. McKiel
A. D. LePan
D. L. McLean
R. S. L. Wilson (acting for R. J. Gibb)
G. A. Walkem
together with
Brig.-Gen. C. H. Mitchell, president of The Institute
and
R. J. Durley, general secretary of The Institute.

The problems with which this committee is dealing are of a nature that cannot be settled hastily. Progress therefore is necessarily slow, but we feel that substantial progress has been made. In response to our suggestion, during the past year, committees, to confer with members of our committee, have been appointed by the provincial associations in all the provinces where engineering professions acts are in effect, and in most, if not all the provinces, informal discussions have taken place between their committees and members of our committee.

The solution of the problems confronting us will require much careful thought and the exercise of a considerable amount of patience. The interests of many independent bodies are involved, and many conflicting views are to be harmonized. It is thought, therefore, that a general statement of the arguments which justify the existence of this committee may be in order.

Associations of professional engineers, operating under the provisions of provincial legislative acts, are now in existence in the provinces of Nova Scotia, New Brunswick, Quebec, Ontario, Manitoba, Alberta and British Columbia. The legislation incorporating these associations was inaugurated by The Engineering Institute of Canada. The acts were intended to be uniform in the several provinces, but the model act was amended by each provincial legislature to suit its own ideas, with the result that considerable variations exist. Likewise, the procedure followed in each province in the administration of its act has been developed by the executive in each province very largely without regard to the procedure in the other provinces. The desire to harmonize the provisions and requirements under the several acts, and bring about a unity of purpose and procedure instead of permitting a wider divergence to develop, was the reason for several informal conferences, one result of which was the appointment of this committee whose duty is "to study the problems involved in co-ordinating the activities of The Engineering Institute of Canada and the several associations of professional engineers, looking forward to the ultimate integration of these bodies into one national organization."

In considering any proposal for the merging of The Engineering Institute of Canada and the several provincial associations of professional engineers, it is necessary and proper to consider the welfare of the provincial associations as well as of The Institute. The members of The Institute's committee are in nearly all cases also members of a provincial association, and are interested in the welfare of the one as well as of the other. But they are interested primarily in the welfare of the engineering profession as a whole, and the problem is to work out a solution which will meet that test.

There is still some difference of opinion as to the advantages to the profession of the legislative acts which provide for the registration for licensing of engineers. But since legislation has been enacted in nearly all the provinces, is simplifies our problem to accept it as an accomplished fact, assuming that the provinces which have not already done so will pass such legislation. Considering the problem for the moment from the standpoint of the provincial associations with a separate organization in each province, each following its own procedure with very little regard to the others, would there not be a very material advantage to the engineers of Canada as a whole to have them all brought into some close co-ordination?

The arguments for such a co-ordination may be stated as follows:

(1) Uniformity of requirements for admission and of regulations governing the practice of engineering.

(2) It would facilitate reciprocal arrangements whereby registration in any province would give a right to practise anywhere in the Dominion.

(3) A large membership, comprising all the professional engineers in Canada, working in harmony through one organization, would provide a Dominion-wide medium for expressing the viewpoint of the engineering profession, and exert a strong influence, otherwise unattainable,

(*a*) On legislation affecting—
  (1) The welfare of engineers;
  (2) The safety and welfare of the public where the construction, operation or control of engineering works and public service utilities are governed by legislative enactment.

and (*b*) On public opinion. Greater public recognition and more favourable publicity would result in Canadian engineers becoming better known and being able to compete more successfully with outside engineers.

(4) The educational functions of the technical societies could be co-ordinated with the administration duties of the professional associations to their mutual advantage, resulting in economy of administration and the prevention of overlapping and duplication. The advantages which could be offered to its members by a strong Canadian organization would compare more favourably with those offered by the technical societies of the United States, and would make a stronger appeal to Canadian engineers and lessen the tendency and necessity of their looking outside of Canada for these advantages.

(5) All this should result in the development of a stronger professional consciousness and esprit de corps among engineers comparable to that existing in the other professions.

Having recognized the advantages of having one Dominion-wide body for all professional engineers, it is necessary to consider how it can be brought about. An affiliation of the associations of professional engineers of all the provinces, (assuming that all secure legislative acts), with all the functions I have outlined, would duplicate the activities of The Engineering Institute of Canada. Then why not utilize the machinery already in existence in The Institute, and by co-ordinating its activities with those of the provincial associations accomplish the whole purpose? It would not mean the swallowing up of the provincial associations by The Engineering Institute of Canada, as someone has put it, but rather the reverse would be more nearly true. The majority of the engineers are already members of both. If they were merged, the membership would be identical. The governing body of The Institute—the Council—is elected from and by the local membership. So if the local membership is composed of the professional engineers, and they elect the Council, the Council is likewise controlled by them. There should therefore be nothing to fear on the part of the professional engineers.

Nor need this proposal injure the Canadian Institute of Mining and Metallurgy. Primarily it represents the industry of mining, and there will continue to be a field of usefulness for it to serve, and the two should strengthen rather than weaken each other if proper harmonious relations were established.

At the meeting of the committee on October 5th, the members present from the several provinces presented the following brief statements of the status in their provinces:

Nova Scotia: The Association of Professional Engineers of Nova Scotia has a committee which has had some joint meetings with the members of The Engineering Institute of Canada and this committee is of the opinion that the standard for admission to Associate Membership in The Engineering Institute of Canada should be raised to the level of the association requirements. The council of the association has gone on record as being in favour of the formation of one national body.

F. R. Faulkner.

New Brunswick: The members of your committee resident in New Brunswick have met with representatives of the provincial association. After consideration of the points suggested for discussion it was felt that there existed a provincial feeling in favour of the reduction of the number of engineering organizations. As a result of this it would seem that the members of the association and Institute would welcome a co-ordination of the functions of those bodies. The only serious difficulty seems to be in the matter of collecting and apportioning fees. No machinery for the collection of fees for transmission to The Institute exists at present and the establishment of such would require an amendment to the act. However, as the memberships of the association and The Institute are largely the same, no great difficulty should be experienced in bringing about the required changes.

H. W. McKiel.

Quebec: In the province of Quebec there is practically no difference between the membership of The Engineering Institute of Canada and that of the Corporation of Professional Engineers, i.e., the two lists would be almost identical. The exceptions, generally speaking, would be the few members of the Professional Corporation who have entered the province to do professional work for a short time, and were obliged to take out membership in the Corporation of Professional Engineers and would not usually join The Institute unless they expected to remain here indefinitely. These would be a very small proportion of the total.

In the beginning the organization meeting of the Corporation of Professional Engineers was held at The Institute headquarters and at that time the corporate members of The Engineering Institute of Canada resident in the province automatically became members of the new corporation. Since then the control of the professional corporation has been in the hands of prominent members of The Institute. Furthermore there has been practically no difference in the requirements of qualifications for membership and it is not anticipated by the members of your committee that there would be any difficulty in adopting the same requirements for admission to the Corporation of Professional Engineers of Quebec as for The Institute.

There has never been any friction between The Institute in the Province of Quebec and the Corporation of Professional Engineers nor any overlapping of activities of the two organizations.

In view of the above I am convinced that the engineers in the province of Quebec will be quite in favour of virtual amalgamation between the professional corporations and The Institute as soon as a uniform standard of qualifications for admission is agreed upon.

Geo. R. MacLeod.

Ontario: In Ontario I think the engineers generally are in favour of and ready for consolidation. The process will necessarily be slow but constant pressure should be exerted towards this end. The Engineering Institute of Canada and the Association of Professional Engineers of Ontario should have no difficulty in co-operating in this matter.

A. D. LePan.

Manitoba: In Manitoba The Engineering Institute of Canada and the Association of Professional Engineers of Manitoba are closely interlocked and work in close harmony.

The qualifications required for admission to and registration with the Association of Professional Engineers of Manitoba are virtually the same or very similar to those required of corporate members in The Engineering Institute of Canada.

The one man serves as registrar of the Association of Professional Engineers of Manitoba and as secretary of the Winnipeg Branch of The Engineering Institute of Canada, the only one in Manitoba. The two associations have at present very largely a common membership.

D. L. McLean.

Saskatchewan: While Saskatchewan has no professional engineers' act, it is reported that progress has been made in the sentiment favouring legislation and joining with the other provinces in the co-ordination of all the engineering organizations in the Dominion. Unfortunately neither member of the committee representing Saskatchewan was able to attend our meeting.

S. G. Porter.

Alberta: The Association of Professional Engineers of Alberta has a committee working towards a practical scheme of amalgamation. This committee is willing and ready to co-operate with similar committees of The Engineering Institute of Canada and other provincial associations, and has power to negotiate subject, of course, to final approval by the Association of Professional Engineers of Alberta.

R. S. L. Wilson.

British Columbia: The individual members of the Association of Professional Engineers of British Columbia are favourable to the ultimate joining of The Institute with the Association, and the Association will co-operate with The Institute in any steps toward that end.

Geo. A. Walkem.

In submitting to you the recommendations contained in this report we wish to emphasize the fact that the objects of The Engineering Institute of Canada and of the Associations of Professional Engineers are in entire harmony and in many respects identical. Furthermore that The Engineering Institute was instrumental in bringing the associations into existence and even at the present time the same men who are most active in the one are usually also most active in the other. Our objects and our interests therefore are common. To refresh your memory I quote the objects of The Engineering Institute as stated in the By-laws.

Objects

> Section 1.—The objects of The Institute shall be (a) to develop and maintain high standards in the engineering profession, (b) to facilitate the acquirement and the interchange of professional knowledge among its members, (c) to advance the professional, the social and the economic welfare of its members, (d) to enhance the usefulness of the profession to the public, (e) to collaborate with universities and other educational institutions in the advancement of engineering education, (f) to promote intercourse between engineers and members of allied professions, (g) to co-operate with other technical societies for the advancement of mutual interests, (h) to encourage original research, and the study, development and conservation of the resources of the Dominion.

Now, therefore, in view of the conditions in the various provinces as outlined herein, and of the legal limitations imposed by the British North American Act and by the several provincial acts, and in order to carry out the intention of Council's instructions to attain the "co-ordinating of the activities of The Engineering Institute of Canada and the several associations of professional engineers" and for the advancement of the profession in Canada, we submit the following recommendations:—

(1) That this committee or a similar one be continued.

(2) That at least one member of council in each province be added to the committee to act during his term of office in all cases where council is not already represented.

(3) That this committee be authorized to appoint a small sub-committee whose duty it shall be to approach the provincial associations and in conjunction with them devise a detailed proposal to bring about a co-ordination of the interests and activities of the various professional associations and The Engineering Institute of Canada; and further it is recommended that a sum of $1,800 be appropriated towards a fund to provide for the expense of this work.

(4) That The Engineering Institute of Canada, through The Journal and otherwise, continue to encourage and support the activities of the professional associations and contribute in every reasonable way to their success.

(5) That immediate steps be taken to arrive at an agreement among the professional associations and The Institute for the adoption of standard uniform requirements for admission to membership and that these requirements be rigidly adhered to.

(6) That upon the acceptance of such standard requirements The Institute should adopt the policy of accepting membership in a professional association as sufficient evidence of qualifications for admission to The Engineering Institute of Canada.

(7) That steps be taken to secure the necessary amendments to the By-laws so that membership or registration in a professional association be one of the requirements for admission to corporate membership in The Engineering Institute of Canada for all applicants residing in a province where an engineering professions act is in effect.

Respectfully submitted,

S. G. Porter, M.E.I.C., *Chairman.*

Branch Reports

Border Cities Branch

The President and Council,—

The work of your Branch has been carried out during 1929 by the following committees:

Papers and Entertainment..............A. J. M. Bowman, A.M.E.I.C., chairman, assisted by K. E. Fleming, S.E.I.C., until April, when their term expired. H. J. Coulter, Jr.E.I.C., was then appointed chairman of that committee, with power to add, his term to run until next April.
Publicity...............R. J. Desmarais, A.M.E.I.C.
Membership............Orville Rolfson, A.M.E.I.C.
Nominating............F. H. Kester, M.E.I.C.
Branch News Editor and Assistant-Secretary..Eugene Chorolsky, S.E.I.C.
By-Laws...............Harvey Thorne, M.E.I.C.
Representative on directorate of the Border Chamber of Commerce.A. E. West, A.M.E.I.C.
Welcoming Committee.,.Messrs. Armstrong, Coulter and Thorne.

The followings meeting have been held.

Jan. 11.—Annual meeting and election of officers, which had been adjourned from December 14th, 1928. The business was preceded by an address by Mr. S. A. Thoresen on the **"Detroit-Windsor Tunnel."** Attendance, 20.

Feb. 8.—Mr. R. G. Cone spoke on **"The Construction of the Ambassador Bridge"** and showed moving pictures of the work. Attendance, 37.

Mar. 15.—C. M. Goodrich, M.E.I.C., chief engineer of the Canadian Bridge Co. Limited, spoke on **"Engineering English."** Attendance, 25.

Apr. 12.—Dr. H. M. MacKay, M.E.I.C., Dean of the Faculty of Applied Science of McGill University, spoke on **"The Position and Experience of Engineering Graduates."** Attendance, 38.

May 10.—Mr. Torris Eide, of the Detroit Water Works Department, spoke on the new water supply system in that city. Attendance, 26.

Oct. 25.—We had a visit from the Executive and several out of town members of the Association of Professional Engineers of Ontario. Mr. R. G. Cone again described the bridge. Attendance, 73.

Nov. 15.—Mr. G. T. Bentley, Assistant Superintendent of Manufacture of the Detroit City Gas Co. spoke on, **"The Manufacture and Distribution of Gas."** Attendance, 20.

The average attendance at meetings was 34. This average compares with an average of 31 for 1926; 20 for 1927 and 38 for 1928.

Financial

Following is a summary of our receipts and expenditures up to and including December 13th. There will be one or two small items to come in yet before the end of the year.

FINANCIAL STATEMENT
(1929)

Receipts		
Balance in bank December 29, 1928	$174.55	
H.Q. rebates, balance of 1928	6.00

Stamps and telegrams	9.42	
Typing	11.00	
Speaker's expenses	43.72	
Meals	353.25	
Cigars	35.00	
Miscellaneous	54.50	
	555.38	
Balance on hand Dec. 31st, 1929	239.79	
		$795.17

Respectfully submitted,

R. C. LESLIE, Jr.E.I.C., *Secretary-Treasurer.*

Calgary Branch

The President and Council,—

On behalf of the Executive Committee we beg to submit the following report of the activities of the Calgary Branch for the calendar year 1929:—

OFFICERS

The officers elected at the annual meeting held on March 9th and the *ex-officio* officers for the Branch year were as follows:—

Chairman	F. J. Roberston, A.M.E.I.C.
Vice-Chairman	W. St.J. Miller, A.M.E.I.C.
Secretary-Treasurer	W. H. Broughton, A.M.E.I.C.
Executive (Elected)	F. M. Steel, M.E.I.C.
	F. J. Heuperman, A.M.E.I.C.
	R. C. Harris, M.E.I.C.
Ex-officio	J. H. Ross, A.M.E.I.C.
	T. Lees, M.E.I.C.
Auditors	A. W. P. Lowrie, A.M.E.I.C.
	C. C. Richards, M.E.I.C.
Branch Editor	H. R. Carscallen, A.M.E.I.C.

MEMBERSHIP

A statement of the membership at the end of 1929 and a comparison with that at the end of 1928, follows:—

Dec. 31st, 1928	Resident	Non-Resident	Total
Members	22	7	29
Associate Members	47	23	70
Juniors	5	1	6
Students	1	2	3
Branch Affiliates	11	..	11
Totals	86	33	119

Dec. 31st, 1929	Resident	Non-Resident	Total
Members	22	8	30
Associate Members	49	18	67
Juniors	3	1	4
Students	5	4	9
Branch Affiliates	12	..	12
Totals	91	31	122

MEETINGS

The executive met ten times during the year and once jointly with the policy committee to draft telegrams which were sent to the Premier, the Minister of Finance, the Hon. Chas. Stewart and the Federal Members representing Calgary, regarding increases of salary for professional Federal Civil Servants.

The committee in charge of arrangements for the annual ball met four times and as a result of their efforts a very successful ball was held at the Palliser hotel on Friday, Nov. 22nd, at which 318 guests and members with their ladies were present. This function is now established as a regular event in the social life of the city and is an excellent publicity feature of the local Branch of The Institute.

Nine general meetings were held which were all announced in the local press, with the result that there were usually a few non-members present; the press generally give us a very fair write-up of our meetings.

Details of the meetings and speakers were as follows:—

Jan. 10.—**"Considerations of Industrial Railway Trackage"** by J. McL. Nicol, A.M.E.I.C., of the engineering department, C.P.R., Calgary.
"Carrier Telegraph Systems" by L. A. B. Hutton, A.M.E.I.C., inspector of telegraphs, C.P.R., Calgary.
"Evaporation as a Factor in Hydrology" by J. A. Spreckley, A.M.E.I.C., hydrologist, D.W.P. and R.S., Calgary.
"Portland Cement Concrete" by K. MacKenzie, Jr.E.I.C., of the Canada Cement Company. Attendance, 36.

Jan. 24.—**"Engineering and Public Service"** by Dr. R. C. Wallace, President of the University of Alberta, Edmonton. Attendance, 43.

Feb. 7.—**"Deep Well Drilling Practices"** by C. W. Dingman, Esq., chairman of the petroleum section of the Canadian Institute of Mining and Metallurgy. Attendance, 55.

Feb. 21.—**"Aerial Topics"** by C. W. Leggatt Esq., B.S.A., M.Sc., President of the Calgary Aero Club.
"Aviation, Review and Prophecies" by W. St.J. Miller, A.M.E.I.C., vice-chairman of the Branch. Attendance, 26.

Mar. 9.—Annual meeting and election of officers. Attendance, 18.

Mar. 9.—Annual dinner. Attendance, 61.

Mar. 27.—**"Hydraulic Regulating Gates"** by F. Newell, M.E.I.C., mechanical engineer, Dominion Bridge Co., Montreal. Attendance, 33.

Nov. 7.—**"The Romance of Map Making"** by M. P. Bridgland, M.E.I.C., of the D.W.P. & R.S., Calgary. Attendance, 36.

Nov. 22.—Annual ball. Attendance, 318.

Dec. 5.—**"The Oil Industry in Alberta"** by B. L. Thorne, M.E.I.C., coal mines branch, D.N.R., C.P.R., Calgary. Attendance, 36.

Dec. 19.—**"Closer Relations with the Professional Associations"** by S. G. Porter, M.E.I.C., chairman of The Institute Committee dealing with this subject.
J. H. Ross, A.M.E.I.C., also gave a resumé of other business done at the Plenary Meeting of Council.
"Static Electricity" by F. N. Rhodes, A.M.E.I.C., in charge of the electrical department, Institute of Technology and Art, Calgary. Attendance, 17.

The average attendance was 36, excluding the annual ball and the annual dinner.

A business meeting to discuss the proposed increase in dues has been arranged for January 9th, 1930.

FINANCIAL STATEMENT

(Year ending December 31st, 1929)

Cape Breton Branch

The President and Council,—

The Executive Committee of the Cape Breton Branch submits the following report of the Branch activities during the year ending December 31st, 1929:—

Financial Statement

Receipts

Balance in bank	$ 66.15	
Dues collected	10.00	
Rebates from Headquarters	118.26	
Rebate on telegram	3.24	
Receipts annual dinner	106.00	
		$303.65

Expenditures

Telegrams	$ 3.24	
Printing	6.93	
Rent	45.00	
Board of Trade Rooms	2.00	
Wreaths	46.10	
Journal subscriptions	4.00	
Expense annual dinner	130.40	
Stenographer	10.00	
Stenographer	10.00	
Miscellaneous	5.89	
	$263.56	
Balance in bank	40.09	
		$303.65

Papers

Papers read during the year—as follows:—

Jan. 22.—"**Coal Mining in Spitzbergen**" by Louis Frost.
Jan. 24.—"**The St. Lawrence Waterways**" by O. O. Lefebvre, M.E.I.C.
Apr. 22.—"**The Zinc Coating of Steel Wires**" by A. D. Turnbull, S.E.I.C.
July 23.—"**Anaconda Copper Mining Company**" by W. L. Strewe.
Nov. 26.—"**Tendency in Coal Mining Machinery**" by F. W. Gray, M.E.I.C.
Dec. 12.—Annual Dinner—Isle Royale hotel.

Membership is now 39 against 42 for 1928.

New Executive

Chairman........A. L. Hay, M.E.I.C.
S. C. Mifflen, A.M.E.I.C.
C. M. Smyth, A.M.E.I.C.
J. P. Cotter, A.M.E.I.C.
Y. C. Barrington, A.M.E.I.C.
J. A. Fraser, A.M.E.I.C.
E. L. Ganter, A.M.E.I.C.

Respectfully submitted,

M. Dwyer, A.M.E.I.C., *Chairman.*
E. L. Ganter, A.M.E.I.C., *Secretary-Treasurer.*

Edmonton Branch

The President and Council,—

The Executive Committee of the Edmonton Branch begs to submit the following report on the activities of the Branch during the year 1929.

Officers

January to August

Chairman........Vernon Pearson, A.M.E.I.C.
Vice-Chairman........R. W. Ross, A.M.E.I.C.
Secretary-Treasurer........H. R. Webb, Jr.E.I.C.
Committee........R. W. Jones, M.E.I.C.
J. Garrett, A.M.E.I.C.
C. F. Corbett, A.M.E.I.C.
C. R. Crysdale, M.E.I.C.
Ex-officio........A. I. Payne, M.E.I.C.
R. J. Gibb, M.E.I.C.

August to December

Chairman........R. W. Ross, A.M.E.I.C.
Vice-Chairman........J. Garrett, A.M.E.I.C.
Secretary-Treasurer........H. R. Webb, Jr.E.I.C.
Committee........W. H. Greene, M.E.I.C.
A. W. Haddow, A.M.E.I.C.
C. A. Robb, M.E.I.C.
E. Stansfield, M.E.I.C.
Ex-officio........Vernon Pearson, A.M.E.I.C.
R. S. L. Wilson, M.E.I.C.

Meetings

Lectures and papers given before the Branch during the year were as follows:

Jan. 22.—"**Mechanics and Power of Expression**" by the Rev. Thomas Tait.
Feb. 28.—"**The Ghost Water Power Project**" by I. F. Morrison, Professor of Applied Mechanics, University of Alberta, Edmonton, Alberta.
Oct. 30.—Report from Plenary Council Meeting, by R. S. L. Wilson, M.E.I.C., dean, Faculty of Applied Science, University of Edmonton, Alberta.
Nov. 20.—"**The Development of Long Distance Telephony**" by J. D. Baker, deputy minister and general manager, Alberta Government Telephones, Edmonton, Alberta.

Membership

The Branch membership is now as follows:—

	Resident	*Non-resident*
Members	15	2
Associate Members	24	8
Juniors	4	1
Students	13	1
Branch Affiliates	1	..
Total	57	12

H. R. Webb, Jr.E.I.C., *Secretary-Treasurer.*

Halifax Branch

The President and Council,—

On behalf of the chairman and Executive Committee of the Halifax Branch I wish to submit the following report on the activities of the Branch for the past year.

Including the annual meeting there have been seven regular meetings of the Branch, and one special meeting in August to meet President Mitchell who came from the Professional Meeting in Moncton for this purpose, and eight meetings of the Executive.

The regular meetings were as follows:—

Jan. 23.—"**St. Lawrence Waterways Project**" by Mr. O. O. Lefebvre, M.E.I.C., chief engineer of the Quebec Streams Commission. Attendance, 45.
Feb. 21.—"**Manufacture of Paper**" by Col. C. H. L. Jones, President of the Mersey Paper Company, Ltd. Attendance, 55.
Mar. 21.—"**Heating of Modern Buildings**" by Mr. F. W. Spencer of the C. A. Dunham Company. Attendance, 23.
Apr. —"**Natural Resources and Reforestation of Nova Scotia**" by Mr. Otto Schierbeck, chief forester, Province of Nova Scotia. Attendance, 35.
Oct. —"**The Submarine**" by Mr. John Patterson. "**Canada, the Land of Opportunity**" by Mr. C. H. Wright, M.E.I.C. Attendance, 150.
Nov. —General business meeting to hear reports from committee on amalgamation of Professional Society and The Institute. Attendance, 28.
Dec. —The annual meeting at the Halifax hotel at which the following officers for the year 1930 were elected:—

Chairman........Professor W. P. Copp, M.E.I.C.
Executive........J. L. Allan, M.E.I.C.
C. St.J. Wilson, A.M.E.I.C.
L. M. Allison, A.M.E.I.C.
J. D. Fraser, S.E.I.C.
W. H. Noonan, A.M.E.I.C.
J. J. Sears, A.M.E.I.C.
G. S. Stairs, M.E.I.C.
W. G. Matheson, M.E.I.C.
H. F. Bennett, A.M.E.I.C.
G. T. Medforth, A.M.E.I.C.
D. S. Wickwire, A.M.E.I.C.
Auditors........F. R. Faulkner, M.E.I.C.
G. W. Burchell.

Branch representative on Nominating Committee: W. A. Winfield, M.E.I.C.

Attendance: 38.

The attendance record is worthy of special attention, there being a total of 336 at six regular meetings or an average of 56 which shows an increased interest in Branch activities and the appreciation of the members to the speakers and the work of the Papers Committee.

The midsummer meeting to greet President Mitchell was very successful as thirty seven members were present at the midday meeting at the Halifax hotel.

Considerable progress was made during the year toward amalgamation with the Professional Society and the efforts put forward by the

Executive and Committee in charge of this work deserve your commendation.

The following is a statement of the finances to date:—

FINANCIAL STATEMENT

Receipts

Cash on hand January 1, 1929	$123.58
Rebates	233.20

Hamilton Branch

The President and Council,—

The Executive Committee of the Hamilton Branch submits the following report for the year 1929.

The Branch year dates from June 1st so that two Executive Committees acted as follows:—

January to May		*June to December*
W. L. McFaul, M.E.I.C.	Chairman	H. A. Lumsden, M.E.I.C.
J. A. McFarlane, M.E.I.C.	Vice-Chairman	A. H. Munson, A.M.E.I.C.
F. P. Adams, A.M.E.I.C.	Committee	J. B. Carswell, M.E.I.C.
W. D. Black, M.E.I.C.		H. S. Phillips, M.E.I.C.
H. A. Lumsden, M.E.I.C.		F. P. Adams, A.M.E.I.C.
G. R. Marston, A.M.E.I.C.		W. D. Black, M.E.I.C.
W. F. McLaren, M.E.I.C.	Sec.-Treasurer	W. F. McLaren, M.E.I.C.
R. K. Palmer, M.E.I.C.	Councillor	R. K. Palmer, M.E.I.C.
L. W. Gill, M.E.I.C.	Past Chairman	W. L. McFaul, M.E.I.C.
J. R. Dunbar, A.M.E.I.C.	News Editor	J. R. Dunbar, A.M.E.I.C.

The oustanding event of the year was the Annual General and General Professional Meeting held at the Royal Connaught hotel, Feb. 13th, 14th and 15th during the chairmanship of W. L. McFaul, M.E.I.C.

The main committee handling the arrangements was composed of the chairmen of the sub-committees and consisted of the following:—

Chairman	W. D. Black, M.E.I.C.
Entertainment	J. B. Carswell, M.E.I.C.
Papers	L. W. Gill, M.E.I.C.
Reception	R. K. Palmer, M.E.I.C.
Ladies	A. H. Munson, A.M.E.I.C.
Advertising	C. C. Wimperley.
Visits	J. A. McFarlane, M.E.I.C.
Luncheons	J. R. Dunbar, A.M.E.I.C.
Finances	W. L. McFaul, M.E.I.C.
Ladies	Mrs. R. K. Palmer.
Secretary	W. F. McLaren, M.E.I.C.

MEETINGS

The following meetings were held:—

Jan. 25.—Welded Structures by the late Prof. Peter Gillespie. Attendance 25.

Feb. 13 to 15.—Annual General and General Professional Meeting. Attendance 450.

Apr. 3.—Research by Dr. H. M. Tory. Attendance 73. Joint Meeting with C.M.A. and Chemists.

Apr. 26.— Vacuum Tube Devices by J. V. Breisky. Attendance 360. Joint Meeting with Toronto branch A.I.E.E.

May 31.—Annual Business Meeting and dinner with address on a **"Trip Through Ireland"** by Rev. G. W. Tebbs.

Sept. 27.—Joint meeting with Niagara Peninsula Branch. Address on **"Institute Affairs from the Branch Viewpoints"** by E. G. Cameron, M.E.I.C. Attendance 35.

Oct. 15.—**"Production Testing of Vacuum Tubes"** by K. S. Weaver and W. S. Jones of the Westinghouse Lamp Co., Bloomfield, N.J. On the invitation of the Toronto branch of the Institute of Radio Engineers.

Oct. 23.— Invited by Niagara Peninsula Branch to inspection trip of Welland ship canal in afternoon and addresses in St. Catharines in evening by F. E. Stearns, M.E.I.C., and A. A. Northrop of Stone & Webster Engineering Corpn.

Nov. 6.—Addresses on **"Machine Tools"** by H. G. Bertram, M.E.I.C. **"Plenary Meeting of Council"** R. K. Palmer, M.E.I.C. **"Coke Ovens of the Steel Co. of Canada"** J. E. Grady, A.M.E.I.C. **"Power Factor"** by J. R. Dunbar, A.M.E.I.C. Attendance 36.

Dec. 5.—**"Engineering Developments in the Army"** by Major Gen. A. G. L. McNaughton, M.E.I.C. Attendance 50.

Dec. 11.—Invited by Ontario Section A.S.M.E. to afternoon and evening meeting at Galt.

Kingston Branch

The President and Council,—

During the year 1929 the Branch held four meetings.

On February 26th a dinner was held at the Students' Union, Queen's University at which 22 members were present. Unfortunately the speaker scheduled for this occasion was at the last moment prevented from attending.

On March 19th the Branch was addressed by Mr. R. O. Wynne-Roberts, M.E.I.C., of Wynne-Roberts, Son & McLean, on the **East York Sewage Disposal Works.**

On Nov. 15th Mr. A. S. Wall of the Dominion Bridge Company gave a paper on **Structural Steel Welding.**

On Nov. 22nd the President of the E.I.C. visited Kingston and addressed the members of the Branch on **Institute Affairs.**

The average attendance at meetings was twenty-three.

The membership is at present as follows:—

Honorary Member	1
Members	13
Associate Members	14
Junior Members	2
Student Members	40
Total	70

The finances of the Branch are satisfactory and a detailed statement is appended:

Lakehead Branch

The President and Council,—

On behalf of the Executive Committee, I beg to submit the following annual report of the Lakehead Branch of The Engineering Institute of Canada.

Membership

On January 1st, 1929, there were 44 corporate members and 11 non-corporate members and on December 31st, 1929, there were 41 corporate members and 10 non-corporate members, showing a loss of 3 corporate and 1 non-corporate members.

Meetings

Four meetings were held during the year as follows;—

Feb. 12.—A meeting of the Branch was held at the new Technical School, Port Arthur, at 6.30 p.m. The school's domestic science class served a most enjoyable supper in their class room to the members. After the supper a meeting was held in the board room. It was at this meeting that the Branch decided to ask that the Professional Meeting for 1929 be allotted to the Lakehead Branch. After the meeting, Mr. McWilliams, the principal, conducted the members through the new school, a trip which was greatly enjoyed by all.

Apr. 23.—A meeting of the Branch was held at the Garrison Officers' mess, Port Arthur. This was a business meeting, at which matters relative to the Branch were discussed.

May 2.—On this date, our General Secretary, R. J. Durley, m.e.i.c., honoured us with a visit. At noon, Mr. Durley had as his guests at the Royal Edward hotel, Fort William, the officers and members of the Executive Committee of the Branch, to luncheon. After lunch, a general discussion of affairs relative to the holding of the Professional Meeting at the Lakehead took place. In the evening, at the Garrison Officers' mess, a meeting of the Branch was held, at which Mr. Durley again pointed out matters relative to the holding of a Professional Meeting. He also spoke on affairs in general relating to The Engineering Institute.

Oct. 2.—A meeting of the Branch was held at the Garrison Officers' mess, Port Arthur, when matters relative to the interests of the Branch were discussed. At this meeting also, Mr. Brophy, who was going to Montreal to attend the Plenary Meeting of Council, was given the views of the various members on matters which were to come before the Plenary Meeting.

I am sorry to have to report the death of two members of the Branch during the past year, Jos. C. Meader, a.m.e.i.c., of Fort William, a member of the Executive Committee of the Branch and one who took a great deal of interest in the affairs of The Institute at all times, and C. N. Wylde, a.m.e.i.c., of Dryden, Ont.

The following were nominated to represent the Lakehead Branch on the Council of The Institute:

F. Y. Harcourt, m.e.i.c., D. G. Calvert, a.m.e.i.c.

Lethbridge Branch

To the President and Council,—

On behalf of the Executive Committee of the Lethbridge Branch, I have the pleasure of submitting to you the following report showing the progress during the last year.

Since January 1st, the executive has held six meetings all well attended, in addition to thirteen regular and special meetings at which the attendance averaged 34. Very great credit has been due to the Programme Committee for the excellent speakers secured for the regular meetings. It was unfortunate that on the occasion of Mr. Durley's visit, so many of the members were away, but as the date fell during the usual vacation period, the small attendance was naturally accounted for.

A list of the regular meetings with speakers and subjects follows:

Jan. 12.—F. J. Robertson, a.m.e.i.c., gen. supt. Calgary Power Company. Subject: **"Some Features of Power Development in Alberta."**

Jan. 17.—Special meeting, discussion of Institute affairs.

Jan. 26.—Dr. R. C. Wallace, President of Alberta University. Subject: **"Engineering and Public Service."**

Feb. 9.—A. W. Shackleford, Manager, Capitol Theatre, Lethbridge. Subject: **"The Dawn of the Motion Picture up to the Third Era."**

Feb. 23.—H. J. McLean, a.m.e.i.c., Calgary Power Company. W. H. Abbott, a.m.e.i.c., Foundation Co. of Canada. Subject: **Engineering and Construction Features of the Ghost River Power Project, Calgary Power Company."**

Mar. 9.—Annual meeting, general discussion on **"Radio Broadcasting."**

Mar. 23.—Joint meeting with Professional Engineers of Alberta. M. L Wade, gen. supt., East Kootenay Power Company. Subject: **"Some Economic Features of the Power Situation."**

July 16.—Special meeting with Mr. Durley present.

Sept. 21.—Special meeting, discussion of Institute affairs.

Oct. 19.—H. L. Seamans, Entomological Branch, Dept. of Interior. Subject: **"The Effect of Weather on Insects."**

Nov. 2.—B. Jordon, Jeffrey Manufacturing Co., Columbus, Ohio. Subject: **"Coal Cutting Machinery and Conveyors,"** with motion pictures.

Nov. 16.—J. Giegerich, Consolidated Mining & Smelting Co., Kimberley. Subject: **"The Sullivan Mine."**

Nov. 30.—H. B. Banks, Consolidated Mining & Smelting Company, Kimberley. Subject: **"The Kimberley Concentrator."**

Dec. 14.—J. E. Duncan, Geophysicist, Canadian Western Natural Gas Company. Subject: **"Geophysical Methods applied to Foundations."**

The Branch annual meeting was held on March 9th, when the following officers were chosen for the ensuing year:

Chairman	J. B. de Hart, m.e.i.c.
Vice-Chairman	C. S. Clendening, a.m.e.i.c.
Executive	J. T. Watson, a.m.e.i.c.
	R. Livingstone, m.e.i.c.
	P. M. Sauder, m.e.i.c.
Ex-Officio	N. H. Bradley, a.m.e.i.c.
Councillor	G. S. Brown, a.m.e.i.c.
Auditors	C. S. Clendening, a.m.e.i.c.
	W. L. McKenzie, a.m.e.i.c.
Secretary-Treasurer	Wm. Meldrum, a.m.e.i.c.

The membership of the Branch as at December 31st, 1929, is as follows:—

	Resident	*Non-Resident*	*Total*
Members	6	0	6
Associate Members	20	7	27
Junior Members	0	1	1
Student Members	1	0	1
Branch Affiliates	31	0	31

J. B. de Hart, M.E.I.C., *Chairman.*
Wm. Meldrum, A.M.E.I.C., *Secretary-Treasurer.*

London Branch

The President and Council,—

On behalf of the Executive Committee of the London Branch, we beg to submit the following summary of London Branch activities for the year ending December 31st, 1929:—

At the call of the chairman nine Executive Committee meetings were held. At these meetings plans were made for the seven regular Branch meetings and the annual inspection trip.

The year began with the annual dinner meeting held in the Hotel London. Reports of the past year's progress were read and officers were elected for 1929. The Branch was honoured in the presence of the late Peter Gillespie as speaker of the evening. His choice of subject was **"Canada's Nearest Neighbour"** and his appeal to each of his hearers to foster the most friendly relationship with our neighbours to the south left a very decided impression on those present and demonstrated the kindly character of the speaker. Vocal music brightened the evening.

In order to allow as many members as possible to attend the Annual General Meeting in Hamilton, the regular February meeting of this Branch was cancelled.

For the March meeting Mr. Lesslie R. Thomson's paper on the **"St. Lawrence Problem"** was discussed. The following members of the Branch led the discussion; Messrs. W. M. Veitch, G. H. Chalmers, D. M. Bright, V. A. McKillop and G. E. Martin. At the close of the meeting light refreshments were served.

In April, Mr. W. E. Barker of the Portland Cement Association, gave two lectures before the London Branch on **"The Design and Construction of Concrete Street Pavements."** As in the past these lectures were well attended and proved very instructive.

For the meeting of May 17th, there were two speakers. The Branch was pleased to have a visit from Mr. R. J. Durley who addressed the meeting on Headquarters matters. Mr. Andrew Vogel, of the General Electric Co., Schenectady, spoke on **"Arc Welding in the Fabrication of Structural Steel."** The advantages of welding in certain construction jobs were clearly explained by Mr. Vogel.

The annual inspection trip was taken on October 5th. Members of the Branch with friends motored to Windsor where they were met by members of the Border Cities Branch to be conducted over the new Ambassador bridge and the new Detroit-Windsor tunnel. After dinner at the Prince Edward hotel, Mr. Thoreson gave an illustrated address on the construction of the tunnel. This trip proved to be one of the most instructive trips that the Branch has had.

On November 8th, Prof. R. W. Angus, of the University of Toronto, addressed the meeting on **"Engineering in Europe."** Prof. Angus has had an extended trip on the continent, visiting engineering works of prominence and paying particular attention to hydro-electric power development. His illustrated address brough a great deal of engineering information to his audience.

The London Branch was honoured in the presence, on December 12th, of Brig.-Gen. C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., President of The Institute. After dinner at the Hotel London the President spoke on **"The Engineering Institute and the Progress of Engineering in Canada."** The activities of The Institute were outlined, with special attention being devoted to the work being done to bring about union between The Institute and the various provincial professional associations. Brig.-Gen. Mitchell's comprehensive outline of the engineering work being done in Canada impressed his audience with the vast construction programme that is in progress, the greater part of which is being designed and supervised by members of The Engineering Institute of Canada.

Membership

The membership of the London Branch for 1928 and 1929 was as follows:—

	1928	*1929*
Members	14	15
Associate Members	32	29
Juniors	4	5
Students	10	14
Affiliates	2	2
Branch Affiliates	5	4
	67	69

W. M. Veitch, A.M.E.I.C., *Chairman.*
Frank C. Ball, A.M.E.I.C., *Secretary-Treasurer.*

Moncton Branch

The President and Council,—

On behalf of the Executive Committee we beg to submit the tenth annual report of Moncton Branch.

The Executive Committee held six meetings. There were eight meetings of the Branch held, four of which were supper meetings. The usual mid-winter meeting was held at Sackville for the benefit of the engineering students of Mount Allison University.

During the past summer the Branch had the honour of acting as hosts to a Maritime Professional Meeting. The total registration was 138. Four papers were read, all of timely interest and excellence.

Membership

Our membership at present consists of sixty-three members, as follows:—

	Resident		*Non-Resident*
Members	10	Members	3
Associate Members	22	Associate Members	12
Juniors	3	Juniors	3
Students	2	Students	6
Affiliates	2		
Total	39	Total	24

Officers

The annual meeting of the Branch was held on May 26th, 1929. The following officers were elected for 1929-30:—

Chairman .... M. J. Murphy, A.M.E.I.C.
Vice-Chairman .... L. H. Robinson, M.E.I.C.
Secretary-Treasurer .... V. C. Blackett, A.M.E.I.C.
Executive .... T. L. Landers, M.E.I.C.
J. G. Mackinnon, A.M.E.I.C.
C. S. G. Rogers, A.M.E.I.C.

The members of the Executive Committee in addition to the above are:—

J. R. Freeman, A.M.E.I.C.
G. E. Smith, A.M.E.I.C.
Frank Williams, A.M.E.I.C.
Ex-officio....................F. O. Condon, M.E.I.C.
H. J. Crudge, A.M.E.I.C.
A. S. Gunn, A.M.E.I.C.

FINANCIAL STATEMENT

The financial statement for the year ending December 31st, 1929, is as follows:—

Montreal Branch

The President and Council,—

We have the honour to submit the following report on the activities of the Montreal Branch of The Engineering Institute of Canada for the year 1929.

During the year there were eleven meetings held by the Executive Committee, and these were all well attended. The personnel of the Committee was as follows:—

Chairman..............J. A. McCrory, M.E.I.C., 1929.
Vice-Chairman..........D. C. Tennant, M.E.I.C., 1929.
Past Chairman..........F. C. Laberge, M.E.I.C.
Committee..............R. deL. French, M.E.I.C., 1928-29.
Huet Massue, A.M.E.I.C., 1928-29.
E. A. Ryan, M.E.I.C., 1928-29.
P. E. Jarman, A.M.E.I.C., 1929-30.
J. A. Lalonde, A.M.E.I.C., 1929-30.
Fred Newell, M.E.I.C., 1929-30.

Ex-officio the following members of Council:—
W. C. Adams, M.E.I.C.
F. A. Combe, M.E.I.C.
F. S. Keith, M.E.I.C.
O. O. Lefebvre, M.E.I.C.
G. R. MacLeod, M.E.I.C.
P. B. Motley, M.E.I.C.
P. L. Pratley, M.E.I.C.
F. P. Shearwood, M.E.I.C.
Julian C. Smith, M.E.I.C.

PAPERS AND MEETINGS COMMITTEE

Among the various activities of the Branch, the weekly meetings occupy the position of primary importance. The Committee appointed by this Executive had the arranging of the programme for the season 1929-30 and the personnel was as follows:—

Chairman........................N. L. Morgan, A.M.E.I.C.
Vice-Chairman....................P. E. Jarman, A.M.E.I.C.
Civil Section, Chairman...........L. L. O'Sullivan, A.M.E.I.C.
Electrical Section, Chairman.......A. S. Runciman, A.M.E.I.C.
Vice-Chairman...J. L. Clarke, A.M.E.I.C.
Mechanical Section, Chairman......H. G. Thompson, A.M.E.I.C.
Vice-Chairman.L. H. Birkett, A.M.E.I.C.
Municipal Section, Chairman......A. Cousineau, A.M.E.I.C.
Vice-Chairman..E. Roy, A.M.E.I.C.
Railway Section, Chairman........W. J. McAllister, A.M.E.I.C.
Vice-Chairman....Lt.-Col. F. F. Clarke, A.M.E.I.C.
Student Section, Chairman.........J. H. Haines, S.E.I.C.

A great deal of time and effort is involved in the preparation of these programmes, and in arranging details of the meetings. In addition to a large amount of private time spent in personal effort by the members of the Committee seven meetings were held at which the average attendance was nine.

There were forty-four papers or speakers considered, and from these the programme of twenty-eight papers given below was arranged. Many of the speakers are outstanding in the engineering world, and your Executive feel that their acceptance of invitations to address the Branch indicates the high esteem in which the Branch and The Institute is held. This position can only be maintained by the personal endeavour of each member to attend the meetings and take part in the discussion.

We feel the Papers and Meetings Committee is to be congratulated on the good work in obtaining this programme.

Oct. 3.—**"Carborundum Refractories,"** by Messrs. J. A. King and B. H. Shaw.

RECEPTION COMMITTEE

The Reception Committee, under the chairmanship of W. McG. Gardner, A.M.E.I.C., has been very active in welcoming to the meetings members and guests and in the other duties assigned to them. The Committee consisted of:—

W. McG. Gardner, A.M.E.I.C., Chairman
J. H. Forbes, A.M.E.I.C.
C. J. LeBlanc, A.M.E.I.C.
H. W. B. Swabey, M.E.I.C.
L. A. Ste. Marie, A.M.E.I.C..

The Committee reports that the average attendance at the weekly meetings was 94 which is somewhat above the average for previous years. However, the Executive feels that the attendance, being less than ten per cent of the total membership of the Branch, is not what it should be and indicates that a large number of the members do not realize the value to themselves and to the Branch of attendance at the meetings. Refreshments were provided at four of the meetings and served by the Reception Committee.

MEMBERSHIP

Although the total membership of The Institute has fallen during the past year, we are glad to be able to report an increase of 24 corporate and 14 non-corporate members, or a total of 38.

It is with the deepest regret that we have to record the loss by death of the following six members:—

A. W. K. Massey, A.M.E.I.C., Designing Engineer, Canadian Vickers Ltd.
H. S. Quigley, Affil.E.I.C., Manager, Canadian Airways Ltd.
Albert Dawes, M.E.I.C., Structural Engineer, Canadian Vickers Ltd.
A. W. Robinson, M.E.I.C., Consulting Engineer, Melbourne, Que.
R. W. T. Robb, A.M.E.I.C., District Manager, Robb Engineering Works, Ltd.
L. T. G. Boisseau, A.M.E.I.C., Engineer, Technical Service, City of Montreal.

Publicity Committee

H. B. Montizambert, A.M.E.I.C., was appointed Chairman of this Committee at the beginning of the year and served until early in the fall, when he accepted a position which necessitated his leaving Montreal, and he tendered his resignation. The duties of the Publicity Committee, consisting of editing the Branch News and supervising reports of the meetings and other publicity work in the press, require a great deal of time and thought which Mr. Montizambert devoted faithfully to the work.

Summer Excursion

The Branch is indebted to the Montreal Island Power Company for their kindness in extending an invitation to visit the power development on the Riviere des Prairies. This invitation was accepted and on September 4th, a party of 150 members was conducted over the plant by guides supplied by the Power Company. Construction work on the development had reached a very interesting phase, one of the units having been completed and three others being in various stages of erection.

The Executive Committee in addition to routine work such as appointment of sub-committees, consideration of various matters of policy, and recommendations on application for admission and transfer, had a number of problems to consider notably those giving contact to other organizations. We were called upon to give support in the work of the following committees, and were represented on them by the members named.

Montreal Terminals Committee....O. O. Lefebvre, M.E.I.C. and J. A. McCrory, M.E.I.C.
Smoke Abatement Committee of the Citizens Association..........F. A. Combe, M.E.I.C.
City Improvement League.........R. deL. French, M.E.I.C.
Placement Bureau Committee, Board of Trade..............N. E. D. Sheppard, A.M.E.I.C.
Metropolitan Town Planning Board.R. deL. French, M.E.I.C.

Respectfully submitted,

J. A. McCrory, M.E.I.C., *Chairman.*
C. K. McLeod, A.M.E.I.C., *Secretary-Treasurer.*

Niagara Peninsula Branch

The President and Council,—

The Executive of the Niagara Peninsula Branch present herein the report of another successful year.

Meetings were well attended and a keen interest was shown in Institute affairs.

The attendance at thirteen executive meetings averaged 12, or 75 per cent. Failures to attend were almost invariably due to absence from the district, or similar good reasons.

The meetings have all been reported in the Journal. They are summarized hereunder:—

Jan. 15.—Discussion on Institute Affairs. Guest speakers—E. F. Sterne, President Association of Professional Engineers of Ontario, T. R. Loudon, M.E.I.C., Member of Council. Attendance, 38.

Feb. 16.—Luncheon to the President and party from the Annual Meeting. Attendance, 50.

Mar. 13.—Trip over the steam plant of the Buffalo General Electric Company, followed by joint meeting with the Buffalo Engineering Societies. Speaker:—A. A. Northrup, of the Stone and Webster Corporation—**"The Conowingo Power Development."** Attendance E.I.C., 48.

Apr. 17.—Discussion of Institute publications, followed by A. J. Grant, M.E.I.C., Vice-President E.I.C., **"Reminiscences of an Engineer's Holidays in Europe."** Attendance, 60.

May 9.—Electoral Meeting. Attendance, 30.

May 16.—Annual Meeting. Speaker:—F. I. Ker, A.M.E.I.C., **"Some Political Phases of the St. Lawrence Waterways Question."** Attendance, 230.

Oct. 23.—Joint outing and meeting with Buffalo Engineering Societies. Trip over Welland ship canal; dinner meeting at St. Catharines; Speakers:—F. E. Sterns, M.E.I.C., **"Some Engineering Features of the Welland Ship Canal."** A. A. Northrup, of the Stone and Webster Engineering Corporation. **"Power."** Attendance, 114.

Nov. 12, 13 and 14.—Short course in the design of concrete mixes. Speaker:—J. W. Kelly, of the Portland Cement Association. Registration, 130.

Ottawa Branch

The President and Council,—

On behalf of the Managing Committee of the Ottawa Branch we beg to submit the following report for the calendar year 1929.

During the year the Managing Committee held nine meetings. In addition the Branch held six evening meetings, thirteen luncheon meetings and three tours of inspection. One luncheon was a joint meeting with the Ottawa branch of Queen's University Alumni Association and one was a joint meeting with the Ottawa Branch of the University of Toronto Alumni Federation. On the 5th, 6th and 7th of November a short course of lectures on the **"Design and Control of Concrete Mixtures"** by J. W. Kelly was given in co-operation with the Society of Chemical Industry, the Architects Club of Ottawa and the Canadian Construction Association.

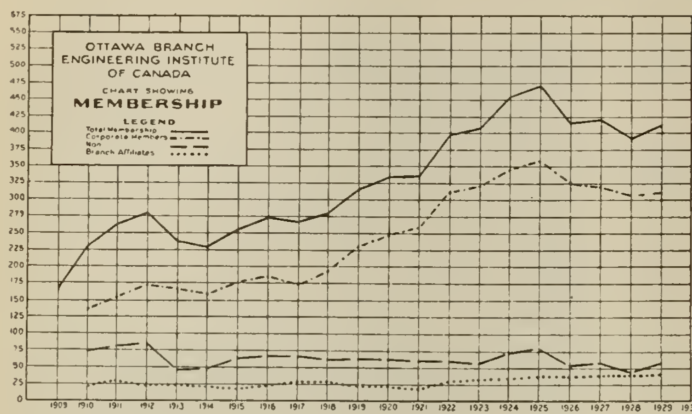
The balance sheets show a very successful year financially, our assets having increased by $163.74 so that our working capital is now $2,308.82.

It is with deep regret that we report the loss, through death, of one Member, E. V. Johnson, and one Branch Affiliate, William Clark.

Proceedings and Publicity

During the year thirteen luncheons, four tours of inspection and six evening meetings were held as follows:—

Jan. 10.—Annual Meeting—Daffodil Tea Rooms.



Jan. 17.—**"The St. Lawrence Waterways in History"** by Prof. Duncan McArthur; joint luncheon meeting with the Ottawa branch of Queen's University Alumni Association at the Chateau Laurier.

Feb. 14.—**"Patent Law and Its Application to Engineering"** by Russell Smart, K.C., B.A., M.E., luncheon meeting at Chateau Laurier.

Feb. 28.—Inspection tour of laboratory and equipment of the Forest Products Laboratory, Dept. of Interior, Ottawa.

Mar. 7.—General discussion of Branch affairs—Address by R. J. Durley, M.E.I.C., General Secretary of the E.I.C.—evening meeting at the University Club.

Mar. 14.—**"Some Impressions of Australia and New Zealand"** by D. Roy Cameron, B.Sc.F., M.E.I.C.; luncheon meeting at Chateau Laurier.

Mar. 28.—**"The Engineer from a Layman's Point of View"** by Dr. M. J. Maloney, M.P.; luncheon meeting at Chateau Laurier.

Apr. 4.—Inspection tour to No. 1 depot, Civil Government Air Operations, Victoria Island, Ottawa.

Apr. 11.—**"Lake St. John District and Its Water Power"** by J. E. A. Dubuc, M.P.; luncheon meeting at Chateau Laurier.

Apr. 25.—**"Transportation and the Upbuilding of Canada"** by Simon J. McLean, LL.B.; luncheon meeting at Chateau Laurier.

May 13.—**"Engineering Education"** by Lt.-Col. E. J. Schmidlin, M.C., M.E.I.C.; luncheon meeting at Chateau Laurier.

June 8.—Inspection tour of plant and logging operations of the Singer Mf'g., Co., Thurso, Quebec.

Oct. 1.—**"The Control and Distribution of Production"** by Major Clifford Hugh Douglas, R.A.F. (Res.), M.E., Mech.E., M.I.E.E.; luncheon meeting at Chateau Laurier.

Oct. 17.—**"Acoustic Sounding and Radio-Acoustic Position Determination"** by Commander N. H. Heck, United States Coast and Geodetic Survey; luncheon meeting at Chateau Laurier.

Oct. 24.—Inspection tour—Publication and Preparation of Maps and Reports, Geological Survey of Canada, Dept. of Mines.

Oct. 31.—**"The Beauharnois Power Scheme"** by R. O. Sweezy, B.Sc., M.E.I.C., M.C.I.M.M.; luncheon meeting at Chateau Laurier.

Oct. 31.—**"Designing Concrete for Durability"** by J. F. Hough, C.E.; evening lecture at the Victoria Memorial Museum.

Nov. 5, 6 and 7.—**"Design and Control of Concrete Mixtures"**—short course of lectures by J. W. Kelly of the Portland Cement Association; this course of lectures was given in co-operation with the Society of Chemical Industry, the Architects' Club of Ottawa and the Canadian Construction Association.

Nov. 14.—**"Ottawa Water Supply"** by Dr. George C. Nasmith, C.M.G., D.Sc.; joint luncheon meeting with the Ottawa branch of the University of Toronto Alumni Federation at the Chateau Laurier.

Nov. 28.—**"Ontario Association of Professional Engineers"** by E. T. Sterne, B.Sc.; luncheon meeting at the Chateau Laurier.

Dec. 12.—**"The Navy as a Public Force"** by Commander R. L. Edwards, R.N.; luncheon meeting at the Chateau Laurier.

Dec. 16.—**"Recent Engineering Developments in the British Army"** by Major Gen. A. G. L. McNaughton, C.M.G., D.S.O., M.Sc., LL.D., M.E.I.C.; illustrated evening lecture at the Victoria Memorial Museum.

The average attendance at the luncheons was 102, the largest being at the luncheon address by Professor McArthur when 240 were present. Six evening meetings were held, five of which dealt with technical subjects, but the luncheons appear to be more popular as a means of bringing the members together.

Due to the construction of the new wing of the Chateau Laurier and the alterations to existing structure the Branch was unable to secure accommodation for the annual ball and the event was consequently postponed.

Membership

Although several members were lost during the year through resignations, transfers, death, etc., a number of new members were added so that the total membership shows a net increase of 21 for the year. The membership of the Branch from 1909 to date is shown graphically on the accompanying chart.

The following table shows in detail the comparative figures of the Branch membership for the years 1927, 1928 and 1929:—

	1927	*1928*	*1929*
Honorary Members	1	1	1
Members	110	107	108
Associate Members	212	199	204
Affiliates of Institute	8	7	7
Juniors	28	23	24
Students	22	14	27
Branch Affiliates	41	40	41
Total	422	391	412

Rooms and Library

The Branch library is still situated on the third floor of the Stephen building, where it is open to consultation by members under the same conditions as have previously prevailed.

The library has not been used to any great extent recently as there are other technical libraries in the city much more extensive and up-to-date, but the collection has been kept in good order and available for use.

Journal Advertising

Commissions due for advertising in The Journal during 1929 amount to $130.50, which is equivalent to the rebates from 65 associate members.

Finances

The attached statements of assets and liabilities and of receipts and expenditures show that the Branch closed the year with a balance of $848.20 in the bank, $8.12 cash on hand, and $1,000.00 in Victory Bonds, a total balance of $1,856.32. In addition to this balance the Branch has assets of $41.00 in rebates due from Headquarters, $130.50 in commissions due for advertising in The Journal, and $281.00 in refunds due, furniture, stationery, etc., making a total of $2,308.82, an increase of $163.74 over the assets for 1928. The accompanying chart shows the financial standing of the Branch from 1910 to date.

The income for the past two years was:—for 1928—$879.07 and for 1929—$864.67; the expenditure for 1928—$568.61 and for 1929—$940.03. The annual income from Victory Bonds is $52.50.

Officers for 1930

The annual meeting of the Branch will be held in Ottawa on January 9th, when the officers and members of the Managing Committee for the year 1930 will be elected.

Peterborough Branch

The President and Council,—

On behalf of the executive of the Peterborough Branch, we take pleasure in submitting the following report covering the various activities of the Branch during the year 1929.

Meetings and Papers

Jan. 10.—Ladies Night. Travel talk by F. L. Roy.
Jan. 24.—**"Recent Mining Developments in Northern Manitoba,"** by Dr. Charles Camsell, M.E.I.C, Deputy Minister of Mines, Dept. of Mines, Ottawa.
Feb. 14.—Student night, **"Stave Falls, Power Development,"** by F. G. A. Tarr, S.E.I.C.; **"Fabricated Steel Construction for large Generators"** by M. V. Powell, Jr.E.I.C.; **"Labrador"** by B. H. Zwicker, S.E.I.C.
Mar. 14.—**"Manufacture of Bakelite or Synthetic Resins"** by W. A. Campbell, Bakelite Co. of Canada.
Mar. 28.—**"Electrical Insulations"** by W. P. Dobson, M.E.I.C., chief testing engineer, H.E.P.C. of Ontario.
Apr. 11.—**"Gatineau-Toronto Transmission Line,"** by A. E. Davidson, transmission engineer, H.E.P.C. of Ontario.
Apr. 25.—**"Telephotography"** by Mr. W. C. Dancy, transmission engineer, Bell Telephone Co. of Canada.
May 9.—Annual meeting.
Sept. 21.—Annual picnic.
Nov. 7.—**"Automatic Screw Machines and Their Importance and Use in Industry Today"** by W. W. Appleton, Brown and Sharpe Tool Company.
Nov. 12.—Annual dinner.
Dec. 12.—**"Recent Developments in Hydraulic Turbines"** by H. S. Van Patter, A.M.E.I.C., hydraulic engineer, Dominion Engineering Works.

Membership

The following is our present standing:—

Members	20
Associate Members	31
Juniors	20
Students	30
Affiliates and Branch Affiliates	25
Total	126

This is a net gain of 9 per cent during the year.

The Student and Junior Section continues to be the most active section of the Branch. They were responsible for one meeting as listed above. They were in charge of all arrangements for the very successful annual picnic at Clear lake, also supplied the entertainment for the annual dinner of the Branch.

An event of importance to the Branch and the community of Peterborough was the erection by the Branch of a tablet on the lift lock at Peterborough to the memory of the late R. B. Rogers, M.E.I.C., who was resident engineer during the construction of the Trent Valley canal.

The following were the members elected to the Executive Committee on May 9th, 1929.

Chairman.....R. C. Flitton, A.M.E.I.C.
Secretary.....S. O. Shields, Jr.E.I.C.
Treasurer.....A. B. Gates, A.M.E.I.C.
A. L. Killaly, A.M.E.I.C.
B. Ottewell, A.M.E.I.C.
W. E. Ross, A.M.E.I.C.
E. R. Shirley, A.M.E.I.C.
H. R. Sills, Jr.E.I.C.
Ex-Officio.....R. L. Dobbin, A.M.E.I.C., Councillor.
W. M. Cruthers, A.M.E.I.C., Past Chairman.

Quebec Branch

The President and Council,—

The council of the Quebec Branch has the honour of submitting the following report for the year 1929:—

Membership

	Resident	Non-Resident	Total
Honorary Members	1	..	1
Members	17	..	17
Associate Members	60	9	69
Juniors	11	5	16
Students	11	3	14
Affiliates	2	..	2
	102	17	119

Annual Meeting

The annual meeting of the Branch was held on June 26th, 1929, under the chairmanship of A. B. Normandin, A.M.E.I.C., president of the Branch; the following officers have been elected for the year 1929-30:—

Honorary President, for life	A. R. Décary, D.A.Sc., M.E.I.C.
President	A. B. Normandin, A.M.E.I.C.
Vice-President	S. L. de Carteret, M.E.I.C.
Secretary-Treasurer	Philippe Méthé, A.M.E.I.C.
Councillors	Alex. Larivière, A.M.E.I.C.
	L. C. Dupuis, A.M.E.I.C.
	F. T. J. King, M.E.I.C.
	Hector Cimon, A.M.E.I.C.
Ex-officio	W. G. Mitchell, M.E.I.C.

MEETINGS

The council of the Quebec Branch held its meetings regularly during the year 1929.

All questions submitted by the Council of The Institute were studied, discussed and transacted.

Our Branch followed with interest the deliberations of The Institute and devoted its full energy to all matters aiming to the protection and promotion of the interests of The Institute and its members.

Our special committee followed closely, studied carefully, and made as complete reports as possible on all applications for membership referred to our Branch, and the necessary recommendations were made to the Council of The Institute.

ADDRESSES

The following addresses were delivered at our various luncheons and evening meetings:

Jan. 28.—**"The North Shore of the St. Lawrence River"** by Mr. Edgar Rochette, M.P.P. for the county of Charlevoix-Saguenay.

Feb. 15.—**"Canada's Natural Resources"** by Major G. G. Ommanney, chief of development service, C.P.R.

Mar. 18.—**"Quebec Mines"** by Hon. J. E. Perrault, Minister of Colonization, Mines and Fisheries for the Province of Quebec.

"The Press Through the Ages," by Mr. Henri Gagnon, managing director of "Le Soleil" of Quebec.

Apr. 8.—**"The Evolution of Modern Locomotives"** by C. E. Brooks, Esq., chief of motive power, C.N.R.

Apr. 22.—**"High Pressure in Steam Boilers"** by C. M. McKergow, M.E.I.C., professor of mechanical engineering at McGill University.

Apr. 19.—General meeting, to discuss proposed amendments to the rules and regulations of The Institute.

Oct. 28.—Welcome to Brig. Gen. C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., President of The Institute, and Mr. R. J. Durley, M.E.I.C., Secretary.

Cash in bank, Jan. 1st, 1930	$225.85	
		$518.51

Respectfully submitted,

A. B. NORMANDIN, A.M.E.I.C., *President.*

PHILIPPE METHE, A.M.E.I.C., *Secretary-Treasurer.*

Quebec Branch

Au Président et au Conseil,—

Le conseil de la Section de Québec a l'honneur de vous soumettre son rapport annuel pour l'année 1929, comme suit:—

ROLE DES MEMBRES

	Résidents	*Non-résidents*	*Total*
Membres honoraires	1	..	1
Membres	17	..	17
Membres associés	60	9	69
Membres Juniors	11	5	16
Membres étudiants	11	3	14
Membres affiliés	2	..	2
	102	17	119

ASSEMBLEE ANNUELLE

L'assemblée annuelle de la Section de Québec eut lieu le 26 juin 1929, sous la présidence de monsieur A. B. Normandin, président de la Section; les officiers dont les noms suivent ont été élus pour 1929-30:—

Président honoraire à vie	A. R. Décary, D.A.Sc., M.E.I.C.
Président	A. B. Normandin, A.M.E.I.C.
Vice-Président	S. L. de Carteret, M.E.I.C.
Secrétaire-trésorier	Philippe Méthé, A.M.E.I.C.
Conseillers	Alex. Larivière, A.M.E.I.C.
	L. C. Dupuis, A.M.E.I.C.
	T. J. F. King, M.E.I.C.
	Hector Cimon, A.M.E.I.C.
Ex-officio	W. G. Mitchell, M.E.I.C.

ASSEMBLEES

Le Conseil de la Section de Québec a tenu ses assemblées régulièrement pendant l'année 1929.

Toutes les questions soumises par le Conseil de l'Institut ont été étudiées et expédiées.

Notre Section a suivi avec intérêt les travaux de l'Institut et a prêté son plein concours à toutes les questions ayant pour but de protéger et promouvoir les intérêts de l'Institut et de ses membres.

Notre comité spécial s'est efforcé, après étude, de faire un rapport aussi complet que possible sur toute demande d'admission à lui référée, et les recommandations nécessaires ont été faites au Conseil général de l'Institut qui a bien voulu en tenir compte.

CAUSERIES

Les causeries suivantes furent données à nos différentes réunions:—

"La Côte Nord," par M. Edgar Rochette, avocat, député de Charlevoix-Saguenay.

"Les Ressources Naturelles du Canada," par le Major G. G. Ommanney, chef du Service de Développement au Pacifique Canadien.

"Les Mines de Québec," par l'Hon. J. E. Perrault, Ministre de la Colonisation, des Mines et des Pêcheries de la Province de Québec.

"La Liberté de La Presse à Travers les Ages," par M. Henri Gagnon, Directeur-gérant du Soleil de Québec.

"L'Evolution des Locomotive Modernes," par M. C. E. Brooks, Ingénieur en chef du département de la force motrice, Chemins de fer Nationaux.

"L'Emploi des Hautes Pressions dans les Chaudières à Vapeur," par M. Chs. M. McKergow, professeur de mécanique, Université McGill.

Assemblée générale, le 19 avril, pour discuter certains amendements proposés aux règlements de l'Institut.

Bienvenue au Brig. Gén. C. H. Mitchell, Président de l'Institut, et à M. R. J. Durley, secrétaire général, le 28 octobre 1929.

Saint John Branch

The President and Council,

On behalf of the Executive Committee we beg to submit the following report concerning the activities of the Saint John Branch.

The Executive Committee met eight times during the past year, and the Branch nine times. The members also made an inspection of the brush plant of T. S. Simms & Co.

The meetings were well attended, not only by members of the Branch but also by the public in general who are at all times welcomed. Continuing the policy adopted some years ago, the members made their annual trip to the University of New Brunswick on April 12th last. This meeting affords the members resident in the Fredericton district an opportunity of listening to our papers and also taking part in the discussions.

We have to comment again on the absence of unemployment among engineers in this district during the past year. We have co-operated with the Civil Service Commission by notifying our membership of positions in which they might be interested.

Last year this Branch adopted the policy of serving light refreshments after the meetings. This seemed to meet with the approval of the membership and certainly increased the attendance. This year, however, we have had to change our meeting place and as a consequence are not yet in a position to furnish refreshments.

Membership

A statement of membership as at December 31st, 1929, is as follows:—

	Resident	Non-Resident	Total
Members	13	7	20
Associate Members	26	17	43
Juniors	3	4	7
Students	3	12	15
Affiliates	1	..	1
	46	40	86

The total at the end of 1928 was 78, making a gain of 8.

Papers

Jan. 17.—A paper on **"Automatic Telephone"** by William Brebner, an engineer of the Northern Electric Co., Montreal.

Jan. 20.—Inspection of the brush plant of T. S. Simms & Co., Ltd., Fairville.

Jan. 28.—Dinner meeting at the Admiral Beatty hotel held with the N.B. Association of Professional Engineers. The speaker on this occasion was O. O. Lefebvre, D.Sc., M.E.I.C. whose subject was **"Some Engineering Aspects of the Saint Lawrence Waterways."**

Feb. 21.——**"Highway Bridges of New Brunswick,"** C. A. McVey, New Brunswick Department of Public Works, Fredericton, N.B.

Mar. 21.—**"The Rayon Industry,"** Adam Cameron, D.Sc., University of New Brunswick, Fredericton, N.B.

Apr. 12.—Joint meeting with the U. N. B. Engineering Society at Fredericton.

Paper on **"Lightning and Its Effects"** by G. A. Vandervoort, A.M.E.I.C.

Paper by K. S. LeBaron on the **"Manufacture of Bleached Sulphite Pulp at the Nashwaak Plant."**

Paper on **"The Rise of the Technical Societies"** by W. J. Johnston, A.M.E.I.C.

Slides of Newfoundland bridges by A. R. Crookshanks, M.E.I.C.

May 2.—Annual meeting.

This took the form of a dinner after which reports of Committees were submitted.

Oct. 21.—**"Metals and their Alloys,"** by James S. Hoyt, plant manager, T. McAvity & Sons, Ltd., Saint John, N.B.

Nov. 21.—**"The Grand Falls-Dalhousie, Transmission Line,"** R. A. Lawther, Saint John River Power Co., Dalhousie.

Dec. 12.—**"The N. B. Power Co. New Plant,"** by J. D. Garey, A.M.E.I.C., chief engineer, Saint John, N.B.

The new meeting place of the Saint John Branch is in the Board of Trade rooms, 162 Prince William street.

Financial Statement

St. Maurice Valley Branch

Au Président et au Conseil:

Le conseil de la Section a l'honneur de vous soumettre son rapport annuel pour les opérations de la Section de la Vallée du St-Maurice, pour 1929.

Cette section comprend les ingénieurs de Trois-Rivières, Grand'-Mère, Shawinigan Falls et Cap de la Madeleine. Durant l'année, il y eut deux assemblées, la première fut à Grand'Mère le 4 de mai 1929. Elle coincida avec l'ouverture du nouveau pont suspendu, qui relie Grand'Mère avec St-Georges de Champlain. Une conférence fut alors donnée par le Dr. B. Steinman, M. P. L. Pratley et autres sur les avantages et les développements anticipés de la région dus à la construction du nouveau pont.

La deuxième assemblée eut lieu au Chateau de Blois, Trois-Rivières le 2 novembre 1929. La Branche avait l'honneur de recevoir le Général C. H. Mitchell, président de l'Engineering Institute. Après l'expédition des affaires de routine, la Branche a pris un dîner en l'honneur de son hôte distingué.

Le même bureau de direction a été gardé en force pour 1930, et comprend M. Ellwood Wilson, président, MM. Henri Dessaulles, A. A. Wickenden et Bruno Grandmont, conseillers, et R. Morrissette comme secrétaire.

La Branche a acquitté tous ses comptes pour l'année 1929 et a une balance à son crédit de $66.13.

Le tout humblement soumis.

Ellwood Wilson, M.E.I.C., *Président.*

Romeo Morrissette, A.M.E.I.C., *Secrétaire.*

Saguenay Branch

The President and Council,—

On behalf of the Executive Committee, we submit the following report covering the activities of the Saguenay Branch during the year 1929:

Membership

On December 31st, 1929, the membership of the Branch was as follows:—

Members	7
Associate Members	26
Juniors	6
Students	7
	46

Financial Statement

(As at December 31st, 1929)

Receipts

Balance on hand—December 31st, 1928	$250.65	
Rebates from Headquarters	121.43	
Interest	2.07	
		$374.15

Expenditures

Printing, postage, stationery, etc	$ 27.95	
Postal box	2.00	
Telephone and telegrams	7.75	
Expense of meetings	88.20	
Express charges	2.95	
	$128.85	
Balance on Hand	245.30	
		$374.15

On May 28th, O. O. Lefebvre, D.Sc., M.E.I.C., addressed a meeting of the Saguenay Branch held in Kenogami, on the subject of **"The St. Lawrence Waterways,"** which proved most interesting.

The general meeting of the Branch was held in Riverbend on June 21st, 1929. The following officers were elected:

Chairman	R. E. Parks, A.M.E.I.C.
Vice-Chairman	S. J. Fisher, M.E.I.C.
Secretary-Treasurer	M. R. Lanctot, Jr.E.I.C.
Executive Committee	H. R. Wake, A.M.E.I.C.
	G. E. LaMothe, A.M.E.I.C.
	J. A. Knight, A.M.E.I.C.
	G. O. Vogan, A.M.E.I.C.

After the business part of the annual meeting the members were the guests of Price Brothers and Company at luncheon, and later visited the surrounding industrial establishments.

General C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., President of The Institute, visited the district on August 23rd. On the evening of that day a meeting was held in Arvida at which General Mitchell gave a short talk on things of interest to The Institute.

On November 7th there was a meeting of the Branch held in Arvida. A paper by Mr. I. E. Burks on **"Concrete Work"** was read and proved to be very interesting to all.

Respectfully submitted,

R. E. Parks, A.M.E.I.C., *Chairman.*

M. R. Lanctot, Jr.E.I.C., *Secretary-Treasurer.*

Saskatchewan Branch

The President and Council,—

On behalf of the Branch Executive we beg to submit the following report concerning the activities of the Saskatchewan Branch for the calendar year 1929.

Membership

The membership of the Branch shows an increase of nine over last year, with the usual fluctuations due to transfers, etc.

The present membership of the Branch is:

	Branch Residents	Branch Non-Residents	Total
Members	13	3	16
Associate Members	57	20	77
Juniors	4	6	10
Students	4	7	11
Affiliates	1	1	2
Branch Affiliates	7	0	7
Total	86	37	123

EXECUTIVE COMMITTEE

The present Executive was elected on March 22nd at the Branch annual meeting and with those continuing in office is as follows:—

Chairman .... H. R. Mackenzie, A.M.E.I.C., Regina, Sask.
Vice-Chairman .... W. G. Worcester, M.E.I.C., Saskatoon, Sask.
Sec.-Treas. .... R. W. E. Loucks, A.M.E.I.C., Regina, Sask.
Executive (2 years)...D. W. Houston, A.M.E.I.C., Regina, Sask.
A. P. Linton, A.M.E.I.C., Regina, Sask.
P. C. Perry, A.M.E.I.C., Regina, Sask.
(1 year)....J. M. Campbell, A.M.E.I.C., Moose Jaw, Sask.
J. W. D. Farrell, A.M.E.I.C., Regina, Sask.
Stewart Young, A.M.E.I.C., Regina, Sask.
A. M. Macgillivray, A.M.E.I.C., Saskatoon, Sask. (Past Chairman.)
D. A. R. McCannel, A.M.E.I.C., Regina, Sask. (Councillor.)
Auditors .... W. H. Hastings, A.M.E.I.C., Regina, Sask.
D. D. Low, Jr.E.I.C., Regina, Sask.

COMMITTEES

Chairmen of the standing committees are:

Papers and Library...Stewart Young, A.M.E.I.C., Regina, Sask.
Legislation .... P. C. Perry, A.M.E.I.C., Regina, Sask.
Nominating .... H. S. Carpenter, M.E.I.C., Regina, Sask.
Attendance .... D. C. M. Davies, A.M.E.I.C., Regina, Sask.
H. A. Jones, S.E.I.C., Regina, Sask.
Publicity .... R. W. E. Loucks, A.M.E.I.C., Regina, Sask.
Meetings .... C. D. Lill, Br.AFFIL., Regina, Sask.

The Saskatchewan Branch representative on the Nominating Committee of The Institute is H. R. Mackenzie, A.M.E.I.C., Regina, Sask.

MEETINGS

The Executive held seven meetings for the transaction of Branch affairs. There were five regular meetings of the Branch and two special meetings. Mr. R. J. Durley, M.E.I.C., General Secretary of The Institute, met the members of the Branch at a special meeting in July. The Branch meetings in all cases were preceded by a dinner. The attendance and general interest in the meetings has been satisfactory.

Much interest at present centres around the Engineers Bill which is expected to be introduced in the Provincial Legislature early in the year, particularly in view of the fact that legislation incorporating the engineers is now in force in almost all other Provinces of the Dominion. This Branch has endeavoured and will endeavour to encourage and guide this effort to a satisfactory conclusion.

PROGRAMME

The programme for the year was as follows:—

Jan. 25.—Debate—**"Resolved that in Engineering Projects the Contract System is Preferable to Day Labour."**
Speakers for affirmative:
Messrs. W. W. Perrie, A.M.E.I.C.
W. R. Allen, A.M.E.I.C.
T. S. McKechnie.
Speakers for negative:
Messrs. C. H. Biddell, A.M.E.I.C.
D. D. Low, Jr.E.I.C.
Harry Jones, S.E.I.C.
Judges—R. N. Blackburn, M.E.I.C.
H. S. Carpenter, M.E.I.C.

Feb. 22.—**"Industrial Relations"** by P. C. Perry, A.M.E.I.C., division engineer, C.N.R., Regina, Sask.

Mar. 22.—"Twelfth Annual Meeting" reports of committees, election of officers, banquet, toast list and other entertainment.
Address by C. J. Mackenzie, M.E.I.C., Dean of the Faculty of Engineering, University of Saskatchewan, on **"The Future of Urban Centres in Saskatchewan and Some Problems Arising Therefrom."**

May 3.—Complimentary dinner to and short talks from R. O. Wynne-Roberts, M.E.I.C., of Toronto, Ont. and Nicholas Hill, Jr., of New York, N.Y.

July 8.—Informal address by R. J. Durley, M.E.I.C., General Secretary of The Institute, on Institute Affairs.

Nov. 22.—Report on Plenary Meeting of Council by D. A. R. McCannel, A.M.E.I.C., City Commissioner, City of Regina. Report on Legislation for incorporation of Engineers in Saskatchewan by P. C. Perry, A.M.E.I.C., division engineer, C.N.R., Regina, Sask.

Dec. 18.—**"The Einstein Theory"** by R. N. Blackburn, M.E.I.C., chief mechanical supt., Department of Public Works, Regina, Sask.

SCHOLARSHIP

The annual scholarship of $50.00 offered by the Branch to the most deserving student in the graduating class in Engineering at the University of Saskatchewan, was awarded to Mr. B. P. Scull.

FINANCIAL STATEMENT

Revenue

Balance from 1928	$241.65	
Headquarters rebates	280.05	
Branch dues	33.00	
Sundries, Branch news, etc	36.98	
		$591.68

Expenditure

Meetings	$ 31.70	
Stationery, notices, etc	37.76	
Scholarship	50.00	
Honorarium	130.00	
Sundries	15.90

Cash on hand	17.40	
		$591.68

Respectfully submitted,
H. R. MACKENZIE, A.M.E.I.C., *Chairman.*
R. W. E. LOUCKS, A.M.E.I.C., *Secretary-Treasurer.*

Sault Ste. Marie Branch

The President and Council,

There were four regular meetings and two special meetings held during the year, with an average attendance of twenty-two. Both in number of meetings and attendance we are below our 1928 figures.

The papers and meetings that were arranged for by the Papers Committee were much appreciated by all. The committee this year found it very difficult to obtain speakers and the incoming executive will be well advised to make every effort to meet this difficulty in 1930.

The meetings held and the papers given were as follows:—

Feb. 22.—An inspection trip through the plant of the Soo Falls Brewery. Enough said, much enjoyed by all.

Mar. 25.—**"The St. Lawrence Waterway"** by Prof. G. A. Cornish of the Department of Science of the Ontario College of Education of Toronto.

Apr. 27.—A visit to the engineering department of the Sault Ste. Marie Michigan ship canal. Mr. Edmonds outlined methods he used in metering the St. Mary's rapids.

May 31.—**"Industrial Relations"** or **"Human Engineering"** by Mr. Douglas Chant of the Abitibi Power and Paper Company.

Aug. 29.—Special luncheon at the Country Club in honour of R. J. Durley, M.E.I.C., the General Secretary.

Sept. 22.—A round table discussion by the members on the **"Organization of The Institute."**

	Branch Resident	Branch District	Total
Members	9	16	25
Associate Members	15	37	52
Juniors	2	12	14
Students	0	18	18
Affiliates	2	1	3
Branch Affiliates	16	0	16
			128

This is a decrease of ten members from last year. The incoming membership committee for 1930 should get busy and wipe out this decrease as locally there are several engineers not members.

FINANCIAL STATEMENT

Receipts

Balance from 1929	$131.34	
Income from H.Q. rebates	183.75	
Income from H.Q. advertising	30.00

Toronto Branch

The President and Council,—

The Executive Committee of the Toronto Branch respectfully submits the following report for the calendar year 1929:—

The Executive Committee holding office during this period are as follows, the present members being elected at the annual meeting of the Branch on April 4th, 1929.

EXECUTIVE COMMITTEE

January to April, 1929		*April to December, 1929*
L. W. Wynne-Roberts, A.M.E.I.C.	Chairman	T. Taylor, M.E.I.C.
T. Taylor, M.E.I.C.	Vice-Chair	J. J. Traill, M.E.I.C.
J. J. Spence, A.M.E.I.C.	Sec.-Treas.	J. J. Spence, A.M.E.I.C.
J. J. Traill, M.E.I.C.	Executive	G. H. Davis, M.E.I.C.
G. H. Davis, M.E.I.C.		A. B. Crealock, A.M.E.I.C.
A. B. Crealock, A.M.E.I.C.		H. N. Mason, A.M.E.I.C.
J. W. Falkner, A.M.E.I.C.		*C. S. L. Hertzberg, M.E.I.C.
C. S. L. Hertzberg, M.E.I.C.		*J. R. Cockburn, M.E.I.C.
H. N. Mason, A.M.E.I.C.		*C. B. Hamilton, M.E.I.C.
T. R. Louden, M.E.I.C.	*Ex-officio*	T. R. Louden, M.E.I.C.
J. M. Oxley, M.E.I.C.		J. G. R. Wainwright, A.M.E.I.C.
J. G. R. Wainwright, A.M.E.I.C.		L. W. Wynne-Roberts, A.M.E.I.C.
W. B. Dunbar, A.M.E.I.C.		R. B. Young, M.E.I.C.

*Elected for a period of two years.

STANDING COMMITTEES

The following standing committees, with the chairman of each, were appointed by the Executive at a meeting on April 25th, 1929.

January to April, 1929		*April to December, 1929*
L. W. Wynne-Roberts, A.M.E.I.C.	Papers	T. Taylor, M.E.I.C.
T. Taylor, M.E.I.C.	Finance	J. J. Traill, M.E.I.C.
J. J. Traill, M.E.I.C.	Publicity	C. S. L. Hertzberg, M.E.I.C.
C. S. L. Hertzberg, M.E.I.C.	Membership	H. N. Mason, A.M.E.I.C.
J. W. Falkner, A.M.E.I.C.	Meetings	G. H. Davis, M.E.I.C.
A. B. Crealock, A.M.E.I.C.	Library	J. R. Cockburn, M.E.I.C.
W. B. Dunbar, A.M.E.I.C.	Student Relations	W. B. Dunbar, A.M.E.I.C.
H. N. Mason, A.M.E.I.C.	Branch Editor	A. B. Crealock, A.M.E.I.C.

The Executive Committee of this Branch held nine meetings during the year for the transaction of Branch business, and thirteen general meetings.

In addition to this, a dinner was tendered to the President of The Institute, Brig. Gen. C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., by the Toronto Branch. This event took place in the Engineers' Club on December 4th, and was attended by some seventy-eight members.

This Branch still maintains the policy of welcoming out-of-town speakers at informal dinners held previous to the meetings.

The various meetings for the year 1929 were as follows:—

Jan. 3.—"**Development of Hydro-Electric Power on the Gatineau River**" by Major Jas. H. Brace, M.E.I.C., of the Fraser-Brace Engineering Company, Limited.

Jan. 15, 16 and 17.—Three-day short course on "**Design and Control of Concrete Mixtures**" by R. S. Phillips of the Portland Cement Association of Chicago.
Attendance 240, 240 and 230.

Jan. 25.—"**Ontario Research Foundation and its Objects.**" Speakers—Sir Joseph Flavelle, Chairman of Foundation, and Dr. Speakman, Director.

Feb. 7.—"**The Construction of the North Toronto Sewerage System**" by Geo. Phelps, A.M.E.I.C., sewer engineer, City of Toronto.

Feb. 21.—"**The Motor Ship**" by J. L. Busfield, M.E.I.C., of Montreal.

Mar. 7.—"**The Welland Ship Canal and its Relation to the St. Lawrence Project**" by A. J. Grant, M.E.I.C., engineer-in-charge Welland ship canal.

Mar. 21.—"**General Erection Methods on Steel Construction**" by Jas. Robertson, A.M.E.I.C., erection engineer, Dominion Bridge Co. Limited, Montreal.

Apr. 4.—Annual meeting of the Branch.

Oct. 24.—"**The Story of Iron and Steel**" by film kindly loaned by United States Steel Products Company, through the courtesy of Mr. F. Brunke.

Nov. 7.—"**Engineering in Europe**" by Prof. R. W. Angus, M.E.I.C., Faculty of Applied Science, University of Toronto.

Nov. 21.—"**Planning and Development Act of Ontario and its Operation in Toronto**" by Tracy D. leMay, city surveyor, City of Toronto.

Dec. 5.—"**Toronto Waterworks**" by Wm. Gore, M.E.I.C., of Gore, Nasmith and Storrie, consulting engineers, Toronto.

Dec. 19.—"**Inspection**" by Robert R. Deans, Vice-President of Canadian Inspection & Testing Company.

MEMBERSHIP

The membership as listed at December 31st, 1929 is as follows:—

	Residents	*Non-residents*	*Total*
Members	127	4	131
Associate Members	255	13	268
Juniors	56	3	59
Students	65	4	69
Affiliates	5	..	5
Branch Affiliates	2	..	2
Total 1929	510	24	534
Total 1928	530	25	555
	−20	−1 net loss	−21

The falling off in the membership from the previous year is partially due to a number of names being dropped by Headquarters and to several resignations and deaths.

We regret the loss by death of E. A. Wallberg, Prof. Peter Gillespie, Jas. Hyslop and Edmund Wragge.

THOS. TAYLOR, M.E.I.C., *Chairman.*

J. J. SPENCE, A.M.E.I.C., *Secretary-Treasurer.*

Vancouver Branch

The President and Council,—

I beg to report upon the affairs of the Vancouver Branch for the year 1929 as follows:—

MEETINGS

Jan. 16.—J. B. Alexander on "**Structural Timber.**"

Feb. 4.—Frank P. McKebban, Esq. on "**The Arc Welding of Steel Buildings.**"

Feb. 20.—Student Section night. Four student papers presented.

Mar. 21.—W. H. Powell, M.E.I.C. on "**The Development of Mountain Lake Reservoirs.**"

Apr. 3.—F. Newell, M.E.I.C. on "**Hydraulic Regulating Gates.**"

Apr. 11.—Luncheon meeting. Brig. Gen. C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C. addressed the Branch.

July 31.—R. J. Durley, M.E.I.C., on "**Institute Affairs.**"

Oct. 30.—Vancouver Engineering Works. Inspection trip to see manufacture of new arc-welded steel water-pipe.

Dec. 18.—Annual meeting.

EXECUTIVE COMMITTEE

The Executive Committee held nine regular meetings during the year, the business of the Branch being transacted by it. General meetings were confined to a speaker and his subject, with the exception of the annual meeting.

GENERAL REVIEW OF 1929 ACTIVITIES

Walter Moberly Memorial Prize

The fifth award of the prize, consisting of technical books to the value of $25.00 was made on May 21st, to Clifford E. Lord for his essay on "The Physiography of the Coast Range of British Columbia and South-Eastern Alaska."

Library

The question of the library is one that must be faced very soon. The cost to the Branch is $100.00 a year against which should be credited the use of the University Club for Branch meetings, making the net cost somewhere in the neighbourhood of $50.00 per annum. As the members make very little use of the library, the above sum is a dead loss to the Branch.

As a result, the Executive are working with the association of Professional Engineers in an endeavour to establish a proper engineering library that will be of use to the members of the profession in the city. Some progress has been made but much remains to be done before this ideal can be realized.

Co-operation with Association of Professional Engineers

The Executive have met with the Council of the Association to discuss mutual problems, particularly with regard to the extension of the licensing principle. The resolution passed at the last Plenary Meeting of Council, pledging the support of The Institute toward obtaining uniform licensing acts in the various provinces, where such do not exist, is due in some measure to the work of these joint meetings.

PAPERS

The papers delivered before the Branch this year have been of high standard, two of them being printed in full in the Journal. Attention should be drawn to the fact that it is becoming increasingly difficult to persuade members to contribute papers.

FINANCIAL STATEMENT

(December 12, 1928 to December 18, 1929)

Receipts

Bank balance as at December 12, 1928	$ 61.00	
Cash in hand	2.50	
Rebates from Headquarters (August 1928 to August 1929)	378.75	
Branch news	12.89	
Branch news (Student Section)	17.37	
Library rent (Association of Professional Engineers)	50.00	
Rent for Women's building (A.I.E.E.)	12.50	
Rebates on telegrams from Headquarters	28.75	
		$563.76

Disbursements

Office Expenses:		
Secretary's expenses	$ 14.45	
Postage and stationery	18.77	
Telegrams	39.81	
Rent	75.00	
		$148.03
Meetings:		
Notices and ballots	$ 66.55	
Rent—Women's building	25.00	
		$ 91.55
Student Section:		
By cheque	$ 13.42	
By cash	5.00	
		$ 18.42
Stenographer		$ 15.00
Honorarium—secretary (1928)		$ 50.00

Branch Non-Resident			
Members	17	16	17
Associate Members	37	40	46
Juniors	5	8	9
Students	7	17	19
Affiliates	0	0	0
	66	81	91

STUDENT SECTION

The Student Section of the Branch is a very vigorous and growing youngster. Those of the members who heard the papers delivered at the Student night on February 20th, 1929, realized that the calibre of those papers was exceedingly high.

The Section has held weekly noon-hour meetings throughout the University year, to hear engineers of all branches describe their work and difficulties.

ELECTION

Sixty-five ballots were returned out of a total of 158 mailed, which is about the average.

Respectfully submitted,
A. D. CREER, *Chairman.*
JOHN OLIVER, S.E.I.C., *Secretary-Treasurer.*

Victoria Branch

MEMBERSHIP

The changes notices in our Branch membership during the year are:—Three Members, four Associate Members and two Students have left us, while two Associate Members have come to the Branch territory. In the Branch non-resident membership three Associate Members have left and we have two new Students and one new Affiliate Member. The numerical standing being as follows;—

	Branch Residents	*Branch Non-Residents*
Members	20	1
Associate Members	22	3
Juniors	1	..
Students	4	2
Affiliates	2	..

Total Branch membership is 55.

The Branch Executive Committee for the year has been as follows:—

Chairman .... F. G. Aldous, A.M.E.I.C.
Vice-Chairman .... H. F. Bourne, A.M.E.I.C.
Secretary-Treasurer .... K. M. Chadwick, M.E.I.C.
Executive Committee .... A. L. Carruthers, M.E.I.C.
L. W. Toms, A.M.E.I.C.
F. C. Green, M.E.I.C.
O. W. Smith, M.E.I.C.
Ex-officio .... R. F. Davy, A.M.E.I.C., Councillor and Past-Chairman.

The Executive Committee held four meetings during the year at which Branch business was transacted.

The convenors of committees were:—

Papers Committee .... F. L. Macpherson, M.E.I.C.
Social Committee .... F. C. Green, M.E.I.C.
Town Planning .... H. F. Bourne, A.M.E.I.C.
Publicity Committee .... J. N. Anderson, A.M.E.I.C.
Library Committee .... F. W. Knewstubb, A.M.E.I.C.

The whole Executive Committee acted as Legislative, Credentials and Attendance committees.

In the latter part of May the secretary instructed by the Executive Committee, sent several night letters to the Ministers at Ottawa urging increase of salaries to the Civil Service employees as recommended by the Royal Commission.

The Branch has been fortunate in having som excellent lectures, visits and luncheons, a list of which follows. Reports of these have already been published in the Branch News in the Journal.

"Wooden Pipes," by J. B. Holdcroft, A.M.E.I.C., of Vancouver.

Jan. 21-22.—Two joint meetings with Vancouver Island Prospectors Association. **"Workings of the B.C. Mineral Act,"** by F. C. Green, M.E.I.C., and **"Opportunities of the Prospector in Northern British Columbia,"** by Dr. Forest Kerr.

"Electric Welding of Steel Buildings and Bridges," by F. P. McKibben of the General Electric Company, Black Gap, Pa.

Feb. 22.—"**Education of the Engineer,**" by E. A. Wheatley, A.M.E.I.C.

Mar. 20.—"**Structural Timber,**" by J. B. Alexander, timber mechanics supervisor of the Forest Products Laboratory, Vancouver.

Apr. 13.—Visit of President of The Institute, Brig.-General C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C. Inspection of New Dry Dock under J. P. Forde; luncheon at Spencers Dining rooms with short address by the President.

Apr. 25.—Through courtesy of Lincoln Electric Company of Cleveland moving pictures were shown by Mr. C. L. Harrison, of the electrically welded construction of the Upper Carnegie building, Chicago.
Visit of General Secretary R. J. Durley, M.E.I.C. Luncheon and address to members.

Oct. 23.—Through courtesy of J. P. Forde, M.E.I.C., members visited the Dry Dock.

Nov. 13.—Nominations for new officers for the coming year. R. F. Davy's report of the Plenary Meeting of Council in Montreal.

FINANCIAL STATEMENT
(From December 1st, 1928, to November 30th, 1929)

Receipts

Balance in hand December 1st, 1928		$117.08

K. M. CHADWICK, M.E.I.C., *Secretary-Treasurer.*

Winnipeg Branch

The President and Council,—

The following report for the year ending December 31st, 1929, of the Winnipeg Branch, is respectfully submitted.

The membership at the end of the year stood as follows:—

	Resident	*Non-Resident*	*Total*
Members	42	3	45
Associate Members	99	27	126
Juniors	22	2	24
Students	47	3	50
Affiliates	6	0	6
Branch Affiliates	12	0	12
	228	35	263

There were eleven regular meetings held as tabulated below:—

Jan. 10.—Dale J. Graham, "**Street Car and Bus Transportation.**" Attendance, 35.

Jan. 24.—C. H. Attwood, F. H. Martin, J. W. Sanger, "**Winnipeg River, Seven Sisters and Slave Falls.**" Attendance, 74.

Feb. 7.—W. Sanford Evans, "**Manitoba Interests with Respect to Transportation Routes to the North.**" Attendance, 38.

Feb. 21.—J. Gilchrist, "**Specifications and Testing of Steel.**" Attendance, 46.

Mar. 21.—F. Newell, "**Sluice Gates.**" Attendance, 59.

Apr. 25.—N. M. Hall, "**Construction and Operation of Water Tube Boilers.**" Attendance, 54.

Aug. 13.—Prof. Smith, "**Thirty-five Years of Ventures in High Voltages.**" Attendance, 69.

Sept. 26.—J. F. Cunningham, "**Heat Treatment of Steel.**" Attendance, 23.

Oct. 24.—Paul C. Nanton, "**The Respective Merits of Stocks and Bonds as Investments.**" Attendance, 44.

Nov. 28.—W. E. Barker, "**Design and Construction of Concrete Pavements.**" Attendance, 59.

Dec. 12.—A. A. McCoubrey, "**Early Western Railway Surveys.**" Attendance, 37.

On Wednesday, April 17th, the officers and members of the Branch were fortunate in having as a luncheon guest, President Brigadier-General C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C.

Twice during the season the Executive Committee was honoured by a visit from General Secretary R. J. Durley, M.E.I.C.

It must be reported with regret that the Chairman of the Branch, F. H. Martin, has been so seriously ill, that an extended visit to the south has become necessary for his recovery.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XIII MARCH 1930 No. 3

Second World Power Conference

The attention of all members of The Institute is drawn to the Second World Power Conference Meeting in Berlin, June 16th-25th, 1930, at which engineers, economists, statesmen and others from practically all countries of the world will gather to discuss, from every aspect, problems associated with the development of power.

The Canadian Executive Committee of the World Power Conference has been fortunate in arranging for the presentation at the Berlin Meeting of seven papers comprehensively covering the power situation in the Dominion, by such authors as Dr. F. A. Gaby, M.E.I.C., chief engineer, Hydro-Electric Power Commission of Ontario, Dr. T. H. Hogg, M.E.I.C., chief hydraulic engineer, Hydro-Electric Power Commission, Dr. Julian C. Smith, M.E.I.C., vice-president and general manager, Shawinigan Water and Power Company, and Professor C. V. Christie, M.E.I.C., McGill University, Dr. O. O. Lefebvre, M.E.I.C., chief engineer, Quebec Streams Commission, J. T. Johnston, M.E.I.C., director, Dominion Water Power and Reclamation Service, G. Gordon Gale, M.E.I.C., vice-president and general manager, Gatineau Power Company, and B. F. Haanel, M.E.I.C., chief engineer, Division of Fuels and Fuel Testing, Department of Mines, Ottawa. This assures that Canada will be substantially represented in the programme and the effort of the Executive Committee is being supported by an Honorary Committee of Dominion wide influence in power matters, under the Honorary Chairmanship of the Honourable Charles Stewart, Minister of the Interior.

It remains to support the Canadian effort by sending a strong delegation to Berlin and with the interest already manifest, there is every indication that many from this country will seize this rare opportunity to meet and discuss with the power authorities of other countries problems which are of common interest.

Membership in the Second World Power Conference is obtained by paying a fee of ten dollars to the German National Committee and membership forms are to be secured by addressing N. Marr, M.E.I.C., acting secretary, Canadian National Committee, 81 Metcalfe street, Ottawa. Prompt action in filling out and forwarding these membership forms to the German National Committee is urged upon those intending to go in order that the German Committee may have an opportunity of making proper provision for accommodation, etc.

Fiftieth Anniversary Celebration of the A.S.M.E.

The fiftieth anniversary celebration of the American Society of Mechanical Engineers will take place on April 5th to 9th, 1930, in New York, Hoboken, and Washington; an extensive programme will make it an event of international significance interpreting the social and economic influence of engineering on civilization.

The proceedings will commence on Saturday, April 5th, with the unveiling of a memorial tablet in the Engineering Societies Building, New York City, followed in the afternoon by a pageant at the Stevens Institute of Technology, Hoboken, N.J., featuring engineering progress. On Sunday the 6th, a special commemorative service will be held at the Cathedral of St. John the Divine, and the delegates will leave for Washington, where, on Monday, the 7th, a welcoming assembly will be held in the National Council Chamber, United States Chamber of Commerce Building, at which addresses will be made by the delegates from the various countries represented and by representatives of the other American engineering societies. In the afternoon monographs covering the humanistic aspects of engineering will be presented by representatives of all the principal industrial countries of the world. There will be a convocation for the conferring of honours, and the day will close with the fiftieth anniversary formal dinner of the Society.

On the concluding day of the gathering, Wednesday, April 9th, excursions have been arranged to the Bureau of Standards, the United States Navy Yard, and the various government buildings, and places of interest in and around Washington.

A cordial invitation to attend this anniversary has been extended to members of The Engineering Institute of Canada, and preliminary registration blanks can be obtained from the General Secretary of The Institute at Headquarters.

Progress in Steam Research

The rapid development of the last few years in the use of steam at high pressures and high superheat has greatly changed our outlook on the problems of steam power generation. Progress as regards knowledge of combustion engineering problems has been remarkable, and marked advance has been made in the difficult task of obtaining reliable data as to the physical properties of steam at the high temperatures and pressures which are now either in actual use or are contemplated in installations under design.

The determination of these properties has been the object of prolonged scientific research. One hundred and fifty years ago, when the steam engine was being developed by Watt, the search for the true properties of steam began, and the accuracy of the measurements of the pressure, temperature and total heat of steam made by Regnault and other early experimenters in the early nineteenth century was such that until quite recently, within their limited range, they afforded a sufficient basis for calculations. Since that time, however, quite different conditions have arisen, and to-day steam plants are in operation with working temperatures up to 1,000° F. and working pressures approaching 1,000 lbs. per square inch. Experimental work dealing with the properties of steam under these conditions is much more arduous and expensive than in the days of Rankine. It involves complications and difficulties with which the early physicists were not faced. Its necessity, however, has become increasingly evident, since it was found, some ten years ago, that available tables of the thermal properties of steam were not reliable in those higher regions; further, there was no international agreement on such figures as had been obtained. Investigators were at work, however, in many countries, and after much had been done independently, principally in England, the United States and Germany, an International Steam Table Conference was held in London last year, at which the work of such men as Callendar, Mollier, Jakob, Keyes and Osborne was discussed, with a view to the preparation of a set of international steam tables. As as result of the examination by this conference of all available figures, a network of selected values was agreed upon for the saturated and superheated regions of the steam table, taking temperatures up to 350° C. (about 650° F.) for saturated steam, and pressures up to 250 atmospheres, or say, 3,600 lbs. per square inch, for superheated steam. It is interesting to note that the conference decided upon the use of the International scale of temperature, and the unit of heat employed was the kilo-calorie, defined as the heat value of an international kilowatt-hour divided by 860. The selection of this unit avoids the difficulty caused in the case of the British Thermal Unit by its dependence on the value of gravity and the specific heat of water.

The conference assigned tolerances, or measures of uncertainty, to the various quantities, such as specific volume and total heat, at each selected point, and it was agreed to regard as international any steam table which, at each of the test points selected, differs from the selected value by an amount less than the assigned tolerance. The report of this conference* marks a notable advance, for it provides a method of handling the results of the work of many independent investigators on an international basis, and furnishes at the same time a foundation for further extended research.

*See "Engineering," Dec. 6th, 1929, pp. 751-752; also "Mechanical Engineering," Feb., 1930, pp. 120-141.

The Forty-Fourth Annual General and General Professional Meeting

Convened at Headquarters, Montreal, Montreal, January 23rd, 1930 and adjourned to the Chateau Laurier, Ottawa, Ontario, February 12th, 1930.

Annual General Meeting at Institute Headquarters

The Forty-fourth Annual General Meeting of The Institute was held at Headquarters on Thursday, January twenty-third, nineteen hundred and thirty, at eight o'clock p.m., with Councillor O. O. Lefebvre, D.Sc., M.E.I.C., in the chair.

The Secretary having read the notice convening the meeting, the minutes of the Forty-third Annual General Meeting were submitted, and on the motion of J. H. Hunter, M.E.I.C., seconded by F. P. Shearwood, M.E.I.C., were taken as read and confirmed.

Appointment of Scrutineers

On the motion of J. T. Farmer, M.E.I.C., seconded by J. D. Alder, M.E.I.C., Messrs. J. A. Burnett, M.E.I.C., and J. L. M. Tait, A.M.E.I.C., were appointed scrutineers to report the result of the Officers' Ballot.

Appointment of Auditors

On the motion of J. G. Caron, A.M.E.I.C., seconded by C. K. McLeod, A.M.E.I.C., Messrs. Riddell, Stead, Graham and Hutchison were appointed auditors for the ensuing year.

There being no other formal business it was resolved, on the motion of P. B. Motley, M.E.I.C., seconded by H. G. Thompson, A.M.E.I.C., that the meeting do adjourn to reconvene on Wednesday, the twelfth day of February, nineteen hundred and thirty, at ten o'clock a.m. at the Chateau Laurier, Ottawa, Ontario.

Adjourned General and General Professional Meeting at the Chateau Laurier, Ottawa

The adjourned meeting was convened at ten o'clock a.m. on February 12th, 1930, President C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., in the chair. The Secretary having read the messages of regret received from members and invited guests, the membership of the Nominating Committee appointed to nominate officers of The Institute for 1931 was announced as follows:—

Nominating Committee 1930

Chairman: A. Duperron, M.E.I.C.

Branch	*Representative*
Halifax Branch	W. A. Winfield, M.E.I.C.
Cape Breton Branch	J. R. Morrison, A.M.E.I.C.
Saint John Branch	J. L. Feeney, A.M.E.I.C.
Moncton Branch	T. L. S. Landers, M.E.I.C.
Saguenay Branch	N. D. Paine, A.M.E.I.C.
Quebec Branch	Philippe Méthé, A.M.E.I.C.
St. Maurice Valley Branch	A. A. Wickenden, A.M.E.I.C.
Montreal Branch	H. G. Thompson, A.M.E.I.C.
Ottawa Branch	D. W. McLachlan, M.E.I.C.
Peterborough Branch	W. M. Cruthers, A.M.E.I.C.
Kingston Branch	D. S. Ellis, A.M.E.I.C.
Toronto Branch	G. A. McCarthy, M.E.I.C
Hamilton Branch	H. S. Philips, M.E.I.C.
London Branch	F. C. Ball, A.M.E.I.C.
Niagara Peninsula Branch	C. G. Moon, A.M.E.I.C.
Border Cities Branch	F. H. Kester, M.E.I.C.
Sault Ste. Marie Branch	J. L. Lang, M.E.I.C.
Lakehead Branch	F. C. Graham, A.M.E.I.C.
Winnipeg Branch	J. W. Sanger, A.M.E.I.C.
Saskatchewan Branch	H. R. MacKenzie, A.M.E.I.C.
Lethbridge Branch	N. H. Bradley, A.M.E.I.C.
Edmonton Branch	R. S. L. Wilson, M.E.I.C.
Calgary Branch	F. M. Steel, M.E.I.C.
Vancouver Branch	W. B. Greig, A.M.E.I.C.
Victoria Branch	F. L. Macpherson, M.E.I.C.

A letter was presented from the Hon. Charles Stewart, Minister of the Interior, dated February 4th, 1930, and drawing attention to the fact that the second plenary meeting of the World Power Conference will be held in

Berlin from June 16th to 25th, 1930, and that a number of papers by representative Canadian engineers have been arranged for. The letter further requested the support of The Engineering Institute of Canada in making the Canadian effort effective and invited the President of The Institute to act upon the Canadian Honorary World Power Conference Committee. The Minister of the Interior also asked that the invitation to participate in the Berlin Conference should be brought to the attention of members of The Institute, with the object of encouraging the attendance of as many as possible as official delegates. The President stated that the Hon. Mr. Stewart had been assured of the co-operation of The Institute in any way possible, and that the matter would come up for consideration at an early meeting of Council.

Presentation of Medals and Prizes

In regard to the prizes and medals of The Institute, the President announced that for the year 1928-1929, it had not been considered advisable to make any award of the Sir John Kennedy Medal, and that the committees judging the competitions for the Past-Presidents' Prize, the Gzowski Medal and the Leonard Medal had been unable to recommend any award. The President then called upon A. S. Wall, M.E.I.C., to whom the Plummer Medal had been awarded for his paper on "Arc Welding in Structural Fabrication," and the medal was handed to Mr. Wall. The President next presented the Phelps Johnson Prize to E. Gray-Donald, Jr.E.I.C., for his paper on "Distribution Transformers" and the John Galbraith Prize to Morley V. Powell for his paper on "Fabricated Steel Construction for Large Electric Generators." It was announced that the examiners had been unable to make any award for the Ernest Marceau, H. N. Ruttan and Martin Murphy Prizes.

Reports of Council and Committees

The President requested the Secretary to outline the principal features of the Report of Council, which was accordingly done, this report being printed on page 179 of this issue of the Journal.

Report of the Finance Committee

G. R. MacLeod, M.E.I.C., the chairman of the Finance Committee, then discussed the principal features of the Finance Committee's report and the financial statement.

Report of the Committee on Engineering Education

The President remarked that Fraser S. Keith, M.E.I.C., the chairman of the committee on Engineering Education, who was unfortunately unable to be present, had hoped that there would be discussion on the recommendations of that committee, and he asked the Secretary to read the report containing them. In regard to these recommendations, E. M. Proctor, M.E.I.C., drew attention to the committee's fourth recommendation, that immediate steps be taken to confer with university heads with a view to adopting a six-year course for engineers. This course Mr. Proctor thought inadvisable, if it contemplated a six-year college course, although he believed that two years of practical experience at the end of a four-year course would be a satisfactory arrangement. He then moved that suggestion number four be referred back to the committee, and his motion, being seconded by J. B. Carswell, M.E.I.C., was carried unanimously. Discussion followed, in which A. F. Baird, M.E.I.C., commented on the fifth recommendation, namely that the universities be urged to give consideration to the inclusion of public speaking and literature in the curricula of their engineering courses. He felt that if the whole of the college training of an engineer had to be covered in four years, it would be impossible to give additional time to such a subject, and was doubtful whether it would be desirable to adopt this recommendation, though he would not press this point to a motion. Messrs. J. W. Whyte, M.E.I.C., George R. MacLeod, M.E.I.C., O. O. Lefebvre, M.E.I.C. and J. A. McCrory, M.E.I.C., took part in further discussion on this report.

Report of the Committee on Publicity

The report of the Committee on Publicity, of which Mr. Keith was also chairman, was next given consideration. In Mr. Keith's absence, it was presented by W. C. Adams, M.E.I.C., who pointed out that the benefits arising from well-managed publicity had been illustrated by the very successful activities of the Ottawa Branch in connection with the present meeting. Mr. Adams drew attention to the fact that the various recommendations of the Committee on Publicity were difficult if not impossible to carry out in the present state of the finances of The Institute, and the discussion was continued by F. P. Shearwood, M.E.I.C., and others.

The President suggested that in view of the amount of business before the meeting it would perhaps be desirable to take together those reports upon which comparatively little comment would be expected. Among these he would name the reports of the Library and House Committee, the Board of Examiners and Education and the Service Bureau Committee. The reports were, however, open for discussion. There being no further comment, W. G. Mitchell, M.E.I.C., moved that the following reports be received and adopted: the Reports of Council, Finance Committee, Library and House Committee, Legislation Committee, Board of Examiners and Education, Service Bureau Committee, Canadian National Committee of the International Electrotechnical Commission, Committee on International Co-operation, the report of The Institute's members on the Main Committee of the Canadian Engineering Standards Association, and those of the Honour Roll and War Trophies Committee and the Committee on Publicity. This motion was seconded by George R. MacLeod, M.E.I.C., and being put was carried unanimously.

Report of the Committee on the Relations of The Institute with the Provincial Associations of Professional Engineers

On the suggestion of S. G. Porter, M.E.I.C., the chairman of the committee, the Secretary outlined the leading features of its report, and stated its final conclusions, after which Mr. Porter, in a striking address, gave his views on the present situation. He remarked that if the scheme proposed by his committee were carried to its conclusion, with the support of the associations, the election of the Council of The Engineering Institute of Canada would be in the hands of men who would all be members of one or other of the provincial organizations, The Institute thus becoming a co-ordinating body. Mr. Porter then commented on the seven recommendations of his committee, and said that in his opinion a system similar to that outlined by his committee afforded the only way in which the engineering profession in Canada could reach real consolidation and solidarity. The profession would then form one Dominion-wide body of engineers and would attain a position which would give it a strength and influence which it had never yet possessed in Canada. If there were a Dominion-wide organization, embracing all the engineers in Canada, into which only those would be admitted who had received proper education and training, engineering could properly take its place along with the other professions. The public would then be able to rest assured that when an engineer belonged to this Dominion-wide body and was also registered in his province as being able to practise engineering, he must have received proper training and experience; this would give the engineer a definite standing, with a resulting increase in the confidence felt by the public in the engineering profession. Such a development would take time, but by deciding on a common high standard and living up to it, the whole body of engineers would be in a position far superior to that held to-day. Further, such action would do much to discourage the practice of going outside of Canada to get engineering work done, and the engineering profession would be more favourably known to the Canadian people and to the industries and governments of Canada. Mr. Porter believed that upon an analysis of the problem it would be found to be one which could be solved if we had the will to solve it, and he hoped that his committee's report would convince the meeting that this was the case.

The President pointed out that the report had already been received and adopted by the 1929 Plenary Meeting of Council, after prolonged discussion, but that Council properly felt reluctant to embark on a policy of this kind until it had been endorsed by the Annual Meeting. He would ask Mr. Porter to move the reception and adoption of this report so that the opinion of the meeting might be taken. It was accordingly moved by S. G. Porter, M.E.I.C., seconded by George R. MacLeod, M.E.I.C., that the report of the Committee on the Relations of The Institute with Provincial Associations of Professional Engineers be received and adopted.

The discussion was opened by P. B. Motley, M.E.I.C., who stated that in his opinion the Provincial Associations were now in somewhat the same position as the Canadian provinces at the time of Confederation, and the policy advocated by Mr. Porter's committee, if put in effect, would have the same beneficial results as Confederation had for the Dominion. He thought that the benefits of such a policy had been strikingly shown by the progress made by the Canadian National Railways since the various roads constituting that organization had been brought together and consolidated. He hoped that the committee's report would be endorsed and that the committee would be placed in a position to continue and develop its work.

He was followed by J. L. Busfield, M.E.I.C., who was unable to agree with Mr. Porter or Mr. Motley, and considered that the policy recommended in the committee's report was undesirable from the point of view of The Institute. He felt that the distinction between the real purposes of the Professional Associations and those of The Engineering Institute of Canada had not been sufficiently emphasized. While he was himself quite in accord with the committee's sixth recommendation, he could not approve of the seventh, feeling that if membership or registration in a Professional Association were made a requirement for admission to corporate membership in The Institute, this would exclude from The Institute hundreds of men who ought to be members, having regard to the fact that one of the principal objects of The Institute is educational. If recommendation number seven were acted upon, The Institute would practically be handed over to the Professional Associations, and he would deprecate putting The Engineering Institute of Canada under the control of any group of associations with such diversified constitutions and powers. If the action contemplated in the seventh suggestion were to be postponed until the associations had themselves attained uniformity, this would involve a long period of waiting, and to his mind the possibility of standardizing the various provincial acts was very remote. The provincial legislatures, in passing these acts, had done so for the purpose of protecting the public, not for the protection of the engineers, and he felt that the difficulty of obtaining uniformity in provincial legislation was almost insuperable. He further believed that even if the provincial associations were co-ordinated so as to form a coherent body, the objects and purposes of that body would certainly not be identical with those of The Engineering Institute of Canada, and he did not see that The Institute could function as such an organization. Mr. Busfield pointed out that two policies appeared open to The Institute at the present time, on the one hand that of confederation with the Professional Associations, a course which was admittedly beset with great difficulties, and on the other hand there was the course of independent growth which he considered far safer and more promising, as it would permit The Institute to develop along its own lines independently of the provincial associations.

After expressing appreciation of the great amount of work accomplished by Mr. Porter and his committee, P. L. Pratley, M.E.I.C. observed that the committee's report had not convinced him that the objects of The Institute were "in many respects identical" with those of the Professional Associations. In his opinion educational effort and legislative functions should be divorced. He felt that the committee, before making a proposal for co-ordination, integration or confederation, should have studied the various duties of the associations on one hand and The Institute on the other to see whether such action would be possible. Mr. Pratley pointed out that at the time when the professional associations were formed there was a natural desire to protect the engineer, and this was, in fact, the motive which prompted the action then taken. The provincial legislatures, however, would not accept that point of view, being concerned with the protection of the public, and this had led to many changes in the provincial acts. He believed that the work of the committee should be the study of co-ordination of the associations rather than endeavouring to combine The Institute with these various bodies. If the differences in the functions of the associations and of The Institute were clearly realized, it would be seen that there must necessarily be a difference in the qualifications for membership. Mr. Pratley was quite opposed to the fifth recommendation of the committee, contemplating the adoption of uniform requirements and qualifications for admission as between the associations and The Institute. He though it quite right that there should be a standard requirement for all the associations for registration purposes, but did not think that The Institute should adopt the same requirements or necessarily have the same membership as the associations. Many hundreds of men interested in the engineering profession and employed in the technical offices of large corporations should have a place in The Institute, which could offer them educational advantages and the information and experience of senior members. These men in the offices of large companies had no intention of practising engineering as a profession, and did not need licenses to practise, since they carried on their engineering work under the guidance of those who were in responsible positions. In his opinion there was no need for many of these junior members to belong to any professional association, but they certainly should belong to The Institute. Accordingly, he thought it would be wrong on the part of The Institute to exclude them from its membership simply because of the special requirements for membership which might properly be insisted upon by the associations. Mr. Pratley felt that the committee's report had failed to distinguish clearly between the functions of the various organizations and had come to the wrong conclusion as to the necessity for uniform requirements for admission.

H. N. Mason, A.M.E.I.C., believed that although some of the professional associations were operating under acts which gave them but little power, it was wrong to continue to divorce The Institute from the professional associations. The Institute must co-operate with such associations so that engineers throughout the country could co-ordinate their efforts.

D. W. McLachlan, M.E.I.C., continued the discussion, and was of the opinion that The Institute should accept the membership of those belonging to professional associations, but he saw no reason why there should not be a large number of additional members belonging to The Institute and not belonging to any association.

E. M. Proctor, M.E.I.C., drew attention to the suggestion in recommendation number seven that membership or registration in a professional association be a requirement for admission to The Institute, and enquired whether if this were put into effect difficulties would not arise in regard to engineers from the United States, Great Britain and elsewhere who desired to join The Institute. He hoped that the professional associations would aid in defraying the cost of the further investigations contemplated by Mr. Porter's committee.

C. G. Moon, A.M.E.I.C,, did not think that amalgamation with the provincial associations would be a good thing for The Engineering Institute, and held that The Institute should go on its way as an educative body, taking in every man who was sincere in his desire to become an engineer and follow the engineering profession. This might involve a slight lowering of The Institute's present requirements for admission, but he believed that it would be in the true interests of the engineers of the country and of The Engineering Institute of Canada.

G. E. Bell, M.E.I.C., referred to the very large proportion of the membership of The Institute which consisted of employees of contracting manufacturing corporations, and pointed out that while these men were not interested in the question of registration for private practice, they were interested in belonging to a technical organization whose function was educational, and consisted in the exchange of professional experience and information. He thought that The Institute had a great deal to gain from the membership of such men, and feared that if the scheme contemplated by Mr. Porter's committee went into effect, a large number of them would resign from The Institute and possibly join other organizations.

A. F. Baird, M.E.I.C., fully endorsed the report of Mr. Porter's committee and believed that it would have the support and approval of the professional associations in New Brunswick and Nova Scotia. Professor Baird could assure those who doubted whether the associations really protected the public that in New Brunswick, where they had a rather strict act, several cases had occurred where the association had proved its value in this respect, and he would point out that effective acts existed in other provinces also. The discussion was continued by A. F. Macallum, M.E.I.C., J. B. Carswell, M.E.I.C., F. H. Peters, M.E.I.C., B. S. McKenzie, M.E.I.C., and A. J. Grant, M.E.I.C.

J. L. Busfield, M.E.I.C., believed that sufficient differences of opinion had been expressed during the discussion to justify further consideration of the report, and he therefore moved as an amendment to the main motion that this meeting approve of the principle of The Engineering Institute of Canada helping the provincial associations of professional engineers to standardize their requirements, and co-ordinate their activities, but that we do not commit ourselves to definite action of combining with them until such time as it has been found possible to co-ordinate the professional associations.

J. P. Hodgson, M.E.I.C., read a telegram which he had received from the registrar of the Association of Professional Engineers of the Province of British Columbia urging The Institute to encourage all its members to comply both in spirit and letter with the engineering acts of the various provinces since this course would aid the movement for confederation.

Colonel H. J. Lamb, M.E.I.C., remarked that when the movement for closer relations between The Engineering Institute of Canada and the Provincial Associations was initiated, he was president of the Ontario Association, and at that time was impressed with the great difficulties attending the carrying out of such a scheme. Since that time, having served as a member of Mr. Porter's committee, he had entirely changed his mind and now believed that it would be in the interests of the engineering profession throughout the Dominion if the movement were successful. He was sure that The Institute would prosper and be better able to help engineers throughout the country if such relationship could be brought about. Colonel Lamb was strongly in favour of standardizing the requirements for admission to the professional associations and particularly those as regards admission by examination. He hoped that the meeting would give its support to the movement by approving the report of Mr. Porter's committee.

After further discussion, the President pointed out that Mr. Busfield's amendment had not been seconded, and Mr. Pratley, in seconding it, remarked that while the majority seemed quite ready to help in furthering some form of co-operation between the various provincial associations, he believed there were quite a number who would hesitate in committing The Institute to the adoption of the fifth recommendation in the report. He felt that Mr. Porter's committee was to be commended, it had done a great deal of admirable work and should continue that work in the direction of persuading if possible the professional associations to get together and standardize their own attitude. He thought The Institute should await some such action on the part of the associations before committing itself to the approval of uniform regulations for admission.

Harold S. Johnson, M.E.I.C., observed that there were many members of the Association in Nova Scotia who were not members of The Engineering Institute of Canada and were not likely to become members. The present meeting was of course a general meeting of The Engineering Institute of Canada but could not be considered as being fully representative, as it could not bring expressions of opinion from each of The Institute's Branches. He did not think that a vote of this meeting could, therefore, be regarded as expressing the views of the whole membership.

The President pointed out that Mr. Porter's committee comprised representatives from all parts of the country, and that its report had been considered and approved by a Plenary Meeting of Council, at which Councillors from almost all the Branches were present. He believed that the Council had been satisfied that the Branches were generally in favour of the proposals. Council had, however, been reluctant, notwithstanding this general approval, to embark upon the proposal until it had been formally endorsed by the Annual General Meeting.

Mr. Busfield enquired whether it was the intention to put immediately into effect the suggestion in the seventh recommendation that amendments to The Institute's By-laws should be secured so that membership or registration in a professional association be one of the requirements for admission to corporate membership in The Engineering Institute of Canada. The President replied that it was not the intention to take immediate action in this respect; Mr. Busfield then said that in such a case he would be willing, with the permission of his seconder, to withdraw his amendment. The President remarked that as recommendation number seven would not come into effect until numbers five and six had become operative, the necessity for Mr. Busfield's amendment was not so apparent. On Mr. Pratley's agreement, the amendment was then withdrawn.

After further discussion, the main motion was put and carried, one member dissenting.

Report of the Committee on Policy

Dr. O. O. Lefebvre, M.E.I.C., in presenting the report of the Committee on Policy, explained that this report was not a final one, since some of the subjects dealt with depended upon the action taken by the membership in connection with the proposed amendments to By-laws which were shortly to be voted upon. His committee had reported at The Plenary Meeting of Council, previous to which the Branches had been consulted by questionnaire, and replies from them had been used in connection with the discussion at the Plenary Meeting, the results of which had been available in preparing this report now submitted. The question of the publications of The Institute, which was among those referred to the Committee on Policy, was being dealt with by a special committee and would form the subject of another report later on.

Mr. Lefebvre outlined the recommendations of his committee and moved the reception and adoption of the report; the motion being seconded by Mr. J. A. McCrory, was carried unanimously.

Special Committee on the Publications of The Institute

The President stated that this committee, which was appointed at the Plenary Meeting of Council in October 1929, had not completed its work, and no report had yet been received from it, but he would ask the chairman to make a statement regarding the information obtained and the conclusions arrived at. W. C. Adams, M.E.I.C., accordingly stated that his committee had made a progress report at the meeting of Council on February 4th, and their enquiries were still proceeding, but he desired to place before the annual meeting such information as had already been obtained. He felt that the work of his committee would have to be continued, and thought that some discussion might now take place which would be of assistance in this further work. A record of the information obtained by his Committee and a questionnaire had been sent to each of the Branches of The Institute, but at the time of speaking replies had been received from only about half the Branches. On the receipt of the remaining replies he hoped that his committee, or some other committee to be appointed by Council to continue its work, would shortly be able to present definite recommendations.

The Secretary read a letter dated February 11th, 1930, addressed to the Council, and received from Councillor C. H. Scheman, M.E.I.C., in which the views of the Niagara Peninsula Branch regarding the publications of The Institute were set out in some detail. After some discussion Dr. Lefebvre moved that the progress report of Mr. Adams' committee and the communication from the Niagara Peninsula Branch dated February 11th, be received, and the incoming Council be instructed by this meeting to continue the committee. The motion being seconded by C. G. Moon, A.M.E.I.C., was put and carried unanimously.

Proposals for Amendments to By-Laws

In connection with the amendments to the By-laws proposed by Council, the President remarked that these were brought up for discussion in accordance with Section 75 of the By-laws, previous to their submission to the membership for decision by letter ballot. He asked G. R. MacLeod, M.E.I.C., to make a statement with regard to the proposed amendments.

G. R. MacLeod, M.E.I.C., pointed out that the principal proposal (that to amend Section 34) involved an increase in the annual fees of members, and was a repetition of the proposal which failed to carry in 1929. He called attention to the memorandum on this subject which had been sent to all corporate members and urged that the additional funds asked for were required for vital services required by The Institute. On the motion of Hew M. Scott, M.E.I.C., seconded by T. Taylor, M.E.I.C., it was unanimously resolved that this meeting go on record as endorsing the memorandum regarding the increase of fees issued by Council, dated January 31st, 1930, and forwarded to all corporate members.

Dr. Lefebvre drew attention to the fact that when the amendment proposed to Section 34 goes out to ballot, it would be very desirable for it to be accompanied by a statement of the reasons advanced in its support, and from further discussion it appeared to be the unanimous opinion of the meeting that a statement of the reasons in favour of the proposed increase should be drawn up with the approval of Council, and issued with the ballot.

In regard to the amendment to Section 75 dealing with a proposed change in the procedure at the Annual Meeting regarding proposals to introduce new By-laws or to amend or repeal existing By-laws, Mr. Busfield was of the opinion that the change now suggested by Council would not prove satisfactory in actual practice, as if it were adopted the procedure would practically revert to the conditions obtaining in 1926, when the Annual General Meeting could do nothing except discuss any changes in the By-laws proposed by Council or by twenty corporate members. The present proposal, however, added the complication that after discussion by the Annual General Meeting the proposals would have to go back either to the Council or to twenty corporate members. He thought that some method should be worked out by which the Annual Meeting would have the definite power to modify such proposals, the difficulty as to voting on so many propositions being taken care of by proper direction from the chair.

Dr. Lefebvre remarked that at the Annual Meeting of 1929 a number of modifications had been proposed to one of Council's amendments, and these had all to go out to ballot; as a result the proposal of Council and all of the modifications thereto suggested by the Annual Meeting failed to carry, because the vote was so split that no one item could secure the necessary 66 per cent majority. Further discussion on this point was then postponed on the suggestion of the President, until Council's proposals respecting Sections 13 and 37 had been dealt with. On the motion of Dr. Lefebvre, seconded by Mr. G. R. MacLeod, it was unanimously resolved that this meeting endorse Council's amendment to Section 13. On the motion of Dr. Lefebvre, seconded by Mr. Hew M. Scott, it was unanimously resolved that Council's proposal with regard to Section 37 should have the endorsement of the meeting.

Discussion having been resumed on the proposed amendment to Section 75, the President stated that in view of the differences of opinion disclosed with respect to this matter, he would appoint a committee in accordance with the provision of Section 75, to prepare reasons for and against the proposal, such reasons to be sent out with the ballot papers. He nominated for this purpose Dr. Lefebvre and Mr. MacLeod to state reasons in favour of the proposal, and Mr. Busfield and Mr. Shearwood to state reasons against the proposal.

Reports of the Branches

The President having pointed out that it was not customary to read these reports in full, enquired if any members present desired to make any remarks regarding them. No comment being made, it was unanimously resolved, on the motion of Major L. R. Grant, M.E.I.C.

seconded by E. M. Proctor, M.E.I.C., that the reports of the Branches as submitted in printed form be taken as read and received.

President's Retiring Address

The President next gave his retiring address, which is printed *in extenso* on pages 219-226 of this number of The Engineering Journal.

On the conclusion of General Mitchell's address, Dr. Lefebvre moved a hearty vote of thanks to the retiring President for his interesting and valuable address, and this proposal was at once carried by acclamation.

Election of Officers

The report of the scrutineers appointed to canvass the Officers' Ballot for 1930 having been read by the Secretary, the following officers were declared elected:

President	A. J. Grant, M.E.I.C.
Vice-Presidents:	
Zone B	T. R. Loudon, M.E.I.C.
Zone C	W. G. Mitchell, M.E.I.C.
Zone D	F. R. Faulkner, M.E.I.C.
Councillors:	
Victoria Branch	F. M. Preston, A.M.E.I.C
Vancouver Branch	A. K. Robertson, M.E.I.C.
Calgary Branch	T. Lees, M.E.I.C.
Edmonton Branch	E. Stansfield, M.E.I.C.
Lethbridge Branch	G. N. Houston, M.E.I.C.
Saskatchewan Branch	D. A. R. McCannel, A.M.E.I.C.
Winnipeg Branch	C. H. Attwood, A.M.E.I.C.
Lakehead Branch	F. Y. Harcourt, M.E.I.C.
Sault Ste. Marie Branch	A. E. Pickering, M.E.I.C.
Border Cities Branch	L. McG. Allan, A.M.E.I.C.
Niagara Peninsula Branch	C. H. Scheman, M.E.I.C.
London Branch	W. P. Near, M.E.I.C.
Hamilton Branch	E. H. Darling, M.E.I.C.
Toronto Branch	L. W. Wynne-Roberts, A.M.E.I.C.
Kingston Branch	W. L. Malcolm, M.E.I.C.
Peterborough Branch	R. L. Dobbin, M.E.I.C.
Ottawa Branch	J. E. N. Cauchon, A.M.E.I.C.
Montreal Branch	J. L. Busfield, M.E.I.C.
	J. A. McCrory, M.E.I.C.
St. Maurice Valley Branch	B. Grandmont, A.M.E.I.C.
Quebec Branch	J. M. H. Cimon, A.M.E.I.C.
Saguenay Branch	H. R. Wake, A.M.E.I.C.
Moncton Branch	V. St.C. Blackett, A.M.E.I.C.
St. John Branch	E. A. Thomas, A.M.E.I.C.
Cape Breton Branch	S. C. Mifflen, A.M.E.I.C.
Halifax Branch	H. F. Bennett, A.M.E.I.C.

The Secretary reported with regret the decease of one of the gentlemen thus elected to the Council, Mr. E. A. Thomas, of the Saint John Branch, whose sudden death occurred subsequent to the issue of the ballot papers to the membership; it was pointed out that in such a case the By-laws provide that the Council shall fill the vacancy by selecting from a list of nominees furnished by the Branch concerned. The Secretary was instructed to take the necessary action.

Induction of Newly-Elected President

On relinquishing the presidency, General Mitchell requested the new President, Mr. A. J. Grant, M.E.I.C., to assume office. Mr. Grant was escorted to the platform by Dr. O. O. Lefebvre, M.E.I.C., and Dr. A. R. Decary, M.E.I.C., and on taking the chair expressed to the meeting and to the members of The Institute his very great appreciation of the honour conferred upon him.

President Grant remarked that one of the most important duties confronting this year's Council and those of several years to come would be that of continuing the work so well begun by Mr. Porter and his committee toward bringing about a confederation of the provincial associations and The Engineering Institute of Canada.

He considered the idea of the confederation of the provincial associations and the Engineering Institute a matter of paramount importance, and trusted that the members of The Institute would do all in their power to encourage the development of a sentiment favourable to this result.

Mr. Grant pointed out the responsibilities of Branch Executive Committees in connection with the affairs of The Institute. The Council was largely dependent upon the suggestions and criticisms from Branch Executive Committees in dealing with any questions regarding the policy of The Institute.

He regarded it as a most happy circumstance that his installation as President of The Institute should take place in the city of Ottawa where many of his early years were spent. He desired to express to the officers and members of the Ottawa Branch his appreciation of the success which had attended their onerous work in connection with the Annual Meeting.

Mr. S. G. Porter desired to have the honour of making the first motion under Mr. Grant's presidency, and remarked that the retiring President and retiring members of Council had most effectively served The Institute and had devoted a great deal of time and energy to its affairs. He therefore moved that the thanks and appreciation of The Institute be expressed to General Mitchell, the retiring President, and to the retiring members of Council for their valuable work on behalf of The Institute during the past year. The motion was seconded by Mr. G. R. MacLeod and carried unanimously.

On the motion of Mr. W. C. Adams, seconded by Mr. Busfield, it was unanimously resolved that the thanks of the meeting be conveyed to the scrutineers for their services in preparing the report on the ballots for the election of officers, and that the ballot papers be destroyed.

R. K. Palmer, M.E.I.C., remarked that as coming from the city where the Annual General Meeting of 1929 was held, he was able to appreciate the very great amount of work involved and the consideration which had to be given to multifarious details in connection with an Annual Meeting, and he therefore desired to move a hearty vote of thanks to the Ottawa Branch in recognition of their hospitality and activity in connection with the Forty-fourth Annual General and General Professional Meeting of The Institute in Ottawa. The motion, being seconded by J. B. Carswell, M.E.I.C., was unanimously carried.

There being no further business, the Annual General Meeting then terminated.

Luncheon

On the first day of the meeting, on Wednesday, February twelfth, a luncheon was given in the Ball Room of the Chateau Laurier, at which John McLeish, M.E.I.C., Chairman of the Ottawa Branch, presided. Mr. McLeish expressed the pleasure of the Ottawa Branch in having the Annual Meeting in that city, and was followed by Mayor Frank H. Plant, who welcomed the visiting members and ladies. G. J. Desbarats, M.E.I.C., Deputy Minister of National Defence, delivered a felicitous address in French in which he referred to the presence side by side in Canada of the two races. The next speaker was Sir Henry Thornton, M.E.I.C., who discussed the factors that have contributed towards the upbuilding of Canada, touching on the romantic history of France, and sketching England's development from the days of Queen Elizabeth. He felt that it should be a matter of pride to Canada that such a large proportion of French-speaking people in this country were Canadians. Dealing with the engineering profession, Sir Henry declared that the first requisite of an engineer was imagination, and there was no calling in which greater loyalty and fidelity to tradition had been exhibited.

Ladies' Tea

During the afternoon a visit was arranged for the ladies to the Memorial Chamber and the Peace Tower, and this was followed by a ladies' tea.

Smoking Concert

In the evening a very successful smoking concert was held in the Jasper Tearoom, various items of the programme being broadcast over CNRO. Meanwhile the ladies were entertained at bridge in the Quebec Suite.

First Technical Session

On Thursday, February thirteenth, the technical sessions began, the papers presented being as follows: In the Assembly Hall, under the chairmanship of O. O. Lefebvre, M.E.I.C.,

"Rigid Air Ships," by Group Captain E. W. Stedman, M.E.I.C., Chief of the Aeronautical Engineering Division, Royal Canadian Air Force, Department of National Defence, Ottawa.

"The Engineers' Work in Surveying and Mapping," by F. H. Peters, M.E.I.C., Surveyor General, Department of the Interior, Ottawa.

In Salons B and C, under the chairmanship of J. L. Busfield, M.E.I.C.

"Development of Radio in Canada," by A. N. Fraser, A.M.E.I.C., Chief Engineer, Radio Branch, Department of Marine and Fisheries, Ottawa.

"Recent Developments in Mechanical Transport Vehicles with Particular Reference to Multi-Wheeled Cross-Country Commercial Types," by Captain N. G. Duckett.

"Radio Communication as an Aid to Aviation in Canada," by Major W. A. Steel, A.M.E.I.C., Radio Engineer, Royal Canadian Corps of Signals, Department of National Defence, Ottawa.

Visit to Rideau Hall

During these sessions Her Excellency Viscountess Willingdon graciously received the visiting ladies at Rideau Hall.

Luncheon

At the luncheon on Thursday, under the chairmanship of Mr. McLeish, the principal speaker was Dr. H. M. Tory, President, National Research Council, who spoke on the contribution of the National Research Laboratories to Canadian industrial life. Dr. Tory's address was of peculiar interest in view of the present developments in the organization and construction of the laboratories of the Research Council, some phases of which were dealt with in the technical papers.

Second Technical Session

At the technical sessions in the afternoon the papers presented were as follows: In the Assembly Hall, under the chairmanship of R. L. Dobbin, M.E.I.C.,

"Aerial Surveys as Applied to Engineering," by A. M. Narraway, M.E.I.C., Chief Aerial Surveys Engineer, Surveys Bureau, Department of the Interior, Ottawa.

In Salons B and C, under the chairmanship of Major L. F. Grant, M.E.I.C.,

"Aeronautical Laboratories of the National Research Council of Canada," by J. H. Parkin, M.E.I.C., Chief of the Aeronautical Research Division, National Research Council of Canada, Ottawa.

Mechanical Transport Demonstration

Arrangements had been made through the kindness of the Department of National Defence to hold an interesting demonstration at Rockliffe during the afternoon. A number of various types of six-wheeled vehicles were shown working across country in snow. These trials were largely attended and served to illustrate the paper presented on Thursday morning by Captain Duckett. During the event the ladies were entertained at tea at the Chelsea Club.

Reception and Engineers' Ball

In the evening a reception and dance took place in the Ball Room of the Chateau Laurier, to which Their Excellencies the Governor-General and Viscountess Willingdon gave their distinguished patronage. On the arrival of Their Excellencies, Lord Willingdon, as an Honorary Member of The Institute, accepted an Institute badge, which was presented by President A. J. Grant, and the gift was accompanied by a bouquet of roses for Lady Willingdon. The Ball was admittedly a great success, and attracted a gathering of nearly eight hundred.

Third Technical Session

On Friday, February fourteenth, the papers presented in the Assembly Hall, under the chairmanship of Dr. H. T. Hogg, M.E.I.C., were as follows:

"Fabrication and Erection of the Superstructure of the Montreal South Shore Bridge," by Major LeRoy Wilson, M.E.I.C., Vice-President in Charge of Operations, Dominion Bridge Company, Montreal.

"The St. Hubert Airship Mooring Tower," by R. deB. Corriveau, M.E.I.C., Assistant Chief Engineer, Department of Public Works, Canada, Ottawa.

Visit to Paugan Falls

Many of the members and visitors accepted the hospitality of the Gatineau Power Company and visited Paugan Falls, a special train leaving at twelve noon, on which luncheon was served. The inspection of this very interesting power development was timed so as to permit the visitors' return to Ottawa in time for dinner.

Visit to Department of Mines Laboratories

Many of those who were unable to visit Paugan took part in a visit to the Fuel Research Laboratory and the Ore Dressing and Metallurgical Laboratories of the Department of Mines, Ottawa, the whole afternoon thus being given up to technical visits.

Annual Dinner

The closing function of the meeting was the Annual Dinner of The Institute, held in the Ball Room on the evening of the fourteenth, at which President Grant occupied the chair. The speakers included the Hon. Charles A. Dunning, Minister of Finance; the Hon. Charles Stewart, Minister of the Interior; the Hon. T. A. Crerar, Minister of Railways and Canals; Mr. Norman R. Fisher, President of the Canadian Institute of Mining and Metallurgy; Mr. P. E. Nobbs, President of the Royal Architectural Institute of Canada, and Mr. G. R. Mickle, President of the Association of Professional Engineers of Ontario.

Mr. Dunning, with many happy touches, said that for the first time for many years he was head of a department of the Government which had no engineers on its roster. He paid particular tribute to the President, Mr. A. J. Grant, and referred to the many associations he had had with members of the engineering profession, particularly while Minister of Railways and Canals. Mr. Stewart's address indicated a robust faith in the future of Canada, and referred to the wonderful development of the north country. Mr. Crerar pointed out that while engineers had already played a great part in the development of the country, yet as Canada continued its growth quite as great, if not greater, engineering problems would have to be faced in the future. Mr. Fisher, Professor Nobbs and Mr. Mickle brought the greetings of the organizations they represented.

Everyone attending this Forty-fourth Annual Meeting felt that its success was due to the untiring efforts of the Ottawa Branch, and that the previous Ottawa meetings had, if possible, been surpassed.

Alexander Joseph Grant, M.E.I.C.

President of The Engineering Institute of Canada

The approaching opening of the Welland ship canal, giving the great freight carriers of the upper lakes access to Lake Ontario, will be a notable event in the history of transportation in North America. This canal, with its terminal harbours and flight locks, is an outstanding engineering achievement, and it is peculiarly fitting that The Engineering Institute of Canada should choose this year, as its President, the man upon whom the responsibility has rested for the successful completion of this great work.

Alexander Joseph Grant, M.E.I.C.

The highest office in the gift of The Institute has been conferred upon one of its eminent members, Alexander Joseph Grant, the engineer in charge of the construction of the Welland ship canal, and a man of ripe experience and mature judgment. Mr. Grant, long connected with the Niagara Peninsula Branch, has already served The Institute as vice-president, and has now been chosen to direct its destinies as President for 1930.

Mr. Grant was born in Scotland on May 10th, 1863, at Dufftown, Banffshire, and came to Canada in 1872. He was educated at the University of Ottawa and St. Mary's College, Montreal.

His professional career began in 1880 on a survey party under H. D. Lumsden, for the Canadian Pacific Railway, west of Winnipeg. In 1883 he worked on the Baie des Chaleurs Railway, and in July 1886 he entered the outside service of the Department of Railways and Canals by joining the engineering staff of the Cape Breton Railway, under Hiram Donkin, M.E.I.C., where he was assistant engineer on the construction of the railway from 1887 to 1891. In the latter year he was transferred to the engineering staff of the Soulanges canal under Thomas Monro, remaining as an assistant engineer until the completion of the canal in January 1903, when he was appointed to the position of engineer in charge of the Port Colborne improvements. Here he remained until April 1906, when he was promoted by the department to the position of superintending engineer of the Trent canal.

During his tenure of this appointment, the construction of the Ontario-Rice Lake Division of the waterway was carried out, and the surveys and plans made for the Severn River Division of the canal. The works for improving the navigation of the Severn river were begun under his supervision, but, owing to war conditions, were suspended in 1916-17.

On January 1st, 1919, Mr. Grant was transferred to his present position as engineer in charge of the construction of the Welland ship canal, which project is now nearing completion.

Mr. Grant joined The Institute before its change of name, having been elected an Associate Member on October 8th, 1891, and a Member on November 21st, 1901.

His well-deserved professional reputation rests on a solid basis, and he is an example of the excellent type of engineer in the service of the Dominion Government. Frequently such men as Mr. Grant are not well-known to the general public, but it is to their professional capacity that the sound design and substantial construction of our great public works are so largely due.

Address of the Retiring President

Brig.-General Charles Hamilton Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C.

Delivered before the Forty-fourth Annual General Meeting of The Engineering Institute of Canada, Ottawa, Ontario, February 12th, 1930

Gentlemen:—

It is with interest that we have listened to the Reports of Council and of the various Committees, during this day's business session, and I am sure that you will all realize that the members of your Council and of these committees have put into their work of the year much of their time and effort to guide the affairs of The Institute through this period. I wish personally to thank the members of these most important bodies for their generous assistance to The Institute, and especially do I desire to express my deep appreciation of the untiring and able efforts of the chairmen of these committees.

I desire also to record my sincere thanks to the Secretary for his able and constant assistance to me during my term of office as President and to assure you that his helpful efforts in this respect have been distinctly reflected by the office staff in their loyal support.

To the officers and members of the twenty-five Branches of The Institute, spread across the Continent, I offer my congratulations on the progress they have reported and I wish for them continued successful years for the future.

The Engineering Institute, as the national foundation of the engineering profession, upon which has been erected the technical structure of Canada's development, is more than ever recognized throughout the country. Its solidity, its quality, its broad extent are all reflected in the type, ability and wide interests of its members.

The wisdom of the founders and of their successors in office throughout the various periods of The Institute's history, is now amply manifested in the wide outlook of its membership comprising as it does, professional men engaged in all the principal spheres of engineering. In this respect our Canadian organization is, with one exception, unique in the national engineering societies of the world.

As a nation-wide organization, with its membership approaching five thousand of all classes, it is so geographically distributed from coast to coast as truly to represent all those regions of the Dominion where engineering activities are being carried on.

It is with no small degree of pride in our profession that we survey the broad scope of the service which is being given to the country in the development of its resources. We receive with gratification the generous assurances of our fellow-citizens discribing how indispensable the engineer is to this young country and how his versatility is called upon to contend with the many varied problems which are peculiar to Canada.

With this sense of pride but with one of humility, we can pardonably record the work which has been done and is today being done by the engineers of Canada, and it is with this view that I now offer to you my retiring address on the subject of "The Extent and Quality of Canadian Engineering."

The Extent and Quality of Canadian Engineering

Once again we are assembled in the Annual Meeting of The Engineering Institute to consider our progress during the past year and to endeavour to foresee the future. This Forty-fourth Annual Meeting marks a distinct stage in the history of the organization and indeed this year provides an index to the unprecedented progress of engineering in Canada.

It may be a platitude to draw attention to the advances and diversities which have made their appearance in recent years, especially since the war. If, however, we wish to look at the engineering profession and to visualize the kaleidoscopic readjustments made necessary by modern invention, application, and practice—even only in the period of the past five years—we will do well to think about these successive advances and their significance.

In considering the diversity of engineering, we can well reflect upon this progression in Canada during the past few years, embracing as it has:—agriculture, now passing into the mechanized age; aviation, in the air business of the nation; railway transportation in its newest motive power and its march to the far north; water transportation on the Great Lakes; our great harbours, with their grain elevators; the disclosures of our mineral resources in the northern portions of the country; the developments of paper manufacture from our forest resources; our metallurgical and chemical industries; structural engineering in the construction of huge buildings; unprecedented development of water power, both in efficiency and quantity, and its electrical and mechanical application to the thousand and one industries for providing new commodities only made possible by having available ample power.

As we look back to the history of engineering in Canada the past forty or fifty years, we now can see how some of the problems, apparently similar in their beginnings, have come to their present day magnitude and complexity through the natural growth of the country and the efforts of its citizens to take advantage of the rapid advances of science and invention.

This Annual Meeting of The Institute in the capital city of Ottawa this year brings to our thought a historical reminiscence bearing on our engineering development, which, at this juncture in our history, it may be well to record.

Seventy years ago there was incorporated under the laws of Upper Canada what appears to be the first engineering organization in Canada. It was called the "Association of Provincial Land Surveyors and Institute of Civil Engineers of Canada." Its first General Meeting was held in Ottawa on Wednesday, the 10th of October, 1860. The composition of this organization was largely land surveyors, but there were also numerous civil engineers and architects. One item of business at this meeting was the establishment of an "Engineers' committee to form a Board of Examiners for admission of candidates."

The inaugural address of the president of that first meeting is of much interest as indicating the progress of engineering in the country as at that time and as anticipating the trend for the future. The first railways had just been constructed up into Ontario (the old Grand Trunk). Extensions of roads and railways and the opening up of new country appeared to be in the mind of everyone. Expressions such as the following are to be found in this president's address:—"Road engineering, applicable to new countries, therefore, would be one of the most useful subjects the Association could take up" and "It is to be borne in mind that by far the larger part not only of Lower Canada, but also of Upper Canada, is still unknown and unexplored." Speaking of the upper portion of the Ottawa, he says "The best representatives of it in the most recent maps published prove, as exploration advances, to be quite visionary."

The address goes on to say "It is but lately, comparatively, that we had any engineering works in progress to observe; and latterly, it has justly been the pride of Canada to boast of having constructed some of the most extensive and stupendous works" (including the Victoria bridge at Montreal and railway suspension bridge at Niagara). A plea is then made for papers and descriptions of engineering works, bearing in mind that among the objects of the Institute are "the advancement of the interests of the members—the attainment of a higher degree of efficiency in the theory and practice—and the promotion of objects affecting the public interest." Among the suggestions put forward with regard to contributions are "Essays by experienced members on the adaption of engineering to the peculiarities of our climate, on the effects of extreme cold on structures and the action of ice in its formation and departure." How very similar this train of thought is to the one we nowadays are still pursuing in The Engineering Institute of our time! Such subjects were first principles to our engineering forefathers of those days and naturally enough are still basic with us.

This early address foresees the extraordinary position that engineering is destined to take in the development of the new country of Canada for he makes the bold statement that "It is singularly remarkable that a profession—a branch of scientific art that dates its separate existence as such from about thirty years ago—seems likely to govern the future destiny of the race more than any other pursuit of man." That too can be repeated today with similar assurance and is even more applicable today than it appeared seventy years ago.

The president's address of that day anticipated also the great development of Canada in the succeeding years by reason of the extension of railways:—"Commerce will take its course directly over continents, as formerly it did over the ocean that divided them. Interior regions before inaccessible to immigration and commerce will, ere long, be laid open to enterprise, and to none of them will the advantages of railway communication be of more importance than to our vast prairie lands on the Red river and the Saskatchewan." He seemed to have some information about the coal of Alberta for he considered that this "would powerfully contribute to render the opening of a railway by that route to the Pacific a practical reality" and he then proceeded to say, as they at that time said in England, that "men and manufactures will follow coal; and the site of future great cities and the concentrations of industrial population, are to be found where it prevails."

All these things were said in 1860, seventy years ago, by a forward-looking engineer. Could he have foreseen what succeeding decades would produce, would he, in the main, have altered his views? He obviously could foresee the march of development by the railway building of the sixties. Everyone at that time was foreseeing the Confederation of the provinces to form the Dominion. But the succeeding decades were not so easy to anticipate. So many questions of statecraft, of national ambitions, and of administration were involved with the practical problems of engineering and the material development of the country, that anyone in those days would have been courageous if he attempted to foretell the course of the young Dominion. If he had, he would have fallen far short in his estimates, as it has now turned out, for we have progressed and developed very much faster than the boldest could then have dreamed.

Who could have foreseen the networks of railways that sprung up in eastern Canada in the seventies? The Intercolonial Railway, the "bargain" of Confederation, and the enlarged Welland Canal and the St. Lawrence Canals were the answers to the transportation demands of the provinces. The movement westward had begun.

Now that we look back on the very busy eighties, it seems so reasonable that in those years the great national highway of the Canadian Pacific Railway should have come into being and entered into our national life. It seems now, to the present generation, only a matter of history that its first trainload of wheat eastward came out in December, 1885, and its first passenger train westward crossed to the Pacific in June, 1886, in five days, nineteen hours. It may seem only history that the deep water terminus at Halifax was completed in 1860 and that the great drydock there, then the largest on the continent (601 feet long, 102 feet wide), was opened in 1889. It may now only be history that the first sailing ship from the Orient with cargo consigned to the Canadian Pacific Railway arrived at Vancouver (Port Moody) with tea in July, 1886. But this is the history which was the very start of our national commerce, of our Empire trade. It was in this decade that The Engineering Institute was founded as the Canadian Society of Civil Engineers, following all this national activity.

In the nineties, the railways and the opening up of the west, brought our immigration, our beginnings of large agriculture and grain milling and our first copper mining in British Columbia, the first shipment being eight carloads to England in 1897. This decade brought the greater development of municipal engineering and saw the general introduction of electric lighting and electric railways.

It was in the first decade of the new century, however, that our engineering and the development of our national resources broadened out and began to acquire the diversity that has more recently become so distinctive in our national progress. It was in this period that our water powers began to be developed on a large scale as hydro-electric power, the most notable ones being the great Niagara developments, then the largest in the world. The steel and the pulp and paper industries acquired a distinct importance, and engineering was applied on a large scale to lumbering. The discovery of silver in northern Ontario gave the real start to its remarkable mining development, and together with the copper and nickel mining already in progress, turned the attention of mining engineers to eastern Canada. Agriculture in the west made large advances and was assisted by the irrigation projects which introduced irrigation engineering.

The second decade of the century will always be remembered by its two-fold character in our national development. The first period marked a notable prosperity in all directions, and the latter half engaged all our energies in carrying on the Great War. In both these periods there were extensive, even remarkable advances in the diversity and quality of our engineering. The early portion of the decade saw widespread application of electric power to industry by means of transmission from the many power plants which had sprung up. This activity brought on an extensive diversity in mechanical and electrical engineering. Gold discoveries in northern Ontario gave a further impetus to mining. The inception and construction of the Transcontinental and Grand Trunk Pacific Railways, and the great expansion of the Canadian Northern System again put the country into an extraordinary period of railway building, even feverish in its competition, providing as they did the second and the third transcontinental routes to the Pacific and opening up fresh agricultural regions further north.

The war period in the last half of the decade produced a distinct effect on the extent and character of our engineering. Not only were hundreds of our engineers at the front engaged in a great diversity of technical activities, thus gaining valuable and wide experience, but those who remained to fight the war at home were plunged into all manner of industrial problems and undertakings to provide those munitions and war supplies for which Canada became notable. This war period was, so far as Canadian professional engineers were concerned, a distinctive one of railway, municipal, mechanical, electrical, road, dock, and mining engineering of such wide diversity and location in the different war theatres that they came back to civil life rich in new engineering experience and organizing ability.

The third decade, that which has just now ended, has been by far the most remarkable in engineering that this country has yet experienced. To appraise the value of all that engineers have contributed to the country's development during the past ten years would be out of the question, but it is recognized on every hand as being a very large factor in the material progress of the country.

There are many notable hydro-electric undertakings which were constructed and brought into operation during this ten-year period, mainly the following:—The Queenston plant at Niagara Falls of the Hydro-Electric Power Commission of Ontario with its output of 550,000 h.p., the largest single plant in the world, which, with other plants, brings the total of the Commission's capacity up to its recent peak output of 1,200,000 h.p. The Duke-Price plant on the Saguenay river, Quebec, with over 500,000 h.p. The newer plants of the Shawinigan Water and Power Company in Quebec which, with its plants previously built, bring its total capacity up to 625,000 h.p. and with other recently acquired sources, bring its available power to over 800,000 h.p. Three new plants on the Gatineau river, Quebec, aggregating 430,000 h.p. Plants in the Maritime Provinces built by the Provincial Governments and the paper industry aggregating 120,000 h.p. New plants for the paper and mining industries in northern Ontario aggregating over 200,000 h.p. New plants on the Winnipeg river comprising those of the Winnipeg Electric Company and extensions to the city plant which aggregate 225,000 h.p. since 1920. The new plants of the British Columbia Electric Company mainly for transmission to Vancouver and the West Kootenay Company, which aggregate nearly 200,000 h.p., with several very large additions at present under construction. With all of these there have been constructed long transmission lines, the most notable of which are the Ontario Commission's line from Gatineau to Toronto, 260 miles, at 220,000 volts, and that of the Shawinigan Company from the Saguenay to Quebec, 136 miles, at 165,000 volts.

Bridge engineering has, during the past decade, been quite marked, not only in steel but in reinforced concrete. In the larger cities many new structures have been built which formed a part of the remarkable municipal expansion which took place in this period. Throughout the various provinces, especially in the east, the road construction programmes have included hundreds of steel and reinforced concrete highway bridges.

Highway construction itself has run into many thousands of miles of new work in all the provinces of the Dominion, a large portion of which has been of concrete type. There are now many trunk motor highways in Quebec and Ontario and various ones in the western provinces, while a through transcontinental highway is all but completed.

Building construction too, during this decade and especially in the past few years, has formed a large part of the expansion and progress of prosperity. It has been notable in its recent yearly increases at rates from 10 to 22 per cent in value in all types of large buildings and in all provinces from stores and industrial types to schools, churches, hospitals, banks, and public buildings. The value of the yearly construction has trebled in ten years until last year it was almost 600 million dollars. This has demanded the attention of a large proportion of the engineering profession in conjunction with the architects.

In communication engineering there have been very great strides during the past ten years. In the telephone field by the rapid adoption of the automatic apparatus and the expansion and extension of the systems, a new generation of telephone engineers has come into being. This is even more marked in the wireless and radio which, since the war, has become so much a part of our daily life as to be now inseparable from it. The demand for radio engineers seems to be increasing by geometric progression.

What is to be said with regard to the increasing establishment of industries and manufactories which have grown up with all this activity during the period, can only be indicated. The enumeration of those basic industries of food, flour milling, steel, wood, and textile products; those which comprise agricultural, mechanical, hydraulic, electrical, and other machinery; those of railway equipment and automobiles; of cement, glass and clay industries and those of the rubber, paint, sugar, beverage and other chemical industries, only partly visualize the many fields in Canada into which the engineers of this decade have entered.

In all this great national activity, the engineering in the civil services of the Dominion and the provinces has greatly expanded in volume and diversity, its importance in the national development and to the various regions and communities being served, has been very much greater than in earlier days and the abilities displayed have been so remarkable as to bring praise from all quarters of the world. Into this have entered the engineering services of railways, canals, river improvement, harbours, docks, public buildings, highways reclamation, topographical and geological surveys, water power, aviation and wireless communication.

This picture of the past decade, and indeed of the preceding decades, would not be complete without the inclusion of engineering education in its relation to the many activities of the country and to the quality of the engineering ability which has entered into them. Thirty years ago there were but two universities in Canada which provided regular courses for an engineering education: Toronto and McGill, and two engineering schools: The Royal Military College and Ecole Polytechnique. There are now ten, mostly provincial universities, providing courses in from three to eight of the main branches of the profession. During the past six years these universities have been producing between 400 and 600 engineers yearly in various branches. A few years ago, following the war, there was an excess of engineers and for a while a dearth of employment. Now there is a reversal, a marked shortage of engineers to supply the large demand that has developed by reason of this activity. It is gratifying to add that recently these engineers and university graduates are practically all being employed in our own country and many are returning who had formerly left.

Neither would the picture be complete without including the very valuable research agencies that have been established by the universities and the governments. The National Research Council at Ottawa and the Ontario Research Foundation at Toronto are performing most valuable services in co-ordination with these activities of national development.

From the earlier times, when there were only three or four classes of engineer, we have now emerged with a diversity of engineering which counts the branches of the profession in many times the number. These have been developed by our growing requirements and by advancing civilization and discovery. They have had their influences of course from Britain and from the United States but at the most these outside influences have assisted us only in so far as adapting practice elsewhere to our own peculiar

Canadian requirements. After all, that is the spirit of engineering and indeed of all scientific practice the world over. It is international but it becomes national practice by its employment under peculiarly national conditions.

It took some time after the war for us to reconstruct and change to peace conditions. To absorb our energies in civil occupation and to properly distribute them in the different fields of engineering caused some dislocation and many readjustments. However, when the new conditions were met and the readjustments accomplished, the progress of the country was marked and as the years followed each other with their fresh advances in all engineering fields, we realized the great diversity and the high quality of Canadian engineering.

The past decade has seen the acquisition by the government and the reconstruction and consolidation of the two newer transcontinental railway systems into the Canadian National, of which, as a nation, we are justly proud, now with its 23,000 miles of operated system. This period has seen great advances in railway organization and operation and in new equipment adapted to our Canadian conditions, by both of our great systems. The ten-fold increase in the use of the automobile has brought about yearly programmes of new road construction which have demanded contributions from many engineering fields in civil, mechanical, and electrical work.

In water transportation and all the engineering which attends it, there has been remarkable activity. Within the decade our overseas shipping capacity has been more than doubled on both oceans and the expenditures by the Government on harbour works for it have run into tens of millions. On the Great Lakes progress has also been marked by a three-fold increase in tonnage passing through our existing canal systems, now eight million tons per annum. This period has marked the construction of the New Welland Ship Canal, the greatest in the world with the exception of the Panama. With its depth of 27 feet and locks 860 feet long, 80 feet wide with 30 feet depth of water on the sills it becomes the measure of what the new St. Lawrence and Great Lakes navigation system will ultimately provide for ocean shipping to penetrate to the heart of the country.

Again our agricultural industry has claimed its position as first of our industries by more than doubling the crop yield in the decade, the maximum for wheat being 560 million bushels in 1928. The significant feature of this, however, lies in the rapid change that has come over the industry in these later years by the processes of mechanization, due to the adaptations of motor equipment. This has been rapidly replacing man and animal labour, especially on western farms. That this is so is evidenced by the absence of the harvesters' excursions which were an almost national summer event in the two previous decades but which, in the past two seasons, have been discontinued. This really means the entry of the mechanical engineer into this industry in a new and a very large way.

In the development of our forest resources, the past decade has provided what has already been called "the miracle of paper." It has indeed been a miracle in its rapid development, in its magnitude as an industry, in its distribution among five of our provinces, and in its widespread demand on the engineering profession. It is now our second greatest industry, not only in extent, but in value in our exports. This has brought prominently into the Canadian industrial field the chemical engineer in co-operation with nearly all other branches of engineering.

Mining, during the decade, has taken an entirely fresh hold on the activities of the country. The gold, silver, copper, and nickel mining of northern Ontario has trebled in this period and production has reached a value of well over a hundred millions. Ontario is now producing a third of the output of the Dominion, British Columbia has attained a quarter of the whole and Quebec, Manitoba and Saskatchewan have come actively into production of copper, silver, and zinc. The great oil fields of Alberta are also new since the war. The coal mines of Nova Scotia and British Columbia have greatly increased their output and Alberta coal has, during the decade, come into the national picture. The discovery, within recent months, of large deposits of coal of the lignite type in northern Ontario, may quite change the fuel balance of the country where formerly we had coal only at the two coasts. Iron mining, too, has been revived by encouragement of the means of treating our vast quantities of low grade ore. The fact is that, within the past few years, we are just coming to realize the significance and the possibilities of the great pre-Cambrian shield which lies across Canada from Labrador to Saskatchewan and which, up to the present, has been explored in any depth only at a few localities:—Rouyn in Quebec; Cobalt, Kirkland, Porcupine, Sudbury, and Michipicoten in Ontario; Northern Manitoba and Flin Flon in Saskatchewan.

Metallurgical industries have fast followed the mining during the decade and now, added to the older copper and nickel plants in British Columbia and Ontario, new ones in Quebec and Saskatchewan have been quickly coming into operation. These, with the expansion of our steel industries, have created a distinct demand for Canadian metallurgical engineers.

The development of commercial air transportation during the past four years has been very marked. It is naturally another outcome of the war whereby we have the advantage of many trained airmen. There are certain geographical, economic, and climatic features that are peculiar to Canada with reference to air transportation. In some of these respects Canada has already been leading all countries as in forest patrol, mapping, prospecting for minerals and exploration in the far north. In the organization of commercial flying routes, ground organization, airports and the industries attendant on aviation, the engineering profession is having a large part in an entirely new field.

The past decade has been most remarkable in the development of our water power. There had been notable construction in the two previous periods but upon the conclusion of the war, Canada entered into large programmes of development in all parts of the country from Nova Scotia and New Brunswick to British Columbia. The activity has been maintained throughout the whole period and now at the end of the past year it is announced by the Water Power Branch of the Dominion Government that, whereas the total installation in Canada in 1920 was 2,460,000 h.p., there is today 5,720,000 h.p., or an increase of 125 per cent in ten years. There is in Canada today 0.6 installed horse power per capita, which places this country in second place in the world, Norway still being first. Of these totals Quebec has increased in the 10 years by about 1,650,000 h.p., bringing its total to nearly 2,600,000 h.p.; Ontario has increased about 830,000 h.p. to a total of nearly 2,000,000 h.p.; and British Columbia about 300,000 h.p. to a total of 600,000 h.p.

That the quality of the engineering necessary to have accomplished these things is of the highest, there can be no question. That our heavy transcontinental passenger trains can now cross Canada in the dead of winter, making the 2,900 miles in less than four days and arrive on the minute, is certainly an achievement. That our huge Niagara and Quebec hydro-electric power plants can continue absolutely reliable operation producing hundreds of thousands of horse power continually, year in and year out, with interruptions, if any, measured only in seconds, is another achievement. That our steel mills can produce the largest and best railway rails and our locomotive works the heaviest and fastest engines in America, are matters of pride. That we can build such a stupendous public work of such high quality as the New Welland Canal, is an outstanding achievement of Canadian engineering ability. That our great Quebec bridge takes its place with the greatest in the world, is a further proof of quality and Canadian ability. That our manufactories can now produce the largest hydraulic turbines and electric generators, are accomplishments that have attracted universal attention. That our harvesting operations, our grain elevators, our nickel and our paper production are unique in the world, display a combination of the highest qualities of Canadian engineering and business ability.

The enumeration of the varied activities during these decades and especially of those of the one just closed, while giving us some picture of the great strides which the country has been making, does not quite get us up to date—to this year of 1930.

In order to bring this survey closer home, both geographically and in point of time, and to place on record more in detail on this occasion the remarkable engineering activities which are actually in progress in Canada today, it may be useful to review or tabulate them proceeding from coast to coast. This review of all branches of engineering covers the more important works which have been under construction in 1929 or on which construction is proceeding in 1930.

Engineering Activities in Canada 1929-1930

Halifax, N.S.—New grain elevator recently completed, now doubling capacity.
Additional docks under construction.

Sydney, N.S.—Production of 127 lb. steel railway rails 39 ft. long, heaviest yet rolled, on severe specification. A second order now going through.

Liverpool, N.S. — Three new N.S. Government hydro power plants on Mersey river; 20,000 h.p. just completed and installation continuing.
New paper mill of Mersey Company completed and commenced operation in 1929, 250-ton mill.

Saint John, N.B.—Two new docks each 1,250 ft. for ocean ships. Harbour improvements to cost 5 million proceeding. Bridge under construction over harbour. New grain elevator 2,500,000 bushel capacity.

Grand Falls, N.B.—New power plant completed 1929 for 40,000 h.p. 20,000 more now being installed.

Dalhousie, N.B. — New paper mill being constructed by Can. Int. Paper Co., also a pulp mill near Chatham.

Moncton, N.B.—Oil fields being developed; a new area, producing heavy fuel and lubricating oils.

Anticosti Island—Wood pulp supply on large scale under development supplying four paper companies in Eastern Canada.

Gaspe, Que. — Highway around peninsula completed summer of 1929. Railway being reconstructed by Canadian National Railways.
Minerals and oil being discovered.

Chicoutimi—New harbour works and channel Saguenay river under construction; 20 ft. depth at low tide.

Arvida, Que. — Power plant at Chute-à-Caron under construction for American Aluminum Co. Arvida plant (Second largest aluminum plant in world). Power development 250,000 h.p. initial, 750,000 ultimate.

Isle Maligne, Que.—The Duke-Price power plant on the Saguenay river fully completed in 1929 with 500,000 h.p.
Transmission line Shawinigan Power Co. from this plant to Quebec, 136 miles completed 1929.

Murray Bay, Que. — New Manoir Richelieu hotel completed June, 1929, replacing old one burned September, 1928. Winter construction in reinforced concrete accomplished in 9 months under wooden housing heated for zero weather.

Quebec—Remainder of 5,000 ft. docking wall completed for harbour 1929.
Harbour shed 1,700 ft. long and 14 miles tracks for 1930 with 3 new grain elevators each 2 million bushels following.
Roadway constructed over Quebec bridge for motor vehicles.

St. Maurice River — Storage dam for power under construction on Mattawin (tributary) for 33 billion cu. ft. to be operated by Quebec Streams Commission.
Shawinigan Power Co. added 43,000 h.p. unit (No. 8) in 1929 and is adding two 25,000 h.p. units at Grand Mere and one of 30,000 h.p. at La Gabelle plant in 1930. This company also expects to commence in 1930 construction of a new plant on the Upper St. Maurice above La Tuque, with initial power of 200,000 h.p. and transmission 150 miles to Montreal.

Three Rivers, Que.—Improvements to port facilities now contracted for (3 million).

Montreal—New harbour works and extension on a three-years programme; includes 1,000 ft. in 1929.
City street extension and subways completed.
New city main sewer completed.
High level "South Shore" bridge over harbour joined up in July, 1929, and completed in 1930.
Canadian National Railways Terminals project started; programme involving several years and 50 million cost.
Particular activity in manufacture of hydraulic and paper mill machinery. (Dom. Eng.)
Large orders continuing for bridge construction. (Dom. Bridge.)
Power Plant, Montreal Island Power Co. on Riviere des Prairies placed 72,000 h.p. into operation autumn 1929, installation continuing to 120,000 h.p. (Feature in this is adjustable propeller turbine blades for heads 18 to 26 ft.)
Building construction completed 1929:—
Royal Bank Head Office.
Bell Telephone Head Office.
Dominion (Office) Building.
Sun Life Co. (still continuing.)
Montreal University buildings (starting.)

Quebec Province — Extensive highway construction continuing.

Gatineau River, Que.—Three power plants stlil continuing installation. Fourth units, 24,000 and 34,000 h.p. to Farmers and Chelsea plants respectively and a 25,000 h.p. unit to Bryson plant all in 1929. Paugan Falls plant to be added to in 1930. This company is supplying 180,000 h.p. to Ontario Hydro, 150,000 of which is over the 220,000 volt line, 260 miles to Toronto. A new 110,000 transmission line completed 1929 to Hawkesbury.
Storage dam Cabonga completed providing capacity 45 billion cu. ft.

Lievre River, Que.—High Falls power plant under construction; 60,000 h.p. expected to be completed in 1930, ultimate 120,000 h.p.
A new (second) paper mill near Buckingham under construction and expected to go into operation in 1930.
A storage reservoir 25 billion cu. ft. under construction.

Ottawa River — Chats Falls power; preliminary construction started. Initial 100,000 h.p., ultimate 200,000 (under interprovincial plan).
Carillon power project; prospects of early commencement of 200,000 h.p. development by Ontario Hydro and Quebec interest jointly.

Ottawa — City waterworks extension, under construction, including filtration system.
Chateau Laurier extension completed 1929.
Government departmental block completing 1930.
City Planning Commission's operations continuing on a large scale.

Beauharnois, Que. — Hydro - electric power project commenced on St. Lawrence river. 500,000 h.p. by means of 15-mile canal Lake St. Francis to Lake St. Louis. First power expected in 1932. Half of this contracted for transmission to Ontario Hydro Commission.

Prescott, Ont. — Dominion Government grain elevator under construction; 5,400,000 bushel capacity.

Kingston, Ont.—New grain elevator under construction; 2,500,000 bushel capacity, ultimate 5,000,000.
Harbour extension works and new docks.
New series of locomotives ("6100" class) built for Canadian National Railways, largest and fastest on continent, 70 miles per hour for heaviest passenger trains.
Similarly new heavy locomotives now under construction for Canadian Pacific Railway; "5900" class, oil-burning, for mountains.
Construction completed and trial run made August, 1929, of new oil-electric locomotive for Canadian National Railways heavy trains—"the newest thing." (All the foregoing by Can. Loco. Co.)

Peterborough, Ont. — Particular activity manufacturing electrical and mechanical equipment for power and ndustries. (Can. Gen. Elec. and Wm. Hamilton.)

Toronto — Viaduct construction for railways at front completing after 5 years work. First trains into new station on high level, January, 1930.
Harbour development still continuing deepening to 24 ft. and new docks.
Waterworks construction; duplicate system of intake, pump house, mains and reservoir (cost 14 million).
New bridges, street extensions and reconstruction contemplated under city planning for 1930.
The Ontario Hydro Commission is constructing a second main transmission line from the Gatineau, 260 miles to Toronto, at 220,000 volts.
The Commission completed about 1,000 miles of new rural transmission lines in western Ontario in 1929 and expects to construct about 1,400 in 1930.
Building construction completed 1929:—
Royal York Hotel (Canadian Pacific Railway; cost 16 million, completed in 21 months).
Star building.
Canada Permanent.
General Hospital extensions.
Building construction continuing 1930:—
Bank of Commerce Head Office (32 floors).
Eaton's new store.
Federal building (Custom House).
Canada Life building.

Niagara Falls—Additional unit Queenston plant Ontario Hydro, 55,000 h.p. (the 10th).
A second main transmission line to St. Thomas is under construction at 110,000 volts.

Welland Canal — New Ship Canal nearing completion after 10 years' active construction since war. Costing about 116 millions. Expected to open July, 1930 for through traffic. Locks 860 ft. long, 80 ft. wide with 30 ft. depth water on sills. (Reaches 25 and 27 ft. depth.)

Hamilton—New docks Can. Steamship Co.
Street railway extensions (about 2 million).
Special activity manufacturing electrical equipment for power and industries (Westinghouse).

London, Ont.—Reconstruction of streets and subway crossings for railways commencing. (Total cost about 4 million.)

Windsor — Highway "Ambassador" suspension bridge, Detroit river, completed 1929.
Highway tunnel under Detroit river under construction; expect complete 1930.
Canadian National Railways terminal works and shop expected to commence 1930.

Collingwood—Ship building on Great Lakes; 3 new vessels from here in 1929.

Midland — New 2 million bushel grain elevator commenced to bring total capacity to 14 million bushels.

Northern Ontario — Power plant under construction Montreal river, 13,000 hp.. to be completed 1930.
New power plant completed Spanish river, 28,000 h.p.
Mining activity continuing, especially copper and nickel.
New 500-ton smelter under construction in Sudbury district.
Coal discovery, lignite near James Bay.
T. & N.O. extension to James Bay 1930.
Fire clay discoveries, same locality.
Chemical plant construction at Copper Cliff for sulphuric acid.
Kapuskasing; completion Spruce Falls Power 1929.
Power plants completed Michipicoten river, 11,000 h.p. and transmission line to Sault Ste Marie.

Northern Quebec—Mining activity continuing at Rouyn.
Noranda Copper smelter into full operation 1929 at 2,000 tons daily capacity. Estimated copper output for 1930 to be 50,000 tons.
Zinc plant under construction (third in Canada).

"Lakehead"—Additional grain elevator capacity at Port Arthur and Fort William building to bring total capacity about 55 million bushels.
The Ontario Hydro Commission is completing a second power development on the Nipigon river (Alexander) for 54,000 h.p.

Winnipeg—Power plant under construction Slave falls, Winnipeg river, by city, initial 25,000 h.p., ultimate 100,000. Expect into operation 1931.
Power plant of Winnipeg Electric Co. at Seven Sisters falls, construction commenced 1929; initial power about 70,000 h.p., ultimate 220,000. Expect into operation 1931.

Manitoba—Mining activity in north in gold, copper, etc.
Extensions of railway to mining areas.
Completion of Hudson Bay Railway, 154 miles to Churchill Harbour; first trains over in autumn of 1929.
Churchill terminal and harbour construction by Dominion Government and erection of grain elevators; expected into operation in 1930.

Saskatchewan — Mining activity in north in copper, gold, lead and zinc.
Coal (lignite) mining and development in south Concentrator at Flin Flon mine nearing completion to handle 3,000 tons per day.

Electrolytic zinc plant at Flin Flon nearing completion (second in Canada).
Power plant at Island falls on Churchill river (Latitude 56); 40,000 h.p. initial expected ready in 1930 for transmission to above mines; 84,000 h.p. ultimate.
Steam power plant of Saskatchewan Government at Saskatoon completed 1929.
Provincial programme of road construction proceeding.

Alberta —Railway extension to north and Peace river.
Much activity in coal mining, treatment and shipment to eastern Canada.
Oil fields in very active development and operation in Turner Valley.
Peace river agricultural region being opened up; roads, municipal works, etc.

Calgary—New Bow river power development "Ghost river" plant (30 miles west); one unit 18,000 h.p. into operation 1929, two more for ultimate 54,000. Transmission connected with other Bow river powers to Calgary and new line being built to Edmonton.
Additional water supply by city duplicating gravity system from foothills (expenditure 4 million.)

British Columbia—New power extensions of B.C. Electric Co. as follows:—
Ruskin Plant (Stave river) under construction first unit 43,000 h.p. in 1930 and a second expected in 1931.
Bridge river plant under construction includes 13,200 ft. tunnel and head of 1,500 ft. Ultimate capacity intended 600,000 h.p. Work has been progressing for several years. Expected initial installation 60,000 h.p. in 1933. Transmission 140 miles to Vancouver.
New power plant by West Kootenay Co. at Slocan, 75,000 h.p. completed 1929. Same company about to commence new one for 80,000 h.p. on Pend d'Oreille river.
Preliminary work started on railway in northern British Columbia from Stewart at coast eastward to Fort Grahame on Finlay river for new mines.
Extensions to plants of Consolidated Smelters (Trail) for copper, silver, zinc, lead, aggregating cost 7 million. This includes new sulphuric acid plant for fertilizer manufacture (soluble phosphate and ammonium nitrate form). All now under construction.
Nitrogen fixation plant in connection with above for making synthetic ammonia and hydrogen by electrolysis. Electric power from West Kootenay Co.
Additional hydro-electric power project of Powell River Co. at coast on Lois river now commencing. Initial 18,000 h.p.
Dominion Government Highway construction on new programme through Rockies, 150 miles, in progress.

Vancouver—Harbour works continuing on a large scale, total now 13 miles developed water frontage.
New grain elevators construction bringing total capacity to 14 million bushels.
New bridge under construction across "Narrows" to North Vancouver.
City street and municipal works extensions.
Building construction, third largest in value in Canada in 1929. Five commercial buildings aggregated 10 million.

Victoria, B.C. — Jordan river power plant of B.C. Electric now extending and installing fourth unit, 18,000 h.p. to be completed 1930.
Final completion 1928-1929 of Dominion Government dry dock at Esquimalt, 1,150 feet long, 126 wide at sill, 150 feet at coping and for 30 feet depth at low tide. The largest dry dock on the Pacific coast.

GENERAL

Agriculture — The introduction of the "Swather" and the "Combine" harvester into the Agricultural industry the past few years has culminated in a large production the past year by the manufacturers. The indications are this will increase in 1930 in all fields of agricultural mechanization.

Railway Extensions—During 1929 there has been a marked activity in railway extensions throughout Canada, mainly in the west, and all trending northward.
Betterments and new equipment have also formed a large part of the programmes of the two railway systems.
The Canadian Pacific Railway in 1929 completed over 300 miles of new lines in the west and spent 30 million in new engines and rolling stock as well as huge sums on new ocean ships.
The Canadian National Railways by authority given by parliament in 1929 commenced the construction of 700 miles of extensions on the 1929-32 programme, 550 of which is in Saskatchewan and Alberta. During the year construction was continued on several hundred miles previously authorized.
Programmes for 1930 for both systems include many miles of new lines and betterments. The Canadian Pacific Railway only yesterday, announced its programme for 1930 proposing to expend 50 million.

Civil Aviation—Increased activity in employment of air transportation across the country in 1929. New routes and establishment of air ports and "ground organization" by Government, municipalities and private interests. The Dominion Government in 1929 has lighted and prepared a total of 1,000 miles for night flying and follows in 1930 with a similar programme. Development of air mail, air exploration and air prospecting in northern regions. Large increases in industries supplying equipment. Indications are that these activities will increase in 1930.

Radio Communication—Expansion, by government and other agencies, of communication throughout country and especially to stations in far north, extending from Hudson Straits to Arctic Ocean.

In tracing through the increasing engineering activities of this country for the past decades, endeavouring to visualize their progress and sequence and to relate the quality of the engineering ability that has been necessary, it is quite obvious that what we have produced has been by our own initiative, by our own efforts and by our own native abilities. These things have been accomplished, in spite of what once appeared to be our geographical and climatical handicaps. We have gradually discovered our resources and our assets which our forefathers suspected but faintly guessed. Even today, we in this generation, can but dimly imagine the possibilities of the distant future, but we are beginning to appreciate the immensity of these natural assets and to realize how best they may be turned to our advantage with the march of discovery and the introduction of new methods of use with the changing times.

No one can say that we are at the end. Far from it. It does not now require much imagination to look into the more immediate future in view of the activities of the present. If these national activities be projected for a futurist picture of only the next five or ten years, we may gain a fair idea of where the country is heading in its material advancement. It may not be too optimistic to foresee in this picture many of the following developments in this further expansion:—

1. The extension of agriculture with new areas further north where newer types of weather-resisting hard wheat may be developed and grown, may bring into production in the Canadian west, quantities approaching a billion bushels yearly, enabling the export of two or three times as much as heretofore. When this happens the engineering of agricultural equipment and of grain storage, milling and transportation will double the present.
2. Rail transportation constantly reaching out northward into new zones, may alter its present geography. It is conceivable that the further development of agriculture, mining and forest resources may bring about new routes into northern Quebec and Labrador, to James Bay, to the regions west of Hudson Bay and Churchill and across to the Pacific between latitudes 55 and 57.
3. The inevitable further development of our ocean ports will carry them far beyond their present trade limitations on the Atlantic and Pacific, both in winter and summer.
4. The development of the enlarged St. Lawrence and Great Lakes waterway now almost within sight, will bring our inland ports into easy ocean connection for cargoes of large dimensions from the heart of the continent, either on direct routes or by single trans-shipments, and give a great impetus to water transportation.
5. Air transportation, now arrived, will expand far beyond present conceptions. No one can foresee what this may mean in Canada's development, particularly northwards.
6. Mining, now well started, will accelerate its development across Canada throughout the pre-Cambrian areas, not only in doubled or trebled outputs of precious and economic minerals now worked, but of others known to exist.
7. Metallurgical and similar processes will be very greatly increased in extent and application. Normal processes will develop with other progress. To treat Canadian ores or materials which have special peculiarities, however, new processes will inevitably be developed by necessity, as, for example, our low grade iron and coals, our oils and tar sands. Fuels in proximity to such mining and metallurgical works will be a large factor, especially in northern Alberta and northern Ontario (if coal is found in large quantity). The transformation of our coals into their chemical constituents by liquefaction or otherwise, following recent research progress, will doubtless be among the earlier steps.
8. Water power development will also continue to increase for some years to come at a still greater rate. Installations even in present programmes ensure this. More remote prospects and programmes themselves are not unduly optimistic when power is considered in conjunction with development in other fields. The most significant fact regarding water power development in Canada is that today the installations total less than 14 per cent of the aggregate developable power of all water sources. A marked economic advantage we have is that most of our water power is contiguous to the other great resources of the mine and the forest. When the great power resources of the St. Lawrence are fully brought in, to the extent in Canada of nearly four million horse power, and with deep water transportation alongside, these combinations will place Canada in a singularly advantageous position for further production of all kinds. It is notable that heretofore the curve of increasing Canadian production has closely followed the curve of increasing development of her water powers.

These are some of the tasks which we, as Canadians and Canadian engineers, have before us. If they are tasks which we may not approach lightly, we will the more readily remember that such tasks have their rewards. The rewards are in the progress and further development of Canada for the decades to follow. It is clear, from past experience and achievement, that we can carry our country a very great way along the road to national prosperity by diligent, careful, and skilful management. Moreover, as a nation of alert and energetic people, we can do it ourselves, with our own financiers, our own business men, and our own engineers.

OBITUARIES

Albert Thomas Spencer, A.M.E.I.C.

Members of The Institute will learn with regret of the death of Albert Thomas Spencer, A.M.E.I.C., which occurred at Montreal on January 26th, 1930, following a long illness.

Mr. Spencer was born at Port Morien, N.S., on February 18th, 1876, and received his primary and technical education in that province.

He commenced his engineering work in 1901 with the Dominion Coal Company, and the Sydney and Louisburg Railway, Glace Bay, N.S., in various capacities in connection with surveys, construction and mining work for these companies. From 1905 to 1907 he was transitman and chief of party for the Canadian Pacific Railway on grade revision surveys in New Brunswick, Quebec and Ontario. In 1907 Mr. Spencer joined the Montreal Park and Island Railway as special engineer in charge of surveys, and later was engaged on the construction of certain suburban electric railway extensions.

From the following year he was assistant engineer with the Montreal Street Railway and its successor, the Montreal Tramways Company, in the way and structures department, until February 1921, when he joined the staff of the Railway Department of the Hydro-Electric Power Commission of Ontario as assistant engineer. In May of the same year Mr. Spencer was appointed engineer of way for the Toronto Transportation Commission, and was in charge of the extensive rehabilitation and extension programme of trackwork done on the Toronto system from 1921 to 1923.

In April 1924 Mr. Spencer was appointed assistant to the general manager of the Toronto Transportation Commission, of Toronto, which position he held until December 1926, when he returned to Montreal as general superintendent of construction and maintenance for the Montreal Tramways Company.

Mr. Spencer's splendid executive capacity and outstanding ability as a street railway engineer won him a widespread reputation in the United States and Canada. He was appointed a member of the standing committee on the way and structures division of the American Electric Railway Engineering Association. As a chairman for a special committee of that Association, he conducted a study on the use of alloy steels in special trackwork. He was a member of the Association of Professional Engineers in both Quebec and Ontario, and a member of the American Society of Municipal Improvements. Mr. Spencer joined The Institute as an Associate Member on October 12th, 1905.

John William Harkom, M.E.I.C.

In the death of Lieutenant-Colonel John William Harkom, M.E.I.C., which occurred at his home in the Eastern Townships, Quebec, on February 16th, 1930, The Institute has lost one of its first members.

Colonel Harkom was born at Enfield, England, and was in his eighty-third year at the time of his death. He came to Canada at the age of twenty-one, and engaged on a survey for the Northern Railway from Toronto to Barrie, Ont. He was employed as an engineer by the Grand Trunk Railway, the Canadian Pacific Railway and the Canada Foundry Company. Colonel Harkom received his early training at the Enfield Rifle Works, England, and was one of the oldest members of the Canadian militia in Eastern Canada.

Colonel Harkom joined the Canadian Society of Civil Engineers at the time of its incorporation, on February 24th, 1887.

Ulric Valiquet, M.E.I.C.

It is with regret that we record the death of Ulric Valiquet, M.E.I.C., which occurred at his home at Ottawa, Ont., on February 3rd, 1930.

Mr. Valiquet was born at Terrebonne, Que., in 1856, and received his education at the Terrebonne College, with an additional two years of private tuition in mathematics.

In 1873 he secured the position of assistant engineer to the late William Kingsford, then chief engineer of the Department of Public Works, which then included Government railways. He was occupied at harbour works on lakes Ontario, Erie and Huron particularly, from 1876 to 1880, where he had charge of dredging work and wharf construction on the Great Lakes. In 1880 he was recalled to Ottawa to prepare contract plans for numerous public works undertaken at that time, remaining in that capacity until 1889 when he was appointed district engineer of Public Works at Quebec City, and superintendent of Lorne dry dock.

In 1900, Mr. Valiquet was again recalled to the head office in Ottawa to prepare the construction plans for the high level permanent piers of the Maisonneuve end of the Montreal harbour. During that period he acted as arbitrator to settle certain difficulties arising between the department and the contractors. Mr. Valiquet had much to do with the construction of the Canadian harbour developments. He was intrusted with the preparation of the plans for the dry dock at Levis, Que., and the harbour improvement in the rivière St. Charles at Quebec City, and later was put in charge of the Saint John harbour works which included the improvement at Courtney bay and west Saint John, until 1917, when he was appointed to examine works connected with the harbours of Halifax, Toronto and British Columbia, at the same time preparing the plans necessary for the dry docks at Halifax and Victoria. He was also during this period deputed to examine all applications filed in connection with an act of 1910 to provide subsidies to those desirous of building private dry docks.

Mr. Valiquet acted as chief engineer of the Department of Public Works on several occasions. In 1920 he was made chairman of a board of engineers to examine the contract plans from the different districts, remaining in that capacity until 1924, when he retired to private life after fifty-one years of continuous service with the department.

Mr. Valiquet joined The Institute as a Member on January 28th, 1892, and on December 23rd, 1924, was made a life member.

ULRIC VALIQUET, M.E.I.C.

PERSONALS

P. D. Dalton, S.E.I.C., has joined the staff of the Geo. A. Fuller Company of Canada, Ltd., Toronto, Ont. Mr. Dalton graduated from McGill University in 1928, with the degree of B.Sc.

John C. Aitkens, S.E.I.C., who was formerly located at Pointe du Bois, Man., is now with the City of Winnipeg Hydro-Electric System at Slave Falls, Man.

H. F. Donkin, A.M.E.I.C., a resident engineer with the Canadian National Railways, is now located at Aspen, N.S. Mr. Donkin was formerly at The Pas, Man., engaged on the Flin Flon survey.

J. E. McClung, S.E.I.C., has become connected with the Alcoa Power Company, Ltd. at Arvida, Que. Mr. McClung, who graduated from McGill in 1926 with the degree of B.Sc., was formerly on the staff of the Northern Electric Company at Montreal.

E. F. Good, S.E.I.C., is now on the staff of Messrs. Harkness and Hertzeberg at Toronto, Ont. Mr. Good graduated from the University of Toronto in 1924 with the degree of B.A.Sc., and since 1928 has been engaged as structural designer with Smith Hinchman and Crylls of Detroit, Mich.

J. E. Thicke, S.E.I.C., is now employed by Aluminum Ltd., Montreal. Mr. Thicke graduated from Queen's University in 1928 with the degree of B.Sc. Following graduation Mr. Thicke took the students' test course with the General Electric Company at Pittsfield, Mass., and was later located at Schenectady, N.Y.

Lewis N. Moore, S.E.I.C., who was formerly power engineer, Montreal division of the Bell Telephone Company of Canada Ltd., at Montreal, has been transferred to Ottawa where he is assistant equipment engineer with the Eastern Ontario Division. Mr. Moore graduated from McGill University in 1927 with the degree of B.Sc.

C. Oldrieve Thomas, A.M.E.I.C., has joined the engineering staff of the Dominion Rubber Company, Montreal. Mr. Thomas was formerly with the Dominion Bridge Company, Ltd., Montreal, and in 1928 was granted patents on a metal-to-metal flexible shaft coupling without springs or back-lash. From 1923 to 1928 Mr. Thomas was on the designing and estimating staff of Canadian Vickers, Ltd.

A. H. Pattenden, M.E.I.C., who was formerly industrial engineer of the new business department of the Montreal Light, Heat and Power Consolidated, Montreal, has resigned from that position to become sales engineer with Callard and Company, Montreal. From 1918 to 1928, when he accepted the position from which he has just resigned, Mr. Pattenden was electrical engineer of the eastern and western plants of the Dominion Rubber Company, Ltd.

J. J. White, A.M.E.I.C., has been appointed building inspector of the city of Regina, Sask. Mr. White graduated from the University of Saskatchewan in 1925 with the degree of B.E. From 1915 to 1919 Mr. White was overseas with the Canadian forces and the Royal Air Force. From 1920 to 1927 he was with Miners and Ball Limited, Saskatoon, from 1923 having been superintendent of general construction work and design. In 1928 he joined the staff of C. M. Miners Construction Company, Ltd. at Saskatoon, Sask.

H. J. Edwards, S.E.I.C., is now attached to the municipal department of the Hydro-Electric Power Commission of Ontario at Toronto, Ont. Mr. Edwards graduated from Queen's University in 1924 with the degree of B.Sc. and has been connected with the Commission since that time, having at one time been connected with the Employees' Relations Department at Toronto. Mr. Edwards was previously located at Oshawa, Ont., where he was assistant to the manager.

A. C. Fleischmann, A.M.E.I.C., who since 1926 has been technical engineer on sewers commission and the design of reinforced concrete works with the Technical Service of the City of Montreal, has entered private practice as a consulting engineer in the same city. Mr. Fleischmann graduated from the University of Cluny, France, in 1922, with the degree of C.E. He also graduated from the Artillery School of Fontainebleau (France.)

T. H. Nicholson, A.M.E.I.C., is now engaged as vice-president and general manager of the Compania Nacional de Electricidad, operating the principal electric light and power, telephone and tramway properties in Costa Rica. Mr. Nicholson was formerly consulting engineer with the Brazilian Telephone Company with headquarters at Rio de Janeiro, Brazil. With the exception of five years when he was with the New England Telephone and Telegraph Company, Mr. Nicholson was on the engineering staff of the Bell Telephone Company of Canada, Ltd. at Montreal continuously since 1904.

J. G. W. Campbell, M.E.I.C., who since 1919 has been town engineer of Truro, N.S., is now connected with the Halifax Harbour Commissioners at Halifax, N.S. From 1904 Mr. Campbell was town engineer of the town of Sydney Mines, N.S., being engaged on waterworks, sewerage design and construction. In 1914 he obtained the degree of C.E. from the Ohio Northern University and in 1914 and 1915 was engaged on land surveying in Nova Scotia. In 1917 Mr. Campbell was with the Nova Scotia Tramways and Power Company, Halifax, on design and construction work, and in 1917 and 1918 he was on the staff of the city engineer of Halifax.

J. P. Chapleau, A.M.E.I.C., is now connected with the Beauharnois Construction Company at Beauharnois, Que. Mr. Chapleau graduated from the Ecole Polytechnique in 1920 with the degree of B.Sc. and in 1923 was resident engineer for the Quebec Development Company on the Alma and Jonquiere Railway at St. Joseph D'Alma, Que. In 1927 he joined the staff of the Shawinigan Engineering Company and was for a time at Hebertville station, Lake St. John, Que., and later became field engineer at Shawinigan Falls.

Archibald Cox is at present chief engineer with the Brazeau Collieries at Nordegg, Alta. Mr. Cox was for several years superintendent engineer of the City of Regina Light and Power Plant, following which, in 1924, he occupied a similar position with the Winnipeg Standby and Central Heating Plant, and in 1926 he was town engineer and superintendent of utilities for the town of Estevan, Sask. He was later in charge of all construction and mechanical departments with the Corbin Coal Company at Corbin, B.C.

K. A. Dunphy, A.M.E.I.C., is now division engineer with the Canadian Pacific Railway Company at Fort William, Ont. Mr. Dunphy graduated from the University of New Brunswick in 1907 with the degree of B.Sc. and following graduation was engaged as a transitman on the location of the International Railway. In 1909 he entered the service of the Canadian Pacific Railway Company as rodman and transitman on maintenance and was located at Medicine Hat and Calgary, Alta. Later, he was resident engineer at Calgary and at the Vancouver terminals. From 1914 to 1920 he was division engineer and bridge and building master at Souris, Man., and in 1924 was appointed division engineer at Brandon, Man., which position he held up to the present time.

J. A. Knight, A.M.E.I.C., is now designing engineer with the Beauharnois Construction Company at Beauharnois, Que. Mr. Knight graduated from the University of Toronto in 1914 with the degree of B.A.Sc. He served overseas with the 2nd Canadian Tunnelling Company and the 11th Battalion Canadian Engineers during the war and was awarded the Military Cross. Returning to this country, Mr. Knight joined the staff of the Hydro-Electric Power Commission of Ontario, and was engaged on hydraulic design with the Commission until 1928 when he was appointed to the engineering staff of the Aluminum Company of Canada at Arvida, Que., where he was engaged on the design of the power plant at Chute à Caron on the Saguenay river.

W. T. Brickenden, Jr.E.I.C., recently joined the organization of Thorne, Mulholland, Howson and McPherson, of Toronto, as mechanical engineer, to take charge of the engineering department which has been inaugurated by that firm to work in conjunction with the practice of public accounting. Mr. Brickenden graduated from the University of Toronto in 1922 with the degree of B.A.Sc., and following graduation became connected with the Under-Feed Stoker Company of Canada, Ltd. as assistant engineer. In January 1923 he became sales engineer and assistant manager with the A. W. Cash Company of Canada Limited, and later in the same year returned to the Under-Feed Stoker Company as chief engineer. In 1928 Mr. Brickenden was appointed chief engineer of the Riley Engineering and Supply Company, Ltd., and remained with that firm up to the present time.

Professor E. A. Allcut, M.Sc., M.E.I.C., associate professor of mechanical engineering at the University of Toronto, Toronto, has been awarded a Herbert Akroyd Stuart prize for his paper entitled "Further Tests on a Two-Stroke Cycle Oil-Engine" which was published in the Proceedings of the Institution of Mechanical Engineers, London, England. The prize was offered for the best paper published in the Proceedings during the years 1927, 1928 and 1929 on the general subject of "The Origin and Development of Heavy Oil Engines." This is the first time that one of the Herbert Akroyd Stuart prizes has been awarded outside of Great Britain. Professor Allcut's paper contained the results of researches carried on by him in the Department of Mechanical Engineering at the University of Toronto. Professor Allcut, who has been on the staff of the University of Toronto for ten years, is a graduate of the University of Birmingham.

A. I. Cunningham, A.M.E.I.C., has been appointed vice-president and general manager of Merritt-Chapman and Scott, Limited, general contractors, Montreal. Mr. Cunningham graduated from McGill University in 1914 with the degree of B.Sc., and was employed for the next year by the Bathurst Lumber Company, and then for a time was with the Grand Trunk Railway. From 1915 to 1919 he was in the Canadian Siege Artillery with the rank of captain. Following the war, and until 1922, Mr. Cunningham was field engineer for the St. Maurice Lumber Company at Three Rivers, later joining the staff of the Parklap Construction Corporation as field engineer on the Sherman Island hydro-electric development at Glen Falls, N.Y. In 1923-1924 he was attached to the Moreau Manufacturing Corporation at Glen Falls, N.Y., as resident engineer on the construction of the Feeder dam hydro-electric development. From 1924 to 1927 Mr. Cunningham was in charge of the construction of an extension to the St. Maurice Lumber Company's paper mill at Three Rivers, and in 1927 was resident engineer for the Canadian International Paper Company at Gatineau, Que. In 1928 Mr. Cunningham accepted the position of resident engineer with the New Brunswick International Paper Company at Dalhousie, N.B.

BOOK REVIEWS

Canadian Electrical Code—Part 1

No. C22-1930.

The long continued work of the Canadian Engineering Standards Association which resulted in 1927 in the publication of the first edition of Part 1 of the Canadian Electrical Code, received such general approval, and the code itself obtained such wide adoption, that in three years a second edition was found necessary and has now been issued.

This edition embodies the result of the work of the Canadian Engineering Standards Association Code Committee and its various provincial committees during a period of more than twelve months, and is considerably enlarged.

The new material included covers additional regulations for the protection of motor feeders and motors, and rules covering demand factors and wattage of outlets. Regulations covering garages and motion picture studios have been included in the section on hazardous locations, while motion picture and projection equipment have been dealt with in the section dealing with theatre installations. The book contains a very complete index and a cross reference list which will assist in comparisons between the present and previous editions.

This code affords an admirable illustration of the method adopted by the Association in the development of its work, for as may be judged from the list of committees given on pages 6 to 11, it is evident that no effort has been spared to obtain the co-operation and assistance of the local and provincial authorities throughout Canada, as well as authorities on electrical work who are not definitely connected with any provincial or city organization. The preparation of the code has in fact been handled on a Dominion-wide basis, and it represents a great step towards interprovincial agreement on this important subject.

Standard Specification for Steel Structures for Buildings—Second Edition

No. A16-1930

A copy of the Standard Specification for Steel Structures for Buildings, second edition, has been received from the Canadian Engineering Standards Association. This specification, originally issued in 1924, has been widely used, and the first edition having become exhausted, the committee has had the opportunity of making a thorough revision.

During the past five years the design of steel structures for buildings has undergone considerable development, and it is interesting to note that the specification now permits a unit stress for axial tension of 18,000 pounds per square inch as compared with 16,000 in the previous edition. Corresponding changes have been made in other units in order to correspond with the latest recognized practice; the column formula has also been revised, and certain changes have been made in the conditions for snow loads and wind loads. The specification for structural carbon steel has also been brought up to date.

In the preface, the committee very properly stresses the importance of making a competent professional engineer responsible for the computations involved in any structural design, and this point is of increasing importance, owing to the continued development in the size and importance of steel structures in our cities. The specification is in fact, careful to note many of the points on which the trained judgment of an engineer is indispensable, as for example in the paragraphs regarding welding and the methods to be adopted for protection against corrosion.

This publication is intended for the use of city authorities in the preparation of their building codes, and can be recommended as being eminently adapted for this purpose.

Workshop Receipts for Manufacturers and Scientific Amateurs Supplement
(Aluminium to Wireless)

By E. & F. N. Spon, Ltd., London, 1930, cloth, 7½ x 5 in., 458 pp., figs., tables, $1.50.

This volume, which E. & F. N. Spon have just issued, is supplementary to their well-known series of four volumes of workshop receipts, and brings up to date what is practically an encyclopaedia of workshop processes, dodges, and materials. The professional or amateur who consults "Spon" can get practical information on a variety of subjects, ranging from anemometers, basket-making, clock-mending, and engraving, to luminous paints, plastering, ropemaking and taxidermy, selecting only a few examples at random.

We now have a book containing recent information on subjects not to be found in the four original volumes, and the work is characterized by the same commonsense usefulness as before. It tells us how to cane chairs, test metals for hardness, do lacquering and use microscopes, use etching reagents, and do oxy-acetylene welding; these, with over seventy other topics, make up a most useful handbook.

An Introduction to Mechanics

By J. W. Campbell. Houghton Mifflin Company, Boston, 1929. Cloth, 5 x 7½ in., 384 pages, diagrs., $3.50.

Also

Numerical Tables of Hyperbolic and Other Functions

By the same author and publisher. Cloth, 5¾ x 8 in., 76 pages, tables, $1.25.

Dr. Campbell states in the preface of his book that the elementary principles of mechanics are more poorly understood by students than the elementary principles of any other subject. He quotes an eminent teacher by saying that students will solve successfully with complicated mathematical machinery problems that he is confident they do not understand, and will fail lamentably in the solution of simple commonsense problems where the canonical machinery is in the way.

The author's remedy is to teach the subject with the help of, and in conjunction with, the calculus. He has therefore used the calculus throughout. He is very sound in saying that the student should not have anything to unlearn as he progresses in his knowledge of the subject, but that rather the fundamental ideas he learns should be capable of expansion. It is a debatable point which should be taught first, calculus in order to understand mechanics, or simple mechanics to help in the comprehension of the calculus.

In order to understand Dr. Campbell's book the student should have an elementary working knowledge of the calculus and, as he proceeds, should expand this knowledge. The subject is treated rightly, with great pains, and from a purely academic standpoint. The book covers rectilinear kinematics and dynamics, plane kinematics and dynamics, gravitation, centres of mass, plane statics, some properties of matter such as Hooke's Law and friction, simple harmonic motion, plane dynamics of particles in the earth's field, moments of inertia, plane motion of a rigid body, flexure and torsion, kinematics of plane motion of rigid bodies, further conditions for equilibrium, flexible chains and strings, and the general motion of a rigid body.

The above chapter headings show that Dr. Campbell has written a very full introduction to mechanics, except in statics. His examples are designed to bring out the principles he is teaching, irrespective of whether they are practical or not. It is difficult to see how the student at the end of the chapter on "Flexure and Torsion" will be able to solve the problems, which cover a wide range in "Strength of Materials," without consulting other text-books.

The chapter on "Flexible Chains and Strings" is well written and should prove of use to engineers engaged in transmission work. Its use needs the help of the excellent tables on hyperbolic and other functions. The author has not considered the effect of comparatively long strings of insulators at the ends of relatively short spans. The existence of the tables and the fact that for long spans the effect of the insulators is usually neglected, ought to make the use of the hyperbolic formulae more general. By publishing these tables he has done a service for which engineers should be thankful.

G. J. Dodd, A.M.E.I.C.,
Assistant Professor in Civil Engineering and Mathematics, McGill University, Montreal.

Practical Design of Simple Steel Structures

Vol. 1: Shop Practice, Riveted Connections and Beams, etc.
Vol. 2: Plate Girders, Columns, Trusses, etc.
Vol. 3: Tables.

By David S. Stewart. Constable & Company, Ltd., London, 1929' cloth, 5½ x 8¾ in.; Vol. 1: 183 pages, illus., diagrs.: $3.65; Vol. 2: 215 pages, plates, diagrs.: $4.75; Vol. 3: 19 pages, tables: $1.50.

This book, which is published in three volumes, is intended as a textbook for students in engineering and for junior draughtsmen. All problems are, of course, worked out on the basis of British standard practice but the author points out where American practice differs.

The first eight chapters of volume 1 deal with problems which are usually neglected in books on structural design but which, when first encountered, present real difficulty to engineering students and junior draughtsmen. The first chapter gives a description of the various sections used in structural work together with a short section on the method of rolling structural shapes. Chapter 2 deals with the function of the structural drawing office and the amount of detail that it is necessary to show on a structural drawing to allow of the fabrication of the structure. Chapter 3 describes the method of making templates, and describes and illustrates the principal machines used in a structural fabricating shop. In chapters 4 to 8 the calculations necessary in designing and detailing splices in plates and angles are shown in great detail. Chapter 9 deals with wind pressure and factors of safety; chapters 10 and 11 with the design of simple beams and crane girders.

Volume 2 deals with the design of such structures as plate girders, crane girders, columns and their foundations, roof trusses, lattice foot bridges, and railway through plate girder spans. The method followed is to work out a design in detail in each case with accompanying notes explaining the reasons for the steps taken. The volume is illustrated with plates giving detail drawings of the structures designed. The method used in designing columns differs considerably from that used in this country as the allowable unit stress depends on the assumptions made as to the end restraint of the column. In chapter 8 a method of calculating the equivalent uniform live load for a series of wheel concentrations is given, and its use suggested in the design of short spans. In the writer's opinion, considerable time would be saved by using the actual wheel concentrations. Volume 3 contains 17 pages of tables.

The book is well printed and the illustrations are clear and well drawn. Volume 1 particularly is recommended to students and draughtsmen who are having difficulty in their first encounters with structural steel detailing.

Dominion Bridge Company, Limited

BRANCH NEWS

Halifax Branch

R. R. Murray, A.M.E.I.C., Secretary-Treasurer.
W. J. DeWolfe, A.M.E.I.C., Branch News Editor.

The January meeting of the Halifax Branch of The Institute was held at the Halifax hotel on January 23rd, Chairman W. P. Copp, M.E.I.C., presiding. The meeting was preceded by supper at 6.30 p.m. and there were 34 present, including Mayor Gastonguay and several other guests. The minutes of the annual meeting were read and approved. Committees were appointed as follows:—

Vice-Chairman	C. St.J. Wilson, A.M.E.I.C.
Papers and Meetings	R. R. Murray, A.M.E.I.C.
	C. St.J. Wilson, A.M.E.I.C.
	J. D. Fraser, S.E.I.C.
Membership	H. F. Bennett, A.M.E.I.C.
	J. L. Allan, M.E.I.C.
	W. H. Noonan, A.M.E.I.C.
	Karl Whitman, A.M.E.I.C.
Publicity	W. J. DeWolfe, A.M.E.I.C.
	L. A. Allison, A.M.E.I.C.
	J. J. Sears, A.M.E.I.C.
Students' Prize	F. R. Faulkner, M.E.I.C.
	H. R. Theakston, A.M.E.I.C.
	H. S. Johnston, M.E.I.C.

The Chairman then introduced the several guests, bidding them welcome and hoping for a pleasant evening for them all, after which he introduced the speaker of the evening, J. A. Wilson, A.M.E.I.C., who is controller of civil aviation at Ottawa, and addressed those present on "Civil Aviation in Canada."

Mr. Wilson was accorded a hearty reception on rising and he expressed great pleasure at being in Halifax again (Mr. Wilson had been here during the World War), and was pleased with the interest shown in aviation. He did not apologize for coming to speak before engineers because the members of that profession should, and do, lead in all matters which are of interest to the public and which come before them. He stated that aviation needs their help.

Mr. Wilson went on to sketch the history of flying and of experiments made by individuals and governments to foster and develop aviation, and then proceeded to the main topic of his address, "Civil Aviation in Canada."

In speaking particularly to Halifax, Mr. Wilson said that his Department does not wish any community to spend a lot of money on an airport with great expectations, only to be later disappointed in not realizing their hopes. An airport may be in or out of a city, according to conditions. With large areas of prairie land it is possible to be close in but otherwise, with the scarcity of large plots of level lands in the east, it is difficult and you must do the best you can—get in as closely as you can. Mr. Wilson explained that American fields were some distance from a city, in cases.

A very hearty applause greeted Mr. Wilson at the close of his address, which was heard with deep interest.

Mayor Gastonguay complimented Mr. Wilson on his clear and interesting address and was glad to be present. His Worship said that an airport in Halifax is a matter of financing which is engaging the active attention of the city council and he hoped for early results. He wished to resent the criticism of the local press and high government authority that Halifax is not doing all it might to put the city on the air mail route.

C. H. Wright, M.E.I.C., in a few words stressed the point that hydroplanes must be our first consideration but, to combat ice conditions in fall and in spring, and to accommodate planes from other places which use only wheels, we must have an airfield also if we are to retain our place as a high class commercial port.

W. J. DeWolfe, A.M.E.I.C., asked what effect airplanes, carrying mails from ships at sea, would have on an airfield in Halifax, in the matter of size of airfield to be constructed. Mr. Wilson could not prophesy, at present, though the subject is receiving the attention of his Department. He said we have the best of facilities for water planes but land fields are difficult because of the topography.

H. F. Bennett, A.M.E.I.C., agreed with Mr. Wright as to getting on with the job but he was not sure that all the possibilities had been exhausted. He referred to Moncton and Saint John airports and hoped to see one here in the near future.

Mr. B. F. Saunders, air pilot, and several other pilots expressed the view that the Halifax chosen site is a very good one for the purpose.

C. H. Wright, M.E.I.C., moved a vote of thanks to Mr. Wilson for his coming and his fine address, and coupled with it thanks to Headquarters for assisting in having Mr. Wilson come.

K. L. Dawson, M.E.I.C., seconded the motion and remarked that he now sees the airport question as he had not before seen it.

The motion was unanimously carried and Chairman, Prof. W. P. Copp, M.E.I.C., conveyed the thanks of the Branch to Mr. Wilson for his address, adding that we all have a clearer viewpoint than formerly.

Mr. Wilson in acknowledgment of the vote said he was glad to have been of assistance now and that he will be always ready to help out, incidentally remarking that he had made his first flight in Halifax. Several reels of motion pictures showing fire fighting by airplane, parachute jumping and other features were very much appreciated.

Kingston Branch

L. F. Grant, M.E.I.C., Secretary-Treasurer.

On January 10th, Mr. J. W. Kelly of the Portland Cement Association read a paper on "The Internal Structure of Concrete," an abstract of whieh has already appeared in the Journal.

Development of Architecture

On January 30th, 1930, a paper was presented by Major L. F. Grant, M.E.I.C., on "The Development of Architecture."

The speaker pointed out that a talk of forty-five minutes on such a subject must be remarkable for what it omitted, rather than for what it included, and then gave a brief résumé of the principles of design formulated by Ruskin.

He then gave a short discussion on Egyptian architecture, next describing that of Greece in the Periclean age, and illustrating his remarks with pictures of the Thesion, the Parthenon, and other Greek masterpieces. Next followed Roman architecture up to the time of the removal of the capital from Rome to Byzantium, which led naturally to a description of Byzantine work.

The speaker then spoke of the later Roman period, merging into the Romanesque school, and finally into the transition to Gothic, of which a number of examples were given. The Renaissance was next discussed, including the influence of the Turkish conquest of the Eastern Empire.

Turning then to modern architecture, the development of the skyscraper was traced, and a comparison made between its suitability and that of the classical type of building for modern conditions. In concluding the speaker pointed out that the skyscraper, formerly the "ugly duckling" of architecture, had been transformed into dignified and even beautiful structure, and suggested that a similar development was possible in the case of the grain elevator.

A few pictures of futuristic architecture closed the address.

Lethbridge Branch

On Saturday, January 25th, the Lethbridge Branch was singularly favoured by hearing two excellent speakers; namely, Mr. W. P. Campbell, chemist, Department of the Interior and Mr. R. S. Trowsdale, sales engineer, Canadian General Electric Company.

The subjects and subject matter were as follows:

The Water Problem in Oil and Gas Fields

by W. P. Campbell.

In what way is water a problem? What difficulties does it create?

(1) In drilling of wells.
(2) In maintenance of producing wells.
(3) In proper abandoning of wells which have become unproductive or have been abandoned for other reasons.

Only 10 to 20 per cent of oil underground is recovered, due to water being permitted to enter the oil sands from points above or below, in the drilling process, or is found in contact with the oil or gas in the drilling zone. Therefore, any measure which can be adapted to prevent this is to be welcomed.

Efficiency in oil field development is the production of oil free from water for the longest possible time in a manner to recover the greatest ultimate quantity from the underlying field.

Oil Sands

Oil and gas are found in sandstone beds and limestone formations. These act as reservoirs. Sandstone and porous fractured limestone offer less resistance to the movement of gas and oil than do shales and clay. Lack of uniformity of the structure has important bearing on recovery of oil from horizons in which water has penetrated, as the tendency is for the segregation of oil to take place in the tighter lenses of the sands, and be held there while water replaces the oil in the looser areas. The result is that the well will finally produce largely water in spite of the fact that a large quantity of oil is still in the oil sands.

Oil waters are classified in their relation to the oil producing zone as:

(1) Top water; (2) Middle water; (3) Lenticular water; (4) Edge water; (5) Bottom water.

Top water is above the oil sands.

Middle water between oil and gas sands.

Lenticular water is carried by water sands; but pinches out.

Edge water is found in oil sand in contact with the oil.

Bottom water comes from beneath the lowest oil bearing zone.

With the exception of edge water, all can be satisfactorily dealt with. When edge water appears it marks the beginning of the end of the field.

All water sands should be carefully recorded even in wild cat wells, where the primary object is information as to oil sands. The record so obtained may be of the greatest value in the event of the well proving to be a productive one. It is essential that the initial wells be drilled with percussion tools, of which the familiar cable tools are a type, for only by their use can the lesser water sands and oil and gas sands be detected and the exact depth at which they occur be determined.

In dealing with water problems, the petroleum engineer has to call in the chemist to his aid. Then in addition to logging carefully the exact depth at which water sands occur, he takes a representative sample of the water from the particular sands. The sample should be free from contamination of mud fluid and water used in the drilling operation. Government regulations make sampling of all oil water obligatory.

Oil fields are identified by the particular salts in the water. The constituents which predominate in oil field water, and the quantitative determination of which is sought are: sodium, potassium, calcium, magnesium, chloride, sulphate, lucarbarates and corborates.

There are various methods of reporting water analyses. The Palmer system is generally adopted, giving the chemical constituents of water in the exact proportions in which they are present. These may be represented graphically. This was shown on the lantern slides.

In Alberta and Saskatchewan deep waters are almost wholly chlorides of sodium and calcium of magnesium. An interesting fact is the entire absence of sulphates. The theory of this is that sulphate removal is brought about by dead organic matter or by the action of bacteria.

The amount of dissolved solids in surface water is very much lower than in deep waters.

With reliable records on hand, the petroleum engineer can estimate the depths at which water shut off jobs will have to be done, the amount and dimension of casing required for any new wells. Water which may make its appearance can be traced to its source and the trouble overcome.

The next step in a properly drilled well is to shut off the water. First ascertain exact depth of water sand; this is important as setting the casing too high is just as bad as a poor job. It is useless to attempt to pump a well dry. The only really effective method is cementation. This consists of surrounding the casing, at a convenient point below the water sand, with cement, from the bottom of the casing to a point well above the water sand. There is a feeling that anyone can do this but it really requires an expert, judging by the number of failures. No money should be spared in getting a complete shut off. Pure cement is used and ample time should be allowed for thorough setting before drilling is proceeded with. Agitation from gas or movement from other sources should be avoided during the setting period.

A simple case of cementation procedure is as follows:

(1) Circulation is established; that is, a free passage between inside and outside of casing.

(2) Neat cement is introduced into the bottom of hole.

(3) Pressure is applied on the column of cement and maintained until the cement is thoroughly hardened.

There are many methods though, and some are protected by patent.

Cementation applies chiefly to "top" and "intermediate" waters.

Water may get into producing wells through defective casing joints, or damaged casing. The producing zone itself may contain water in the form of edge water, or, bottom water may have been permitted to invade the producing zone.

When water does appear, the first step is to determine the source. If the samples have been well taken and classified, this can readily be done, and the depth at which the trouble is seated is known.

The next step is to find out how the water is getting in. When bottom water is under considerable head, the shutting off presents many difficulties. Lead and lead wool plugs have been employed with fair success but cementation, if possible, is more satisfactory. For edge water, little can be done. Examples of methods of dealing with water troubles might be multiplied. A number of slides were shown to illustrate problems as applied to producing wells.

Defective shut-offs were drawn, in which cementation had been made above or below the true water sands, thereby permitting water to travel either up or down and enter adjacent oil sands, resulting in their ruin as producing zones.

Another series of interesting slides depicted the migration of water from an abandoned well which had not been plugged. The water was shown to rise in the oil well hole and penetrate oil bearing sands to travel along these sands, entering and spoiling producing wells.

An interesting discussion followed, the subject being of very live local interest.

The paper by Mr. R. S. Trowsdale was entitled:

The Electrical Industry and its Control

Mr. Trowsdale proceeded to disillusion the members of the hope that they may have held of being admitted to some secret of the mysteries of big interests controlling the electrical industry by pointing out that the electrical industry was really in the hands of the small investors and users of power. His paper, he maintained, was to deal with administrative and mechanical control.

A short history of electrical development was given. Short because the life of electricity, as we know it, is short. A mere fifty years, the first incandescent lamp being developed in 1879. Some of the incandescent lamps were huge things, five feet high. Brief reference was made to the pioneers, Edison and Brush. The story of Edison erecting his first Canadian plant in Cornwall, Ontario, was an illustration by which to gauge the remarkable progress of electricity. Edison arrived personally at Cornwall in 1882 to install an electrical plant for the Canadian Copper Company. After an inspection the local newspaper brought out an editorial the next day, the gist of which was that electricity had seen its day and was due for failure for the simple and clear reason that the human eye could not stand the glare of the lamps. As contrast with this, in 1928 the total revenue from electricity in America amounted to 1,908,000,000 dollars. Behind this present-day huge production was a long, lone line of service which has made electricity an agency accomplishing more in production and in human comfort and convenience than any other known agency, and at a lower cost.

This has been achieved by endless research and application. Mr. Trowsdale described the setting of a research laboratory where the most eminent men obtainable of any and all nationalities are given unlimited means, time and assistance to develop and conclude their experiments.

Fifty per cent of the experiments proved at these laboratories are given to the industry in general and fifty per cent to the particular firm by whom these experts are employed.

The secondary unit in the process of development is the commercial laboratory. Here all the materials are thoroughly tested by the most scientific methods, cost of production computed and an economical commercial principle of production developed. Next are the shops and factories and so on down the line to the user.

Electrical, mechanical and chemical engineers constitute the main operative staffs and these huge electrical concerns are the greatest plants of absorption of trained technical men. Young university trained engineers from all countries are selected on the advice of their professors and invited to join the firm. At the plant they are given an extended course in their particular work, lasting 15 to 18 months. Another system is the training of apprentices for a four-year period. Positions are guaranteed. This applies to all the large firms.

With the theory of Brush and Edison, that "Work is the only thing that keeps a man fit," all encouragement is given to the employees to concentrate on their work, by relieving them of all sources of worry. This they achieve by insurance, pension and health schemes, house-building and investment clubs, etc. Also by offering valuable and large prizes for various experiments. Prizes so important that engineers throughout the world compete. Proof of the particularly fine treatment of the employees is evident by the very small labour turnover.

The consumption of electrical energy is far greater on the North American continent than in European countries, and Canada is branching out into Europe, buying up plants and installing equipment. In this country every man has as his disposal, 4½ h.p. As a result, man becomes the most productive unit.

In the material world of the industry, equipment changes are very rapid, an efficient article of to-day becomes obsolete in a couple of years. To-day a 5,000-k.w. hour machine is being reassembled, polished and placed on a pedestal in a museum, as a model for posterity, development has gone so far.

To meet the problem of the high value of real estate in congested areas, larger electrical power plants had to be designed to cover only the small floor space of the plants which they were replacing. This has been achieved by the development of the vertical compound or superimposed turbine machine. A later type is the mercury turbine, using mercury in place of water. Experiments with hydrogen as a cooling substance is proving a success. Hydrogen prevents oxidation of insulation and has lower density. Underground transmission is a goal that will soon be won and high voltage cables will then be hidden from sight and all the network of unsightly poles will be cleared away.

The magnetic switch control was greatly stressed, and it was pointed out that by its installation momentary drops in power can be provided against. Also, in plants consisting of a series of correlated units. by the adoption of the magnetic switch control if one unit breaks down all other units are automatically stopped, avoiding the necessity of a man having to turn off each individual unit.

In the branch of highways, some control of traffic from minor feeder roads to entrance to the main arteries was necessary. An electrical ear was developed, sensitive to the horn note of an automobile, the vibrations set up by the note turns on a red light on the one face and a green light on the other.

An electrical eye is used in the taking of traffic census. This consists of a light on the one side of the road trained on a sensitive cell at the other side. Passing traffic interrupts the beam of light and each interruption causes one to be registered on a dial attached to the cell. This device has numerous other uses.

Past achievements have only unlatched the door of an unlimited future in electrical development.

A film was shown illustrating the various principles and devices mentioned.

A truly interesting discussion followed.

A vote of thanks and a suitable compliment to both speakers was expressed by the chairman.

The meeting closed at a very late hour with all members very eloquent in their thanks to both speakers for two unusually interesting and well delivered papers.

Preceding the address was a dinner, and the orchestra, violin and vocal solos followed by folk singing, gave a cheerful tone to the meeting.

The Lethbridge Branch held its fortnightly meeting at the Marquis hotel on February 8th. The usual dinner preceded the meeting and orchestral selections were rendered by Mr. Morgan's orchestra, while Miss Allison entertained the gathering with very delightful vocal solos.

The speaker of the evening was Dr. K. A. Clark, research professor in road materials at the University of Alberta, who gave an illustrated talk on "The Bituminous Sands of Alberta."

Considerable prospecting has been done on the bituminous sand deposits of northern Alberta, and it has been found that in the neighbourhood of Fort McMurray there are about 1,000 square miles of these beds. They average in thickness 200 to 300 feet, and are covered by considerable overburden, except where outcroppings occur along the valleys of the Athabasca river and its tributaries.

Mining up to the present time has been carried out on a small scale, cutting back on the face of the outcroppings, but it is proposed to investigate the use of power shovels for this work.

The work on developing these sands is now being undertaken jointly by the Dominion Research Council and the Scientific and Industrial Research Council of Alberta, the latter being a committee appointed by the government of the province of Alberta, and whose activities are centred at the University of Alberta.

The Alberta organization is devoting its share of the work to the problem of extracting bitumen from the raw product, which is composed of 15 per cent bitumen and 85 per cent sand.

It was in 1920 that Dr. Clark first started his investigations and in the following two or three years he carried out many laboratory tests to determine the nature of the bitumen and the possible methods of treatment. Three general schemes of separation were considered; first: hot water separation; second: dissolving in organic material; third: retorting. The first method showed most promise and in 1923 a small experimental plant was erected at the University and good results were obtained. The process consisted essentially of mixing water glass solution with the raw sand which destroyed its viscosity, after which the bitumen was mixed in a jet of hot brine solution, and the sand permitted to settle, the bitumen rising to the surface of the settling tank and being scraped off as a scum.

The principle proved satisfactory and in 1925 a larger experimental plant was erected and 600 tons of sand were treated. Certain modifications in detail were effected, resulting in lower costs and better extraction. Last year the plant was moved to a point near Fort McMurray and was set up adjoining a quarry of sand which was suitably located near the railway. A few test runs were made before freeze-up and in 1930 it is hoped to carry out an extensive production programme.

The uses of the separated bitumen fall under two headings: road material and fuel.

Considerable experimental work has been done on various sections of Alberta highways and this material promises to play a large part in the future development of Alberta's rural highways.

Various oil refineries have investigated the possibilities of the bitumen as a fuel, and it has been found that it is readily treated by the existing cracking methods, and gives a high yield of good grade "anti-knock" gasoline.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

"The Progress of Aviation in Canada" was the subject of an address of unusual interest delivered before the Branch on January 22nd, by J. A. Wilson, A.M.E.I.C., Controller of Civil Aviation, Ottawa. The attendance taxed the capacity of the Y.M.C.A. banquet hall, and included not only members of the Branch but other prominent citizens, the staff of the local airport and almost the entire city council. M. J. Murphy, A.M.E.I.C., Chairman of the Branch, presided. During the evening the meeting was favoured with several excellent vocal selections by Mr. H. S. Austin.

The Progress of Aviation in Canada

Although the theory of flight had been known for many years, it remained for the Wright brothers to develop an engine light enough to make human flight possible. The new science progressed rapidly and by 1914 aviation was a recognized mode of transportation. During the war the scientific development of the airplane was interrupted. Since then enormous studies have been made, particularly in the United States and Europe.

In Canada, planes were first used in forest protection and exploration, a service which has now reached a high state of perfection. It was next employed by the surveyor in mapping unexplored sections of Canadian territory. Already the aviator has accomplished with his camera what would have taken 100 years to do if carried out by ordinary ground methods.

In 1927 the Canadian Air Mail was instituted, first for the benefit of parts of the country inaccessible by ordinary means, such as the Yukon and the winter service between Moncton and the Magdalenes. The air mail service has since been considerably extended.

Aviation is on the verge of great development, and that within the next two or three years. It will cost money but so do our railways, canals, telephones, etc., yet who would dispense with these. Our aerial progress depends entirely upon public opinion—"the man in the street" is the one who is to determine just how soon we are to take our proper place in the sphere of aviation.

Following Mr. Wilson's address, four reels of motion pictures were shown depicting aerial meets, parachute jumping, and also in a very graphic manner the use of the plane in fighting forest fires.

Brief remarks were made by Deputy-Mayor R. A. Frechet, Ex-Mayor C. H. Blakney, City Engineer J. D. McBeath, and Alderman Fred Brown of the Civic Airport Committee.

A vote of thanks on behalf of the Branch, moved by C. S. G. Rogers, A.M.E.I.C., and seconded by T. H. Dickson, A.M.E.I.C., was tendered Mr. Wilson by the presiding Chairman.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

The annual meeting of the Montreal Branch was held on January 9th, and was honoured by the presence of the President, Brig.-Gen. C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., Vice-Presidents Dr. O. O. Lefebvre, M.E.I.C., and W. G. Mitchell, M.E.I.C., and a number of members of Council.

The reports covering the activities of the Branch were read and will be found in the report to Council contained elsewhere in this issue. Appropriate remarks were made by the retiring and incoming chairmen, Messrs. J. A. McCrory, M.E.I.C., and D. C. Tennant, M.E.I.C., respectively.

General Mitchell, in addressing the meeting, referred to the many activities and their importance, emphasizing the necessity for increased financial support by the members. Charts and figures were shown, giving comparisons of expenditures of The Institute as compared to similar bodies in other countries.

Many other prominent members followed the President in urging the importance of raising more money for the support of The Institute's activities. A number of other important matters presently under discussion were also presented and explained to the meeting by the members of Council present.

Scientific Developments Leading to Sound Pictures

On the evening of January 30th, Mr. Paul B. Findlay, managing editor of the Bell Laboratories Record, delivered a most instructive address entitled, "Scientific Developments Leading to Sound Pictures."

Descriptions of the photo-electric cell; the string oscillograph, an instrument designed to record accurately and sensitively, alternating current wave forms used to test the new high-speed permalloy cables and their associated terminal equipment and mechanical resonators for analyzing complex currents, were given. Again emphasis was placed on the important part played by duraluminum which vibrates with the voice from the microphone, and on the intensive research work carried on in the Bell Telephone Laboratories of study of sound pressures and microscopic photography.

Mr. Findlay's explanation of the sound picture film was as follows:—Air-waves of the original sound create through the microphone, a faithful representation of themselves in an electric current. Enormously amplified, this current controls the intensity of a beam of light which is focussed on the moving films. After development and printing, the trace on the film constitutes, in its variation from light to dark, a record of the original sound waves. When this trace or sound track passes between a steady light and a photo-electric cell, the current from the cell is a copy of the microphone output. Again amplified, this current through loud speakers recreates the original sounds.

Through the courtesy of the Northern Electric Company, Ltd., a novel talkie picture was presented. This portrayed in an entertaining manner the different stages through which the "finished product" passed before completion.

Process of Zinc Coating Steel Wires

A paper entitled "The Process of Zinc Coating Steel Wires" was read by A. D. Turnball, S.E.I.C., before the Montreal Branch on January 16th, 1930.

The author, in his paper, referred to the following factors that influence the rate of corrosion of metals:

1. Chemical composition of the metal.
2. Contact with relatively electro-negative metals.
3. Stray currents.

4. Dissolved oxygen in moisture in contact with the wire.
5. Rate of motion of water in contact with the wire.
6. Acids, salts or alkalis in the water.
7. Previous rust conditions.
8. Temperature.
9. Physical condition of the metal.
10. Quantity of light falling on the metal.

It will be seen from the above possible causes of corrosion that the phenomenon is very complicated.

One of the methods of protecting iron wire from corrosion is by coating it with zinc, which gives an efficient protection as long as the zinc remains intact. Even though the zinc coating is scratched exposing the iron, the zinc being electro-positive to the iron protects the latter.

Zinc-coated wires may be classified as: (1) wiped wire; (2) unwiped wire; (3) annealed galvanized wire.

The first and second classes of wire are differentiated by the method of removing the wire from the zinc pan, while the third class covers wire that is heat-treated subsequent to the galvanizing process.

Iron and steel of the best grade should be chosen so as to eliminate the exaggeration of any defects while rolling from an ingot 2½ feet thick down to a ¼-inch rod. The ingots pass through the roughing rolls of the blooming mill and are then reheated and further rolled in the billet mill. The billets are again reheated and go to the rod mill to receive the last rolling operation. The rods are then passed to the wire mill to be acid washed or pickled. Twelve pickling vats will usually handle about 240 tons of rod in a 10-hour day. The pickling solution usually contains about 3 to 4 per cent sulphuric acid and is kept hot to accelerate the cleaning action which must be thorough to prevent trouble in the subsequent drawing and galvanizing operations. The pickling solution sometimes consists of cold hydrochloric acid, which greatly reduces the danger of dissolving out any iron carbides. The pickling acid is inhibited by the use of organic carbohydrates which prevent the action of the acid on the steel after the oxide scale has been removed. The rods are then washed and rusted, the rust acting somewhat as a lubricant in the subsequent drawing operation. The rods are then dipped in a hot lime solution and baked at about 400° F. to drive out any occluded hydrogen which might spoil the lubricant. The wire is then ready for the drawing operation. The wire-drawing dies consist of steel plates with holes of suitable size. The wire passes through successively smaller holes until it is of the desired size. The wire drawing lubricant may be either grease, soap, flour, graphite or lard depending on the type of metal, the condition of its surface and the purpose to which it is to be put. After the wire has been drawn to the desired size, it is ready for galvanizing.

In the galvanizing mill, the wire is annealed to reduce the ferrite and cementite to a finegrained austentite. This annealing is performed in pans of molten lead, and is continuous. The wires pass from the annealing bath over rollers to be air-cooled, into a tank of water to be washed, into an hydrochloric acid tank for cleaning and then into another wash-tank of water. The wires then pass into a fluxing tank containing either zinc chloride or sal-ammoniac, and are dried by passing over a hot metal plate.

The wires are now ready to be zinc-coated, two different methods being used according to whether the wire is to be "wiped" or "unwiped." The wire passes through a long bath of molten zinc. "Wiped" wire passes through two asbestos wipes to remove the excess zinc, leaving a coating that is comparatively high in iron. The wire then passes through a bath of cold water, or if a particularly tough coating is desired, the cooling bath is omitted, and the wire is then bundled. In "unwiped" wire there is no wiping action other than that caused by the surface tension of the molten zinc which forms a cone around the wire where it emerges from the zinc bath.

The zinc used in the galvanizing of wire should be of the best quality and cadmium-free, as cadmium affects the tightness of the coating. Lead impurities do not alloy readily with zinc and will settle to the bottom of the bath.

The thickness of the zinc coating may be tested by the Preese copper sulphate test or by the lead acetate test. The toughness may be tested by subjecting the wire to a wrapping test. Photomicrographs of "unwiped" wire show several layers of different alloys of zinc and iron as well as the layer of pure zinc.

Development of Communication Systems Throughout World

Mr. J. L. McQuarrie, vice-president and chief engineer of the International Telephone and Telegraph Company, presented on January 24th a comprehensive review of the development of communication systems throughout the world.

Charts and tables were presented showing graphic comparisons of the use of telephones in different cities and countries, indicated that European and other countries were for the most part very far behind Canada and the United States in this respect. Comparisons were also made between the extent and development of public and privately owned systems, the latter controlling 69 per cent and the former 31 per cent of the world's systems. Government control of communication predominated in Europe and was, in Mr. McQuarrie's opinion, largely responsible for the backwardness of development in those countries. On the other hand, the speaker pointed out that considerable progress was being made in long distance communication between the larger cities and from one country to another. An instance of this was that a person could speak from London to Madrid without difficulty.

The grouping of all kinds of modern communication methods into one system had reached a very advanced state and an experimental communication recently joined Stockholm with certain cities in the United States, a connection of over 14,000 miles, which used the telephone, radio-telephone, and submarine telephone cable, and excellent results were reported.

For twenty-four hour service, Mr. McQuarrie considered that it would not be possible to depend on the radio-telephone service alone, so that the day of the cable was by no means past. In fact, he believed it to be due for expansion in the near future and said that in two years' time there would be a telephone cable across the Atlantic. Volcanic submarine disturbances caused the greatest trouble to the cable companies. The most recent one having affected ten out of the twenty-one cables—and even with seven cable ships at work only four had been put in working order to date.

The extent of some of the various communicating mediums was illustrated by Mr. McQuarrie in the following statements, "Capital invested in radio telephone systems,—$200,000,000; annual messages transmitted between the continents of Europe and North America,—18,000,000; investment in submarine cable companies,—$450,000,000; miles of telegraph line in the world,—306,000; offices,—4,800; annual messages,—15,000,000; total investment,—$1,000,000,000."

A brief historical résumé, illustrated by slides was used by Mr. McQuarrie in introducing his talk, which was greatly appreciated by the large audience.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.

Executive Meeting

An executive meeting was called for the afternoon of January 29th, to consider the questionnaire recently sent out by Headquarters.

Our Committee on Publications took grave exception to the manner in which this question has been dealt with and presented to the membership and particularly to the use of the word "demand" in paragraphs 3 and 19 which suggested that some Branch has been attempting to dictate to Council. The Committee advised in effect as follows:—

> This Branch has been advocating, not demanding, a change in the size and method of publishing the Journal, also a return to the issuance of yearly transactions. We have also pressed Council to thoroughly investigate the whole matter and lay the results before the membership at large with a view to getting a definite expression of opinion prior to attempting any change. To some members, transactions are valuable; others prefer to limit the size of their library and keep only such papers as are of particular interest to themselves.
>
> Quite appreciating the fact that the Journal almost pays its own way due to the revenue from advertising, yet we have submitted that the ultimate value to members should be the prime consideration. More and better papers will be sent in if the writers feel that such papers will become part of a permanent record and available to other societies for reference.
>
> With this in mind we have been consistently "advocating," for more than a year, that the Journal should be continued as a monthly publication but decreased in size to either 7″ by 10″ or 6″ by 9″ and that it be punched and bound in a manner suitable for tearing apart and thus incorporating individual papers in a loose-leaf system.
>
> Our reasons have been threefold; firstly that the smaller size is most suitable for the standard book-case; secondly that the punching will allow members to separate individual papers and file them in cardboard binders which could be supplied by The Institute at a cost of not more than ten cents each; thirdly, and most important, that no re-setting of type will be necessary in order to print the extra copies required to take care of the demand for yearly bound transactions or for individual papers and distribution to other societies.
>
> Value to our membership and to the public should precede the question of cost; and yet cost is important. Failing to get any detailed comparative estimates from Council, or from the committees appointed by Council, this Branch has made certain inquiries which lead it to believe that the net cost of issuing the Journal in the smaller size would be about the same as at present and not one-third more as indicated in the questionnaire. The size of the sheet is not so important to advertisers as the circulation and if the circulation can be increased through larger sales or distribution to outsiders then the value of the advertising space is increased. It has come to our notice that at least two privately owned technical publications of the smaller size subsist entirely on the revenue from their advertising pages. One of these magazines is published in Toronto and the other in Chicago.

This Publications Committee had also drafted a resolution of protest which was read and received the support of the twelve executive members present, who unanimously voted that it be forwarded to Headquarters.

The Future of Engineering

Professor C. R. Young, M.E.I.C., department of civil engineering, University of Toronto, was the speaker at a dinner meeting held by the Branch at Niagara Falls on January 29th. The meeting drew a larger attendance than was expected and consequently some of the wider or lengthier members laboured under a grave disadvantage at the tables. Despite this handicap however the meeting was voted a success and Prof. Young's speech was followed with close attention.

The first proceeding after dinner was in the nature of a presentation to our esteemed confrère Emmet Patrick Murphy, A.M.E.I.C., of semi-Irish extraction, who, according to newspaper reports, has recently resigned his position as canal manager in order to take over and fill the vastly more lucrative station of habour master at Port Colborne. With a few graceful words and gestures Chairman Cameron presented to this astonished young man a full-fledged H.M. regalia, or shipping toque, which will command the instant respect of every rum-runner on Lake Erie.

Probably the title of Professor Young's address held a promise of surprise or a hint of mystery which accounted for many turning out who had failed to send in their cards to the secretary. The Professor however, at the start, disclaimed any pretentions to necromancy and explained that he proposed to deal with the subject in the only way a true engineer could comprehend—that is to say by the use of a curve projected into space. One feature of this method, he went on to say, was that no one would be in a position to contradict either his axioms, his hypothesis or his finally proved conclusions.

The commencement of his curve was laid in or about the year 175C. There were no civil engineers at that period, or at least the men who did engineering work were not known by that name. "Undertakers" was what the public called them—men who "undertook" to design, carry out and personally supervise, with the limited technical data at their disposal, the construction of canals, bridges, dykes and other progressive or constructive works. Civil engineering was not then a profession; many of these early builders were projected, or rather self-ejected, from entirely different pursuits because of some inherent spiritual quality which demanded that they should turn their attention towards subduing the forces of nature and making them available for the use of man.

James Brindley was a millwright before he constructed the Bridgewater canal and the Barton aqueduct; Smeaton and Watts were instrument-makers; William Edwards was the son of a farmer and later becoming a mason built the famous Pont-y-Prydd arch of 140-foot span after two failures; John Metcalf was a blind carrier and yet he is known as the pioneer of highway engineers; truth was that society—particularly literary society—did not recognise engineering as other than a species of manual labour and, as such, looked down upon it; thus the "commoner" was the only class fit or willing to tackle such problems.

This state of affairs lasted well into the nineteenth century when the advancement of education and the experiences of the past masters led to an accumulation of data which formed the basis of a new science—the science of engineering.

From about the year 1850 the curve has taken on a strong upward trend and the rate of increase has been especially marked, therefore with the aid of few sound premises and facts the future is not so very hard to read.

John Perry popularized calculus and this much maligned branch of mathematics is one of the absolute essentials in real scientific progress despite the attempts to side-step it by some educators.

An intense mechanization of society has been in progress during the last half century and we cannot stop; Stuart Chase has estimated that we are now employing some one and a half billion horse power on this little sphere or the equivalent of nine billion tireless slaves. It has been so easy and it is still so easy to create these mechanical servants that why indeed should we stop?

Many are the ways to be yet devised whereby other forms of energy may be harnessed and made available as power.

Big business is now recognizing the value of the engineer, of his scientific training, and employing him in greater and greater numbers at either executive work or in pure research.

Engineers are no longer traitors to the profession who forsake the slide-rule and transit for other fields of constructive usefulness where their scientific training counts for what it is worth. As many as 20 per cent of the Toronto graduates find their life work in business careers and a personal friend of the speaker has discovered that the larger department store contains many scientific problems.

It is significant that practically all the corporations which have made the greatest strides during the last few decades are those which have employed engineers and given them positions of responsibility. This is true not only of railways, municipalities, mines and such like but also of banks, bond houses, real estate, chain stores, moving pictures and other industries not commonly associated with civil engineering in the stricter meaning of the term.

There is a particular reason for this, namely that an engineering training demands exactness. Elbert Hubbard once said that a successful business man is one who guesses right more than 50 per cent of the time, but the engineer must do better than that; he is accustomed to dealing with an exact science where it is useless to guess and still less to bluff, he is not satisfied unless he is right nearly 100 per cent of the time because otherwise natural laws would quickly call his bluff.

These are some of the reasons why we see fewer consulting engineers than we did say 20 years ago. Regular work and regular salaries as executives or research workers in the larger industries are absorbing the best brains of the profession with mutual benefit.

With this in mind the present trend of university teaching is to give a broad training in the fundamentals of the science rather than to attempt the teaching of practice which is continually changing. The young man who graduates with the fundamental laws firmly fixed in his mind can enter practically any walk in life with the very best chance of success. The department of civil engineering in the University of Toronto is merging four fourth year options with this object in view.

Not all engineers have executive ability. Some of the most famous like Watt and Steinmetz were primarily interested in engineering as a science and cared little for the concrete results of their labour, but the great majority of engineers should be trained, or train themselves, to direct.

One of the prime requisites of an executive is that of being able to choose assistants wisely and then of being able to unload responsibility upon their shoulders. No man can successfully direct any large enterprise such as say, the Welland ship canal, and burden himself with detail. Thrust responsibility upon a good man and he will rise to it, withhold responsibility, or fetter him with restrictions, and he will either break away or deteriorate. Sir Joseph Flavelle has made his name great as an organizer by devoting his interest to the selection of his subordinates rather than to the exact details of how they performed their tasks.

The engineer should also cultivate his moral characteristics, should be dependable and imbued with resourcefulness, frankness and tact. The latter is becoming of more importance now that the trend is from the field to the office. The "rough diamond" character can be vastly improved upon and better results obtained by smoothness rather than forcefulness.

In moving a vote of thanks Mr. F. S. Lazier said that Professor Young had drawn an extremely rosy picture and one which held out great encouragement to every engineer. Personally he felt a distinct relief at hearing of the diversified pursuits which engineers could enter and still retain the right and privilege of being accepted as a brother by engineers. Since that time a few years ago, when he had changed his status from engineer to contractor, he had felt much tribulation which was now lifted. Mr. E. P. Johnson, another ex-chairman, seconded the motion and the meeting adjourned with a feeling that it was indeed a matter of pride and joy to belong to the ranks of this noble profession and with expressions denoting many a secret resolve to "hit the boss for a raise in the morning."

Peterborough Branch

S. O. Shields, Jr.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

Development in the Mining Industry

A regular meeting of the Branch was held on Thursday, January 23rd, 1930, at which W. R. Rogers, B.Sc., A.M.E.I.C., Director of Publications and Statistics of the Department of Mines, Toronto, and Chairman of the Toronto Branch of the Canadian Institute of Mining and Metallurgy, gave an interesting address on the above subject.

Mr. Rogers' paper was of a very comprehensive nature, dealing with all aspects of the mining industry in a general way. The four stages of geological growth of the North American continent were illustrated by slides, and it was shown that of the total pre-Cambrian area of the world, in which all famous metal mines are found, some two million square miles are located in Canada. Many details and statistics of the production of copper, silver, nickel and gold were given, commencing with the discovery of copper and nickel in Sudbury in 1887, the Cobalt area in 1904, and the Porcupine gold district in 1910.

It was pointed out that although gold still heads the list in value of output, it is probable that with the increasing variety of uses for nickel, this metal will soon become the leader. Particulars of the enormous deposits at the Frood mine and the great expansion occurring there at the present time were given.

With regard to iron, the present situation is that Canada imports approximately one and one-quarter million tons of ore per annum from the United States, but attention is being given to the possibility of beneficiation of the vast quantities of available Canadian ore.

The speaker dealt briefly with non-metallic minerals, such as gypsum, building stone, traprock, lignite, etc., the total value of which is about 30 per cent of the mineral output of the Dominion.

The address was followed by an interesting discussion, during which Mr. Rogers answered many questions. B. Ottewell, A.M.E.I.C., acted as Chairman for this meeting, and the vote of thanks was proposed by A. L. Killally, M.E.I.C., and heartily approved.

The Age of Speed

Mr. Phillip N. Cooke and Mr. M. N. Smith, of the Norton Company of Hamilton, carried on a very instructive meeting on the above subject, before the Branch on February 13th, 1930.

Mr. Cooke read a paper on the scope of the grinding industry of to-day. This paper outlined the manufacture and application of the modern grinding wheels. Particular attention was paid to the unusual developments in abrasives and bonds.

The importance of research was stressed and it was pointed out that this was necessary to meet the new demands of the present designs of grinding machine tools, particularly those that have hydraulic speeds and feeds.

Full and semi-automatic, and centreless grinding machines have made necessary extensive research to provide wheels that will meet new conditions.

Four reels of film were projected illustrating many applications of the grinding wheels in industry. These illustrated the application of grinding wheels directly or indirectly in the production of almost every commodity. The manufacture of grinding wheels was illustrated from the raw material to the finished product.

A discussion following the picture brought out the importance of the grinding industry to the low cost and low maintenance expense in connection with internal combustion engines. The balance of the discussion related to questions pertaining to local grinding problems.

A short film entitled "The Thirtieth Part of a Hair" was also shown. This picture show how precision grinding machine tools are being manufactured to limits of accuracy down to one ten-thousandth of an inch.

Mr. Cooke spoke as follows:—

"I know you will all agree with me that grinding today is now one of the major machining operations. Forty years ago it was not known except for the application of the clumsy independable sandstone. The grinding industry can be truly said to be only 45 years old. We can also say that the greatest strides in the industry have occurred since 1914, the outbreak of the war.

"The precision, external cylindrical grinding machine came into existence at the very early part of this century. At first it was a machine for fine finish and accuracy, but never a production tool. Today grinding machines of all descriptions, external cylindrical, internal cylindrical, plain surface grinding, and off-hand snagging machines are all production tools.

"There would be no exaggeration in the statement that the motor car, so common in use today, would cost from eight to ten times more than it does, if it were not for the grinding machine and the grinding wheel. That would assume that the present rate of production would be maintained even at those high selling prices, which of course would be impossible. Then too, without the grinding machine and the grinding wheel, other methods of machining could never produce the working parts in a gasoline engine of the refinement and accuracy that are required to give the motor long life with continuous use. Every year we expect our purchase of an automobile will provide a steady increase in number of miles before the car must be replaced. This has been a part of our education to expect the car to be better each year and so it has proved itself. We can all remember when 10,000 miles was considered excellent for the use of a car without an overhauling and yet today we know of cars that are running several times that with hardly any maintenance expense. Let me assure you, gentlemen, that the grinding industry is to a great measure responsible for this remarkable improvement in motor car performance. We say this in no way attempting to steal the laurels from other industries who have likewise contributed in a large way to this improvement in service.

"It will interest you to know that in the United States the grinding wheel alone has become more than a $25,000,000 commodity in annual sales, and there is at least one individual concern in the United States who can be reckoned as a million dollar consumer.

"The enterprising grinding wheel manufacturer must be ever alert and his research must be unending. New machine tools are continually appearing on the market which introduce new problems to the wheel manufacturer. New alloys of steel or other metals continually introduce new problems and wheels must be manufactured to meet the changing conditions everywhere. The most striking example of a new problem coming before the wheel man is the very recent introduction of tungsten carbide as a cutting tool, known under the trade names of "Carboloy," "Widia" and several others. This gave the wheel man a real problem but it has been quite satisfactorily solved and today tungsten carbide metal can be ground very successfully.

"Centreless grinding machines, automatic cylindrical machines, automatic internal machines, hydraulic table traverses and feeds, have all introduced new problems for the wheel man within the last few years. New wheel processes have had to be developed to meet all these different conditions. Of late we hear a lot about high speed grinding. Until comparatively recently a wheel that travelled between 5,000 and 6,000 surface feet per minute was about the maximum for any grinding wheel. A few rubber-bonded wheels have been used for some years back which were strong enough to operate safety at 9,000 feet per minute, but now with the introduction of Bakelite as a bond, there are many grinding operations performed with wheels operating at 9,000 feet per minute. We are going to hear more about this as time goes on. We do not believe that the surface has been scratched with the high speed wheel idea. We are convinced that the removal of metal is proportional within limits to surface speed and if the metal is there to be removed, the high speed wheel is going to rapidly replace the former 6,000 feet per minute type.

"Lately perhaps you have heard of cutting-off wheels, wheels that are made extremely thin, 3/32, 1/16 or less, running at 12,000 to 15,000 surface feet per minute. For cutting off certain materials you can readily imagine the speed and economy of the work done in this manner.

"Production grinding jobs in a manufacturing plant should constantly be studied with the greatest care. With new abrasives at the disposal of the wheel man, new bonds for manufacturing the grits into wheel shapes, new structures that are coming more and more under exact control, there are bound to be possibilities for decreasing factory costs. Any production grinding items should be continually checked to make sure that the lowest possible cost is present. As engineers, I know you will agree with me, that a grinding wheel that shows maximum life in hours service is not necessarily, and in fact is seldom, the most economical wheel to use. We may say that the longer the life the slower the cutting ability within limits of course and that if we could plot a curve with rate of metal removed per unit of time on one axis and hours life on the other, we are going to get a distinct curve which will first start up at a definite rate and reach its maximum point sloping rapidly down again toward the horizontal axis as the life of the wheel is increased.

"Many grinding wheel users will talk hours life as the measure of the wheels' performance but we are happy to say that more and more we hear of rate of metal removal as a proper measurement rather than hours in service.

"In the reels of pictures we will have the pleasure of illustrating grinding wheels in use varying in cost from 15 cents each to $6,000 each. We will show you operations where manufacturing limits are specified in tenths of thousands. It is common commercially to grind to .0002 inch. It will probably interest you to know too that in the machine shops of the automobile manufacturers who are placing the lowest-priced cars on the market today, are many grinding operations where these limits are specified and are definitely held."

Every person attending this meeting seemed to be particularly interested in the subject under discussion.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer.

About forty members were present at the regular dinner meeting of the Branch, held at the Kitchener hotel, Regina, on January 24th, 1930. Stewart Young, A.M.E.I.C., acted as chairman in the absence of Chairman H. R. Mackenzie, A.M.E.I.C.

Engineers' Legislation

P. C. Perry, A.M.E.I.C., chairman of the Legislation Committee, reported progress on the bill respecting the engineering profession in Saskatchewan. The bill has been drafted and reviewed by the committee and will be placed in the hands of counsel with instructions to pilot same through the Committee of the Legislature.

Dinner to Dr. W. C. Murray—President University of Saskatchewan

On February 27th, a dinner will be given at the Saskatchewan hotel, Regina, in honour of Dr. Walter C. Murray, President of the University of Saskatchewan. H. R. Mackenzie, A.M.E.I.C., chairman of the Branch, will attend this function as a representative of The Institute. The following resolution voicing the opinion of this organization with respect to the public services of Dr. Murray was unanimously passed at the regular meeting of the Branch:—

"We, the members of the Saskatchewan Branch of The Engineering Institute of Canada, take this opportunity of placing on record our appreciation of the eminent services rendered to this province and the Dominion of Canada and to the cause of education in general by Dr. Walter C. Murray, President of the University of Saskatchewan.

"During the twenty-one years in which he has acted as president of our provincial university we have seen many changes and improvements and none more striking than the rapid progress which the university has made under his guiding hand until to-day it is everywhere recognized as one of the leading educational institutions on the continent.

"We as engineers are particularly concerned with engineering education and view with much satisfaction the achievements of the faculty of engineering."

The Nipawin Bridge

H. D. Brydone-Jack, A.M.E.I.C., assistant engineer, Canadian Pacific Railway, next gave an interesting address on the Nipawin bridge which has just been completed.

Designed to take the heaviest locomotives likely to be built, this magnificent structure, a little more than 1,907 feet long, spans the North Saskatchewan river at a point leading from the more definitely agricultural section into timber and mining districts of recognized magnitude. It will afford ready access to still unexhausted farm lands and direct transportation possibilities for those who will explore and develop mineral expanses rich in promise.

This bridge was begun in October 1928 and is one of the exceptionally large steel structures in the west. In symmetrical spans it connects the north and south banks of the Saskatchewan at about 150 feet above water level of the river. It provides not only railroad transit calculated for 60,000 pounds axle load on the engine drivers, but is made in double-deck fashion with a 16-foot highway for vehicular traffic on the lower chords designed for 15-ton loading.

This steel roadway, built on a creosoted understructure with a two-inch untreated wearing surface, will carry the Saskatchewan government's provincial highway across the river. Legislative forces co-operated with the railway company in relieving a situation which naturally proved a hindrance to agricultural development.

Mr. Brydone-Jack reviewed briefly the method of erection, the difficulties met with and illustrated his remarks by snapshots taken during the course of erection.

It was necessary that the five main piers, three of which are in the water (requiring cofferdams) be completed above water level during the winter of 1928-29. For this purpose four pile drivers, three clam shell excavators and five electric pumps were used. A steam generating plant supplied power for the mixers, hoists and for the heating of the materials used in the concrete.

Most of the work was carried out from trestles extending across the river. A 2,000-foot cableway 85 feet high, capacity 6 tons, extending from the high river banks was used to transport men and materials. All gravel was supplied by gravity to the mixers, after which it was elevated to the cableway by a small hoist.

Considerable difficulty was experienced in finding a suitable supply of gravel, but this was ultimately obtained from Foam lake, Sask. It contained much fine material and a high proportion of cement was therefore necessary to obtain the desired strength for the concrete.

The excavation for piers and approach on the south shore of the river was rendered difficult owing to boulders etc., but these only extended to a depth of four or five feet. Below this was a very hard blue clay which had to be bored and blasted as the clam shell excavators would not operate in it. A primitive test of the bearing pressure of this clay was carried out which showed no settlement whatever.

The cofferdams were erected after the river froze up. Two rows of Lackawanna steel piling were driven with the pile drivers. This allowed the cofferdams to be satisfactorily drained. The depth of the water at the three piers in the river was respectively twelve feet, five feet and five feet.

The concrete in all piers was poured in the winter season before the ice in the river broke up. One pier was poured in three days. Movable forms were used. By spring all piers were up 30 to 40 feet, the forms removed and noses protected by steel. The ice went out very gently on May 2nd and 3rd, 1929, after which the tops of the piers were completed.

By August 1st the foundations were completed and erection of the steel commenced by the Dominion Bridge Company on August 5th. Falsework was erected on all except one span where the cantilever system was used. A travelling crane weighing 90 tons when loaded was used on this work.

Sault Ste. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting was held in the Y.W.C.A., on January 24th. C. H. E. Rounthwaite, A.M.E.I.C., chairman of the Branch, presided.

Mr. J. Kelleher, manager of the Superior Alloys, addressed the meeting on the subject, "Electro-Chemical Appliances." He traced the growth of the electric furnace from its beginning, where a battery of dry cells furnished the energy, through the various stages to the present. At first they were all of the arc type and many of these are in use at present. The speaker himself was more interested in the resistance type of which the electric lamp and the electric stoves are examples. In the furnace as developed by Mr. Fitzgerald, a pure graphite element was used and temperatures so high were obtained that the refractory was melted.

A porcelain kiln was developed with temperatures up to 1,800° C. for making spark plugs. The electric furnace was recently adapted to firing ceramics and with such success that where formerly three dozen green pieces were required to ship one dozen, with the electric furnace but thirteen pieces were required to ship a dozen.

The chief advantage of the electric furnace lies in the ability to control the heat exactly, continuously, and automatically. In conclusion the speaker mentioned some products of the electric furnace, as tungsten filaments, grinding wheels, fertilizer, case hardening compounds, etc.

A short discussion followed.

A vote of thanks was tendered Mr. Kelleher, for his excellent talk on motion of Messrs. Jenkinson and Seymour.

W. S. Wilson, A.M.E.I.C., chairman of papers committee, reported a paper on snow removal for the near future and a paper on "Insulating Materials and General Insulating Practice," by Mr. Jas. Govan, expected about second week in February.

Toronto Branch

J. J. Spence, A.M.E.I.C., Secretary-Treasurer.
Archie B. Crealock, A.M.E.I.C., Branch News Editor.

A meeting of vital interest to engineers was held by the Toronto Branch on January 9th, when Mr. J. W. Kelly of the Portland Cement Association came from Chicago to deliver a lecture. The title of Mr. Kelly's paper was "The Internal Structure of Concrete." As this subject is of general interest to contractors, etc. as well as engineers the meeting was an open one and it was largely attended by representatives from all branches of the profession.

Mr. Kelly in introducing his subject said that probably a better title for his paper would be "How can we make better concrete?" The speaker then made a brief basic analysis of the make-up of concrete in which he showed how the complete process of making concrete consisted of three stages—materials—proportions—and field methods of manufacture. First of all Mr. Kelly described the part played by the cement industry in the studies made by them to produce a better cement and also of the investigations carried out on aggregates as well as the study of the concrete itself, especially with regard to durability.

In elaborating on the subject of durability Mr. Kelly stated "that during the past year alone, more than two hundred surveys were made of the condition of existing structures in all parts of the country, including dams, bridges, pavements, seawalls and other structures subject to severe exposure. These surveys will soon be published, but for the present it is safe to say that they have simply confirmed our laboratory researches, with the added conclusion that improper construction methods are responsible for the greater percentage of all unsatisfactory concrete work."

Following this the speaker then took up the question of curing or protection of concrete during its early life, and also the effect of vibration on dry mixes. A description of the research work on the fire resisting qualities of concrete was then outlined.

Continuing, Mr. Kelly stated that in practically all of the cases of unsatisfactory concrete which had come to their attention the cause of the trouble had been found to be a result of either an improper mix or poor placing and curing and that a realization of the joint responsibility for good quality on the part of the owner, engineer, architect, contractor, cement manufacturer, machinery and accessory manufacturer, inspection organizations, and allied interests is necessary to produce good concrete. It is impossible to cover the complete story of the making of concrete in this brief talk except to say: use standard cement, clean and sound aggregates, proportion with as little water as possible, be sure to have a plastic mix, mix well, handle and place without allowing separation of the materials, don't overpuddle or overfinish, and by all means cure or protect the concrete from drying out as long as possible.

A description of some of the more common faults of concrete then followed and were subdivided under the usual headings of materials, proportions and field methods and a description of how to obtain and the pitfalls to be avoided in obtaining a high quality concrete. In concluding his address Mr. Kelly referred to the excellent specification recently issued by the Canadian Engineering Standards Association.

A fitting vote of thanks was tendered to Mr. Kelly for his interesting and educative address which had been thoroughly enjoyed by all those present.

A Pioneer Canadian Industry

"A Pioneer Canadian Industry" was the title of an interesting paper presented to the members of the Toronto Branch of The Engineering Institute on the evening of Thursday, January 23rd, 1930, by Mr. C. E. MacDonald of the International Nickel Company of Canada, Limited.

In his address Mr. MacDonald first gave an historical sketch depicting the trials and failures incident to the establishing of the nickel industry in Canada from the time that Mr. S. J. Ritchie obtained control of the Copper Cliff, Stobie No. 2 and the Creighton mines in 1885. In the following year the Canadian Copper Company was formed by Mr. Ritchie to take over these mines and later the Frood and Evans mines were acquired, the Frood mine being one of the richest mines ever discovered anywhere. In February 1889 the first smelter commenced operations with a capacity of 150 tons per day. A second furnace was added the same year and the plant rapidly developed to a capacity of 700 tons of ore per day.

Considerable trouble was experienced in the early stages in obtaining a refining process that was satisfactory and finally after much experimenting the process developed by the Oxford Copper Company of New Jersey was adopted. This is the process in use to-day but with many changes and improvements. The second major handicap that faced the builders of this industry was that now they could extract and refine the nickel in their mines the market for it was very limited being only about 1,000 to 1,500 tons in 1890 or less than the amount produced in the same year by the New Caledonia mines. Following an intensive campaign by Mr. Ritchie, United States navy finally adopted nickel steels for their armaments and they were closely followed by the French and British navies. In 1902 the International Nickel Company was organized and secured entire control of the Oxford Copper Company, the Canadian Copper Company and several other companies interested in nickel so that they now controlled the refinery end and the disposal of the metal as well as the production. Mr. MacDonald then showed some 70 slides which visualized the complete industry from the mining operations to the finished product. These were all ably described with particular attention to the refinery at Port Colborne. Following this a description of the various nickel alloys with the particular uses to which each are employed was given as well as the uses of pure nickel and from this description one wondered if there was any metallic substance in use to-day that did not contain nickel in some degree. The lecture was thoroughly enjoyed by all those present and a hearty vote of thanks was tendered to Mr. MacDonald for his address.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Wanted

ELECTRICAL ENGINEER, M.Sc., A.M.E.I.C., graduate, seven years experience in high tension calculation design and construction, seeks connection with consulting engineer. Present employed, married, age 30. Apply Box No. 7-W.

CHIEF ENGINEER, twenty years industrial construction, production and operation. Structures, equipment, steam, hydro. Experienced in conferences, preliminaries, organizing, preparing plans, estimates, specifications, negotiation contracts. Apply to Box No. 36-W.

CIVIL AND MECHANICAL ENGINEER, aggressive practical engineer, with background of experience in design, construction, maintenance and operation of pulp and paper mill, desires change. Especially qualified to reduce mill costs. Apply to Box No. 53-W.

MECHANICAL ENGINEER, with twenty years experience in design, construction, sales and management desires position of an engineering, commercial or executive nature. College graduate, M.E.I.C., M.A.S.M.E., M.P.E.Q., and formerly chief engineer. Apply to Box No. 92-W.

RETIRED LIEUT.-COMMANDER, Canadian, aged 32, A.M.E.I.C. Specialized in engineering from executive rank. Two years and six months chief engineer marine 31,500 s.h.p. Desires position with manufacturing or business concern in Montreal—management. Apply to Box No. 106-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal exgineering, construction work, inspection, estimating. Opening sought with architects as reinforced concrete designer and engineer; other opening considered. Toronto-Hamilton area preferred. Apply to Box No. 107-W.

CIVIL ENGINEER, graduate '26, with fair knowledge of French. Experience as instrumentman on surveys, maintenance engineer on railway construction, and resident engineer on railway construction. Available at once. Apply to Box No. 149-W.

GRADUATE ENGINEER, University of Sask. '25, age 26, desires position. Experience includes one year surveying, one year architectural draughting, three years general construction draughting and superintendence and two years paper mill design and maintenance. Services available immediately. Apply to Box No. 150-W.

ELECTRICAL ENGINEER, B.Sc., E.E., A.M.E.I.C., Canadian, age 29, single, graduate Canadian university 1924. Have been with large power company in U.S.A. since graduation, ten months on sub-stations, remainder of time on design, construction and operation of overhead and underground distribution and transmission system. At present employed by same company. Would like return to Canada. Available on reasonable notice. Apply to Box 236-W.

Situations Wanted

CIVIL ENGINEER, with office in Toronto and extensive connection, is in a position to act as agent for contractors' equipment, building materials or allied lines, or would consider position as sales engineer with large manufacturer or distributor. Apply to Box No. 311-W.

INDUSTRIAL ENGINEER, thirty-five years of age, graduate of a well-known university, twelve years experience in design, construction, maintenance and changes in production methods in industrial plants, including several years in pulp and paper industry in complete charge in large mills of all engineering, maintenances, and development work; still engaged; desires to establish new connection. Apply to Box No. 320-W.

CIVIL ENGINEER, B.A.Sc., A.M.E.I.C., M.P.E.O., age 37, desires a permanent position as chief draughtsman or plant engineer, preferably in Toronto or district. Seventeen years experience with consulting engineers on industrial, structural and railway work, hydro-electric plants and pulp and paper mills. Some mechanical and electrical experience. Apply to Box No. 332-W.

CIVIL ENGINEER, A.M.E.I.C., Reg. Pro. Eng. Ont. and N.B., age 47, married, twenty years experience in this country; twelve years in Scotland as construction and municipal engineer, specializing in roadway, water and sewer works, desires similar position, available forthwith. Just completed sewer and waterworks schemes for town in Maritime Province. Have also been engaged as engineer and superintendent with contractors on steam shovel excavation, concrete and caisson works for large buildings in Toronto, etc. Apply to Box No. 336-W.

CIVIL ENGINEER, graduate '29, desires engineering position with possibilities of advancement. Work in hydro-electric, construction, municipal, railroad, or mining preferred. Past experience consists chiefly of survey work. Location in western provinces preferred. Apply to Box No. 338-W.

CIVIL ENGINEER, B.Sc., fifteen years experience, including surveying, construction, mining and tunnelling. Available at once. Will go anywhere, but prefer Eastern Canada. Apply to Box No. 346-W.

MECHANICAL ENGINEER, Jr.E.I.C., Irish, age 28, graduate '27, seeks connection in British Columbia, varied outdoor and indoor experience. During vacation and since graduation in mechanical, electrical and civil engineering. Versatile, intelligent, and quick to learn. Fast and accurate with slide rule transit T-square or electrical equipment. Prefer maintenance or research work or any opening with opportunity for advancement. Apply to Box No. 349-W.

MECHANICAL DESIGNER, 33 years of age. First class English and Canadian experience (Rolls-Royce, Ford, Platt Bros., G. M. C.) on special machine tool jig and tool designing, maintenance, and production methods; excellent references; desires position. Montreal district preferred. Available immediately. Apply to Box No. 351-W.

Situations Wanted

CIVIL ENGINEER, grad. '29, eleven months on construction, three months on road location, five months in draughting office, desires position on construction or would like to enter draughting office with possibilities in steel and reinforced concrete design. At present employed. Apply to Box No. 352-W.

SUPERINTENDENT, competent electrical superintendent, wishes position with large industrial or power supply company. New construction programme preferred. Experienced in engineering, designing and electrical construction of power houses, sub-stations and industrial control work. Available on short notice. Apply to Box No. 353-W.

CIVIL ENGINEER, graduate A.M.E.I.C., P.E.Q., with sixteen years varied field experience on construction and building work of all types, mostly with contractors' organizations, seeks opening as superintendent or engineer, preferably in Quebec or Eastern Ontario. Apply to Box No. 354-W.

INSTRUMENTMAN, with a total of five years experience in railroad and highway construction, desires a position which holds some prospects for advancement. Would prefer work in Ontario, but not essential. Permanent work most desirable. Apply to Box No. 355-W.

ELECTRICAL ENGINEER, graduate McGill Univ. Experience, draughting, checking, short wave radio research, radio operating (ship and shore), demonstrating, electrical measurements and radio laboratories, department electrical engineering; at present demonstrating physics department. Desires position with opportunities, preferably radio work. Location immaterial. Apply to Box No. 356-W.

CIVIL AND STRUCTURAL ENGINEER, B.Sc., M.E.I.C., and A.M.Inst.C.E. Exceptionally thorough mathematical and theoretical training, 20 years experience, Canada and abroad. Railway location and construction, specialized in bridge and structural design, steel and reinforced concrete, design and construction of harbour and dock works, water and sewerage, grain elevators and industrial buildings, specification writing. Nine years of experience with engineers and contractors, engineering, superintending and estimating, considerable executive work. Just completed engagement on large project. Apply to Box No. 357-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., is open for engagement. Twenty-four years general experience both as engineer and as contractor. Has specialized in the construction of wharves, dams, foundations, etc. Apply to Box No. 358-W.

ELECTRICAI ENGINEER, graduate N.S.T.C., Halifax, 29 years of age, two years experience in power transmission and distribution with a large power company in province of Quebec, two years electric test and inspection, W.E. and Mfg. Co., East Pittsburgh, Pa., one year electrical maintenance in large mill. Experience with telephone transmission, sub-station layout, electrical installation and layout for factories. At present employed. Apply Box No. 361-W.

MINING ENGINEER, graduate, age 32, A.M.E.I.C., ten years experience in design, construction, erection and maintenance of paper mill and mine buildings and machinery. Several years on hydro-electric work in charge of surveys and investigation; desires permanent connection with mining or paper company. Apply to Box No. 362-W.

Situations Wanted

ELECTRICAL ENGINEER—Part time work wanted by experienced graduate electrical engineer. Reports, designs, layouts, power factor, relay and short circuit studies. Apply to Box No. 364-W.

Situations Vacant

STRUCTURAL DRAUGHTSMEN, experienced in detailing steel for industrial plants, city buildings or bridges, for a bridge company located in Winnipeg. Give age, experience, whether married or single, and other particulars to Box No. 474-V.

MECHANICAL ENGINEER, about 35 years of age, with experience in pulp and paper mill maintenance, and to take charge of small construction work in connection with mill. Location Western Province. Apply to Box No. 492-V.

CHEMICAL ENGINEER. Large newsprint company in St. Maurice Valley desires recent graduate in chemical, electrical or mining engineering, who would like to make a permanent connection with the industry. Good living conditions. Apply to Box No. 495-V.

ELECTRICAL ENGINEERS. Wanted, two young electrical engineers with about two years experience since graduation, for three to four months survey of large distribution and transmission system in province of Quebec. Work may result in permanent employment. State experience and salary expected. Apply to Box No. 496-V.

SALES ENGINEERS. Two experienced industrial paint salesmen wanted by a large paint manufacturing company; one for Toronto City, one for London and Border Cities. Applicants should state fully experience, names of three references. Apply Box No. 497-V.

Situations Vacant

DESIGNING ENGINEER, capable of handling details problems or general layout work in a large newsprint mill centraly located. Only men with at least five years experience in this line need apply. State fully experience and salary expected. Apply to Box No. 498-V.

TOWN MANAGER—A new mill town in northern Quebec requires a young civil engineer as town manager. French-Canadian with fluent knowledge of French and English essential. Previous experience in municipal work preferable. State full particulars in application. Apply to Box No. 500-V.

DESIGNING DRAUGHTSMAN wanted by a large pulp and paper mill, ideally situated. The work will comprise general drawings and details for building construction and alterations. Applicant should be able to design reinforced concrete and structural steel. State age, education, experience, salary desired, and other particulars. Apply to Box No. 503-V.

ENGINEER, wide awake and progressive, preferably technically trained man with several years sales experience, familiar with sanitary requirements of municipal and industrial water systems. Submit with application complete details of education and positions held to date. Apply to Box No. 505-V.

DRAUGHTSMEN. Experienced in A.C. and D.C. machines, switchboard wiring diagrams and station arrangements, industrial control apparatus. State age, experience in detail, and salary expected. Location, central Ontario. Apply to Box 506-V.

GRADUATE MECHANICAL ENGINEER required, preferably single man about twenty-five years of age, with special training, operation, maintenance boiler plant equipment. Preferably junior engineer who has completed apprenticeship course offered by Babcock-Wilcox or other boiler manufacturers. Applicant please state particulars, experience, references, etc. Location Mexico. Apply to Box No. 507-V.

RECENT GRADUATE, in electrical or mechanical engineering, for general industrial work. Work part in office and part in the plant. Must be competent to do transit work and levelling in connection with laying out new building sites. Location, Northern Quebec. Apply to Box No. 508-V.

MECHANICAL DRAUGHTSMAN wanted, with good technical training and acquainted with heavy duty cranes, regulating gates, movable bridges, etc. Not over 30 years of age. Apply, giving full personal particulars and salary expected, to Box No. 509-V.

DRAUGHTSMEN—One or two good draughtsmen familiar with heavy wood mill construction. Acquaintance with gold milling desirable but not essential. State age, education, experience, references, if employed, married or single, salary wanted, and how soon you can report, to Box No. 510-V.

CIVIL ENGINEER, with mechanical experience in construction and maintenance work for a pulp and paper company in southern Ontario. Apply at once to Box No. 512-V.

CONSTRUCTION ENGINEER, on hydro-electric power development; capable of taking charge of laying out of work. Reply, stating experience, age and salary. Apply to Box No. 513-V.

MECHANICAL ENGINEER, graduate with three or four years experience in industrial plant maintenance, for metallurgical plant in province of Quebec. Permanent connection for right applicant. Please give complete information. Apply to Box 516-V.

SEALED TENDERS addressed to the undersigned and endorsed "Tender for Esplanade Wharf Reconstruction, Cobourg, Ont.," will be received until **12 o'clock noon, Thursday, March 20, 1930,** for the reconstruction of Esplanade wharf, at Cobourg, Northumberland County, Ont.

Plans and form of contract can be seen and specification and forms of tender obtained at this Department, at the offices of the District Engineers, Equity Building, Toronto, Ont.; Toronto Builders Exchange and Construction Industries, 1104 Bay Street, Toronto, Ont., and at the Post Office, Cobourg, Ont.

Tenders will not be considered unless made on printed forms supplied by the Department and in accordance with conditions contained therein.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Minister of Public Works, equal to 10 per cent of the amount of the tender. Bonds of the Dominion of Canada or bonds of the Canadian National Railway Company will also be accepted as security, or bonds and a cheque if required to make up an odd amount.

Note.—Blue prints can be obtained at this Department by depositing an accepted cheque for the sum of $20.00, payable to the order of the Minister of Public Works, which will be returned if the intending bidder submit a regular bid.

By order,
N. DESJARDINS,
Secretary.

Department of Public Works,
Ottawa, February 27, 1930.

SEALED TENDERS addressed to the undersigned, and endorsed "Tender for a Strauss Trunnion Bascule Bridge, Burlington Channel, Ont.," will be received until **12 o'clock noon, Tuesday, March 25, 1930**, for the construction of a Strauss Trunnion Bascule Bridge, at Burlington Channel, Wentworth County, Ont.

Plans and form of contract can be seen and specification and forms of tender obtained at this Department, at the offices of the District Engineers, Equity Building, Toronto, Ont.; Postal Station "H," Montreal, P.Q.; Toronto Builders Exchange and Construction Industries, 1104 Bay Street, Toronto, Ont., and Builders Exchange, 118 New Birks Building, Montreal, P.Q., also at the Post Office, Hamilton, Ont.

Tenders will not be considered unless made on printed forms supplied by the Department and in accordance with conditions contained therein.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Minister of Public Works, equal to 10 per cent of the amount of the tender. Bonds of the Dominion of Canada or bonds of the Canadian National Railway Company will also be accepted as security, or bonds and a cheque if required to make up an odd amount.

NOTE.—Blue prints can be obtained at this Department by depositing an accepted cheque for the sum of $25.00, payable to the order of the Minister of Public Works, which will be returned if the intending bidder submit a regular bid.

By order,
N. DESJARDINS,
Secretary.

Preliminary Notice

of Applications for Admission and for Transfer

February 24th, 1930

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in April 1930.

R. J. DURLEY, *Secretary.*

---

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for a least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

> The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

CARR-HARRIS—GORDON GRANT MACDONNELL, of Kingston, Ont., Born at Kingston, Ont., April 23rd, 1897; Educ., 1915-16, R.M.C., Kingston, Dec. 1916, took R.E. Commission; 1922-23, 1st and 2nd years, Mech'l. Sciences Tripos, Cambridge University; 1924-25, School of Military Engrg., Chatham, England; 1916-19, overseas. C.F.A. and R.E. Italian "Al Valore" Medal, 1918; 1915, geod. survey party, Quebec-Maine border; 1916, hydrometric survey, St. Lawrence River; 1920-22, ap'ticeship, engr. and traffic depts., South Eastern and Chatham Rly.; 1926-27, instr'man., city engr's office, Vancouver; 1928-29 (summers), instr'man., Ont. Prov. Highway Board; 1927 to date, asst. professor, civil engrg., Royal Military College, Kingston, Ont.

GOOD—EARL FRANKLIN, of Toronto, Ont., Born at Doon, Ont., Feb. 6th, 1900; Educ., B.A.Sc., Univ. of Toronto, 1924; 1921 (summer), yard checker of bldg. materials, Hollinger Gold Mines; 1922 (summer), dftsman., for Herbert Johnston, O.L.S., Kitchener, Ont.; 1923 (summer), instr'man., and 1924 (May-Nov.), asst. to dist. engr., Dept. of Northern Development of Ontario, Muskoka and Parry Sound; 1925 (Feb.-June), i/c of field party for Warner & Warner, of Detroit, Mich.; 1925-29, struct'l. design of bldgs., for Smith, Hinchman & Grylls, Detroit, Mich., also some field work pertaining to above bldgs.; May 1929 to date, struct'l. design of bldgs., for Messrs. Harkness & Hertzberg, Toronto, Ont.
References: A. H. Harkness, C. S. L. Hertzberg, H. C. McMordie, D. T. Welsh, W. A. M. Cook.

HAGUE—EDWARD COUSINS, of Montreal, Que., Born at Montreal, Nov. 15th, 1902; Educ., B.Sc., McGill Univ., 1923; 1923-26, telephone switchboard engrg., asst. engr., broadcasting station C.H.Y.C., asst. engr. gen. communications lab. work; 1926-27, asst. engr., line survey and final install'n. of carrier telegraph and telephone repeaters for Can. National Telegraphs, and asst. engr., carrier telegraph and carrier telephone systems, all with Northern Electric Company, Ltd., Montreal; Oct. 1927 to date, research engr., with Victor Talking Machine Company of Canada, Ltd., in charge of all engrg. and lab. work connected with manufacture of radio receivers, electric phonographs and elect'l. phonograph recording.
References: P. F. Sise, W. C. Adams, H. J. Vennes, W. B. Cartmel, J. G. Bishop.

MITCHELL—JAMES MURRAY, of 596 Lansdowne Avenue, Westmount, Que., Born at Westmount, Aug. 27th, 1900; Educ., B.Sc., McGill Univ., 1923; 1918 (summer), stillman, Can. Electro Products, Shawinigan; 1919 (summer), lab. asst., Milton Hersey Co., Montreal; 1923-24, material testing, Quebec Development Co., Isle Maligne; 1924-25, student engr., and from 1925 to date, district traffic supt., Bell Telephone Company of Canada, Montreal.
References: C. M. McKergow, R. DeL. French, H. G. Cochrane, H. M. MacKay, J. S. Brisbane, N. E. D. Sheppard, E. Brown, E. L. Zealand.

PEACH—WILLIAM HERBERT, of Port Arthur, Ont., Born at Gopsall, Leicestershire, England, Feb. 1st, 1903; Educ., 1915-17, George Dixon Secondary School, Birmingham, England; 1917-19, gen. asst. to res. engr., on rly., canal, dock and bridge constrn., also ironstone mining, for Logan & Hemingway, Rly. & Public Works Contractors, Doncaster, England; 1922-23, (4 mos.), asst. to bldg. constrn. engr. on yard constrn., C.N.R.; 1923 to date, on design and supervision of grain elevators, C. D. Howe & Company, Port Arthur, Ont.
References: C. D. Howe, W. H. Souba, M. H. Jones, J. M. Fleming, F. C. Graham, G. H. Burbidge, M. W. Jennings.

STEEVES—SAMUEL MERRITT, of Ottawa, Ont., Born at Dorchester, N.B., Sept. 29th, 1897; Educ., B.Sc., Univ. of Man., 1925; 1916 (6 mos.), rodman, Dept. Rlys. and Canals, Cape Tormentine: Summers: 1917-18, student asst., Geol. Survey: 1918-19, rodman, C.N.R., Port Arthur; 1920-24, student asst. Geol. Survey; 1925-28, junior topog'l. engr., and 1928 to date, topog'l. engr., i/c party, Geol. Survey, Ottawa, Ont.
References: W. H. Boyd, D. A. Nichols, J. N. Finlayson, L. L. Bolton, J. V. Butterworth, N. M. Hall.

STYLES—HUGH JOHN, of 5 Geneva Street, St. Catharines, Ont., Born at Arnprior, Ont., Sept. 30th, 1898; Educ., B.Sc., Queen's Univ. 1929; 1917-19, mechanic, McLaughlin Bros., Arnprior, Ont.; 1926-27 (summers), elect'l. mfg., English Electric Co., St. Catharines, Ont.; 1928 (summer), hydro-electric development, Shawinigan Engrg. Co.; 1929 to date, elect'l. inspr., and testing, Welland Ship Canal, St. Catharines, Ont.
References: D. M. Jemmett, A. J. Grant, A. L. Mudge.

WEIR—RONALD STANLEY, of Montreal, Que., Born at Montreal, Aug. 2nd, 1901; Educ., 1921-24, McGill Univ., completed 1st year App. Science, and part of 2nd year; Summer work: 1922, timekeeper, H. L. St. George, road constrn.; 1923-24, care of engine, lighting plant, etc., yacht of Col. G. W. Birks; 1925, elect'l. work, Isle Maligne, power house; 1925-26, transitman, and later in charge of party surveying transmission line between Isle Maligne and Port Alfred, Duke-Price Power Co.; 1926 to date, with the Shawinigan Engineering Company, on various surveys in connection with new developments, and at present doing aerial mapping.

VOLUME XIII | MONTREAL, APRIL 1930 | NUMBER 4

The Engineer's Work in Surveying and Mapping

F. H. Peters, M.E.I.C.,

Surveyor General, Department of the Interior, Ottawa.

Paper presented before the Annual General Meeting of The Engineering Institute of Canada at Ottawa, Ont., February 13th, 1930.

INTRODUCTION

It is a difficult task to prepare a paper on the mapping of Canada so as to give a true conception of what is the very foundation of the orderly and economic development of our great country. The mapping of half a continent is an undertaking requiring the utilization of all resources of the science of surveying and mapping.

Today we live in a world built upon engineering work and it would seem that particularly in a young country like our own — rich in so many undeveloped natural resources — our future growth and expansion must primarily depend upon the work of engineers and surveyors. No engineer would commence to develop an estate without first having a plan to show what there is to be developed, and it is equally true that a country cannot be developed economically without accurate maps.

When Jacques Cartier discovered Canada in 1534, he saw perhaps a few hundred square miles of it and no doubt in some rough way mapped as much.

When the first French explorers travelled up the Ottawa river and put it on the map they, in a sense, rubbed the philosopher's stone and created something new in our universe. Since that time explorers, surveyors and engineers have expanded our great country by putting it on the map until in area it is the third largest country in the world.

Looking at the best map available today of Canada and noting the vast blank spaces, some of them of the size of the province of New Brunswick, we feel that they are well described by two lines of a well-known poem by Robert W. Service —

"There's a land where the mountains are nameless,
And the rivers all run God knows where."

Turning to the map of New France, 1754, showing the latest discoveries of La Verendrye and other French trader explorers, it will be realized how much of our country had not yet been brought into existence by the map-makers. Or to get down to more practical facts, explorers' reports written so recently as from 1840 to 1860, described what are now the great wheat growing lands of the west as an arid or a semi-arid waste, and stated that there was no practicable route from east to west through British territory. And to go a step further and come a little closer to home, it is still possible to step into an aeroplane, travel for a period of perhaps an hour and a half and within a hundred and fifty miles of Ottawa or Montreal reach a district of which no reasonably accurate map is yet available.

Just as the necessity exists for mapping the outlying and unknown districts, so it exists also for more detailed mapping of the older districts already settled and partly developed, because as development progresses the need increases for more accurate and more complete maps. In the newer districts a map may be satisfactory if it serves the requirements of the forester, the geologist, the builder of power transmission lines and the like; in the settled districts the map to be sufficient must serve the requirements of the drainage engineer, the road builder, the water supply engineer and many others.

In order to indicate that the necessity for good maps is not peculiar to Canada a short extract from a recent report of the Royal Survey Department of Siam may be quoted as follows:

> "Not only is science in general benefitted, but every branch of the industrial and commercial development of a country is advanced, if good topographical maps of the area of operations are available. The general administration in all its branches, the location of railways and highways, the planning of schemes for water supply, for irrigation, and drainage projects, the installation of electric transmission lines, even the location of the boundaries of reservations and holdings are all dependent on the supply of good topographical maps. Therefore, in order to mobilize all the available resources of this country and to enable them to be exploited to the best advantage, it is expedient that all the territory within its borders should be triangulated and topographically surveyed at the earliest possible date."

MAPS NECESSARY FOR DEVELOPMENT

In addressing a body of professional engineers it is probably quite unnecessary to stress the importance of accurate mapping as a prerequisite and basis for the economic development of the country. But it is a gospel that requires to be preached, because many people do not realize that to try to develop a country without accurate maps is as unsound, and usually in the end as costly, as starting to develop a mine without first diamond drilling.

The history of what has been done in the past by Canadian engineers and surveyors, in building up the maps of the country, is more than interesting — it is inspiring. Engineers are always leading in development and are perhaps more interested in the present and the future, than in the past. This paper will therefore attempt to give a statement descriptive of all the different kinds of maps we have in Canada, and what their particular features are. This is a difficult task, due to the many requirements which exist, and the resulting variety of maps.

To indicate the present situation, however, it may be noted that surveys made especially for the production of maps are now generally carried on by departments of the Federal Government and also by some of the provincial departments. While this paper is largely a description of the undertakings of the Federal Government, there must be no misunderstanding as to the valuable work which has been done and is being done by surveyors and engineers employed by provincial departments, because they are all contributing a very generous share in the work by co-operating in every possible way, and the provincial cadastres have been of inestimable value as control for mapping work.

Provincial Land Surveys

As the provincial cadastres or legal land surveys have been so freely used for developing our earliest accurate maps and as they constitute the basis of all legal titles to land, it may be of interest to indicate the extent to which they have been developed in different parts of the country.

Our garden province of Prince Edward Island has the distinction of being the one where the cadastre has been laid down most completely over all of it. In Nova Scotia the cadastre covers about 17,828 square miles, or 83 per cent of the province, the uncompleted portions being along the central ridge of the peninsula. The cadastre in New Brunswick covers, with more or less completeness, the whole of the province. In our largest province of Quebec, the cadastre covers about 55,000 square miles, or only 10 per cent, the remainder being accounted for in the vast areas still untouched and roughly speaking lying north of the latitude of lake St. John. The Ontario cadastre covers 131,000 square miles, representing 32 per cent of the total area, and includes broadly the portion south of the Canadian National Railway. In Manitoba the cadastre covers 55,080 square miles, or 22 per cent, the area north of the

Figure No. 1.

north end of lake Winnipeg being as yet untouched except for a shoe string along a part of the railway to Churchill. In Saskatchewan 116,340 square miles, or 46 per cent, represents the area of the cadastre which covers approximately the south half of the province. In Alberta the cadastre covers 111,555 square miles, or 44 per cent, including all of the prairie lands and extending northwards into the Peace river district. The area of the cadastre in British Columbia is 44,744 square miles, or 13 per cent, scattered through the fertile valleys and in general south of the Canadian National Railway running to Prince Rupert.

Classes of Maps

The maps now available may be roughly divided into three classes. First of all, there are the small scale maps—say from thirty-five miles to one hundred miles to an inch—of Canada, which show its full extent in outline, but as they progress from the developed, or partly developed areas in the south to the undeveloped, or largely undeveloped areas in the north, they show only the meagre detail, usually as supplied by explorers who have perforce had to keep to the coast-line, or main inland waterways. Then secondly, there are what might be termed medium scale maps of provinces or rectangles, varying in scale from four to perhaps twenty miles to the inch. These maps have been compiled from the best information available and they contain considerable detail, but not always reliable as to accuracy, and again in parts and usually as they go farther north, the information shown is less accurate and less complete in detail. And thirdly, we have the accurate topographic maps based on mapping surveys complete in detail and consistently so throughout any sheet.

A predominant distinction in this rough classification is that the first two are maps compiled in the office from all available sources of information. They are reliable and accurate when the information available is so, but obviously they must fail when the information available is not reliable. And it will be obvious that maps produced in this way are not consistent as to completeness and accuracy throughout. Judged by the strict standards of what a complete geographic map should be, they are not good maps, but they are the best obtainable, and therefore, by comparison, they are very good. There is no doubt that the compilers who have prepared these maps have used great skill and knowledge in their production, and when one thinks of the difficulties of the early explorers and those who have executed what field work has been done upon them, the maps are indeed a monument to their skill and endurance. It must be remembered that, because we have such an immense country with so small a population, it is always a pressing and real necessity to consider economy in expenditures for mapping work, and to use a nice discrimination in determining what kind of map is justified for the different parts of the country. It would not, for example, be reasonable or economical to produce an accurate one-mile map in Baffin island, and in the far north districts the existing maps may be adequate to meet the present requirements. There is little doubt, however, that with regard to the closer-in parts of our unsettled areas, where there is presently being carried on so much prospecting and development, we are behind-hand with maps that are adequate to assist in orderly and economical operations.

The main distinction of the third class of topographic maps is that they are based on mapping surveys executed for the purpose and they are consistently complete and accurate throughout.

Summarizing the last few paragraphs, it will be seen that Canada is in size the third largest country in the world. It comprises an area of 3,684,723 square miles. Of this area about 525,046 square miles or 14 per cent have been accurately mapped. We have maps showing considerable detail, but inaccurately, of an additional 487,559 square miles, or about 13 per cent, and there remains about 2,672,118 square miles, or 73 per cent, of which our maps show only the most meagre outlines of the coast-line and the main inland waterways.

Canadian Practice Up to Date

It will no doubt be apparent to those who study the following descriptions of our typical maps, that Canadian mapmakers are keeping well abreast of the times and that their methods in general represent the best practice of the day. The most outstanding innovation and improvement of recent times has been in the application of aeroplanes to, and the use of air photographs in, mapping work. In this field Canada has been particularly to the fore in developing methods of technique specially suited to her requirements, and it may be said without fear of contradiction that, as regards the actual application of the new methods and the actual production of maps made from air photographs. Canadian surveyors and engineers have done far more than those of any other country in the world.

Standardization of Measures of Length

All lengths measured by Canadian surveyors and engineers are based on the legal standards of the Dominion for the yard and the meter. The reference standards are metal rules of the type usual in laboratory operations of first order precision. These rules have been compared directly with the legal Dominion standards, in the custody of the Department of Trade and Commerce, as well as with prototypes of the British Imperial Yard and of the International meter. They have also been directly compared with the standards of the United States. In this way, and by periodical study, the accuracy of these reference standards is ensured.

There is maintained at Ottawa a physical testing laboratory which is equipped with apparatus for verifying and comparing primary standard rules, and with a reference base for determining the lengths of field tapes. The base consists of a series of concrete piers, set at four-meter intervals, each pier bearing a polished and finely graduated plate forming a bench mark. By means of an Invar (36 per cent nickel-iron alloy) rule, four meters long, the length of the whole base can be measured, one pier interval at a time. Micrometer microscopes are employed in the operation, and an adjustable bench-mark provides means for verifying tapes the length of which is not an exact multiple of four meters.

As the base is housed in an insulated building (having no windows) and provided with electrical heating under thermostatic control, in addition to determining the lengths of tapes at one temperature, it is possible to repeat the operation at different temperatures and determine the thermal dilation coefficients of measuring tapes.

The Problem of Projection

The earth being round, and maps being flat, a difficulty arises, for it needs little consideration to see that it is impossible to represent a spherical surface on a flat plane, without distortion of some kind. The larger the area the greater the distortion would be. In a small area, such as one degree of latitude or longitude, or less, there will be no appreciable distortion; but if a map is to include several degrees, the difference between the curved surface and the plane will begin to manifest itself; whilst in the case of a large area, such as a continent or a hemisphere, the distortion must become very serious.

To meet this difficulty we must resort to the use of some form of map projection. Map projection is the art of depicting on a flat sheet the features of a spherical surface by means of some consistent mathematical formula.

Various Purposes Served

In Canada, there is a great variation in the type of country to be mapped, which is apparent to anyone who travels on one of our transcontinental railways from Montreal to Vancouver and observes the wide differences between the rough tree-covered lands in the east, the smooth and treeless plains of the middle west and finally the mountain regions.

Many different methods have been developed by Canadian surveyors and engineers in order to overcome the difficulties and peculiarities of the different types of terrain. It is to be noted, however, that there are two major divisions of the work which are common to them all. The first necessity is to establish accurate control by which the four corners of the map sheet can, as it were, be pinned down into their proper position on the surface of the earth, and also to provide fixed points from which the features in the interior of the map sheet may be placed in their correct relative positions. And following and dependent on this is the work of locating and drawing in by the use of standard conventional signs all the details of the topography.

Geodetic Control

That country is fortunate in which it is possible to inaugurate a geodetic survey preceding development. Subsequent surveys are connected to the main framework, the governing survey prevents the accumulation of errors and discloses mistakes in surveys made with a lower degree of precision, the effect of any errors is confined to the area between the governing points, surveys for all development purposes, land settlement, irrigation, railways, water-powers, etc., can be co-ordinated and the results of each made available to the greatest extent for the other. The economies which such a policy renders possible save the cost of a geodetic survey many times over.

Vertical Control

As early as 1883 precise levelling had been executed by a federal department in connection with Dominion Government improvements, and subsequently that department has carried on precise levelling mainly in the vicinity of the St. Lawrence river and the Great Lakes. However, nothing in the nature of a national system of levels existed and, prior to the furnishing of vertical control by the federal Geodetic Survey, each engineering project—railway, hydro-electric development or engineering scheme of a municipality—was ocmpelled to take whatever datum was available, or, as was generally the case, to assign an assumed elevation to an initial bench mark, thus marking the beginning of a new arbitrary datum. It was not unusual to find in our larger cities as many as six different datum points, with consequent confusion. To remove this chaotic condition and to co-ordinate such discordances in a country extending 4,000 miles in length, was no mean task.

The geodetic organization started precise levelling in 1906, beginning at Rouses Point, New York state, from a bench mark established by the United States Coast and Geodetic Survey. As the demand for vertical control was received from all parts of the Dominion, the levelling operations were carried simultaneously into the Maritimes, Ontario and Quebec, the Prairie provinces and British Columbia. It was not until 1916 that a transcontinental line of Canadian levels was completed, connecting the Atlantic to the Pacific.

When precise levelling was started in Canada it was manifestly impossible to publish adjusted values, although such values are superior to the observed instrumental values as they represent the composite mean of all instrumental determinations. Accordingly, unadjusted instrumental values for the elevations of bench marks were released as soon as possible after field operations. These values were held until 1928, when the precise level net of Canada was sufficiently developed to permit one general adjustment, and adjusted values of the elevations of the bench marks were then published. This information was issued in nine volumes, grouped geographically according to provinces and these publications are now available for distribution. The amount of precise levelling, which has been carried out almost entirely along railways, has now reached a total of 23,800 miles.

At the same time the need for vertical control in districts untouched by railways led to the establishment of a secondary grade of control levelling of a standard slightly lower than precise. These secondary levels have, in general, been carried over highways and are adjusted to the standard datum by connections to the precise level system. The secondary net comprises, roughly, 11,000 miles at present.

The field operations are confined to control levelling, that is precise or secondary, and the bench marks established during these operations form the starting point for tertiary and detail levelling which may be required in a specific area. This tertiary levelling is carried out by the particular organization which requires such information. For instance, if a topographical map is to be made of any area, the organization conducting this survey receives, on request, the description and elevation of every bench mark which has been established by the federal survey in the district under investigation.

With the object of rendering increased service, a central collecting bureau for all level data of all classes was established. Arrangement was made with the various federal and provincial departments whereby the records of their levelling operations would be filed in this bureau. Similar arrangements were also made with the railways and other organizations performing levelling. This information, when received, is tabulated, correlated and placed on standard datum and is readily accessible to the public. The compilation of tertiary levelling information is not yet completed, but organizations contemplating an engineering project in any area of the Dominion may, on request, receive whatever information is now on record in this bureau, and in addition will be notified of the source where information not on record may be obtained.

The standard datum for elevations is mean sea level, in conformity with the resolution adopted by the International Union of Geodesy and Geophysics, of which practically every country is now a member. In Canada the actual determination of mean sea level was made by the hydrographic service, and was based on the long period tidal records of five primary tidal stations, namely, Halifax, Yarmouth and Father Point on the east coast and Vancouver and Prince Rupert on the west. The published adjusted elevations of bench marks, resulting from the general adjustment of the Canadian net in 1928, are expected to be held indefinitely without further change. The obvious benefits of having Canadian elevation records placed on a standard datum are well known to engineers. It is not to be expected, however, that municipalities and private corporations will transfer immediately to standard datum the enormous mass of records which have been based on arbitrary datum points, although certain corporations, such as the Canadian National Railways, are doing so at present. In this respect it is suggested, in order to reduce the clerical work involved, that all new levelling carried on should be based on standard datum and from time to time as old work is being revised the opportunity should be taken to transfer it to the same datum.

Horizontal Control

The present status of the horizontal control situation in Canada is that a federal geodetic survey is actively engaged in laying down the main and secondary frameworks of triangulation and related operations. The map on page 2 shows its distribution. Other federal and provincial organizations are co-operating with the federal organization by laying down subsidiary frameworks, which already have been or are designed to be co-ordinated with the primary network. In the Prairie provinces the splendidly executed Dominion Lands Survey serves admirably as a secondary and tertiary system which meets all requirements inside the main nets. In British Columbia the Department of Lands is laying down a subsidiary triangulation in close harmony with the federal operations. In the province of Quebec a triangulation organization is being gradually worked out which is also co-operating with the federal survey to an increasingly desirable degree. In Ontario also the provincial survey and federal geodetic organizations work in close accord, with the purpose of gradually increasing the accuracy of geographic data in the province. In the Maritime provinces the primary framework of triangulation is largely completed. Wherever possible all over the country older surveys are being connected to the main nets, their results checked and co-ordinated, and a mass of older data is given new importance. New surveys are naturally connected to and co-ordinated with the primary framework where the latter exists.

In outlying districts, to which the main or subsidiary nets have not yet penetrated, astronomically determined positions, latitude and longitude, are being used for the present to give the best information which the situation permits.

Thus while the primary horizontal control in Canada is far from the desirable position of being everywhere ahead of development, the situation is being met as energetically as possible, having in mind the short time in which geodetic operations have been carried on.

Triangulation

In the ultimate Canadian system the primary triangulation will be laid down in loops of such a size that few points will be farther than one hundred miles from these main nets. The present primary nets are naturally placed where the needs are greatest, such as along coast lines, large waterways, railroads, or near cities, or where easy transportation exists. Lately the aeroplane has had an increasing influence as a means of economical transport, and present nets are being laid down in regions dotted with smaller lakes where planes can land close to the geodetic stations. Fortunately these same regions are also those

Figure No. 3.—Instruments used in Topographic Mapping

Some of the instruments used by a ground party on topographic mapping in the foothills of the Rockies. Prominent in the display are the following:—surveying camera, small and large transit-theodolite, and range-finder, each with its respective tripod, photographic plates, barometers, stadia rod, binoculars, instrument cases, field books, etc.

in which mining and water power development is taking place and which consequently require accurate surveys.

In primary nets the distances between triangulation stations vary according to the topography from ten to one hundred miles or more, the economical distance being about fifteen miles. The accuracy of the calculated distances between primary triangulation stations is of the order of 1 in 100,000 or greater, that is, the error of these distances is generally less than one foot in a distance of twenty miles.

Even in primary triangulation the angular errors accumulate and their effect on the distance between stations and the azimuth of the lines must be periodically checked.

Base Lines

Every 150 miles or so one of the distances between triangulation stations must be measured to determine the difference between the calculated and measured distance. A short triangle side is chosen which passes over comparatively flat land and this distance is measured by the most precise methods. Fifty-meter "invar" tapes under a constant tension are employed on this work, this alloy of 64 parts of iron and 36 of nickel having been chosen because of its very small coefficient of thermal expansion.

Before and after the measurement of each primary base line, the field tapes are standardized. The unit of length used is the International meter, the standard of length employed being a 1-meter nickel bar number 10239 which is frequently compared with international standards.

Laplace Observations

These are astronomical observations for longitude and azimuth at triangulation stations for detecting any azimuth error in the triangulation due to the effect of errors in the angular measurements. It is well known that all astronomical observations are subject to errors due to the unequally distributed density of the earth's crust as typified by mountains and valleys. Latitude and longitude observations may be in error due to this cause by as much as half a mile or more in mountainous regions, and azimuth by as much as 15 seconds. Fortunately the errors of azimuth and longitude are related, and, by observing both, the true or Laplace azimuth can be calculated from the observed. These Laplace observations are made at intervals of six or seven stations in a triangulation net, about every 100 to 150 miles. The highest class of astronomical instruments are employed for primary observations of this kind.

Secondary Triangulation

This class of triangulation has often a more intimate appeal to the engineer than has primary work. The stations are closer together, are generally more conveniently situated to the engineer's work, and the precision is ample for checking most survey operations (except city surveys, in which the requirements are more rigid and for which primary control is needed). This class of triangulation is that generally employed where control is required within 50 to 100 miles of primary nets. The principles underlying the work are similar to the more accurate operations but the methods employed are less rigorous.

Secondary or tertiary triangulation, in conjunction with the primary, is especially valuable in connection with investigations of large areas such as hydraulic studies of large watersheds, timber and other resources of large limits, where the cumulative errors of ordinary surveys produce discrepancies of very appreciable proportions.

Precise Traverse

An economical and accurate substitute for primary triangulation is necessary in flat wooded country where the high cost of primary triangulation is a serious factor. Precise traverse measurements along roads or railroads have a useful place in certain parts of Canada supplementing or substituting for triangulation.

In the class of secondary or tertiary traverses are the meridian and base lines established by various provincial land surveys.

Triangulation Adjustment and Research

It will be realized that, in the primary control of such a large country as Canada, the greatest care is necessary to prevent the accumulation of errors which will destroy the virtue of the control. Thus while the field work must be done with the highest accuracy the proper distribution of the field errors, as disclosed by field tests and by the measurement of base lines and Laplace observations, is an equally important operation which requires the greatest skill and mathematical knowledge. The problems confronting those in charge of the adjustment of triangulation nets are of great complexity, and research work is continually going on to develop the methods by which these problems can be handled and the nets placed in their correct position.

The adjusted angles are used to calculate the distances between stations, the azimuths of lines and the latitude and longitude of all triangulation points, in which shape the data are published. Preliminary results, unadjusted, are available before adjustment for use where such data are sufficiently accurate for the purpose.

All of the triangulation in Canada, the United States and Mexico is based on the North American Datum, that is, all latitudes, longitudes and azimuths are based on the position of one point in Kansas and are calculated on the same assumed spheroid, Clark's Spheroid of 1866. Thus all the geodetic results along the borders separating these countries are in complete agreement, a very important international advantage.

Standard One-Mile Topographical Map—Using Plane-Table Methods

The plane-table method for topographical mapping on the scale of one mile to one inch, constitutes the general method by which the greater part of this work is carried out. It is the method that is best suited for low lying country or country of moderate relief, whether it is open or bush covered. Consequently, it is used extensively over that part of Canada that lies to the east of the Rocky mountains. It is also used in some of the lower lying portions of British Columbia and Alberta.

The standard unit of map sheet for this scale embraces an even 15 minutes of latitude and an even 30 minutes of longitude. This includes an area of about 422 square miles in latitude 45 degrees and about 300 square miles in latitude 60 degrees.

Control Required

In all topographical mapping, the area to be mapped must first be considered in its entirety and a system of control points established over it which will form a rigid framework upon which the whole map is based. In this way alone are the correct relative positions of different portions of the map established, and the necessary accuracy maintained in all of the minor surveys connected with the topographical mapping operations. This control, therefore, to fulfill these requirements must be well distributed over the area.

The general methods followed in mapping an area can be divided into two main groups, namely:—(1) The control, both horizontal and vertical, (2) the topographical mapping.

Horizontal Control

Horizontal control is obtained either by triangulation or traverse, depending on the character of the country. When triangulation is used, there are two requirements that are kept in mind when selecting control points. These are, to place the points where they will be readily accessible as tie points for the topographical mapping surveys and, at the same time, to spread them judiciously over the whole area. To carry this out successfully requires careful judgment as well as a good knowledge of the conditions over the whole area and of the requirements of the topographical work.

A reconnaissance is first made of the area to be mapped; station sites are selected and signalled. The base line and check base line sites are chosen and cleared. If two or more previously located triangulation stations are in or near the area, the necessity for base lines is done away with. During the progress of the reconnaissance, points, other than triangulation stations, which will be useful as tie points and which have no definite object to sight on, are flagged. Objects, such as windmills, churches, water towers, flag poles, lone conspicuous trees, etc., are always "cut in" during the course of the triangulation. They constitute good tie points for topographical traverses.

The triangulation for the control of a 15 by 30 minute sheet is carried out with a transit reading to one minute. Angles are measured by repetition, in sets of three direct, and three reverse. By using care in centreing, pointing, having signals vertical, and by observing great care in obtaining initial azimuths from pole star observations, sufficient accuracy can be obtained for the control of the sheet.

In general, it can be said that for the triangulation control of a 15 by 30 minute sheet only, the accuracy should be such as to give a 15-second or 30-second triangle closure. Base lines, if required, should be measured with an accuracy of 1 in 50,000 or more.

Traverse control is undertaken in areas where triangulation is not feasible or is too expensive, owing to the absence of sufficient relief or to timber obstructing the range of vision. This type of control consists of transit and tape traverses carried over the area with a view to cutting it up into comparatively small blocks. The traverses are run in circuits or tied to some previously located points. The routes of the traverse generally follow the course of railways or roads. In portions of the area where there are no roads, or an insufficient number of roads to fulfill the requirements, the traverses are carried across country. Every part of the area must be controlled.

Transits reading to one minute or 30 seconds are used. Distance is obtained by using a 300-foot steel tape and taking slope measurements. Slope angles are taken with the transit or with an Abney level. Record is kept of all crossings of county and township lines, railway and road crossings, road forks, mileposts, stream crossings and so on. The number of every fifth transit station is painted in a conspicuous place at the side of the route for identification purposes by the topographer.

For the control of a 15 by 30 minute sheet alone by the traverse method, an accuracy of 1 in 5,000 should be obtained. This can be accomplished by taking ordinary care in all of the operations. Observations for azimuth on the pole star are taken at intervals of from 5 to 8 miles depending on conditions.

If the horizontal control is being carried out for more than one 15 by 30 minute sheet, the accuracy with which

Camera station on mountain peak. At the right a stone cairn is being built to mark the location of the station. At the left is a surveying camera shown mounted on its tripod. This tripod is also adapted to supporting the transit-theodolite head. Angles to other stations and prominent points are taken with the transit-theodolite, the topographic detail being filled in from the photographs.

the work is carried out is naturally increased to meet the requirements.

The horizontal control, when completed, is adjusted and plotted on a projection sheet on the scale of one-half mile to one inch. All information relative to the map is laid down.

Vertical Control

Vertical control is obtained by instrumental levelling carried in circuits over the area. Bench marks are established about every 3 miles. Ground elevations, for use by the topographer, are painted in conspicuous places along the routes.

Topographical Mapping

This includes all the operations connected with the work of obtaining the topographical data over the whole map area. The instrument used throughout the major part of these operations is the plane-table. The method of carrying out the operations depends on whether the control was completed a year in advance of the topographical mapping or is carried on concurrently with it.

When traverse control is completed in advance of the topographical work, the control information is transferred to plane-table sheets. These sheets are then used by the topographer in the field. The general procedure in obtaining the topographical information on each plane-table sheet is to travel along the routes of the control surveys, eatablishing locations and elevations on either side of the route, and completing the mapping along the route and as far on each side as possible. The unmapped areas between the routes are then controlled by means of plane-table surveys, using either stadia, tape or pace for distance, depending on the requirements, and the topographical detail completed as before. In this way the plane-table sheets covering the whole area are completed.

When the triangulation or traverse control is carried on concurrently with the topographical mapping operations, the procedure is somewhat different. Plane-table sheets cannot be prepared beforehand, consequently the topographer has to build these up as the work progresses The control survey party and the topographical party have to work in close touch with one another, in order to avoid duplication or omissions. Knowing where the control points or control routes are to be established, the topographer blocks out areas between these by running plane-table and stadia traverses along roads, trails or streams, or across country if need be. The topographical detail is completed along these routes and as far on either side as possible. The areas thus blocked out are then cut up by traverses with plane-table and stadia or tape, until the topography of the whole area is obtained.

In carrying out all of the topographical mapping operations, there are certain things that must be borne in mind in order to obtain an accurate well-balanced map. Briefly stated, some of these are: the proper adjustment of all the surveys; the necessary accuracy in plotting directions and distances; keeping a balance between the precision with which a survey is executed and the degree of accuracy with which it can be plotted on the field scale; obtaining the proper amount of detail and generalization in keeping with the scale; avoiding omissions of important features; obtaining legibility in all that is shown; sketching contours to represent the shape of the ground as well as to give the elevation, maintaining consistent accuracy over all parts of the map.

One-Mile Mapping Using Vertical Aerial Photographs

Vertical aerial photographs have been used in Canada as an aid to mapping since 1924. They are used principally in the production of one and two-mile maps.

Control Used

Prior to the adoption of air photography for mapping, the horizontal ground control for one mile mapping consisted of a network of primary traverses along roads, with practically all roads within each primary circuit controlled by secondary traverses. It was found that detail within the primary traverse network could be plotted from photographs with as great, if not with greater accuracy than by the use of the secondary traverses, and at the present time the horizontal control consists of transit chain traverses run along roads or across country, enclosing areas of approximately seven and a half minutes in latitude by five minutes in longitude, or of about thirty-five square miles. Water areas of sufficient expanse to cause difficulty in the construction of the photographic control are enclosed by traverses. The lines are chained with a 200-foot Invar tape and such detail as will definitely appear on the photograph is recorded. The traverse angles are measured with a one-minute instrument, but at all intersection stations observations for astronomic azimuth are taken with a one-second instrument. The traverses are connected to all geodetic stations within the area and the closure errors of circuits average about 1 in 18,000; with no circuit showing an error of 1 in 5,000.

The vertical control consists of primary level lines run over the traversed roads, with secondary lines within the primary circuit sufficient to leave no point of country more distant than one mile from some elevation thus established. All levels are connected to precise bench marks and the circuit closure aim for primary lines is $.2\sqrt{N}$ feet, where N is a number equalling the number of miles in the circuit. Twice this error is allowed on secondary lines. The level party paints in white, on nearby fence or post, the elevations of all turning points and road intersections for the convenience of the topographers, and notes the elevations of culverts, schools, summits, depressions, transit stations and other important details. A copy of these notes is supplied to the topographer.

A complete control party consists of nine men, including a cook and chauffeur. In a season of six months and in average country one party will run about 1,000 miles of transit line and 1,500 miles of levels, which is sufficient control for about 1,600 square miles of country for one mile mapping.

Plotting the Control

The horizontal ground control is plotted on paper mounted on zinc to prevent expansion and contraction. For convenience in plotting photographic detail, the size of these control skeletons is 10 minutes of longitude by 15 minutes of latitude, three skeletons forming the sheet, which is eventually reproduced on the one mile to one inch scale. After the ground control has been plotted at one mile to two inches a photographic control is constructed over the area within each traverse circuit by one of the graphical methods of plotting. This photographic control fixes on the paper the centres, or points near the centres, of every photograph within the area concerned.

Plotting the Detail

After these points have been fixed, the detail is plotted between them by proportional dividers. Where relief is sufficient to cause distortion at the scale of the plot, additional selected points on hill tops and in valley bottoms are fixed by radial intersections before detail plotting is commenced.

Relief, when sufficiently pronounced to be viewed in the stereoscope, is indicated on the photographs by form lines, which are plotted on the skeletons along with the other detail.

All plotting of control and of photographic detail is carried out by the field staff during the winter months.

Preparation of Base Field Sheets

On the completion of the plotting, all detail is inked in black, the plots are photographed and each skeleton is reproduced in blue on three aluminum mounted plane-table sheets, each including an area of 10 minutes of longitude by 5 minutes of latitude. These form the base upon which the topographer works. All detail is thoroughly checked on the ground, and such as is to be shown on the

Figure No. 6.—Oblique Aerial Photograph and Grid.

A Canadian development, applicable to much of our northern country, has been the use of the oblique aerial photograph for mapping intricate water features on scales of four miles or more to the inch. In this method, grids are selected and superimposed over the photographs as an aid in interpreting the topographic detail. In the selection of the particular grids to be used, ground control must be taken into consideration, the actual data governing the selection in each case being recorded in the upper left hand corner.

Figure No. 7.—C. G. S. "Acadia."

Single screw high-powered steel steamer of some 1,100 tons displacement, built especially to meet surveying requirements and strengthened to withstand ice. This ship is equipped with the latest devices to promote efficiency and economy in charting, including the following:—gyroscopic compass; British Admiralty pattern echo sounding machine; usual radio equipment with the most up to date type of radio compass; deep-sea water bottles with thermometers attached, for oceanographical work; several chronometers, transits, base-measuring chains, sounding and observing sextants, etc.

map is inked in the appropriate colour, the streams being in brown for photographic reasons. The contours are added with the aid of the Indian clinometer and of the form lines where obtained from the photographs, based on the level control.

After the field sheets have been completed they are reproduced and compiled in the one mile to one inch sheet form in the usual way.

In the above method of one-mile mapping what might be termed the straight line method of assembling the details shown on vertical photographs is used.*

Radial Intersection Method

In the radial intersection method, also in use in Canada, each flight line is plotted separately between control points and horizontal control parallel to the flight lines is not required. The spacing of control lines varies with the relief of the country, control being required at greater frequency in rough mountainous country with quickly changing relief than in level or slightly undulating country. Probably an average could be from 5 to 8 miles for one-mile mapping and from 8 to 12 miles for two-mile mapping

In this method the distance between the centres of the first two photographs as shown on the first photograph of the flight line is used as a base from which points are intersected on each side by radial lines from the principal points. A series of such intersections across a flight line gives a plot of the principal and intersected points to the scale of the air base on the first photograph. Additional points to control the sketching of details and to locate points common to adjacent flight lines are located by intersecting rays drawn from principal points. The reduction to the projection scale is obtained by the distances between corresponding points on the strip and on the projection. It is usually made by photography. The reduced strips are assembled directly on to the projection.

*The method is described in detail in the Canadian Defence Quarterly of July, 1925.

Other Methods

Another method commonly used in Canada is to take the photographs themselves into the field and identify and mark on them the details to be shown on the map. Elevations of points are determined by any of the different methods available and the contouring done directly on the photographs with the aid of the stereoscope. The assembly of the details onto the projection is done after the field interpretation and the contouring have been completed.

The use of vertical air photographs in mapping has, without doubt, raised the standard of mapping in difficult country without undue increase in cost, so that the standard in all classes of country has been made more nearly uniform.

Two-Mile Mapping—Using Plane-Table

There are large areas of partly developed country in Canada where maps are urgently needed but for which sufficient money is not available to do standard one-mile to an inch mapping. Methods have been devised to plane-table these areas rapidly for the production of maps on a scale of two miles to an inch.

Control

Control for such mapping is based on primary triangulation, which is extended by secondary triangulation and control traverse. This traverse is of two kinds, the longer lines being chained transit work with an accuracy of better than 1 in 5,000, and stadia control lines usually less than ten miles in length and with an accuracy of better than 1 in 800.

Spirit levels are run over the area in convenient circuits, usually along the chained traverses, with an accuracy of better than one-tenth of a foot multiplied by the square root of the distance in miles between the precise bench marks. Stadia levels are obtained, along the stadia control, that must close within 3 feet on the spirit level bench marks.

It is the practice to leave a great number of marks of the control painted up on the ground for the guidance of the topographer. All traverse stations are painted up distinctly by number as well as their elevation above sea level. Also specially constructed permanent monuments and bench marks are established at about 3-mile intervals along the main control. These monuments are carefully placed and described so that they may be easily found for years to come.

All traverses are reduced by latitudes and departures in the field, and the closings checked. When the survey has been properly closed and adjusted, the plot is made on a Gauss conformal projection of the map sheet.

Plane-Table Sheets

Plane-table sheets are prepared by pricking through the triangulation and traverse stations. All stations are named or numbered on the plane-table sheets in blue or violet inks and the elevations added in pencil. Thus the plane-table sheet is given to the topographer with the positions and elevations of several hundred points accurately located upon it.

Instruments

The instruments with which the topographer is usually supplied consists of a full size plane-table, trough compass, opensight alidade, Cooke transit, a 15-foot self-reading stadia rod, and a Barr and Stroud coincidence range-finder fitted with a special clinometer for work in open country, and for work in the bush a set of three surveying aneroid barometers, trailer tape, military compass and pedometer.

The use of the Barr and Stroud range-finder F.T. 32, Mark 2, with a meter base and fitted with a special clinometer has been a great aid to the topographer in rapid mapping. This range-finder is constructed on the coincidence principle, the upper image being inverted. In the right eyepiece the two images separated by a halving line are seen and brought together, or a coincidence made by a working head on the inside of the right operating handle. Distances are read directly on the scale visible through the left eyepiece.

A table of uncertainty of observation under favourable conditions is given by the marks as follows:

Distance Yards	Uncertainties of Observation Yards
500	1.0
1000	3.8
2000	15.0
3000	34.0
4000	61.0
5000	95.0
6000	137.0
7000	187.0
8000	244.0

The probable error would be about one-half these values.

The figures are based on the best conditions available as to light and ranging objects. It is found in practice that the probable error of observation increases very rapidly with poor visibility and with the indefiniteness of the object ranged on, and one should be prepared to accept a probability of error slightly in excess of the values given above. Thus errors are quite small and unimportant up to about 1,000 yards, but become greater as the distance increases so that at 1,500 yards they are an important factor, and the range-finder cannot be used except for rough measurements over 2,000 yards.

In measuring angles the standard instrument in the past with plane-tables has been the Indian clinometer. This instrument has no means of magnification so that its reliability is restricted to distances of not over half a mile. A new clinometer has recently been designed at Ottawa, that has many advantages. It is attached to the range-finder so that one pointing of the range-finder to read distance may also be used to read the vertical angle, thus saving a second reading and giving the observer the benefit of the range-finder magnification. The clinometer is of the micrometer drum type and is attachable to the platform of the range-finder, which formerly carried the sighting vane, a new sighting vane having been substituted.

The topographer usually finds that his plane-table sheets are prepared with an accurate traverse of the roads and railways, giving both the vertical and horizontal control. Plane tabling in the usual way around the blocks, the topographer finds that the range-finder permits him to map from 300 to 1,500 yards either side of his control. He has the facility of rapidly obtaining the distances and elevations to all objects such as houses, hills and the shores of streams, lakes, etc. Also, when using this range-finder, the topographer always has his helper beside him, and this man may be an inexpensive labourer.

In the bush areas the rivers and lakes are mapped from stadia traverse, creeks by compass and trailer tape traverse, and the contours laid down by cross sectioning, with barometers. This work with barometers in bush requires experienced men who can pace and sketch accurately. The barometers are used in sets of three and their readings adjusted from the gradient obtained by a set of camp barometers that will be more fully described under mapping the three miles to an inch series.

One-Mile and Two-Mile Maps—Using Photo-Topographic Methods

The mountainous regions of Western Canada furnish an ideal field for the application of photo-topographic mapping on account of the physical and climatic conditions which prevail.

The first photographic survey in these regions was undertaken forty-three years ago in the area adjacent to the Canadian Pacific Railway at Banff. During the succeeding seven years methods and instruments were improved and the success of the system was demonstrated by the production of a map, covering about 2,000 square miles, on the scale of 1 to 20,000 and with a contour interval of 100 feet.

Since that time many other surveys of a like nature, plotted on various scales and with varying contour intervals, have been made in Canada by the Dominion Government and more recently by the British Columbia Government.

Instruments

The instruments to be used on photo-topographic surveying should be light and compact, and should be kept in good adjustment. The transit theodolite may be of ordinary pattern with a 3-inch circle, reading to minutes, and with telescope of sufficient power to pick up signals readily from 12 to 15 miles away.

The camera used has a camera box of fixed focus type with lens generally of F. 6.3, and is specially constructed so that the horizontal plane through the centre of the lens and the plane of the photographic plate may be placed at right angles. Photographic plates are of a size, 4¾ by 6½ inches; the camera having a field in a horizontal position of about 51 degrees and in the vertical position of about 37 degrees. Eight plates are usually required in the horizontal position to photograph the horizon completely, providing sufficient overlap between the successive views. Level bubbles are attached to the camera so that it may be kept in a level plane at the time the exposures are made.

Figure No. 8.—Mapping on the Northern Plains.

View taken at survey monument. The man at the left is drilling a hole in which to sink a short bronze survey post. Next to him the rodman is holding a stadia rod. The third man is using a range-finder (mounted on a tripod) for obtaining distances. The surveyor's transit-theodolite and the stone cairn to mark the position of the monument are also shown. View taken on east side of Artillery lake.

The transit and camera should be interchangeable for use on the same tripod, the latter being of very light construction and with either short legs for high mountain peaks, or with legs of standard length for use in country where there is more or less bush at the higher levels.

Methods

In the photo-topographic method, the elements of perspective are made use of. The object of the survey is to record on photographic plates images of the country from each of two or more properly located fixed points, or stations. The resulting photographic prints enlarged twice are then used in pairs, the common points being identified in sufficient number to enable the plotting of the detailed topography of the country.

The surveyor in the field must constantly keep these requirements in mind, and, through experience, he gains an aptitude for the work which allows him to visualize the country to be mapped, and to determine what construction he will apply and what views are necessary for that construction.

Photographic surveys are usually based on a calculated triangulation control accurately plotted. The camera stations may be fixed, either by angles taken from the triangulation points, or by angles measured at the camera stations themselves. It is much easier and more accurate to plot a camera station by means of intersection angles read from two or more other stations, rather than by means of resection with angles read to three or more other stations from the station occupied. Field work, therefore, should be laid out and camera stations selected so as to avoid the resection method, and to make the re-occupation of stations as few as possible. Stations are marked by either a tripod covered with cotton or a stone cairn, according to their location.

The camera work is done at the same time as the transit occupation. Occasionally, it may be necessary to set up the camera, in order to include certain parts of the landscape, at points close to the tied-in station (a few hundred feet, or less). Such subsidiary points may be connected up with the adjacent station by measurement with a light tape and an angle read by the transit.

The experience of the surveyor in laying out his work will be the best guide in his programme of taking views from each station. Every view should be taken from the point where it is best for the construction of the resulting map. A large number of subsidiary stations gives very little extra work, either in taking the angles for fixing their positions, or in plotting them.

In some cases it may be difficult to obtain views which will furnish horizontal intersections of a certain part of the ground. In these cases the method of vertical intersections may be employed, views being taken from different altitudes. If the difference of altitude is large enough, and the points to be determined not too far distant, a similar degree of precision may be obtained, as with horizontal intersections.

Figure No. 9.—Solar Observation for Watch Correction.
Surveyor with transit-theodolite taking observation of the meridian passage of the sun at noon for the purpose of obtaining the correction to his sidereal watch. This watch correction is an important element in other observations as for azimuth, etc.

Knowledge of Photography Required

In addition to his knowledge of ordinary survey practice, of descriptive geometry, and of the principles of perspective, the surveyor on photo-topographic work must be cognizant of the main principles of photography in relation to the comparative values of light, as affecting the sensitized plate. He will gain this last mentioned understanding best through experience.

The photographs must be clear and full of detail, the points to be plotted being well defined and easily recognized. In this connection there will be certain difficulties to overcome inherent in mountain landscape, such as the effect known as "aerial perspective," or the merging of the landscape into a uniform tint in the distance.

To aid in the solution of these and other problems, in connection with the photography in these regions, panchromatic plates, that is, plates susceptible to all rays of light, are used in combination with a yellow light filter, "G." These give excellent results.

Notes and Plotting

The notes of the survey consist of a record of the angles observed to determine the positions of stations and their elevations, of the photographic data such as the numbers of plates and description of the views, the direction of the view and description of fixed points appearing in each. Sketches serve to identify these points with more certainty than a mere designation by letter or figure.

In plotting the features from the photographs after the control itself is laid down, the first operation is to define on each view the horizon and principal lines. This is done by reference to test views which are made at the beginning of the survey to determine the position of the camera bubbles when the plane through the lens is horizontal. The second is the identification of common points, and their numbering in coloured ink, on different pairs of views. These common points should be selected so as to define the topography as accurately as possible with a minimum number of points.

It will quite often happen that a given area cannot be mapped from two stations only, owing to projecting shoulders or intervening ridges. In these cases, of course, views from other stations must be utilized to fill in detail.

After the points have been identified, a strip of paper one-half to three-quarters of an inch wide, and a little longer than the view, is taken. A line perpendicular to the edges of the slip is ruled near the centre. Keeping the strip on the horizon line of the view the distances of the various points identified on the photograph from the principal line are marked on the slip. The slip is then reversed and on the opposite side the distances of the points above and below the horizon line are marked in a similar manner. On the side of the slip showing the horizontal distances it is customary to write the name of the station and the number of the view, and on the opposite side the number of the view and the elevation of the station, using the same coloured ink as for the points. The distances may be marked in pencil or ink, on the photographs when the several points have been identified and the horizon and principal lines have been ruled in their proper positions.

The traces of the principal lines and the picture plane are then laid down on the working plan. The lines from the stations to the line first drawn on the slip represent the principal lines of the views. The slips showing the distances of the points from the principal lines are then placed on their proper traces. Then the line of sight from the station to any point is found by drawing a straight line from the station to the projection of the point shown on the slip, and the position of the point is given by the intersection of two or more of these lines of sight.

Practical Methods Employed

In practice an adaptation of this method is the use of fine threads or hairs, one end of each of which is looped and secured over a needle inserted on the working plan to mark a station, and the other end attached to a small weight. When the hairs lining from the stations to the respective points in each view as marked on the slip, intersect, the intersection represents the points to be plotted. These points are pricked on the plan by a fine needle or pricker, and are marked with a number in coloured ink, as on the view.

In order to facilitate the laying down of traces, methods have been devised consisting essentially of the use of sheets of transparent celluloid cut to convenient size, on which been have previously etched straight lines representing respectively the principal line and the horizon line at right angles thereto.

The elevations of points may be determined mathematically, but for the purpose of the usual mapping operation graphical methods are employed. The instrument known as the "elevation computer" has been successfully used on Canadian surveys.

The precision of a survey executed by the methods described, when all the points are established by intersections, is the same as that of a plan plotted with a very good protractor or made with the plane-table. There is, however, this difference: the number of points which may be plotted by photography is greater than by the other methods.

The photographic survey is weak when there are "blind spots"—areas which do not appear in detail on a pair of views, or which appear only on one view. The experienced photographic surveyor will have very few of these, and when they are apparent sketching must be resorted to, as in the case with the plane-table survey.

The advantage of the photographic method for mapping Canada's mountainous areas is that it enables the topographer to gather conveniently, economically and rapidly during the short field season on the ground, by photography, the material for his maps, and then construct them afterwards at his office during the winter season.

Figure No. 10.—Surveyor receiving Time Signals.

With the advent of the radio and wireless, the taking of observations for longitude has been much simplified. In the illustration, the surveyor is shown receiving time signals for use in connection with such observations.

Three-Mile Sectional Sheets

The map sheets of the Sectional Map series, published on a scale of three miles to the inch, include eight townships north and south and fourteen or fifteen ranges east and west, comprising an area of about 4,200 square miles, and cover the Prairie provinces and the railway belt and Peace river block of British Columbia. These map sheets were first published in 1892 and were compiled from the township subdivision surveys with the addition of information regarding railroads and post offices. In 1919, the policy was adopted of changing these sheets in the more settled parts of the country into topographic maps, and for this purpose field parties were sent out to obtain the necessary information as economically as possible.

The settled parts of Western Canada consist largely of vast tracts of prairie country with comparatively little relief. To map this country accurately and rapidly to the scale required presented a new problem to the topographers. The ordinary methods of topographic mapping were far too costly, so a system of sketching the topography on a much larger scale than the finished map was devised. This system, which makes use of motor cars and aneroid barometers, controlled by lines of instrumental levels, for contouring, has given remarkable results and has solved economically the problem of mapping large areas of settled country to a small scale.

Control

The Dominion Land Surveys System with townships six miles square, and with monuments every half mile on road allowances which run every mile north and south and every one or two miles east and west, provide ample horizontal control. Possibly in no other country have the cadastral surveys been so well planned and executed that no additional horizontal control is required for topographic mapping.

Vertical control is provided by all the level lines previously run, and consists of precise levels along the railways, secondary levels along the base lines, the profile of railways along which precise levels have not been run, provincial road surveys and levels run for drainage and irrigation purposes.

Figure No. 11.—Triangulation Control for One-Mile Mapping.
A typical triangulation station for the control of one-mile mapping in eastern Canada.

With these levels as a skeleton, a net work of levels is run with transit and stadia on practically all east and west road allowances. Each map sheet is thus covered with lines of instrumental levels from 2 to 6 miles apart.

Before commencing field work all the existing information relative to surveyed roads, water areas, edges of valleys and railroads, available in Ottawa or at the Provincial Government offices are plotted on township plans (scale half a mile to the inch).

The available level lines are reduced to mean sea level, and the elevations of all section and quarter section corners, the crossings of the section lines by the railways, as well as the elevations of the summits and depressions are entered on the township plans. In addition to this, the intersections of the contours by the levelled lines are plotted.

Organization of Party

A field party consists of a surveyor in charge, an assistant, a leveller, a camp draughtsman, three helpers and a cook. For transport, three light cars and a truck are used. The field work has been systematized so that the party can cover a map sheet of this series in a field season of about five months.

Field Methods

The party is divided into three working units, each consisting of a technical officer and a helper, and each provided with a car. The leveller is employed in running stadia levels and doing any instrumental traversing required. These levels are run with transit and stadia rod in circuits of from 15 to 25 miles and are controlled by the lines of spirit levels. The chief and assistant do the topographic mapping. Using the township as a unit, the country to be covered from each camp is divided between them. By travelling the road allowances and using the car speedometer for distances between the half-mile survey posts, the following topography is plotted on the township plans, different coloured pencils being used:—

Buildings, streams, railways, telephone lines, water areas, wooded areas, roads in four different classes, pipe lines, irrigation canals, drainage ditches, ferries, dams, mines and quarries, etc.

Contouring

With the network of spirit and stadia levels as control, the townships are contoured to 50-foot intervals by the use of aneroid barometers. The barometers, which have previously been tested and passed by the Physical Testing Laboratory, are carried in sets of three and the mean of the readings taken. During the field day, three barometers are read in camp every half-hour from which the curve or gradient showing the changes in atmospheric pressure is plotted.

The field watches are synchronized with the camp watch and the time of all field readings recorded. In reading the barometers, the foot scale is used and the nearest five feet taken. Care is taken to overcome friction by tapping the glass and to see that the relation between the three barometers remains fairly constant. One barometer may go up twenty feet while the other two only go up ten feet, but this difference should not be exceeded. This relation can usually be kept fairly constant by repeated tapping.

On the average map sheet in Western Canada two distinct classes of country are usually encountered: the one thickly settled with good roads on practically every road allowance, and the other where the country is sparsely settled and very few road allowances are travelled. A different method of contouring has been developed for each of these classes.

In the first case the level control lines are from two to four miles apart. The field barometers are read at a known elevation and carried by car as quickly as possible along a road to the next known point, readings being taken and the topography sketched at all intervening section and quarter section corners, as well as at the more prominent summits and depressions. By arranging the work so that the interval between readings on known elevations does not exceed 30 minutes the elevations of the points noted can be determined directly from the readings. The contours can then be sketched on the township plans, using a hand level for tracing their courses across the interval between the roads. In this case, the camp gradient is only used in checking the accuracy of the elevations as determined in the field, as it has been found that when the interval between readings on known elevations does not exceed 30 minutes, no corrections are necessary to the elevations used in the field. When the time intervals exceed 30 minutes, it is usually necessary to use form line sketching and complete the contouring in the camp office, or else to contour in the field after the barometric readings have been reduced with the aid of the camp gradient.

In the second case, cars can only be partly used and walking has to be resorted to. It is also seldom that more than one line of levels can be run in any one township. The barometers are read as often as possible on known elevations, and when the time interval exceeds two hours the work is laid out to include repeat stations, that is, points whose elevations have been determined barometrically two or more times. In the final corrections to the readings, the mean of the elevations of the repeat stations are used as known elevations. The contours are then drawn in the office with the aid of form line sketching.

Using good barometers, taking care in reading them, and by having the interval between readings on known elevations to be less than one hour, surprisingly accurate results have been obtained. It has been found that approximately seventy-five per cent of the barometric elevations are within five feet of the true elevations and that very rarely is one found to be more than ten feet in error. When the barometers are carried by hand and repeat stations used, no reading should be twenty feet in error, while most of the elevations will be within ten feet. For good barometer work the elevation of camp should not vary more than about 200 feet from the mean elevation of the country worked in. Work should not be done more than twenty miles from camp. The crossing of deep valleys should be avoided during the day as much as possible.

There are, of course, days when the barometers are unreliable owing to high winds, thunderstorms, etc. These days, however, are comparatively rare and when they occur other than barometric work is carried on.

On completing a township in the field, the information shown on the plan is carefully checked to see that no discrepancies exist. This is specially done with the borders of the adjacent townships.

The surveyor returns from the field with all the topographic information shown on township plans. At the head office a projection of the map sheet, on a scale of two miles to the inch, is laid down on cross-mounted bond paper. The topography collected in the field is transferred to this projection which, after it has been checked and place names added, is inked in. The completed projection is then turned over to the photographic and lithographic divisions for the preparation of copies for the use of the map draughtsman.

Four-Mile Maps Using Oblique Aerial Photographs

A large part of Central Canada consists of relatively flat country with numerous water features, and presents a most attractive field for mapping by oblique aerial photography. Recent map sheets issued on the four-mile scale have been prepared in this manner. Each four-mile map sheet extends over one degree in latitude and two degrees in longitude; in latitude 54 degrees the sheet measures 81 miles in an east and west direction, and 69 miles in a north and south direction, comprising an area of about 5,600 square miles. The operations in connection with the preparation of the four-mile map sheet fall into three major divisions consisting of: first, the actual oblique aerial photography to cover the area; second, the ground control for fixing the geographical outlines of the sheet and for determining the scale of the oblique aerial views obtained; and third, the plotting of the oblique aerial photographs, the assembly of the individual plots to form the map, and the finished drafting, photography and printing of the resulting map sheet.

Oblique Aerial Photography

For photographing obliquely the area comprising a four-mile map sheet parallel photographic flights, spaced usually 6 miles apart, are made at an altitude of about 5,000 feet above the area in an easterly and westerly direction across the map sheet, together with north and south flights at the easterly and westerly limits of the sheet and two or three additional north and south flights spaced apart one-third or one-quarter the length of the map sheet. These latter intersect the east and west flights, and serve to supplement the limited ground control and to facilitate flying the long east and west flights in their proper location. To assist the pilot in this work, he is provided with a map compiled from any existing information upon which is projected the lines of flight to be followed.

To be suitable for oblique mapping work the aeroplane or flying boat used must have a "free nose" so that the camera when mounted in front of the forward cockpit has an unobstructed view, not only in the direction of flight, but also 90 degrees to the right and left thereof and downward from the apparent horizon, towards the vertical, through an angle equal to that of the camera angle. To enable the pilot to fix his altitude he is supplied with an altimeter and strut thermometer. He is instructed either to maintain a uniform altitude in photographing or otherwise record the readings of his altimeter or barometer and thermometer, in order that the altitude of the "flying boat," at the time the different photographs were obtained, may be subsequently determined for use in plotting the views. To maintain his direction he depends on ranging and on his compass, nosing his plane into the wind so that the course made good agrees with that projected on his flight map. A surveyor-observer is frequently attached to the flight and assists the pilot in directing the plane over the desired routes. He may also sketch in supplementary information upon the flight map to facilitate the making of subsequent flights and assist the photographer in obtaining the desired photographs with the required overlap. The rate of travel is usually from sixty to seventy miles an hour. At intervals of 2 miles along the routes flown, a set of photographs is taken, the set consisting of a photograph in the direction of travel over the ground, together with one to the left, slightly lapping the central view, and one to the right also lapping the central or straight-ahead view.

Camera and Film

The camera is of the fixed-focus, roll-film type and is so mounted as to dampen the vibrations of the plane. The mounting also allows it to be rotated in a plane perpendicular to the camera axis, to be depressed below the horizon, and to be swung both to the right and left of the line of travel. It is provided with a special sight which, when directed to the apparent horizon, gives the camera the required depression, and ensures that the apparent horizon line is recorded on the resulting photograph in a position parallel to the upper limit of the view. Thus, all photographs are taken with a more or less constant depression angle of about 19 degrees given to the camera axis, the object being to eliminate the necessity of making available a large number of grids for use in plotting the resulting oblique views. The camera is equipped with an

Figure No. 12.—Triangulation Control for One-Mile Mapping.
An unusual triangulation station for the control of one-mile mapping in eastern Canada.

interlens shutter for exposures 1/50, 1/100 and 1/150 seconds, and a wide-angled lens of about 8-inch focal length, which covers an exposure area of approximately 7 by 9 inches and works at an aperture of f/6.8.

Similar wide-angled lenses of greater speed are now available which work at an aperture of f/4 and which will probably be preferable for aerial survey work. A roll of film approximately 75 feet long is contained in a magazine which is attached to the camera, and which allows for 110 exposures. The film is coated with hypersensitized panchromatic emulsion, sensitive to all colours, and in order to penetrate the haze and absorb the highly actinic blue light rays, a yellow filter or screen is capped to the camera lens.

During exposure the film is held in contact with a glass plate in the focal register of the camera and as soon as the exposure is made the pressure back is released and the film is automatically wound up preparatory to repeating the operation. Before undertaking any photography the camera is calibrated to determine its principal distance and the position of the principal point. The latter is marked with a small cross etched on the focal plane glass plate and thus appears on each negative and prints therefrom. As soon as a roll is exposed it is shipped to Ottawa for development, and prints on 9 by 11 inch double-weight, semi-matte paper are supplied for plotting purposes.

Ground Control

In order to plot the features shown on the oblique aerial photographs to the proper scale and in their proper positions it is essential to have ground control. An exceptionally good control would consist of continuous traverse surveys crossing the lines of flight at intervals of twenty-five to thirty miles, the purpose of the surveys being to establish the positions of well-defined points which can be identified and marked on the photographs. We thus have, for each flight, central photographs twenty-five to thirty miles apart on which the distances and bearings between certain marked points are known; these data provide a check on the altimeter record and determine the direction of camera pointing at the instant the particular photograph was taken. With this information the azimuth of the line carried through the intermediate photographs of each flight can be determined, the features shown thereon can be plotted and the plot finally adjusted to fit the actual traverses on the ground.

Such ideal conditions as regards control are seldom possible. The lines of ground control must follow routes along which traverse surveys can be run economically, which, in the type of country to which this method is suited usually means the waterways. When there are no waterways suitably situated it is not economical to attempt to establish ground control by continuous traverse surveys. In such cases it is possible to replace a continuous ground survey by a flight line taken across the regular flight lines, the photographs along this line being controlled by astronomical observations for latitude and longitude at selected points along it.

At or near each place of observation the bearing and length of the line joining two well-defined points in the foreground of a photograph are determined, and this information provides a check on the altimeter record and determines the direction of camera pointing at the instant at which that particular photograph was taken. The photographs along the whole flight may then be plotted and the plot adjusted to the plotted positions of the observation points. This plot may then be used to furnish control for the photographs taken on the regular flight lines just as a continuous ground survey would have been used.

For the type of country to which this method is peculiarly suited it is possible to map a complete map sheet without any ground surveys other than the astronomical observations at certain points, the most desirable points being at or near the four corners of the sheet and at or near the midpoints of the north and south boundaries. These astronomical observations need not be elaborate, as the scale of the map will not reveal refinements of less than 200 feet; they may be taken satisfactorily with a small transit or astrolabe of suitable type, a portable radio receiving set, and specially selected chronometers or watches.

During the course of the ground work, whether it consist of continuous traverse surveys or astronomical observations, the surveyor studies the photographs while on the ground, adding such notes as will serve to properly interpret the information shown thereon, either for mapping purposes or other purposes for which the photographs may be used in the future development of the country.

Plotting of Photographs

All the control information, such as traverse surveys, latitude and longitude observations, and features tied to the observation stations, is plotted on a scale of one mile to an inch on a projection or compilation sheet on good quality paper. This provides the framework for plotting the oblique aerial photographs.

Before plotting is commenced the photographs are arranged so that those on which ground control has been marked, as well as those comprising the central views of each set taken on a straight flight joining such controlled photographs, become readily available. The photographs on which ground control is located are then examined, and the information shown on them which is to be transferred to the map is accentuated thereon with white ink or otherwise. This information is then plotted from the photograph by superimposing on it the proper glass grid and noting the particular grid square on which the feature to be plotted lies and drawing it in its relatively correct position in the corresponding square of the plotting paper. Square by square this operation is proceeded with until the plot is completed, when it is then transferred to the projection sheet on which the control is shown.

The glass grid serves as a graphical method of rectifying to the scale of the projection sheet the portion of the photograph represented by the features accentuated thereon. The area covered in an oblique aerial photograph of the mapping type is trapezoidal in shape, having an approximate foreground width of 1.4 miles and diverging sides extending from the foreground to the apparent horizon. Only a small part of the total area, however, namely that which lies towards the foreground, is usable, as the scale becomes very small in the background part of the photograph. If the ground area shown in the plottable part of the photograph were assumed to be divided by two series of equally spaced parallel lines — each spaced ten chains apart — and if one series of such lines were made parallel to the vertical plane containing the camera axis, while the other series intersected the former at right angles to form a system of squares, a true perspective diagram corresponding to such ground squares could be readily constructed for a particular principal distance, depression angle and altitude of air position. By having an intersection of two lines conform with the principal point and marking the apparent horizon in its relatively correct position on such a diagram, the proper orientation of such a diagram on the photograph is facilitated. In this manner the drawing of each grid is carried out to a scale four times its natural size. The drawing, with its markings to designate the factors entering into its construction, is then photographically reduced and prints from the negative obtained are made by contact either on glass or celluloid.

Such positives are referred to as plotting grids. The principal distance used in the construction of the grid is the predevelopment dimensions of the camera's principal distance, or focal length, corrected for film contraction. The depression angle used is derived from the location on the photograph, relative to the upper marginal line, of the apparent horizon for the approximate altitude; for convenience in plotting each grid is marked with the marginal distance of the apparent horizon expressed in tenths of an inch.

These plotting grids are available for use with the cameras on hand and have been constructed for such apparent horizon marginal distances, differing through the range experienced in actual work by intervals of 0.1 inch and for such altitudes differing by intervals of 25 or 50 feet through the zone from which oblique photography is carried out. If an oblique aerial photograph is to be plotted which contains in the foreground two features whose distance apart is known, then the correct grid is selected after first plotting the two features by a trial grid. This latter is selected from those which have been constructed for use with the particular camera employed and with a marginal apparent horizon distance as nearly equal as is available to that of the photograph to be plotted, the altitude for which the grid is constructed being as near as possible the altitude indicated by the altimeter record or the approximate altitude of the plane. With the same marginal apparent horizon distance, the ratio of the true distance between the two features to that obtained in the trial plot, multiplied by the elevation used in the construction of the trial grid, gives the elevation used in the construction of the correct grid. The selection of the correct grid is thus readily made.

After plotting the photographs on which ground control points are marked, the central view of each set of photographs obtained along the flight between such controlled photographs is examined for the purpose of selecting a line which is usually referred to as an "azimuth line." This line should join two image points, one in the distant background and one in the foreground of the first central view, so that along it, or its extension, definite image points can be clearly identified on the consecutively overlapping central views of the succeeding sets from one end of the controlled flight to the other. This common line, when drawn on the plot of each oblique aerial photograph, will serve to orient them on the projection sheet. If the track of the plane were straight and coincided with the direction of camera pointing when the central view of each set was exposed, then the principal line or lines drawn from the principal point normal to the apparent horizon line would, in each photograph, represent the track of the plane. Such ideal conditions, however, are seldom encountered. To avoid the effect of changes in azimuth resulting from unevenness of the ground, the azimuth line should be chosen so as to be as near radial from the photo plumb points as possible.

Clearly defined points on opposite sides of the azimuth line in the overlap common to the right and left side photograph, respectively, and the immediate foreground of each central view of a set, are next chosen and marked in white ink on the photographs. The corresponding image points are also marked in the central part of the preceding central photographs, and the ground controlled points available, preliminary to a trial plotting of the azimuth line. The grids are then selected for plotting the photographs marked with the azimuth line and other selected points by noting, in the absence of other information, the record of altimeter readings provided with the photographs of the flight and choosing the grid constructed for the particular altitude as given.

In the trial plotting of the strip, only the marked-up points and azimuth line receive attention. Consecutive plots of such points in relation to the azimuth line serve as a check in the uniformity of the altimeter readings; and the overall length of the azimuth line as plotted from the photographs, compared with its true length as measured on the projection sheet, indicates the extent of correction, if any, to the elevations as marked on the grids used in the trial plot. The altitude of the correct grids to be used to effect closure in plotting the central strip of photographs is thus found and recorded on each photograph. All the information to be transferred from the photograph is next marked up on it, being careful to note, however, that owing to the overlap of the photographs along the line of

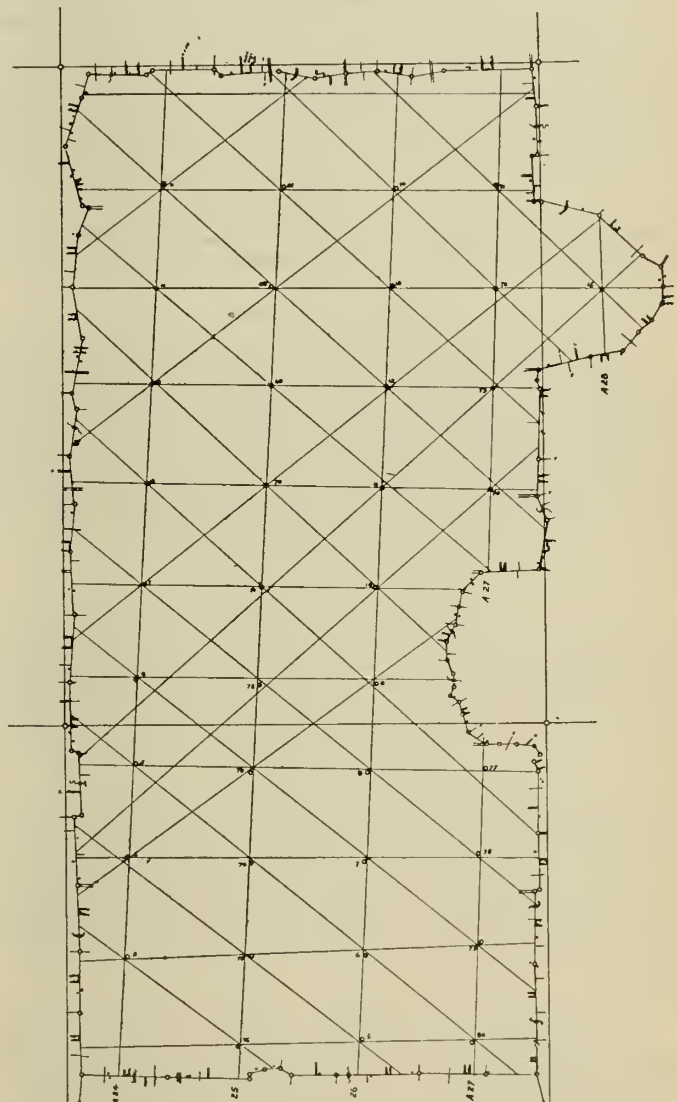

Figure No. 13.—Vertical Photographic Plotting by Straight Line Method—Development of Secondary Control from Ground Traverse.

Diagram showing control lines for vertical photographs as obtained by the straight line prolongation method, in an area the perimeter of which has been controlled on the ground by transit and chain traverses. When straight lines do not pass through the plate plumb points the photographs concerned are viewed stereoscopically and points which appear at about the same elevation are selected for the production of lines. The photo detail is plotted to this photo control by proportional dividers, points which are affected by relief being first fixed by radial intersections. The map graticule shown represent sa quadrilateral of 5′ of latitude and longitude. Details such as fence, stream and road crossing, houses, wood edges, etc., are indicated. This serves to tie in the positions of photo control lines where they cross the traverse.

flight it is not necessary to mark up topography on one photograph much farther from its foreground than a mile beyond its principal point. The individual plots of the central views are then transferred to the projection sheet on which the azimuth line has been drawn; and the plots of the side photographs of each set are traced on the projection sheets by superimposing the plotted positions of the selected side overlap points previously referred to.

When the plots of flights whose terminals have been controlled are fixed on the projection sheets, they serve to furnish control for fixing the plots of intersecting flights. The procedure heretofore outlined is repeated until all the plots of the photographs obtained on the flights over the area have been assembled on the projection sheet. The projection sheet which, as mentioned, has been drawn on the one-mile scale, and in four quarters, is next inked, making slight adjustments to effect continuity of topography where necessary and adding a few names of important topographic features, and the whole is photographically reduced to the two-mile scale. The draughtsman is supplied with prints on the two-mile scale which he assembles and on which he adds the remaining names, title, and any corrections required, and the whole is again photographed. From the negative obtained the photographer makes the zinc plate impression which goes to the printer.

Compiled Maps

The duties carried out by the staff engaged on this work might best be described as the general (or regional) geographic work dealing with Canada, which covers a very wide field. The map-making involved is much more diversified than that normally undertaken by organizations which work directly from information collected by their own field surveyors, under whose immediate direction and supervision the consequent mapping is done.

Sources of Information

As large tracts of Canada are still imperfectly known, it naturally follows that every possible source of information, every thread, official or otherwise, must be investigated and utilized to the utmost possible advantage in order to gradually evolve a more perfect knowledge of the country. As the organization does not maintain or control any field staff, it necessarily relies upon such information as may be collected by others which do employ field staffs. These sources of information, to name a few, are Dominion, Provincial, railway, exploratory and reconnaissance surveys, — development company and other independent surveys — all of which are made use of after a thorough examination has been made to establish their respective values.

General and Specialized Maps

In addition to the regular series of standard maps, based on scientifically fixed points, railway, river, boundary, cadastral surveys, etc., etc., the staff undertakes the compilation and publication of small scale maps of a general nature, railway, physical and political, ethnographical, commercial, historical, industrial, exploration, etc., for the use of the general public.

Other departments and branches as well as the Provincial Governments, requiring a map on which to present some special subject, are given transfers from copper-plates or from original finished drawings to provide the base for their map on which the required special information is added by the department concerned. By this arrangement considerable economy is effected by the avoidance of duplication of work. In addition, many other maps of various sizes and scales, from small sketch maps to large diagrammatic maps measuring 12 by 20 feet, have been prepared for other departments, branches, or individuals for illustrative or lecture purposes.

Methods of Reproduction

On the completion of a manuscript map, the decision is made as to the most advantageous method for reproduction. Should the work be of a more or less permanent nature, recourse is had to copper-plate engraving for subsequent transfer to stone or zinc for printing. In cases where the information available is of such a nature as to lead the geographer to anticipate considerable alteration occasioned by additional field work, the photo-lithographic process is usually adopted. The finished drawing is prepared and is transferred by photography directly to the zinc plate or stone. It has, on occasion, been found necessary to use photo-lithography in many cases where engraving would have been preferable but was not practicable on account of the difficulty of procuring a sufficient number of first class copper-plate engravers. In these cases the results have been exceptionally good.

While the map-printing is not done on the premises, it is closely controlled. All printing, done by contract, must conform to the specifications issued for each individual piece of work. These specifications give detailed instructions for the printers as to the method of reproduction, the stock (paper) to be used, copper-plates from which transfers are to be taken or in the case of a photo-lithographic or photo-zincographic job the correct scales of reduction, etc., the colours with their stipples, rulings and solids and their combination to produce the requisite number of colours with the least possible number of printings.

Method of Making Marine Charts

The nautical, or marine chart, being for navigation purposes, is a map only in the sense that it represents a portion of the earth's surface comprising both land and that unstable element, water, with more particular reference to the latter.

In charting, unlike land operations where everything is visible, one must locate the unseen, against wind and tide. Few mariners, and still fewer landsmen have any knowledge of the operations necessary to produce this indispensable guide to navigation: on the other hand the hydrographic engineer requires a fair knowledge of navigation in order to construct a chart and compile sailing directions for the mariner.

Early Hydrography

Many years ago considerable charting of the waters of Canada was carried out by the British Admiralty. However, owing to the primitive equipment available, using sailing ships and covering large areas, the surveys amounted to little more than a delineation of the coast-line, and few soundings were taken except in the cases of important harbours where an attempt was made to produce a finished chart. These charts were barely adequate to meet the demands of the then existing commerce. Sailing ships never approached the shore except in the vicinity of a harbour, and the saving of time was of little moment.

Present Conditions

Today everything has changed; wood has given place to steel and sail to high-powered steam or motor ships of deep draught and great speed, demanding the best charts that man can produce not only for the safety of the ship but also because in uncharted waters marine underwriters impose prohibitive rates.

The re-charting of the navigable waters of Canada is being carried out by a Canadian service, which was formed for this purpose. The activities of the service are wholly of a marine nature and, although quite separate from the other surveys engaged in the mapping of land, the closest co-operation is always maintained with the latter to avoid duplication of work and effect saving of time and expense.

Equipment

This service employs four steel sea-going steamers on the coastal waters of Canada, with an additional one to be added in the near future. The largest and best equipped of the above fleet is the C. G. S. "Acadia," a single screw high-powered steel steamer of some 1,100 tons displacement, built especially to meet surveying requirements and strengthened to withstand ice. The full establishment of this ship is about forty-five officers and crew, including the hydrographic engineer in charge and six assistants. The officer-in-charge has full responsibility for the upkeep, fitting-out and laying-up of his ship. This ship is equipped with the latest devices to promote efficiency and economy in charting, including the following:—gyroscopic compass; British Admiralty pattern echo sounding machine; usual radio equipment with the most up to date type of radio compass; deep-sea water bottles with thermometers attached, for oceanographical work; chronometers, transits, base-measuring chains, sounding and observing sextants, etc. The gyroscopic compass has proved a great convenience, rendering the true meridian available at all times, which in conjunction with a well-adjusted mariners' compass makes it possible to note magnetic variation as desired. The echo sounding machine is simple to operate and has a range of from 10 to 800 fathoms with, usually, a small operation error of 2 per cent. This method is a great improvement on the old device of line and wire, producing a deep sounding in a few seconds, which formerly would take several minutes to obtain, in addition to the stopping of the ship. Sounding may be carried on continuously at full speed, practically sweeping the bottom, and nothing passed over can escape detection. The ship's equipment includes three gasoline launches and boats fitted with outboard engines, so that several parties may operate at the same time in order to take full advantage of fine weather. The ship is usually fitted out at the port of wintering, and when ready for sea, and the compasses carefully adjusted, proceeds to the field of operations.

Procedure

The production of a coast chart comprises the following: —shore work; establishment of marks; plotting of a field sheet; obtaining of soundings; completion of field sheet; compiling of the fair sheet and printed chart.

On arrival at the scene of operations a location is selected for the installation of a tide gauge for the reduction of soundings to low water datum, and the establishment of a bench mark. Reconnaissance is carried out for the selection of main stations and a suitable place for base measurement, two or three bases being sometimes necessary as a check. If geodetic control points are available, considerable time is saved for devotion to hydrography. Observations are taken for latitude and longitude, usually at two points, and azimuths wherever possible. If the country under consideration proves flat and wooded, necessitating the building of towers and considerable expense of time, ship triangulation is resorted to. In this case stations are built on the coast eight or ten miles apart and the ship being anchored off-shore, a flag at the masthead is "cut in" simultaneously several times by observers ashore at three stations. Starting on a known side obtained from a measured, or geodetic, base very satisfactory results are obtained when the position of the ship has been carefully selected.

The main triangulation stations being built and observed, and the usual computations carried out, the field sheet is plotted, usually on a scale of one and one half inch to one nautical mile for a coast sheet, which would be published on a scale of one inch to one nautical mile. For harbour charts the scale is generally from 400 to 1,500 feet to one inch, according to the locality and circumstances. While the computations and plotting are being proceeded with, parties are employed coast-lining and building intermediate stations for fixing the inshore soundings and, when necessary, building special marks for off-shore work. This class of work is also resorted to during periods when the weather is unsuitable for operations afloat.

Oceanography

During the progress of the off-shore sounding, stations are occasionally observed for the obtaining of water samples at different depths for density and temperature, to be used for the investigation of ocean currents and fisheries. This work is also carried out when the ship is en route from one point to another.

Sounding

Sounding, or depth measurement, is the main object of the season's operations for the purpose of delineating the bottom contours, also the locating of, and obtaining of, the least water over shoals. The mariner having a well-sounded chart is enabled to locate his position off-shore with the use of the lead, or the sailing directions may caution him not to enter shoaler water than a certain depth in a particular locality in fog or at night. Sounding is generally carried out in parallel lines, approximately at right angles to the shore-line, that the area may be well covered. These lines are usually one cable apart to a depth of 10 fathoms and so on, being 10 cables or a mile apart in 100 fathoms of water, frequent sextant angles being taken to objects on shore to locate the soundings. The sounding of shoaler water is carried out in gigs or gasoline launches, two officers in each launch, the depth measurements being taken with a marked line. These soundings are extended off-shore a sufficient distance to ensure an adequate depth for the safe manoeuvering of the ship when connecting with the boat-work.

Examination of Shoals

The most important stage of the season's operations now commences. During the progress of sounding all depths obtained are reduced to low water datum from the tidal records and inked in on the field sheet. These are carefully studied for irregularities or uneven bottom, and every case is carefully examined on the water, and if considered necessary, swept with a wire device to ensure obtaining the least water. Sounding from the ship is carried off-shore as far as possible to fix the ship's position from the masthead. This work has been greatly facilitated by the use of the echo sounding machine by the utilization of which considerably more ground can be covered than by the old method.

Rough or Field Sheet

As the field work progresses it is plotted on the field sheet, and when the season is completed practically all the soundings have been inked in on this sheet. On reaching headquarters the sheet is completed as to the remaining coastline, topography, nomenclature and title.

Fair Sheet

On the completion of the field sheet a Mercator projection is laid down on the scale on which the finished chart is to be published, and all work is transferred from the field sheet to the fair sheet, representative soundings only, including all shoals, being selected, as it would be confusing to transfer every sounding obtained.

Aids to Navigation

As a result of the area being charted, the necessary aids to navigation, lights, buoys, etc., can be determined upon.

Published Chart

The fair sheet having been completed, including nomenclature, title, notes and tidal information, and aids to navigation, the printed chart is produced therefrom, either by transfer from the engraved copper-plate or by photolithography, the latter process being generally resorted to for a first edition if the engravers are fully occupied and delay likely to occur otherwise.

International Map of the World

No paper on maps and mapping would be complete without some reference to the International map of the world. The question of an international map was first raised at the International Geographical Congress at Berne in 1891, but notwithstanding several discussions, nothing tangible resulted until 1909, when the governments of the principal countries of the world sent representatives to a conference at London for the express purpose of discussing the possibilities of the production of a standardized series of maps on a scale of one in a million, which scale is approximately sixteen miles to an inch (15.78 miles to an inch). Canada was represented at this conference.

As a result of the conference the different representatives agreed unanimously on the desirability of adopting definite uniform limits for the map sheets of a map which might eventually cover the whole world and also recommended to the different governments the adoption of a uniform set of symbols and conventional signs.

Advantages of Uniformity

The advantages of such uniformity are obvious. It ensures that all the maps of this international series, no matter what country issues them, can be as easily interpreted as those of one's own country. The study of geography is simplified and encouraged and an added stimulus given to development work and to international commerce. Dealing with the effect upon international relations, the Honourable Sir Charles Hardinge, Under-Secretary of State for Foreign Affairs, said on opening the proceedings of the International Map Committee:

> "The more widely geographical knowledge is disseminated amongst the nations of the world the better will they know each other, and the more fruitful will be the cultivation of feelings towards each other of mutual respect, the forerunner of mutual friendship, and what is more priceless still, of international peace."

Canada's Contribution

Last year Canada's first contribution to this international map was issued in the form of the Regina sheet which conforms to all the requirements of the International Map Committee. The area covered is that between latitudes 48 degrees and 52 degrees and longitudes 102 degrees and 108 degrees. The city of Regina is situated fairly centrally in this area and its name has been adopted for the name of the map sheet. About one quarter of the area covered lies in the United States so that the production of the map necessitated co-operation with the United States map-making organizations, which co-operation was cordially extended. The scale of the map is 1 in 1,000,000, which is approximately sixteen miles to an inch. The area is contoured with 100-metre contours and the relief of the country emphasized by four separate tints of brown. Altogether, in producing the map it was necessary to employ seven separate printings, one for the black, one for the red, two for the blues and three for the browns.

Conclusion

In the descriptions of the several typical maps that have been selected it is largely the field work for which the surveyors and engineers are responsible that has been described. Although in some cases certain of the steps necessary for the office compilation, looking forward to the publication of the finished map, are indicated, no detailed attempt has been made to deal with the very great amount of additional work which has to be completed before the finished map sheet comes off the press. When the field work has been executed it is turned over to others whose occupation keeps them in the office, and to their skill and knowledge as compilers, draughtsmen, photographers, and expert printers is due in a very large measure the excellence of the finished product which goes out to the map-user.

Finally, in bringing this paper to a close the author desires to express his fullest thanks to all those in Ottawa and elsewhere who helped in preparing this paper, by furnishing so freely and generously so much valuable and instructive information for incorporation in it.

The Development of Radio in Canada

A. N. Fraser, A.M.E.I.C.,
Chief Engineer, Radio Branch, Department of Marine.

Paper presented at the Annual General Meeting of The Engineering Institute of Canada at Ottawa, Ont., February 13th, 1930.

Canada, as befits a new and great country, has always been prompt to utilize new engineering and scientific developments, and in no field has this been more marked than in the way in which our government and our people have made use of the art of wireless, — or, as it has later become termed, radio communications — and without detracting in the slightest degree from the work of Marconi, in first conceiving the idea of using Hertzian waves for the purpose of communication, and then in developing the apparatus to attain this end, the importance of the contributions to the radio art, of that brilliant Canadian engineer, Reginald A. Fessenden, born at Milton, Ontario, are becoming more appreciated as the years go by, and it is a fitting tribute to Mr. Fessenden that within the last few months he has been chosen by the American Museum of Safety as the recipient of the "Scientific American" Medal for his contributions to the "Safety of Life at Sea."

Canada's first adventure into radio communication took place 29 years ago when in 1901, the late Mr. D. H. Keeley, a member of this Institute and Superintendent of the Government Telegraphs, entered into a contract with Mr. Marconi to establish two stations in the Belle Isle Straits, one at Chateau bay at the terminus of the landline on the mainland, and the other on Belle Isle, thirty miles distant, to replace the submarine cable which was continually going out of commission on account of icebergs.

It is a far cry from the thirty mile station of 1901, to the 10,000 mile station of today, but it was a still farther cry from nothing at all to 30 miles, and the promptitude with which Mr. Keeley seized on this new means of communication, at such an early date, to solve his difficulties, indicates that he, in common with so many of the founders of our Institute, possessed the true spirit of the pioneer. In fact not only did Mr. Keeley make the contract, but he personally contributed to the success of the experiment. In his report of November 1901, he naively states: "This Chateau bay installation was in readiness on Sunday the 20th October, when signals from Chateau bay were received at Belle Isle, but none were received at Chateau bay. The trouble, on investigation, was attributed to defective coherers, and the company's agents proposed abandoning the plant till next year in the absence of a fresh supply. On the 22nd, however, I personally succeeded in establishing communication and was thereby enabled to avert the threatened postponement of operations; and on the 25th, after considerable practice and careful directions, for all that the working of the system as it stands is erratic, I felt confident in leaving our operators in charge, with the explicit instruction as to future action."

While in this experiment, wireless telegraphy demonstrated its utility to replace a cable, it was in an allied field that it made its greatest contribution to progress and to the safety of human life, in providing the first means for communicating with a ship at sea, and accustomed as we are today to a condition where a ship is never out of communication wherever she may be in the world, it is difficult to appreciate, for instance that only a few years prior to the invention of wireless, the S.S. Borussia left Liverpool, with 344 souls aboard, sprang a leak in mid Atlantic and foundered; 160 persons went down on the ship, and 184 took to the boats of whom only 10 were eventually saved. It is of interest to note that the Marconi Company's records show that the first commercial equipment on board a liner was installed in 1901 on the Beaver Liner "Lake Champlain" plying from Liverpool to Montreal.

Those who heard Marconi during his trans-Atlantic broadcast a few weeks ago, will recall that the first trans-Atlantic signals were received at St. John's, Nfld., by means of an aerial supported by a kite on December 12th, 1901, and Sir Wilfrid Laurier, the Canadian Prime Minister, then in power, quick to appreciate the possibilities of wireless, invited the young inventor to proceed to Canada, with the result that a contract was entered into for the establishment of a transatlantic wireless service between Canada and Great Britain, the Canadian Government to pay a subsidy of $80,000 towards the Canadian stations.

Glace Bay, N.S., was selected as the site, and in 1902 the first messages were exchanged between the Earl of Minto, then Governor General of Canada, and His Majesty King Edward VII. After a somewhat prolonged experimental period, the first commercial trans-Atlantic service— in fact the first long distance service in the world — was inaugurated between the station at Glace Bay and one in Clifden, Ireland, in October, 1907, and it might here be added that the inauguration of this service contributed to the fact that we are today paying a toll of only 18 cents per word on our trans-Atlantic messages, as compared with 25 cents per word, the rate previously in effect.

Concurrently with the contract for the establishment of the first Glace Bay trans-Atlantic station, contracts were entered into for the building of a chain of twenty coast stations along the river and Gulf of St. Lawrence, to the Belle Isle Straits and from St. John and Halifax to Cape Race along the east coast. These stations were of comparatively low power and were installed in 1903, 1904 and 1905, and it is a tribute to the quality of the apparatus that at some of these stations in the more isolated points, where they do not cause interference, the major part of the original plant, is still in operation.

In 1907 work was started on a chain of 9 stations to provide communication along the coast of British Columbia, including the Queen Charlotte Islands, and in 1912 a third chain of eight stations was established from Port Arthur to cover the Great Lakes, incidentally linking up with the east coast chain at Montreal.

At all these stations constant watch was maintained, day and night, 365 days a year, or throughout the season of navigation, as the case might be, and from the time a ship was 250 miles from our shores she was in constant touch with one or other of the stations until she reached her final port.

The original stations all carried about the same plant, the prime mover was a 4 h.p. engine and the transmitter was of the spark type rated at 2 k.w. At first coherers, and shortly afterwards magnetic detectors (the latter due to the research work of Dr. Rutherford of McGill University), were used for reception, and the working range of this combination was some 250 miles.

As the art progressed, higher powered and more efficient sets using the same type of transmitter of 5 k.w rating replaced the original outfits, and with the more sensitive crystal type of detector the range of the stations

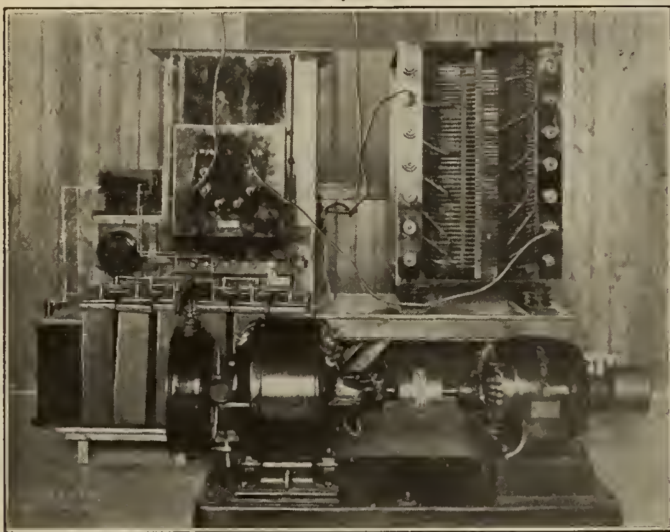

Figure No. 1—Spark Type of Transmitting Apparatus Originally installed at Station on the Great Lakes.

was materially improved. Nevertheless the general design remained fundamentally unchanged, except in minor details, until the year 1918, when transmitters employing the vacuum tube began to be universally adopted.

Prior to this, radio engineers had long recognized that damped Hertzian waves, such as are created by an electric discharge across a spark gap, were by no means ideal for wireless communication. Such transmission occupies a broad band in the ether and its carrying powers are limited.

It is believed that the first practical method of producing a pure continuous wave was due to Dr. Fessenden, when in 1908, he built a high speed alternator making 20,000 revolutions per minute, which gave a frequency of 100,000 cycles. (3000 metres.)

The frequency of an alternator is, of course, a function of the speed, and as there are physical limitations to the latter, it was not found practicable to develop an alternator which would produce electric waves of the frequencies then used for ship to shore communication of the order of 1,000,000 cycles per second. (300 metres.)

For long wave long-range work, however, the alternator was a success, and the General Electric Company developed machines capable of an output of 200 k.w. with frequencies of the order of 30,000 cycles (10,000 metres) which were extensively used for trans-atlantic and other long distance services.

It may be remarked that it was whilst experimenting with these continuous waves that Fessenden contributed his principle of heterodyne reception to the radio art, —a principle simple but eminently effective, and one which is used for reception at all continuous wave radio-telegraph stations today.

Marconi endeavoured to obtain continuous waves by means of a timed spark arrangement, while Poulsen made use of the negative characteristic of an arc in hydrogen. Prior to the war, a large trans-atlantic station of the latter type was built in Canada at Newcastle, N.B., and two or three smaller sets were installed by the Marine Department in coast stations. However, these were all temporary expedients waiting for the development of the vacuum tube, and such of them as are still in existence, will, together with the alternators, ere long be relegated to the historical museum along with the spark sets and be replaced by the three element vacuum tube.

This tube is due to the work of Dr. Lee DeForest of New York, who in 1907, experimenting with the two element vacuum tube detector developed by Fleming, conceived the idea of introducing a third element into the tube, which he called the grid, and thereby he made possible the present phenomenal development in radio, though it is doubtful whether at that time DeForest had the slightest idea of the revolution he was about to inaugurate.

It may perhaps seem strange that this tube can be used both for reception and transmission. However, every one who owns a radio broadcast receiving set probably has a nightly demonstration of the latter, when the owner of a neighbouring one tube regenerative set proceeds to whistle through his concert. He is using his receiving tube as a transmitter and it is made audible to the receiving set through Fessenden's heterodyning effect. In a large transmitting station there is merely a repetition on a large scale of what goes on in the one tube regenerative set. With a vacuum tube transmitter it is possible to produce a pure continuous wave and at the same time to control it when using high power. As compared with a damped wave a continuous wave travels a much greater distance for the same expenditure of energy, occupies a very much narrower band in the ether and when modulated with a microphone it enables us to transmit sounds at voice frequencies.

The large investment in Canada and througout the world in ship-to-shore spark equipments delayed the early adoption of the tube type of transmitter, but insofar as Canada is concerned, the advent of broadcasting rendered such a change urgently desirable in the interest of broadcast listeners, and the Canadian Marconi Co. having, on our behalf, developed a tube transmitter suitable for coast station operation, the government embarked on a programme of replacing all spark sets in its stations, commencing with those in the more populous centres such as Toronto, Montreal, Vancouver, etc., with the result that today, except in one or two isolated points, all our stations are operating on continuous wave.

This transmitter is rated at 1600 watts output and has a frequency range of 500 to 100 kilocycles. For convenience in handling, it is divided into five units, viz., rectifier, oscillator, closed circuit inductance, closed circuit condenser, and aerial tuning inductance. The components of each unit are mounted on angle iron frames which are covered with wire mesh screens to prevent accidental contact with high voltage conductors. All high voltage parts are insulated with porcelain. Power is supplied to the set at 220 volts 60 cycles. This is stepped up to 20,000 volts, and double wave rectification is carried out by two rectifier tubes. The resultant direct current at 10,000 volts, after being passed through a filter, is fed to the anodes of two oscillator tubes operating in parallel in a Hartley circuit. Small transformers of suitable ratio supply current for heating the filaments of the oscillator and rectifier tubes. The condenser in the closed circuit is insulated with porcelain and uses air as the dielectric in order to avoid possible trouble which might result from failure of a solid dielectric such as mica. The aerial tuning inductance is coupled to the closed circuit by means of an aperiodic link and both the closed and aerial tuning units are equipped with selector switches for quickly changing to any one of four predetermined waves. Interrupted continuous wave transmission is obtained by means of a motor driven tonic train wheel and the set is also equipped with a small low voltage motor generator for supplying direct current to operate the keying relay and magnetic send-receive switch.

The keying relay interrupts the primary of the power transformer of the rectifier and also a fraction of a second afterwards a second contact interrupts the grid circuit of the oscillator tubes. This is necessary in order that the morse characters transmitted should be sharply defined.

The transmitter is completely controlled from the operator's desk.

For ships, sets of a smaller and more compact type were developed, and those standardized in Canada are the 500-watt continuous wave and interrupted continuous wave transmitter and the 100-watt continuous wave, interrupted continuous wave and telephone transmitter, short descriptions of which follow:—

The 500-watt ship equipment is a one-unit set delivering 500-watts of high frequency energy to the antenna. It consists of a rigid angle iron frame upon which are assembled the component parts of the oscillatory and control circuits. Continuous wave and tonic train communication are provided over the wave range of the transmitter, and either method of signalling is available by throwing the signal switch mounted on the transmitter panel.

In laying out the transmitter, attention has been paid to the special requirements of ship use. The overall size of the unit is such that it will pass through the ordinary ship's cabin door. All vital parts of this transmitter are clear of the floor.

The transmitter has a wave range of from 600 to 2,400 metres (500 to 125 kilocycles) when used with an aerial having a natural wavelength of 250 metres, and a capacity of .0007 microfarad. Any one of four wavelengths in this range may be selected by a single operation switch. The transmitter is normally wired to permit of two wavelengths in the bands from 600 to 1,300 metres and two in the band from 1,200 to 2,400 metres.

A 2,000 volt d.c. generator, rated at 1,500 watts output and direct connected to a 110-volt d.c. motor, supplies the high tension power for the oscillator valves. This machine is provided with an automatic starter controlled by a push button switch from any convenient place. Provision is also made for opening the generator field circuit when receiving.

A low voltage generator, driven by a 110-volt d.c. motor supplies the heating current for the valve filaments.

The power supply for both motors is drawn from the 110-volt ship's mains. The two machines are independent of the transmitter and may be placed where convenient.

The insulation of the transmitter has been given careful consideration and is designed for an ample safety factor as regards creepage and flash over.

The 100-watt transmitter provides three classes of radio transmission, namely, radiotelephony, continuous wave and interrupted continuous wave telegraphy. It is

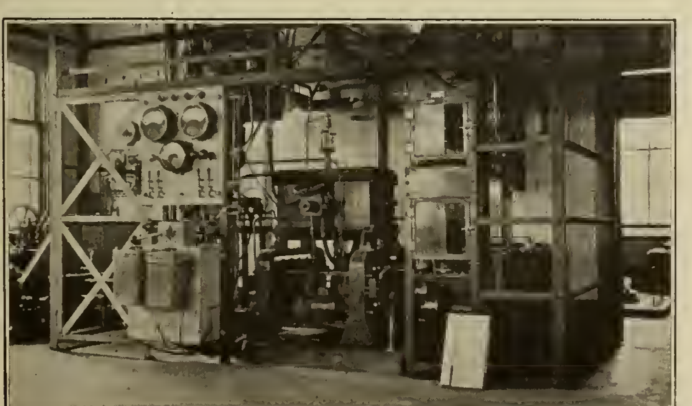

Figure No. 2.—25-Kilowatt Poulsen Arc Transmitter installed at Barrington, N.S.—Now Obsolescent.

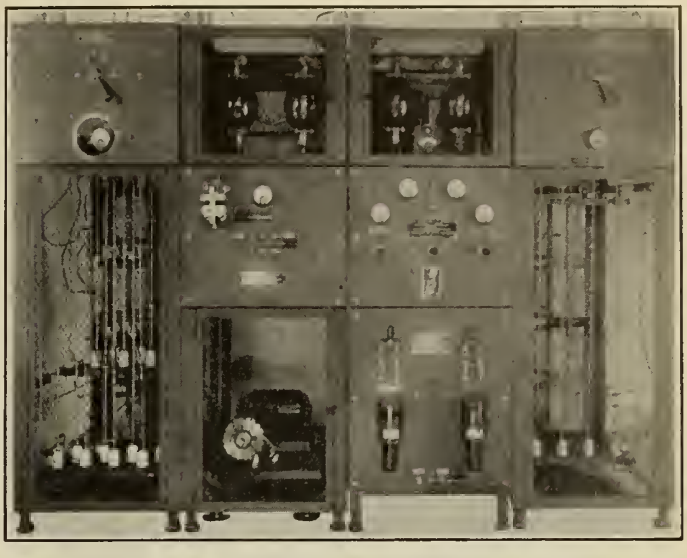

Figure No. 3.—1,600-Watt C.W. and I.C.W. Transmitter used at Canadian Coast Stations.

capable of deliverying 100 watts to the antenna when used for telephony or interrupted continuous wave and 150 watts when used for continuous wave signalling.

The apparatus is ruggedly constructed and is simple to install and operate. Protection to both operator and apparatus is afforded by the necessary screening, fuses, by-pass condensers, etc.

The complete equipment consists of transmitter unit, high and low tension motor-generator unit and associated control rheostat, power control switches, signalling key and microphone equipment.

The power equipment consists of a motor driving a double current generator supplying 1,000 volts d.c. to the valve anodes and 12 volts 12 amperes for the valve filaments and auxiliary equipment such as the tone wheel motor and high tension magnetic switch energizing coil. Switches are provided for the line voltage, and a control rheostat for the regulation of the generator field current.

The wavelength range of the transmitter is between 200 and 800 metres, (1,500 and 375 kilocycles) depending on the aerial dimensions. A wave-change switch is provided which permits the quick selection of any one of three fixed wavelengths within the wavelength band.

The oscillatory circuit is of the Hartley type excited by one *UV-211* Radiotron modulated by a second *UV-211* in the so-called constant current circuit. The microphone circuit is transformer coupled to the modulator valve. For continuous wave communication both valves are used as oscillators, a switching arrangement enabling this to be carried out.

Tonic train transmission is obtained by connecting a small motor and tone wheel with signalling key to the modulation transformer in place of the microphone.

Before being fed to the speech choke, the high tension supply passes through a filter which effectively suppresses the generator commutator ripple.

Modern Tendencies in "Ship to Shore" Traffic

For revenue the ship-to-shore stations look to traffic from ships, and in the early days, when ships could only work some two or three hundred miles, stations such as Cape Race and Belle Isle were of great importance and good revenue producers. For instance, the revenue from

Cape Race for the year 1920 was $82,000.00. Last year, however, the revenue from this same station was only $1,500.00, this being due to the fact that traffic can be much more effectively handled through a central station located at a point with good telegraphic facilities. On the east coast of Canada this service is provided by the Canadian Marconi Company's commercial station at Louisburg, N.S., and on the west coast by the departmental station at Estevan.

Even this arrangement is in a state of flux, as ships are now all turning towards short waves and it may well be that in the near future we will find the traffic going to short wave long distance stations situated at terminal points such as Montreal. Looking towards this end, the Marine Department has just commenced construction on an up-to-date radio station outside of Vancouver, B.C., which, equipped with long waves, intermediate waves and short waves, will be in a position to handle all traffic offering.

The cost and range of this station, as compared with that of the first one on Belle Isle, indicate the growth and change which have taken place. The contract price for Belle Isle complete with buildings was $5,000 and it had a range of about 50 miles. The station at Vancouver will cost $100,000 and on the short wave we expect to be able to take care of traffic from ships as soon as they have left Sydney, Australia, or Singapore, as the case may be.

Radiotelephone Service

An interesting development inaugurated by the Department on the Pacific Coast, in 1924, is a radiotelephone service to and from tug boats and other small vessels plying on the Coast. Radio telephone stations have been established at Vancouver, Merry Island, Cape Lazo, Alert Bay and Digby Island, (see map), and the service has proved of great value to tug owners, some forty-nine tugs being now equipped. This is purely a point-to-point service, and has not as yet been extended to the regular land telephone lines.

The number of paid radio telephone calls handled by these stations last year was 12,540.

Point to Point Communication

The chains of stations established by the government on the east coast, Hudson Straits, etc., whilst established primarily for ship-to-shore communication, serve a second useful purpose in providing facilities for communication with small stations erected at isolated points by private enterprise. On the Pacific coast, for instance, service is given to some 36 local stations located at canneries, pulp mills, etc., which have no access, and, on account of the rugged nature of the country, are not likely to have access to landline facilities for many years to come.

Figure No. 4.

An example recently brought to the public eye was the story of the MacAlpine expedition, which was handled through a small station established by the Dominion Explorers at Bathurst Inlet, communicating with the outside world through the Port Churchill station of our Hudson Bay chain.

Similar communication facilities are available to isolated communities in the interior of Canada through the medium of the radio stations operated by the Royal Canadian Corps of Signals along the McKenzie river in the North West Territories and at several other points across Canada at which that service maintains stations in connection with civil aviation activities.

Point to point communication is also extensively used by public utilities and power companies, for emergency in communication between their power plants and distribution centres in case of interruption of the normal telegraph or telephone communication, and an interesting experiment is being undertaken at this moment by the British Columbia Telephone Co. at Powell river, on the Pacific Coast, looking to the use of radio links in the establishment of regular telephone service to isolated points. If this experiment proves successful, a big development may be anticipated along these lines, there being hundreds of places in Canada to which it is not economical, up to the present, to extend regular telephone service, particularly in the case of plants and communities located on islands.

The use of this phase of radio service by the landline companies of Canada for emergency communication between their important centres in case of interruption of their landlines is also foreshadowed in the immediate future.

Radio Direction Finding

The first use of radio at sea was simply to provide communication, but as years progressed a development of major importance to navigation took place in the application of radio to direction finding, whereby it is possible to determine by means of special antennae and receiving apparatus the direction or bearing of an incoming signal. The principles involved in direction finding had been known for many years, but it required the invention of the vacuum tube with the immensely improved sensitivity of reception secured thereby to make it of utility as an aid to navigation.

Much work was done on this during the war, and the first direction finding stations in Canada were four established on the east coast in 1917, for war purposes. At the close of the war it was decided to continue these stations as an experimental aid to navigation. They were so successful that additional stations were established at Saint John, N.B., St. Paul Island, Yarmouth, N.S., Belle Isle, on the East Coast, and Pachena on the Pacific coast.

The Canadian direction finding stations give approximately 38,000 bearings per annum, and while they are not intended to supersede existing instruments of navigation they act as an accurate check. Fixes are obtained by intersection of the bearings from two or more stations, or a ship can navigate on a line of bearing, as for example, on approaching Saint John up the Bay of Fundy. As an instance of how navigators regard this comparatively new radio instrument, a letter may be quoted from the Captain of a 10,000 ton ship, which arrived in Halifax on December 31st last:—

Figure No. 5.—500-Watt Ship Type Transmitter developed in Canada.

Port of Halifax, N.S.
January 10th, 1930.

Department of Marine and Fisheries,
Radio Branch,
Halifax, N.S.
Dear Sirs:—

In submitting to you a report on D.F. bearings furnished by Chebucto and Canso Stations, the experience narrated hereafter may be of interest.

Being bound from Glasgow to Halifax, and following Track "E" of Atlantic Lane Routes, no position by celestial observation was obtainable after our crossing Longitude 40 West on December 26th, 1929, and recourse was had to W.T.D.F. bearings from Cape Race, first being obtained at a distance of 200 miles. From then onwards bearings were got at intervals and these were checked by ship's D.F. apparatus working on the Newfoundland and Sable Island Stations.

On December 30th a severe Southwesterly storm was encountered, during which steamer had to be hove to, and in six hours was driven 30 miles South-South-east. Bearings from Chebucto and Canso Stations faithfully recorded ship's retrogression.

After storm abated, relying entirely on position obtained by Wireless,—whereabouts by "Dead Reckoning" being merely a guess—a course was set for Halifax Inner

Figure No. 6—General View of the Canadian Direction Finding Station at Saint John, N.B.

Fairway Buoy, at which we duly arrived on the morning of December 31st. Indeed by carrying on long enough we should have collided with the buoy.

I venture to suggest that the W.T.D.F. Stations named could not be given a more severe test than under the circumstances recounted.

Here is a steamer navigated for practically 1,000 miles by W.T.D.F. alone, in a part of which distance and for a period of twelve hours she is exposed to a severe storm and driven far out of her course, various adjustments of courses steered are made as indicated necessary by D.F. bearings, and arrives at her destination not as much as a cable's length in error.

The writer respectfully commends to the attention of the Department the unfailing courtesy, promptitude, zeal and care shown by the Officers operating all Eastern Canadian Stations—D.F.—from Belle Isle to Redhead (Saint John).

Their dutifulness contributes in no small measure to relieve the many anxieties of those "Toilers of the Deep" upon whom devolves the safety of life and property afloat, numbered with the most appreciative of whom is,

Yours faithfully,

....

Master.

Our latest application of direction finding as an aid to navigation is in Hudson Straits and Hudson Bay, where radio may be said to have truly come into its own. There are no lighthouses—there are no fog alarms—and the magnetic compass is sluggish by virtue of proximity to the magnetic pole.

It should not be understood, from the above, that lighthouses or fog alarms have been superseded or will not be installed in these waters in the near future. Nevertheless, it is a tribute to radio direction finding that it was chosen as the most effective way of covering this long stretch of some 1,000 miles as a preliminary measure.

Four stations of the latest type are now in operation at Resolution Island, Hopes Advance, Nottingham Island and Churchill (see map) and have been fully utilized by the ships plying in those waters. The stations are manned the year round and provide a useful service in their weather observations which are of great value to the Meteorological division of the Department of Marine, in making up the daily weather forecasts. Communication with the outside world is maintained by a short wave link from Hopes Advance to Ottawa, by long wave communication between Resolution Island and Father Point or Belle Isle on the St. Lawrence system, and also via Port Churchill and the Canadian National land-line.

Those who are interested in the principle of direction finding will note that when a receiver is connected to an ordinary antenna a polar curve of reception is obtained in the form of a circle, that is to say, the antenna receives with equal intensity from all directions. If however, we substitute a loop antenna and move a transmitter around it through 360 degrees, we find that as the transmitter progresses around the loop, there will be two definite positions 180 degrees apart where the received signal will be of maximum strength, and two other positions 90 degrees from the former where the signal will be at minimum strength.

Similar variations of signal strength will be obtained if the transmitter is stationary and the loop is revolved. If a polar diagram depicting the variation of signal strength in relation to the angular rotation of the loop is drawn as shown in figure No. 9 there will be obtained what is usually referred to as a "figure of eight" diagram, consisting of two circles touching at the origin, minimum strength being obtained when the signals are arriving at right angles to the plane of the loop. Thus if we wish to find the bearing of a ship station we can rotate the loop until we find either the maximum or the minimum signal and we secure a line of bearing. In actual practice the minimum signal is always used, as it is much sharper and better defined than the maximum signal. It is not, however, necessary to rotate the loop, for the Canadian stations use the Marconi-Bellini-Tosi system, which employs two large stationary loops supported with their planes vertical and at right angles to each other. These large loops have much greater receiving power than the comparatively small rotating loop, and since by means of a goniometer arrangement due to Bellini and Tosi there is created in other loops in the receiving apparatus itself a replica of the fields in the large loops, we can secure the bearing by rotating a small search coil carrying a pointer travelling over a graduated scale.

It will be noticed that with a figure of eight diagram, it is impossible to determine on which side the transmitting station is located with reference to the loops. This ambiguity is overcome by combining the type of reception diagram obtained with an ordinary antenna (which as mentioned before is represented by a circle) with that secured with a loop antenna which gives the figure of

Figure No. 7—Interior of the Operating Room at the Canadian Direction Finding Station at Saint John, N.B.

eight. Currents from these two types of antenna, adjusted as to strength and phase, are combined in a common secondary circuit in the receiver, and the resulting polar diagram is a cardioid or heart shaped diagram with only one minimum.

In actual practice the heart shaped diagram is used only to indicate on which side of the station the ship is located, and the actual bearing is taken on the figure of eight, the latter being the more accurate.

The apparatus employed is made in Canada according to the Department's specifications.

Radio Beacons

Following the development of the radio direction finder, for use on shore, came the direction finder for use on board ship. The latter presented special problems in overcoming the effect of funnels, masts, and other large metal objects, which took time to solve, but today the ship's direction finder approaches the accuracy of a similar instrument ashore, and with the important advantage that it is the ship herself who takes the bearings instead of an operator ashore. The importance of this can readily be appreciated.

As a result of this there came into being what are termed radio beacons, which in effect are radio lighthouses, with a range of about 75 miles.

The first series of Canadian beacons were installed at Cape Bauld, Belle Isle straits; Cape Ray, Cabot straits; Seal Island, N.S., and on light ships located off Heath Point (Anticosti), Sambro, and Lurcher shoals.

They consisted of converted sets of the spark type and obtained their power supply from the prime mover of the fog alarm, being worked during fog only. They were operated through a period of useful experiment, and, sufficent data and experience having been secured to form reasonable conclusions, the Department, two years ago, embarked on a regular scheme of installation of an automatic tube type of transmitter. The apparatus was developed in conjunction with the Canadian Marconi Company, and now ten sets are in operation at Lurcher Lightship, Seal island, Cape Whittle, West Point (Anticosti), Pointe des Monts, Main Ducks, Long Point, South East Shoal, Cove island and Michipicoten island, with nine more in course of installation.

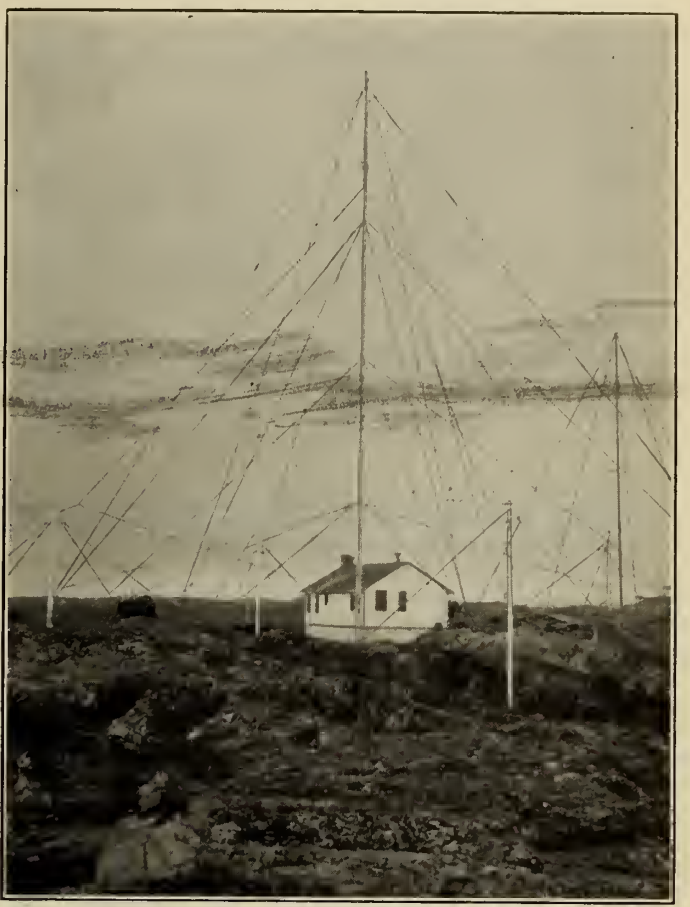

Figure No. 8—Resolution Island 1929—Direction Finding Station showing Combined Operating and Power House with Steel Mast Supporting Loop Aerials.

Our original idea of the beacon was the long distance fog alarm, but as our experience grew, the conclusion was reached that the navigator really desired a 75-mile lighthouse available day and night, 365 days a year, and the new apparatus is designed to attain this end. The transmitter is automatic in all respects. It has as a source of power a gasoline driven electric generator of the automatic start type, and the control of the whole equipment rests

Figure No. 9—Operators' Dwelling at Resolution Island showing Fresh Water Supply in Foreground and Acadia Cove in the Distance.

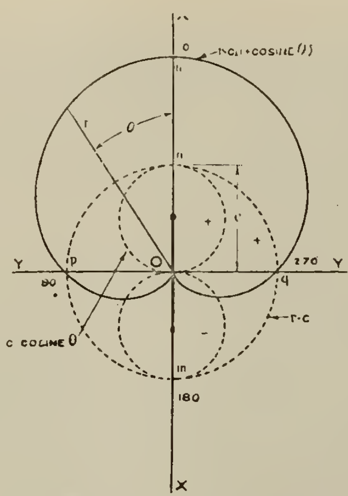

Figure No. 10.—Polar Diagram showing Types of Reception obtained with An Ordinary Aerial and a Loop Which Combine to Form the "Heart Shaped" Diagram with One Minimum.

in a master clock. Each beacon is given a characteristic, whereby it may be identified. In fine weather the clock automatically starts the engine once an hour and automatically puts the transmitter on the air for one minute and off for two, for a period of five minutes, when the clock automatically shuts the whole plant down. In foggy or hazy weather the lightkeeper throws what is called the fog switch and the beacon then functions automatically one minute on, two off, until the lightkeeper throws the switch back to fine weather schedule.

Details of the beacon transmitter may be of interest.

Four transmitting tubes are used, each rated at 50 watts output, arranged to work in what is generally called a back to back self rectifying circuit. The high tension for the anodes of the tubes is obtained from a 500-cycle alternator driven by a 110-volt d.c. motor. This alternator supplies current at 110 volts to the primary of a transformer which raises it to 1,500 volts. The secondary of this transformer is centre tapped and its outside terminals are connected to the anodes of two tubes operating in parallel.

This arrangement gives a note modulated at 1,000 cycles which is distinctive and can be read on a non-oscillating receiver. In addition it has the advantage of avoiding the necessity of using a thermionic rectifier or high voltage d.c. generator for supplying the high tension necessary for the tube anodes and the necessity of providing auxiliary modulating equipment.

Figure No. 11.—Radio Beacon at East End of Cape Whittle.

In order to obtain good regulation of the filament-heating current it is supplied at 60 cycles from a separate small converter.

A hinged gate at the front of the unit gives access to the tubes and is equipped with an automatic safety gate switch which interrupts the a.c. supply and renders the set dead when the gate is opened.

The brains of the equipment rest in a clock controlled time switch. The clock is a high grade eight day spring driven movement with balance wheel escapement suitable for use either ashore or afloat.

The usual hands are replaced by a disc which makes a complete revolution once an hour. This disc carries a series of pins or studs mounted on its face, which engage two light contacts possessing quick make and break features, called clock contact No. 1, and clock contact No. 2. No. 1 controls the starting and stopping of the engine-driven generator and No. 2 the duration of the transmission and silent periods.

Figure No. 14 illustrates the general appearance of the control clock, which is mounted in a water and dust proof metal case.

The source of power for the beacon transmitter is a 2-k.w., 110-volt d.c. generator, driven by and directly connected to a four cylinder gasoline engine rated at four horse power. This unit is automatically started from a 32-volt storage battery when a load equivalent to a 75-watt lamp is switched on across its output terminals.

This initial load is provided by a 150 ohm resistance connected in parallel with the energizing solenoid of a 110-volt shunt relay and is switched on and off by the No. 1 contacts of the control clock.

As soon as the circuit is closed by the No. 1 contact the engine driven generating unit starts and when it has built up to its full voltage of 110 volts, which it will do in approximately ten seconds, the shunt relay will begin to operate to close the remote control contacts on the solenoid operated starter of the motor alternator. This starter is of the progressive contact type and is adjusted, by means of an oil filled dashpot, to bring the motor alternator up to speed in twenty seconds.

The motor which drives the character disc is started at the same time and through the same operation.

Actual transmission is controlled by the second set of contacts on the time switch, and these are timed relatively to the No. 1 contacts so that transmission does not begin until one minute and forty-five seconds after the engine has been started in order to ensure that it will be running evenly and will drive the motor alternator at uniform speed under load.

The No. 2 contact on the clock energizes a relay to close or interrupt the primary circuit of the 500-cycle transformer, which supplies high tension to the anodes of the transmitting tubes. This circuit is closed for a one minute and fifteen seconds transmission period and then opened for a one minute and forty-five seconds silent period. This sequence is transmitted twice at the beginning of each hour day and night during clear weather and is repeated continuously during fog.

The character disc through a keying relay makes and breaks the same circuit to form the signals of the beacon characteristic.

When the clear weather hourly operating period of six minutes is over the clock opens the energizing circuit of the main starting relay which, in turn, drops out and opens the remote control circuit of the solenoid operated motor starter. This results in every output circuit of the generator being open and the engine shuts down.

Figure No. 12.—Combined Lighthouse, Fog Alarm and Radio Beacon Station erected on South East Shoal, Lake Erie, by the Canadian Government.

For continuous operating during fog, a single pole switch, located on the main control panel above the starting relay, is closed, short circuiting the No. 1 contacts on the clock. This takes the control of starting and stopping away from the clock and the generating plant will continue to run so long as the engine is supplied with fuel. The transmission and silent periods are still controlled by the No. 2 contacts of the clock.

In order to draw the attention of the attendant in case of overload or if the filament of a transmitting tube should burn out, an alarm bell operated through an auxiliary relay is provided. This auxiliary relay is energized from the 110-volt d.c. circuit in series with the overload trip coil of the circuit breaker and also through a differential relay in the filament circuit. Of the four filaments, two are connected in each side of the differential relay and under normal conditions the two sides are balanced and the relay is inoperative, but if one tube burns out the two sides of the relay become unbalanced and it will operate to energize the auxiliary relay and through it close the bell circuit. After the auxiliary relay has been tripped by the operation of either the overload or the differential relay the alarm bell will continue to ring until the auxiliary relay is reset by hand.

All beacons are provided with duplicate equipment throughout, and a transfer panel mounted between the two transmitters permits of using either engine with either transmitter and either control clock. (See figure No. 15.)

In connection with radio beacon installations, methods have been developed for synchronizing transmission of the radio signal with that either of a local fog horn or a submarine oscillator, in order to provide means for determining the distance intervening between a ship and the beacon. This is done by observing the time which elapses between the reception of the radio signal and the sound signal of the fog horn or submarine oscillator and by a simple calculation, based on the rate of travel of sound in air or water, as the case may be, a navigator can determine the distance with a fair degree of accuracy.

Long Distance Communication by Means of the Marconi Short-Wave Beam System

Canada's pioneer work in the matter of trans-Atlantic communication did not end with Glace Bay, and it is interesting to note that the first commercial long distance beam short-wave radio service was that established by the Canadian Marconi Co. between their station at Drummondville, near Montreal, and a station at Bodmin, England, which was put in commission on October 25th, 1926. Today hundreds of long distance short-wave stations are in operation in practically every country of the world, and, as a consequence, one of the biggest problems with which those charged with the administration of radio are confronted is to fit them all into the radio spectrum. A station in Montreal interfering with a station in Toronto is a simple matter to sort out, but a station in the Dutch East Indies interfering with a station in London which communicates with Montreal is a much more complicated affair.

Prior to the advent of the beam in 1926, long distance communication was usually carried on on long waves of from 8,000 to 20,000 metres, with frequencies of 37,500 to 15,000 cycles, but since that date there has been a complete revolution in this phase of the art, and while today there are a few long wave stations left, all new development is along short wave lines. Canada has two international short-wave circuits, the one to England above mentioned, and one to Australia opened by the Canadian Marconi Company in June 1928. The frequencies used on the British circuit are 18,180 kilocycles day and 9,330 kilocycles night, and on the Australian circuit the same frequency is used both day and night, but at night signals are shot around the world the other way. In addition there is an experimental short-wave voice telephone circuit between Montreal and London which we look forward to seeing in commercial operation in the not too distant future.

Those who listened in on the speeches given at the inaugural session of the Disarmament Conference had an opportunity of testing the quality of this particular short-wave circuit, over which the signals were brought to Montreal, where they were put on the telephone wires and distributed to the Canadian broadcasting stations from coast to coast.

Telephone communication with Australia has also proved entirely practicable, but it is doubtful if there is sufficient commercial demand for such a circuit to warrant placing it in operation in the immediate future.

The Canadian Marconi Company's beam transmitting station in Canada is situated at Drummondville, thirty miles east of Montreal, and the receiving station at Yamachiche, twenty-five miles north of Drummondville. These stations are linked up by land line to the central office of the Company at Montreal, from which the transmitter is automatically operated.

The moment the operator in Montreal presses his key or feeds his message tape into a high speed telegraph instrument, the signals he is sending are instantaneously recorded at the distant terminal office of the circuit, whether it be 3,000 miles away, in London or the longer distance to Melbourne.

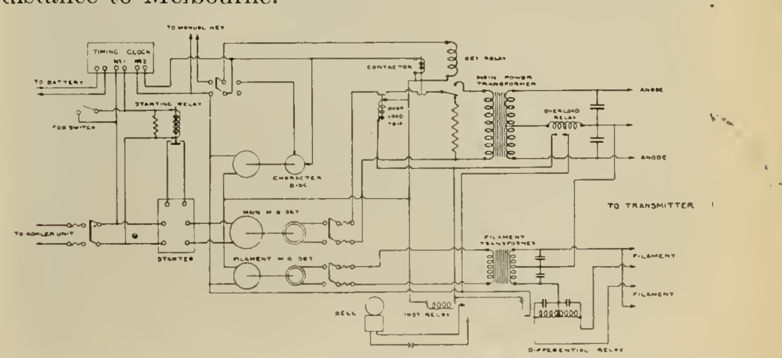

Figure No. 13.—100-200 Watt Radio Beacon Schematic Diagram of Automatic Controls.

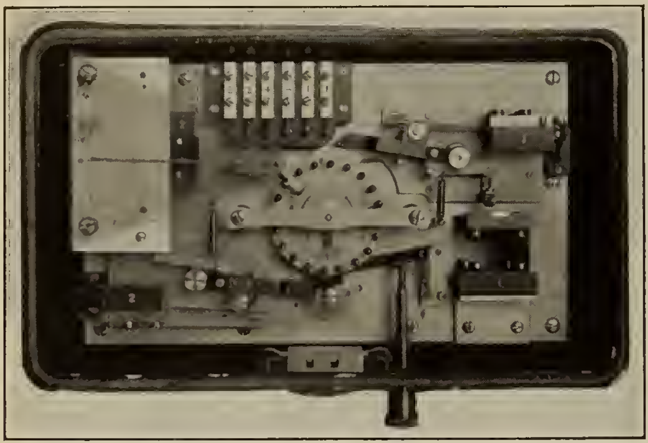

Figure No. 14.—Clock Operated Time Switch which controls the Automatic Transmissions of the Canadian Government Radio Beacon Stations.

Incoming signals from the corresponding stations are received at Yamachiche, and after being heterodyned to a lower frequency, amplified, and filtered, are conducted by landlines, consisting of open wire lines and cables, to the office in Montreal where they are automatically recorded and are transcribed for delivery to the addressee.

For convenience in briefly describing the beam system its distinctive features may be divided in the following four parts:—

(*1*) The aerial and reflector.
(*2*) The aerial feeder system.
(*3*) The transmitter.
(*4*) The receiver.

(*1*) The aerial systems at the transmitting and receiving stations are identical and are supported on guyed steel lattice masts, the exact height depending to some extent on the wavelength used. The usual height is about 277 feet with cross arms at the top measuring 90 feet from end to end.

The design of the masts and aerials is peculiar to the short-wave beam system and is entirely different from the design previously used in commercial radio stations. In the ordinary radio station the aerial consists of a series of horizontal wires suspended at a height on a line of masts and connected with the transmitting apparatus by a vertical or oblique section. With the beam system, the aerials consist of a number of vertical conductors forming a wire curtain suspended from horizontal supporting steel cables attached to the ends of the cross arms at the top of the masts. The aerial system is on one side of the masts facing the distant station and the reflector system similarly constructed is suspended on the opposite side.

There are usually five masts for each service erected in a straight line and aligned so that the great circle bearing on the distant station is at right angles to the line of the masts.

The usual spacing between the masts is 650 feet making the total length of each line of five masts about 3,150 feet.

The beam leaves the aerial system at right angles to the plane of the masts and follows the shortest or great circle track in the direction of the corresponding station and this station, being in the centre line of the beam, receives the maximum strength of signal.

Each service usually employs two waves and therefore two aerial systems, one for day and one for night working.

It may be interesting to note here that in the case of the England to Australia circuit, only one wave length is used projected alternatively in opposite directions. This is accomplished by arranging two similar aerials with one reflector between them, the transmitter being switched from one to the other as conditions require. This simplification was decided upon following the discovery during preliminary tests of this circuit, in 1924, that the position and altitude of the sun had an effect upon the transmission of signals, and that during the morning period the waves travelled from England to Australia starting in a westerly direction across the Atlantic and Pacific Oceans, following the great circle along the longest route, approximately 12,000 miles, but during the evening period they travel in an easterly direction over Europe and Asia, following the shortest route which is about 9,000 miles.

Each aerial occupies two bays between the masts and in radio parlance may be said to consist of a sheet of parallel elements made up of a number of vertical doublets linked by phasing coils.

The aerial wires are spaced about one quarter wavelength from a screen composed of twice as many reflector wires.

The aerial arrangement is such that the currents fed into the parallel wires of the aerial are all in phase. Under this condition the energy radiated from the individual wires cancels out in the plane of the wires, but adds in the direction at right angles to this plane.

The effect of the reflector is to cut off the back radiation from the aerial and to strengthen it in front, the total result being a strong beam of radiation confined almost entirely to one direction and spread over an angle determined by the dimensions of the aerial.

The calculated directional effect of aerials of different widths is indicated below:—

Width of aerial in wave lengths	1	4	20
Approximate horizontal angle within which practically all the energy is confined.....	180 deg.	30 deg.	6 deg.

The greatest energy concentration by directional effect for a given area of aerial, and therefore for a given cost, is obtained by having equal areas at the transmitter and receiver. Thus an aerial of 20 square wavelengths at the transmitter or the receiver may give a concentration equal to 200, but if divided into two aerials one at the transmitter and one at the receiver, each of 10 square wavelengths, the resulting concentration will be equal to 10,000.

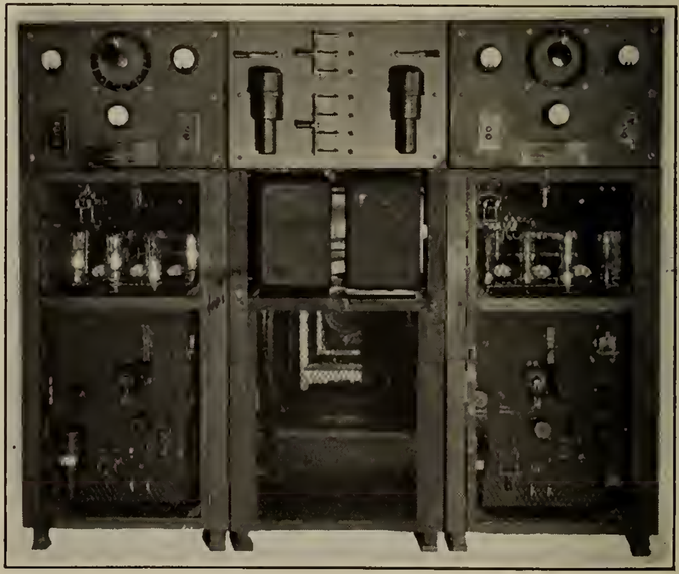

Figure No. 15.—Type of Transmitter installed at Canadian Government Radio Beacon Stations showing Duplicate Units and Transfer Panel.

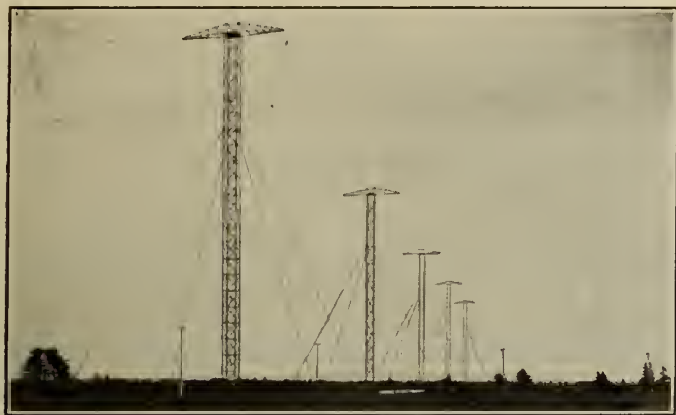

Figure No. 16.—Short-Wave Beam Receiving Station at Yamachiche showing Masts Supporting Reflector Aerial for Receiving from England.

(*2*) The feeder system by means of which energy is transferred from the transmitter to the aerial consists of concentric copper tubes, the outer one of which is earthed and the inner tube insulated from it by means of a special porcelain insulator. This feeder system is so arranged that the length of feeder to each individual aerial element is exactly the same, which ensures that the currents in all the aerial wires are in phase.

(*3*) The transmitter is specially designed to give great stability of wavelength, a point of the utmost importance in dealing with short waves; 20 k.w. is supplied to the anodes of tubes in the final amplifier stage, from which ample energy is fed through the feeder system to the aerial to permit of high speed working.

Stability of wavelength is obtained by means of a master oscillator which controls the frequency of the succeeding amplifer stages and also by careful arrangement and screening of the components. Stability of the emitted wave is further assured by diverting the high tension supply through resistances during the spacing periods and so keeping a constant load on the generators.

In order to deal with the high frequencies encountered in short-wave working, special transmitting tubes are used. These are oil cooled and operate at high efficiencies.

(*4*) The receiver is coupled to the reflecting aerial system by means of a feeder arrangement similar to that employed at the transmitting station, and consists of nine carefully screened units conveniently mounted on a vertical rack.

The signal in passing through the receiver, in addition to being amplified, has its frequency lowered by being heterodyned to a suitable value for efficient transmission over landline to the central office.

The receiver has incorporated in it band pass filters, which allow only certain narrow bands of desired frequencies to pass through, and the intensity of the signal finally transferred to the landline is automatically prevented from exceeding a certain maximum value by being passed through a limiting tube which has its grid so biased as to accomplish this end.

By employing circuits analogous to those extensively used in carrier current telegraphy for superimposing several communication channels on one physical wire circuit, each beam aerial can be efficiently utilized for the simultaneous transmission of telephonic and telegraphic messages or for the simultaneous transmission of telephonic or telegraphic messages without there being any mutual interference between these services.

Facsimile transmission can also be employed with the beam system over practically any distance.

It may be interesting to note here that the carrier current systems of telegraphy now being extensively installed by both the Canadian Pacific and Canadian National Telegraphs on their long heavily loaded landlines for greatly increasing their traffic handling capacity employ apparatus made possible by the use of thermionic tubes, first developed by the radio industry.

With regard to the relative advantages of the beam as compared with the older systems of long wave radio communication, the following may be cited:—

1st Less capital expenditure required.

2nd Less electrical power required to operate the transmitters.

3rd Greater speed of transmission possible. At present this is limited only by the mechanical limitations of the keying and recording instruments.

4th Due to the restriction of the radiation to a narrow beam, to the screening effect of the reflector at the receiving station and to the large number of wave-bands available, a greater number of services can be carried on.

5th Due to the screening effect of the receiving reflector the signal-to-interference ratio is increased, and consequently the traffic capacity is increased, because the possible sources of interference are reduced in proportion to the narrowness of the arc of reception.

The competition of the beam stations has introduced a new factor in international communication and as a consequence a merger has been formed in England to unite the British cable and radio telegraph systems into one.

One advantage enjoyed by the beam system over the cables is the fact that two beam stations capable of communicating half way round the world may be built for approximately half a million dollars whereas the cost of laying a permalloy loaded cable capable of working at similar speed is many times as great and increases in proportion to the distance separating the terminal stations.

In this regard it is interesting to note that a cable of this type laid between New York and the Azores, a distance of 2,328 miles, is reported to have cost four million dollars.

Radio Broadcasting

The extraordinary development of broadcasting is familiar, but it is not generally known that Canada is also a pioneer in this phase of the radio art. The Canadian Marconi Company commenced their first regular weekly

Figure No. 17.—Short-Wave Beam Transmitter at Drummondville, P.Q.

broadcasts from their station "XWA" at Montreal in December, 1920, on a wavelength of 1,100 meters, and they challenge the honour which Westinghouse, Pittsburgh, claims to hold. In protecting the interests of the broadcast listener Canada has been prominent. No other country in the world attempts any such service to broadcast listeners as we endeavour to give, in the matter of clearing up ship interference. In this Canada led the way by making treaties with ten countries, as early as 1925, arranging to have their ships stop the use of any wave in the broadcast band when ships flying their flag were on this side of the Atlantic, or the Pacific.

All spark transmitters on government stations at points where they could cause interference were scrapped and replaced by tube sets, and at the International Radio Convention at Washington in 1927, at which seventy-six administrations were represented, the policy of the Canadian Government was given international effect, and rules were drawn up making international the regulations and arrangements which previously had been in effect in Canada and the United States.

There are today in Canada upwards of half a million radio receiving sets and sixty-six broadcasting stations. The future of the latter is still to be decided. A Royal Commission on broadcasting was appointed to enquire into this matter a year ago, and its report will be dealt with by Parliament during the coming session.

Whereas many of the original stations employed transmitters rated at from 50 to 250 watts output, there are now several stations in Canada equipped with transmitters rated at 5,000 watts.

Our neighbours to the South are employing many broadcast transmitters rated at 50,000 watts, and transmitters of four times this power have been successfully operated in experimental tests, so that it is reasonable to expect to see transmitters employed in Canada of considerably higher rating than those at present in use.

Improvements have been incorporated in the design of amplifying and modulating equipment which now permit the carrier wave to be practically 100 per cent modulated, with the result that the effectiveness of the equipment is quadrupled as compared with the older type of transmitter which was capable of being modulated to only 50 per cent.

In order to prevent stations occupying adjacent frequency channels, which are only 10 kilocycles wide, from deviating from their allotted frequencies and so interfering with each other, crystal control of the carrier frequency has come into prominence. A piezo crystal consisting of a small quartz plate about one inch square is used to control a master oscillating circuit. The faces of the crystal are accurately paralleled and ground to a thickness associated with the frequency of mechanical vibration required. In order to insure frequency stability the crystal is mounted in a heat insulated chamber, the temperature of which is held to very close limits by the use of a sensitive thermostat controlling a heating element.

Tests of this method of control have shown that it is possible with ordinary supervision on the part of the operating staff to maintain the carrier frequency well within 100 cycles of the assigned frequency. When it is recalled that the carrier frequency may be as high as one and one half million cycles per second, control to within 100 cycles is a truly remarkable precision.

With broadcasting stations as originally constituted it was necessary that the programme to be broadcast should originate in a studio located in the same building as the transmitter. However, by the development of portable pick-up and amplifying equipment for use with the local telephone lines, and by improved methods of compensating the latter to give substantially uniform transmission of the frequencies involved, the possible separation of the point of origin of the programme from the transmitter was gradually extended.

The successful application of the thermionic tube to act as a repeater in long distance telephone communication circuits has had a marked effect on the extension of the distances over which such lines can be successfully operated, and in consequence, it is now possible to link up many widely separated broadcasting stations by means of wire lines, in order that a programme of general interest originating at one point may be simultaneously broadcast.

Two of the outstanding uses to which some form of thermionic tube has recently been put are in the development of television and in the production of sound motion pictures. The sound motion picture art has progressed with great rapidity during 1929, and the public reaction is one of increasing acceptance and patronage. The adaptation of radio broadcasting technique to this newest division of electrical engineering is an interesting example of scientific evolution and adaptation.

A few years ago the thermiomic tube was of interest primarily in radio and in landline telephony and telegraphy. Today it is a vital factor in a dozen industries and is of increasing significance in a score of others.

Even in this age of wonders the rapid progress made by radio stands out as phenomenal, and if we pause to consider its future possibilities, there is no doubt that, intelligently employed, it may become one of the most potent factors in bringing about mutual understanding among all peoples and the promotion of an irresistible sentiment in favour of universal peace.

The St. Hubert Airship Mooring Tower

R. de B. Corriveau, M.E.I.C.,
Assistant Chief Engineer, Department of Public Works, Ottawa.

Paper presented at the Annual General Meeting of The Engineering Institute of Canada, at Ottawa, Ont., February 14th, 1930.

Canada's share in airship development, determined at the Imperial Conference, was to provide, as one of the overseas terminals, a mooring tower. The Montreal airport, at St. Hubert, on this side of the Atlantic, selected in 1927 by representatives of the Air Ministry and the Department of National Defence, was placed under the jurisdiction of the Department of Public Works for construction purposes.

The airport, 615 acres in area, is a triangular plot, 90 feet above sea level, bounded by the Canadian National Railway, the Chambly highway and La Savane road, situated on the south shore of the St. Lawrence, seven miles from Montreal, in open country, free from smoke and other flying hazards. The Canadian National Railway and the Victoria bridge, with the new South Shore bridge and improved highways, provide connecting routes with the city.

Provision has been made for railway siding, water, electric power, telephone, hydrogen gas and gasoline fuel supply service to airships and aeroplanes. The Department of National Defence has established radio, wireless and meteorological services.

Airships are built and housed in huge hangars. Several hundred men have to be kept on duty to walk the airship in and out of the hangar in favourable weather. This can be arranged at military bases only. The British were the first to develop the mooring tower, and the mast—so called—at Cardington is the type of structure which the Air Ministry desired to have duplicated in this country.

Following the visit of Major G. H. Scott of the Airship Development Directorate, and Mr. A. R. Gibbs of the Directorate of Works and Buildings, we were supplied with complete plans of the Cardington mast, and the Air Ministry in co-operation with Messrs. Babcock and Wilcox, of London, further improved the design of the mooring head, which was later fabricated in England and shipped here for erection.

In adapting the plans for the steel structure, slightly heavier sections had to be used and certain changes were made to meet conditions in this country.

The Canadian mooring tower is a self-contained structure, anchored to concrete footings.

At the base of the tower is a two-storey building, cruciform in shape, to house the mooring winches, heating plant, etc., and to provide lobby entrance, retiring rooms and offices.

Fairleads for side cables to yaw winches are located 250 feet from the centre of tower. There are 24 concrete blocks, spaced at fifteen degree intervals, on the circumference of a circle of 750 feet radius. These are for anchoring the 25-ton snatch blocks through which the yaw cables pass from nose of ship to fairleads.

The tower is an octagonal structure 171 feet high, surmounted by a steel plate turret 25 feet in diameter, from the top of which projects a telescopic mooring arm to which the nose of the airship is attached. The total height of the tower to the top of the mooring arm is 205 feet, and the arm can be extended 7½ feet.

This telescopic arm, weighing 15 tons, is mounted on gimbal bearings and counterweighted, through a system of cables and pulleys, to swing thirty degrees from the vertical and in any position of the compass. It is operated by compressed air. When the ship's cone is cupped, the arm is contracted, brought back to its vertical position and locked so as to permit the ship swinging with the wind.

The tower proper is made of steel and is composed of eight posts on a base 69 feet 2 inches in diameter, and drawn in to a diameter of 25 feet 8-1/16 inches at the passenger platform level, 171 feet high. The posts are braced diagonally between levels of horizontal bracing, which occur at intervals of 28 feet 4 inches. In addition to this regular system of horizontal bracing, there is a heavy network of I-beams 19 feet above ground to support the reinforced concrete floor, and another 29 feet above ground for the reinforced concrete roof of the building at the base of tower. There are horizontal struts supporting the searchlight platform, and heavy girders covered with checkered plate floors at the elevator landing and passenger platform. In the centre of the tower, there is an elevator and stair shaft 16 feet square. Four columns are placed at the corners of the elevator stair shaft, from ground to roof of base building, to support the floor and roof loads.

To support the Duntile wall enclosing the stair shaft, two additional columns made of 6 by 6 by ⅜ inch angles were riveted to the horizontal bracing on each of the four sides of the shaft.

The searchlight platform, 142 feet 6 inches above ground, is equipped with searchlights which are used to spot the anchorages on the ground, and, generally, to facilitate airship moorings at night.

A movable platform landing stage is provided on the passenger platform, connecting over the guard rail with the airship's gangway. Passengers descend a stairway inside the turret to the elevator landing, 14 feet 2 inches below, and then proceed by elevator to the lobby on the ground floor, 156 feet 10 inches below.

The elevator has a capacity of 3,000 pounds, travels at a speed of 150 feet per minute, and is operated by electric motor taking three phase, 60-cycle alternating current at 550 volts.

The stairway, 3 feet 3¼ inches wide of checkered plates, ascends around the elevator well, and the combined shaft, 16 feet square, is of framed steel braced on all four sides and completely covered in with Duntile hollow cement blocks. The interior is insulated with Ten-test fibre board one inch thick nailed to wooden furring. The insulating material, weighing 14 pounds per cubic foot, was manufactured to have an insulating value of 0.34 B.t.u. per square foot per inch of thickness per degree difference in temperature.

The low pressure steam heating plant installed on the ground floor consists of a 35 h.p. Spencer boiler, with direct driven automatic boiler feed and vacuum pumps, and was designed to heat the two-storey building to a temperature of 70° and the elevator stair shaft to a temperature of 50° F. in severe weather. Cast iron radiators were installed in the lobby, machinery house and rest rooms, as well as in the mooring head. In the elevator shaft, special fin-type radiators had to be used to fit the confined space. The heating plant is fired with oil and includes a jacket-heater and a 1,000-gallon oil tank.

Messrs. Canadian Vickers Limited, of Montreal, were awarded the contract to fabricate and erect the steel tower—645,000 pounds of steel, and to erect the mooring head—87 tons of steel and equipment. The unusual nature of this structural steel job called for special care in the preparation of detail drawings and fabrication, and every member was erected without the necessity of reaming. The mooring arm, 26 feet long with gimbal bearing, the whole weighing about 17 tons, was raised up the elevator well before erecting the stairway.

In the design of the airship mooring tower the contractors provided for a pull at tower head of 90,000 pounds with maximum stresses in the structure within the elastic limit, and a factor of safety against uplift of 1.325. The C.E.S.A. Standard Specification for Steel Structures for Buildings, No. A16—1924, was used. The calculated deflection at top of tower, due to 30 pounds per square foot wind pressure and pull of airship, is 0.995 inch.

The Cardington mast when tested by applying a pull of 67,200 pounds at the top deflected 1¾ inches and went back to the vertical.

The R-101 exerted a maximum pull of 33,600 pounds when riding a gale at the top of the Cardington mast. This dirigible was also reported to have veered over ninety degrees in less than one minute, without any serious strain to ship or mast at Cardington.

In connection with the swinging arm, there is a vertical two-stage air compressor direct coupled to motor at ground level. The compressor charges the air receiver at base of tower to a pressure of 400 pounds per square inch. It is reduced down to 150 pounds per square inch from this receiver and is supplied at that pressure to the receiver on the passenger platform by a 2-inch diameter flanged pipe line.

Air at 150 pounds per square inch is used for the locking cylinder, top and bottom, and for bringing in the ram against the resistance of the ship and the centreing gear.

The air is again reduced to 25 pounds per square inch pressure to the recoil receiver, which is slung underneath the passenger platform. This air is used for pushing out the ram and holding it out until the bucket or cone on the nose of the ship enters the cup on the swinging arm. A recoil gauge graduated in tons is fitted in the control cabinet to show the pressure under the piston in the cylinder of the swinging arm when the ram is hauled down by the main haul winch against the pressure of 25 pounds per square inch.

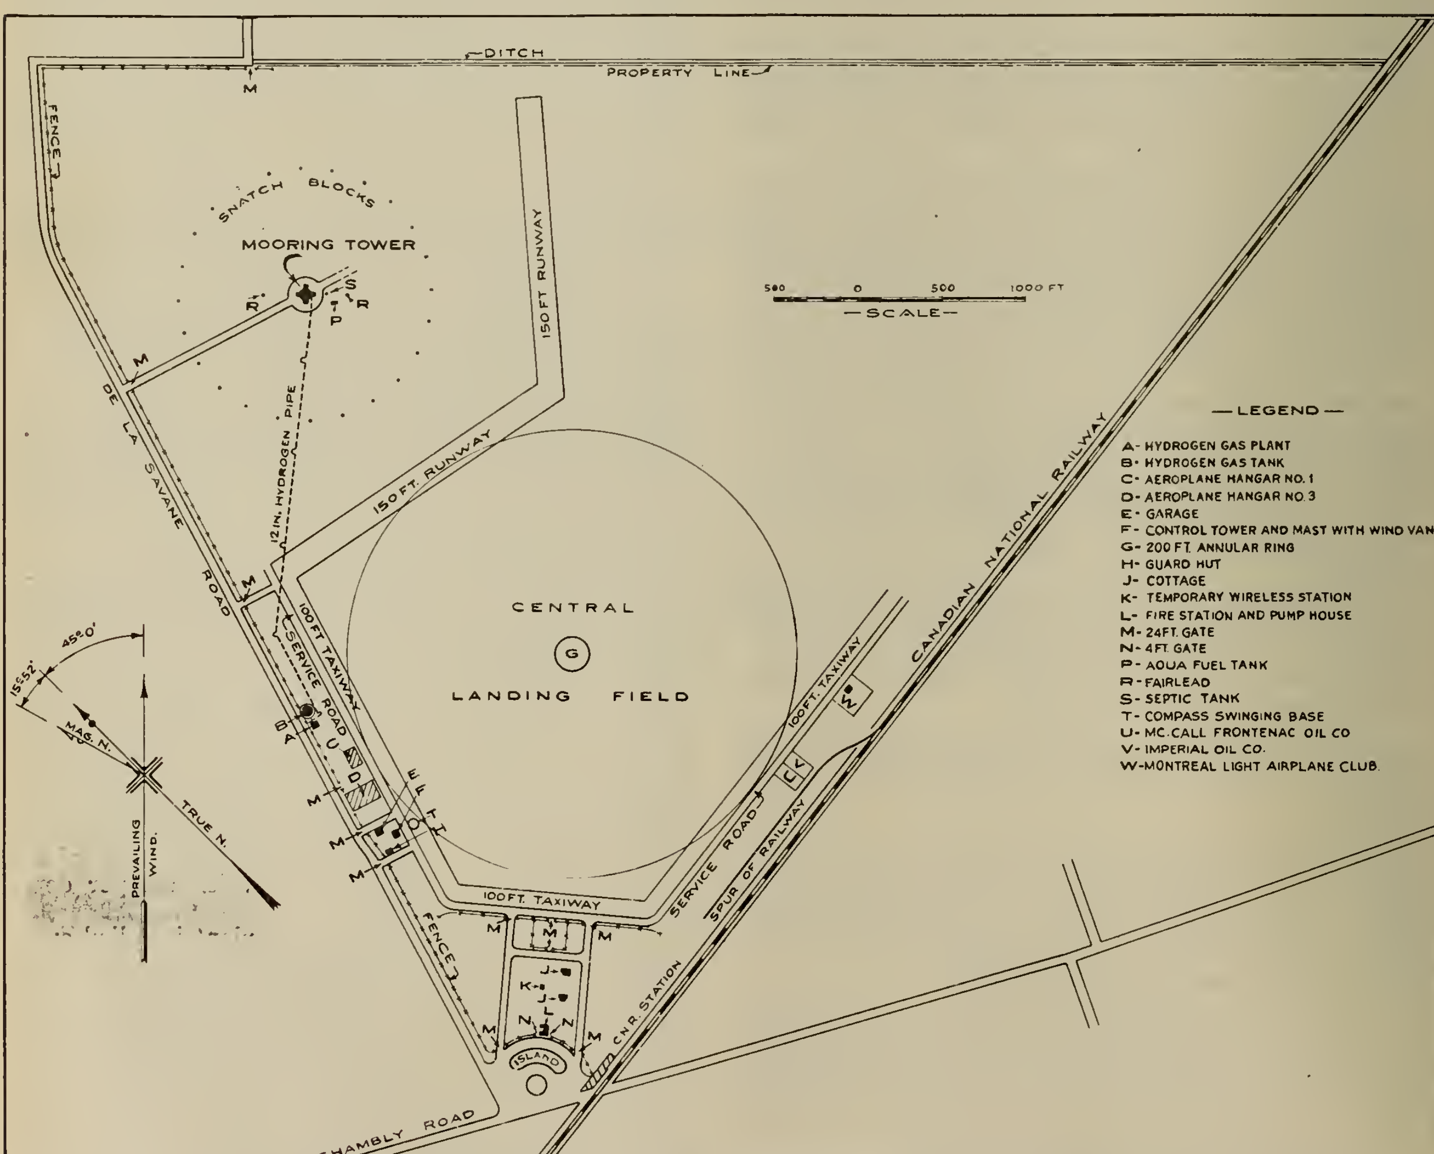

Figure No. 1.—Location Plan of Montreal Air Harbour at St. Hubert, P.Q.

The 400 pounds per square inch and 150 pounds per square inch air receivers are fitted with lock-up safety valves. The 25 pounds per square inch recoil receiver and the reducing valves are fitted with adjustable relief valves.

Each of the eight tower posts rests upon a concrete base 11 feet by 13 feet 6 inches by 9 feet 6 inches deep. These bases act as counterweights to prevent any uplift due to combined wind pressure on the tower and pull of the airship at the top tending to overturn the structure. Each post is anchored with four 2½-inch diameter bolts, 6 feet 3 inches long, which in turn are held in place by four 8-inch I-beams 5 feet 3 inches below the top of concrete footing. The weight of each base is approximately 105 tons.

The possible error in surfacing the concrete footing was 1/16 of an inch. In laying out the 32 anchorage bolts in the eight footings and on either side of a circle of 34 feet 7 inches radius, the resident engineer made use of wooden templets and so thoroughly checked up the locations that the bolts after being fully set in the concrete were found to fit exactly the base plates of the steel posts, which are rigidly connected together, and this facilitated erection of the steel structure.

The base building consists of 12-inch tile walls with stucco exterior, tile partitions and plaster finish inside, reinforced concrete floor and roof finished with copper flashings, metal doors and window sash, chimney, with all necessary plumbing and lavatory fixtures. The building contract also included the curtain walls of Duntile cement block and insulation of the elevator stair shaft.

The whole structure, except the building at the base, which is gray stucco, is painted black and chrome orange; these colours were combined to develop maximum visibility from the approaching airship.

All machinery in the tower is electrically operated; the power cable is carried underground a distance of 2,100 feet; two transformers step down the 2,200 voltage to 550 for machinery, and another transformer to 110 volts for lighting. There is a motor-generator set for charging the airship batteries, and a complete installation of motors and switchboard for all power and lighting services. The tower is flood lighted below the passenger platform, and the mooring head above has obstruction and operating lights. The electrical installation was carried out under the regulations of the Quebec Inspection Bureau.

To develop an adequate water supply for the airport, an arrangement was made with the Canadian National Railways to use St. Lawrence river water from the twin railway tanks at Southwark, 2½ miles from St. Lambert, where there is a hydrant pressure of 25 pounds.

A main of 8-inch class B pipe was laid along the Canadian National Railway right of way, a distance of two miles to the pump house on the airport property. The distribution pipes are 8-inch class D for high pressure raw water to the mooring tower, one mile distant, and 6-inch class C for high pressure raw water to serve hydrants, hangars, etc., located in another direction. To distribute domestic water, 4-inch class B pipe was laid in the same trenches as the high pressure pipes.

The pumps, filter, tanks, etc., are housed in a solid brick building, adjacent to which are located the raw water reservoir of 50,000 gallons capacity, valve chamber and fire station. The reservoir is of reinforced concrete and the roof and exposed side are banked with earth. The reservoir and valve chamber were built for enlargement to double capacity, when necessary.

Under the floor of the pumping station there is a clear water well of 12,000 gallons capacity. Coagulation and alum tanks, and filters, of reinforced concrete, are provided.

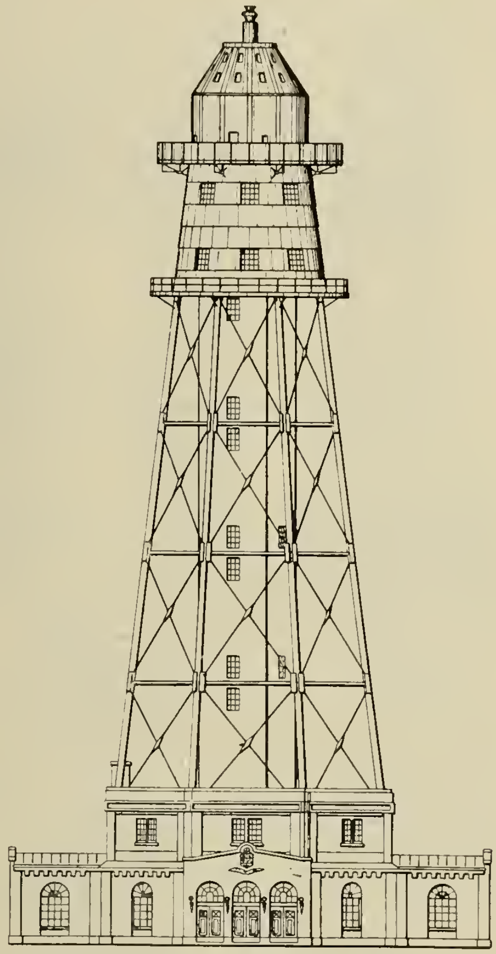

Figure No. 2.—Elevation of Mooring Tower, Montreal Air Harbour at St. Hubert, P.Q.

For raw water there is a centrifugal pump with a capacity of 250 gallons per minute against a head of 260 feet, direct connected to electric motor, and an auxiliary pump operated by gasoline engine. For domestic water distribution, there is an enclosed self oiling power pump of the duplex piston type, with a capacity of 100 gallons per minute against 150 feet head. This pump is automatic, stopping at 70 pounds pressure and starting at 50 pounds pressure. The water is pumped through a Tweed pressure tank of 1,500 gallons capacity. The auxiliary pump is of the centrifugal double suction type.

There is also a centrifugal high rate wash water pump in the pumping station. Booster pumps are installed at the base of the mooring tower to force the water up to total heads of 400 feet, for fuelling and ballasting the airship.

The water supply from Southwark is metered. A recent test showed the filtered water to be of high quality. The whole system was designed by Mr. F. C. Laberge, M.E.I.C., consulting engineer.

To deliver gasoline or Diesel oil to the fuel tanks of the airship, the Aqua flotation system was selected. This makes use of the principle that water and gasoline do not mix, and that the lightest and best gasoline always floats on top. The installation includes a 10,000-gallon pressure storage tank, placed underground and connected to the domestic water service. The water enters the tank under pressure and displaces the gasoline, which is forced up the tower through a 2-inch pipe. There are automatic valves with an auxiliary tank installed at the base of

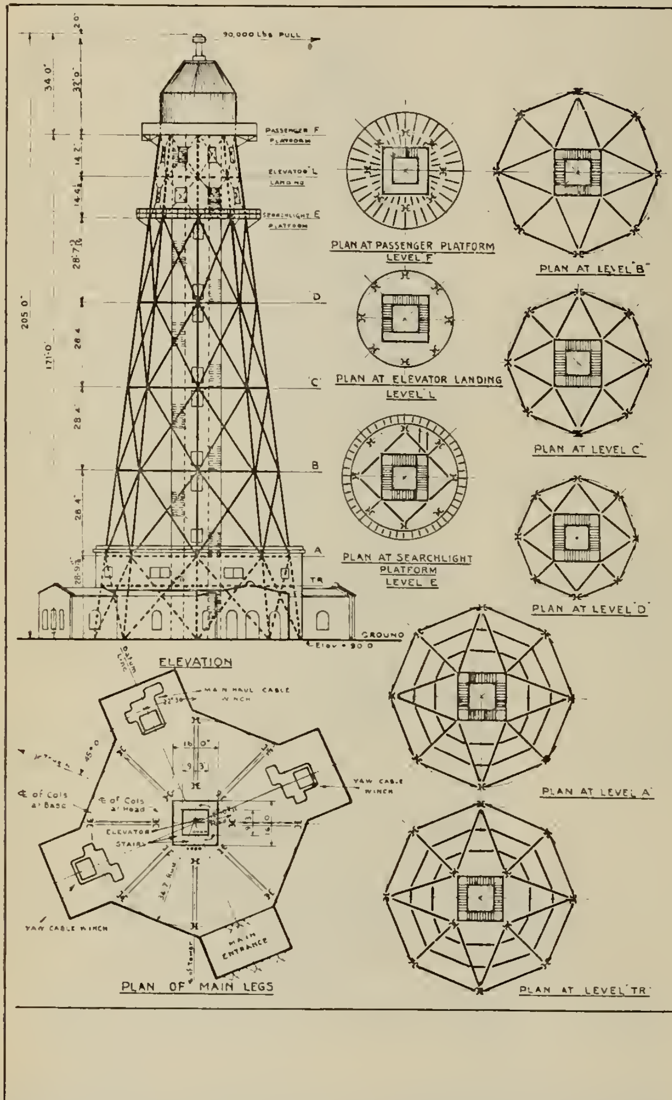

Figure No. 3.—Diagrams showing Elevation and Sections of Mooring Tower at Montreal Air Harbour, St. Hubert, P.Q.

the tower to prevent the water going above ground level and to control the gasoline supply. A sump pit and electric pump are provided to drain the water from the storage tank to field underdrains when gasoline is being stored into the tank. This sump pit is so located that it also takes care of the water seepage along the hydrogen main. The storage tank is equipped with a spray blending header, so that water under pressure can be used for blending fuel oil to any desired degree.

The R-100 requires 5,000,000 cubic feet of hydrogen to fill her gas bags. It is estimated that one-tenth of this supply has to be replenished after a trans-Atlantic trip. To meet this demand a Silicol hydrogen plant of 40,000 cubic feet per hour capacity and a gas holder of 50,000 cubic feet have been provided at St. Hubert.

There are two generating units each of 20,000 cubic feet capacity installed in a special building alongside the gas holder 2,500 feet away from the mooring tower, both being connected to a twelve inch low pressure hydrogen main. Ferro silicon and caustic soda are used to generate the hydrogen. The gas holder operates on a pressure of 5-inch water gauge and facilitates the movement of hydrogen by differential pressure in the gas main.

At the top of the tower the pressure is reduced through a regulator valve to 30 millimeters water gauge, and the hydrogen is then metered before it reaches the airship supply pipes in the mooring head. As the plants can operate above their rated capacity, provision has been made to meter up to 60,000 cubic feet of hydrogen per hour. All connections are electrically welded.

At the base of the tower, on the ground floor of the machinery house, are three variable speed electro-hydraulic winches; two for the yaw cables and one for the main haul cable. These winches are of the spur gear type, each operated by an electric motor through a Waterbury hydraulic transmission, and capable of handling a load of 33,600 pounds at 50 feet per minute and a light line at 150 feet per minute. When the airship's cone is being drawn into the cup of the mooring arm, the speed of the winches will be reduced to a minimum, as for inching heavy loads. Each motor is an a.c. 85 h.p. constant speed motor, 550 volts, three-phase, 60 cycles, 430 r.p.m., and is equipped with a hand starting compensator.

The drums are designed to hold 5,000 feet of ¾-inch diameter special mooring cable coiled in five layers. This is to provide for the larger airships of the future. For mooring the 5,000,000 cubic foot airships, 2,000 feet of cable has been provided for the main haul winch, and 3,000 feet each for the yaw winches. There is an automatic spooling device on each drum, and the main haul cable is guided by a fleeting sheave, 40 inches in diameter, and set 25 feet away from the main winch.

The base plates of the winches provide for the future installation of gasoline engine auxiliary power.

The drums are arranged to be disconnected from the transmission and act as free drums controlled by operator at mooring platform. Valves at control stand permit the flow of compressed air from the reservoir to brake cylinders at drums. The control of braking effect on the three winches can be directed from either of two positions.

There is a klaxon annunciator system for drum release at main haul cable winch and yaw cable winches.

The winches are further controlled from the operating platform by Selsyn-servo-motor remote control apparatus, consisting of transmitter servo-motors at remote control stands, electrically connected to receiver servo-motors mounted on top of the hydraulic transmission of each winch. There is also a cable tension meter for indicating the pull of the main cable.

To prepare for mooring, the main haul cable is let down to the ground through the mooring arm, and hauled to leeward 800 feet; the yaw cables are led through the fairleads and snatch blocks on either side.

The airship approaches slowly up wind and is brought down gradually to 900 feet, paying out its main cable through the mooring cone from a winch in the bow. The speed of the ship is eased off a little more, and the two cables are connected by snatch-coupling, the ground crew signalling to the ship and tower head. Ballast is dropped from the bow. The main cable tautens. The ship is then adjusted for trim and equilibrium, and signals the tower she is ready to haul down. The yaw guys are paid out from the ship's bow winches and connected up by snatch-couplings to the yaw winch cables from the tower. The guys are hauled taut and the main winch then continues to haul until the ship's cone engages in the mooring arm cup. The telescopic arm is contracted, centralized and locked. The ship cables are then unrove from the tower winches and reeled up on the bow winches. When ready to cast off the ship slips a pendant through the mooring arm.

In carrying out the construction of the mooring tower and providing the services connected therewith, the Department of Public Works had the active co-operation of the Department of National Defence through Mr. J. A.

Wilson, A.M.E.I.C., controller of civil aviation, and Group Captain E. W. Stedman, M.E.I.C., chief aeronautical engineer. Through the Department of National Defence, also, the necessary funds were provided, and consultation was had with the Air Ministry. Messrs. Babcock and Wilcox were represented by Mr. F. E. Williams, of their staff, on the erection of the mooring head by Canadian Vickers Limited.

The general plans and specifications for the tower and base building were prepared by Mr. F. G. Smith, A.M.E.I.C., bridge and structural engineer, and Mr. T. D. Rankin, architect. Mr. J. H. Ralph, A.M.E.I.C., electrical engineer, advised on electrical installation, and Mr. F. O. Hamel on matters of heating. Mr. J. A. L. Dansereau, A.M.E.I.C., district engineer in Montreal, and Mr. J. A. Adam, A.M.E.I.C. resident engineer at St. Hubert, had active charge of construction, under the general direction of Mr. K. M. Cameron, M.E.I.C., chief engineer, and the author.

Discussion of Paper on Rigid Airships by Group-Captain E. W. Stedman, M.E.I.C.(1)

MAJOR-GEN. A. G. L. MCNAUGHTON, M.E.I.C.(2)

General McNaughton remarked that the information which the author had given to The Institute was particularly apt at the present time when the great experience in the lighter-than-air field which was initiated in Great Britain in 1924 had reached the point where the new airships were completed and were undergoing their air trials. To engineers this project would be of particular interest because it was an excellent example of the application of scientific methods to the solution of a major problem.

In hearing Group-Captain Stedman's paper he had been struck with the fact that the early development of the airship was rather haphazard and that experience had been bought at the cost of some rather tragic failures. On reviewing the history of these failures it seemed evident that empirical methods of design had persisted long after the other branches of aeronautical engineering had been placed on a thoroughly sound scientific basis.

To the Air Ministry, acting on the advice of the Committee which had investigated the loss of the R.38, belonged the credit for changing all this. Fundamental research on air resistance, the distribution of the air loads and on the stresses induced in the various parts of the frame were undertaken, and, as a result, a design had been evolved in which the air resistance was less than half that of a ship of the same displacement built to the previous conventional form, while all redundant members were eliminated from the structure. This work was necessarily highly confidential and the first intimation received in Canada was from the advance copies of the documents prepared for the Imperial Conference of 1926.

All the Canadian officers who had the privilege of reading those reports were much impressed, perhaps not so much with the projected designs, which they were not in a position to appreciate, as with the thoroughly scientific manner in which the whole proposition had been developed, and also the fact that at last a type of design had been produced which was calculable in relation to the static stress in all members; also this design permitted the greater and far more important dynamic loads developed during manoeuvering to be predetermined with considerable accuracy. It was this that inspired confidence, and, with the able exposition at the Conference by the Secretary of State for Air, led to the notable offer of support by the Prime Minister of Canada. He said "the Canadian Government will only too readily co-operate with the British Government . . . by immediately taking steps to see that mooring masts to secure the landing places for airships in Canada are erected; also that the work of meteorological organization is commenced forthwith," and from that declaration, coming at a time when others hesitated, resulted the continuance of this great experiment and the satisfactory position in the matter which was evident to-day. In fact, it had been stated by Air Ministry and other officials in London that without that promise of support from Canada, implemented as it had been by the construction of an airship mast at St. Hubert, near Montreal, and by the organization of our Meteorological Service, a matter of the highest importance to air navigation, the work would reluctantly have had to be placed in abeyance. Initial steps for the organization of the required meteorological service in Canada were taken within a few hours following the announcement of our Prime Minister in London, and the St. Hubert mooring mast was erected just as quickly as designs could be got out and the material fabricated.

Thus Canada had a particular interest and pride in the achievements of these new ships, and all were deeply indebted to Group-Captain Stedman for placing the facts before Canadian engineers so that the final stages of the experiment could be followed with intelligent interest in the results used to guide our future development.

J. A. WILSON, A.M.E.I.C.(3)

Mr. Wilson had listened with a great deal of interest to Group-Captain Stedman's paper and the discussion contributed by General McNaughton.

Following the decision of Canada to participate in the experiment of developing airships for inter-Empire communications, Major Scott, who had commanded the R.34 on her trans-Atlantic flights in 1919, had visited Canada and made a thorough examination of many sites for airship bases from the Atlantic coast to Western Ontario. The location finally chosen was at St. Hubert, near Montreal. Immediate steps were taken to purchase the site and prepare a base for the reception of rigid airships, by the installation of a mooring mast, a hydrogen plant and refuelling facilities.

The work had been proceeding steadily for the past two years, and the engineering work has been in charge of members of The Engineering Institute of Canada in Ottawa and in Montreal. He desired to place on record his appreciation of the assistance rendered by the members of the staff of the chief engineer, Department of Public Works, on this novel project. They had had most valuable assistance from the Air Ministry, who had placed freely

(1) This paper was presented at the Annual General Meeting of The Institute, Ottawa, Ont., February 13th, 1930, and published in February 1930 Journal.

(2) Department of National Defence, Ottawa, Ont.

(3) Controller of Civil Aviation, Department of National Defence, Ottawa, Ont.

at their disposal the experience gained, not only in Great Britain, but in other parts of the Empire. The United States Navy Department had also been most generous in contributing valuable information.

With the benefit of all this experience they had tried to incorporate the best features from each country, so that the installation at St. Hubert was probably the most advanced of its kind in the world. The whole work was practically complete and they were now looking forward to the first visit to Canada of the R.100 in May of this year.

The trials of the R.100 and R.101 had confounded their critics. Previous to their launching, there had been a great deal of adverse criticism, but the results of the two ships' experimental flights had shown that they had come fully up to their specifications and the expectations of their designers. There was every reason for confidence that the whole venture would be an unqualified success.

It should be kept in mind that these two ships were not designed for passenger carrying on the trans-Atlantic route. The intention of the British Government in building them was to construct two experimental ships to fly to Egypt and India, in which would be incorporated all the fruits of the patient and careful research carried out before they were built. The results of their trials had shown that they are a great advance over any rigid airships ever constructed. Their success indicated the wonderful future which lies in the development of rigid airship construction.

Another gratifying feature was that we had our own men now under training during the trials of the two ships. The reports received from them had been more than satisfactory. One of our officers accompanied R.100 on a 53 hour trip recently made, under most adverse weather conditions, with fog and storm. The ship returned safely to her base, after a trying journey, in good condition, and her crew showed no sign of distress after their experience.

Mr. Wilson was of opinion that a great stride had already been made towards the solution of trans-Atlantic flying by airship.

Major-Gen. J. H. MacBrien[4]

General MacBrien enquired whether any advance had been made in dealing with ice formation on the covers of airships, and had provision been made for travelling in tropical climates. Further was there any hope of these ships being equipped with Diesel engines? The author had dealt with the design and construction of rigid airships in a most informative and interesting way.

J. H. Parkin, m.e.i.c.[5]

Mr. Parkin observed that up to the present time Canadians had had very little experience with regard to airships, and in view of the coming visit of R.100 to Canada this paper had been timely and would serve as a preparation for more intimate contact with aircraft of this type.

One part of the paper which had impressed him was that relating to the design of the transverse frames used in the construction of these two modern ships, the R.100 and R.101. In previous ships the transverse frames had been in direct contact with the outer envelope, and as a result the envelope had a series of transverse ridges which added a great deal to the air resistance.

In these two ships, however, the transverse ridges had been eliminated, since the transverse frames were not in contact with the envelope. This should much improve their performance.

(4) President, Aviation League of Canada.
(5) Asst. Director in Division of Pure and Applied Physics, in charge of Aeronautical Research, Ottawa, Ont.

Group-Captain E. W. Stedman, m.e.i.c.[6]

Group-Captain Stedman replied that the question of ice formation on the covers of airships was at present engaging the attention of all those interested in the work of air navigation. He pointed out that the initial flight of an airship to Canada was purposely to be carried out at a period when ice troubles were not likely to be encountered.

In early airships practically no provision had been made for heating the passenger compartments, but in the two British rigids the radiators from some of the engines were placed so that they could be put into the inlet of the ventilating air, and so provide heat for the passengers accommodation.

In reply to General MacBrien's question upon the engines to be used, the author said that this was a matter of great importance, and that in designing the R.101 the use of a heavy oil engine had been considered as one of the most important features.

With the R.100 it was decided, however, that the ship could not wait for the design of a suitable heavy oil engine, and, therefore, gasoline engines were used. These gasoline engines could always be replaced by heavy oil engines when such were available.

The airship R.101 was at the present time being enlarged by adding a central section which would increase the gas capacity by 500,000 cubic feet.

Mr. Parkin had raised a very interesting question as to the fabric cover of the new rigid airships. The cover of the airship R.101 was the subject of considerable criticism in England. This criticism seemed to have been due mainly to lack of sufficient information, because from the accounts of the trials it appeared that very little difficulty had been encountered in this respect.

With the R.100 the method of attachment of the fabric was different, in that wire rings passed right around the ship, and the fabric was attached to these wires. Some slight difficulties had been encountered with this method of attachment of the fabric, but these had apparently since been overcome.

At the time of the preparation of his paper very little information had been released upon the construction of the R.100, and, therefore, this information could not be included in the paper. The trials of the two ships had taken place since the paper was first written. The author would have liked to have completed the paper by giving more details of the R.100 and also accounts of these trials, but so much information is now available on these matters that another paper would be required to do justice to the subject.

(6) Group-Captain, R.C.A.F., Chief Aeronautical Engineer, Dept. of National Defence, Ottawa, Ont.

Discussion of Paper on the Engineer's Work in Surveying and Mapping by F. H. Peters, M.E.I.C.[1]

Dr. J. L. Morris, M.E.I.C.[2]

Dr. Morris desired to congratulate the author on his instructive paper, and also to compliment the government mapping services on the splendid work they had done and were now doing. He had used not long ago a map prepared by the Department of National Defence on the scale of two miles to the inch, in connection with an area of 32 square miles bordering the Detroit river, and in no place in checking up the scale was there found an error of more than 100 feet. This represented an accuracy of a very high order. He had made use of the plans prepared from this map and had distributed them to the surveyors and engineers in that part of the province of Ontario. That was only a part of the valuable work being done by the surveying and mapping services, and now with the co-operation of the Royal Canadian Air Force large areas were being covered in other portions of Ontario and in the hinterland bordering the provinces of Quebec and Manitoba.

W. H. Connell[3]

Mr. Connell observed that in the United States there had been a steady increase in the accuracy of surveying and mapping required for carrying out engineering projects, and he believed that, in the very near future, the accuracy of the surveying done for the location of highways and railways would be much greater than had hitherto been the case.

The modern demand for quickly-read, light and compact surveying instruments had resulted in some striking departures from conventional designs; for example, British manufacturers had made substantial progress with the production of transits in which circles of about three inches diameter might be read direct to one second of arc. This had necessitated the working out of an entirely new technique in the production of divided circles, since the ordinary method of engraving divisions on a strip of inlaid silver failed to meet the new requirements, and it had been found necessary to use circles of glass.

Speaking generally, the best modern transits and levels represented a saving in weight and bulk of about one-third, as compared with pre-war practice, but in achieving these considerable economies, the makers had been very careful not to impair the reputation which British-made instruments had so long enjoyed in regard to their robust construction and ability to stand up to the rough usage incidental to field work and transport. He knew of at least one firm which submitted its instruments to a thorough bumping test before issue—just as used to be the case with dial sights for the artillery during the war.

In designing surveying apparatus it was necessary to keep in view the very important question of repairs to damaged instruments in places far removed from workshop facilities, and hence, whilst introducing well-tried time and labour saving devices, undue complication should be avoided in ordinary field instruments.

(3) Managing Director, Cooke, Troughton & Sims, London, Eng.

Professor James Weir, A.M.E.I.C.[4]

Professor Weir remarked that the paper deserved the widest publicity, for in it the chief trustee in the matter of graphic description of the Dominion, the Surveyor-General, had given an account that appealed to all. Its non-technical treatment was an advantage.

Nowhere had there been a better illustration of plane-tabling and its concomitant operations.

He would particularly draw attention to the remarkable progress of oblique aerial photography in Canada. Few Canadians realized that in this matter during the past decade Canada had led the world. The factors explaining this were, the crying need of our vast hinterland for inventory, its worth while possibilities, the suitability of the terrain for this method of mapping, the impracticability of any other, the great war's lessons in aerial photography, the personnel available, and finally, the vision of the past and present workers in photographic surveying in Canada. The pioneer work in photogrammetry of the late Dr. E. Deville, and his basic development leading to present methods, should receive whatever tribute present successes might offer.

Professor Weir considered that the topographic maps prepared from oblique photographs were not mere "reconnaissance maps" as somewhere stated. They were complete, and amply accurate for the four-mile scale. In fact, such maps were the inevitable medium for a terrain such as the flat pre-Cambrian peneplain, whose unbroken horizons presented such obstacles to ground work that ten flying hours could bring home as much detail for mapping as ten seasons of ground work.

The author, modestly, had omitted any account of the enormous office labour such a mass of topographic detail required before the map appeared. In comparison with older methods the economy of time would alone be sufficient to justify the adoption of this method. The principles of linear perspective had never before been used to such an extent, nor had their application ever been so simple. The grid method was most ingenious.

A pleasing inference from the paper was the effective co-operation of the various departments of the federal government in advancing the work, and it was to be hoped that each provincial government would realize the paramount advantage of consistency in methods and results so vital in map production.

The necessity, in such a wide area, of mapping years ahead of possible geodetic control, however energetically the geodetic survey was being pushed, might cause some speculation as to the ultimate consistency of these sheets. Their standard was, however, not so absolute, and astronomic positions spaced at intervals of fifty miles or so would, for the present purpose, appear ample. A few hundred feet station-error on a four-mile map could cause but little concern. It was the present feasibility of a radio check on longitude that allowed him to venture on such a statement.

The author had given a most timely compilation and explanation of unique methods, derived from the experiences of very competent technical staffs to meet an urgent need.

Discussion of Paper on the Aeronautical Laboratories of the National Research Council of Canada by J. H. Parkin, M.E.I.C.[1]

ARTHUR S. SUDDES[2]

Mr. Suddes considered that the acquisition of aeronautical laboratories in Canada would prove of inestimable value in research and development.

Being connected with aircraft engine assembly work in Canada, he realized the importance of having suitable equipment to carry out power tests for present and future type engines.

In connection with air-cooled engines considerable assistance could be given in investigations on the correct cooling of engines of this type. At the present time the majority of large powered air-cooled engines were of the radial type, but several makes of *in-line* air-cooled engines were being developed and doubtless it would be essential to have a testing equipment suitable for experimenting with these, and recording their cylinder temperatures at given power and air speeds. At the present time no such facilities were available in Canada and in his opinion the future prospects of aviation in this country certainly warranted the acquisition of aeronautical laboratories.

FLIGHT LIEUTENANT ALLAN FERRIER, A.M.E.I.C., R.C.A.F.[3]

Flight Lieutenant Ferrier inquired as to the velocity attained by the air, with the tunnel working at full speed, in the passages just before entering the open mouth of the nozzle. He would also ask whether it would not be worth while to fill in the corners in the wind tunnel and whether there was any particular reason for reducing the pressure in the experimental chamber below that of the atmosphere. Mr. Parkin had mentioned that this might be done.

With reference to the water channels it seemed to him that the results always obtained by constant velocity tests would not be exactly what was wanted; that is, the maximum resistances obtained after steady conditions had been reached would not be the same as the maximum resistances occurring in actual practice, where the conditions were changing. The velocity would be increasing all the time, and it would seem that a continuous record of the resistances from the beginning of acceleration until the time of "taking off speed," would be of great value.

The AUTHOR replied that the air would reach its lowest velocity in its circuit of the tunnel at the entrance to the nozzle where the cross sectional area of the tunnel is greatest. The cross section at this point would be 17 feet square, giving an area of 289 sq. ft., and the area of the 9 ft. diameter jet would be about 63.6 sq. ft. For a jet velocity of 150 miles per hour the velocity at the entrance to the nozzle would be $\frac{63.6}{289} \times 150$, or about 33 miles per hour, say 48 feet per second. Under these conditions there would be a pressure difference between interior and exterior of tunnel at the entrance to the nozzle of about 50 lbs. per sq. ft.

Flight Lieutenant Ferrier remarked that as the air was turning around a fairly sharp corner, and there was a corner on the outside which was absolutely rectangular according to the plans, it seemed to him that a few guide vanes could be omitted and the corner filled in.

The AUTHOR stated that in tunnels of this general type two constructions were employed for the bends in the air passages. In one the bend was of large radius and two or three large intermediate guide vanes were used. With this arrangement the air tended to crowd to the outside of the bend and the velocity distribution in the passage after the bend, therefore, lacked uniformity. In the other construction—that to be employed in the Ottawa tunnel—the bend was angular, of practically zero radius, and a large number of small vanes were placed along the diagonal of the bend. These vanes would break the air stream up into a number of small streams, each of which was turned separately.

The two methods were comparable, in the one case to a squad of soldiers wheeling as a whole, and in the other to the manoeuvre in which the change of direction was effected by each soldier pivoting on himself.

It was the aim to make the flow around the bends as nearly as possible laminar flow, which would result in the most nearly uniform velocity distribution in the stream. There would thus be very little corner to be filled in; the corner outside the last guide vane would, however, be filled in.

In respect to the pressure as previously stated, at maximum operating speed there would be a pressure difference between inside and outside of tunnel, at the entrance to the nozzle, of about 50 lbs. per sq. ft.; that is, if the experimental room through which the jet flows at 150 miles per hour were at atmospheric pressure, the pressure at the entrance to the nozzle (where the velocity is 33 miles per hour) would be 50 lbs. per sq. ft. above atmospheric pressure. It was expected that the experimental room would be maintained at atmospheric pressure for convenience of operation, ventilation, etc.

It might be necessary to adjust the pressure in the experimental room to some other value, if as had been considered, it were desired to bleed air from the tunnel at one point in the circuit and draw fresh air into the tunnel at another point, in order to prevent excessive rise of temperature of the air in the tunnel.

In tunnels of the Eiffel type, the pressure in the experimental room was below atmospheric, because with open return the pressure in the low speed part of the circuit would be atmospheric.

The question regarding the speed in the testing tank touched on a more or less fundamental principle. They started out by providing ideal conditions both in the wind tunnel and in the test tank, because they could not adequately define or control actual or non-ideal conditions. If a drive could be arranged so that constant speed over the test part of the run would be secured, then it would not be difficult to insert a variable control so that variable speed test runs could be made.

Flight Lieutenant Ferrier observed that reports of that nature were seldom seen.

The AUTHOR agreed as to the desirability of such tests, and said that with the system now in mind records could, if necessary, be made, starting at the beginning of the acceleration and covering the whole run, including acceleration, constant speed and deceleration. Even for the constant speed tests they were planning to start the recording drum some time before the constant speed part of the run commenced.

THE
ENGINEERING JOURNAL
THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XIII APRIL 1930 No. 4

The Past-Presidents' Prize 1929-1930

The subject selected by Council for the competition closing June 30th, 1930, is "The Engineering of Aviation." This subject may be taken as including any or all of the phases of engineering involved in aeronautical activities, and authors are expected to deal with broad features rather than with details.

It is recommended that in preparing papers the following directions be adhered to as far as possible:

Manuscript: Copy should be typed double space or triple space, preferably the latter, on one side of the sheet. Authors should retain carbon copies of their papers.

Illustrations: All illustrations and diagrams should be numbered, and a concise descriptive caption written on the back of each photograph or drawing. Photographic prints should be of glossy finish clear and distinct, unmounted, and in no case folded, as the cracks thus caused will show in the reproduction. Line drawings should be in black ink on white paper or tracing cloth. Blue prints and photostats cannot be reproduced. Working drawings do not reproduce satisfactorily, for when reduced photographically to the necessary size the lettering is so small as to be illegible, and details cannot be seen clearly. As far as possible, curves or diagrams should be drawn with the base line about 7 inches ong and with cross rulings spaced not closer than 3/16 inch. Such diagrams should be carefully drawn in black ink on white paper for tracing cloth.

The Council desires to leave the competitors the fullest latitude as to their treatment of the subject. It is suggested, however, that detailed descriptions should be avoided, and that papers should not exceed ten thousand words in length.

Rules Governing Award

(1) The prize shall be awarded for the best contribution submitted to the Council of The Institute by a member of The Institute of any grade on a subject to be selected and announced by the Council at the beginning of the prize year, which shall be July first to June thirtieth.

(2) In deciding on the subject to be specified, the Council shall confer with the Branches, and use its discretion, with the object of selecting a subject which may appear desirable in order to facilitate the acquirement and the interchange of professional knowledge among the members of The Institute.

(3) The papers entered for the competition shall be judged by a committee of five, to be called the Past-Presidents' Prize Committee, which shall be appointed by the Council as soon after the Annual Meeting of The Institute as practicable. Members and Honorary Members only shall be eligible to act on this committee.

It shall be within the discretion of the committee to refuse an award if they consider no paper of sufficient merit.

(4) The prize shall consist of a cash donation of the amount of one hundred dollars, or the winner may select books or instruments of no more than that value when suitably bound and printed, or engraved, as the case may be.

(5) All papers eligible for the competition must be the bona fide work of the contributors and must not have been made public before submission to The Institute.

(6) All papers to be entered for the competition must be received during the prize year by the General Secretary of The Institute, either direct from the author or through a local Branch.

(7) The award shall be announced in The Engineering Journal and at the Annual Meeting, and, if possible, the presentation shall take place at that meeting.

The Scientific Study of Fire Hazards

In the past our fire record in Canada, as judged from the losses paid by insurance companies, has been an uncurable one, although during the past few years there has been a progressive improvement. In 1922 the total loss of insurable property was over fifty-four million dollars; in 1928 it was still over thirty-six millions. It is notable that this reduction has not been accompanied by a diminution of the number of individual fires, of which in 1928 Canada had thirty-two thousand. The lessened property loss however has been reflected in the average insurance rate, which has fallen from over one dollar in 1922 per one hundred dollars of property at risk, to eighty-seven cents in 1928. These results, encouraging as far as they go, have been largely due to such causes as the wider use of improved fire appliances, better quality of building construction, and the use of more reliable electrical and heating equipment in buildings. But they have been greatly aided by the close technical study given to the subject by the under writers and by such bodies as the Dominion Fire Prevention Association, all of whose constituent bodies are greatly interested in the protection of life and property against fire.

Some striking instances of the benefit to be derived from scientific study of this subject are given in a paper recently published by that Association on "Unseen Hazards in Hospitals, Clinics and Other Institutions," a question which was brought very prominently to the public view after the disaster which occurred in Cleveland on May 15th, 1929, when over one hundred people were killed as a result of a fire in the X-ray department of a clinic.

Real progress as regards a matter of this kind can only result from a complete investigation of the causes of such events, and the publication just named affords an excellent example of work of this kind. To begin with, a study had to be made of the properties of X-ray films, of which, as is well known, there are two kinds; those in which the photographic emulsion coats a film of nitro-cellulose, and others in which the film is composed of cellulose acetate. Both these materials are inflammable, but the former not only ignites at a comparatively low temperature but burns with almost explosive violence and gives out a mixture of poisonous gases including carbon monoxide, nitric oxide and nitrogen dioxide. On the other hand, the acetate film when burning has combustible properties which render it not much more dangerous than ordinary paper.

Investigation of the Cleveland disaster drew attention to the great dangers arising from nitro-cellulose film, particularly when stored in large quantities as is the case in the X-ray departments of large hospitals. The recommendations which have been made to render impossible the recurrence of such a deplorable event are all based on careful study covering not only the inflammable natures of the films and their keeping qualities, but their suitability as regards photographic exposure, development, and fixation. There seems no reason to doubt that the supply of cellulose acetate films is now assured in such quantities as to render unnecessary any further use of film of the more dangerous type in hospitals. Many of the more important hospitals in Canada have adopted the use of acetate X-ray film, and in some places in the United States the use of nitrate film in hospitals has been prohibited by law. Attention has been paid to the vaults or rooms where films are stored, and proper methods of arrangement and construction have been prescribed.

An example of another type of special fire hazard which can only be controlled as a result of intensive scientific study is that arising from explosions of anaesthetic gases in operating rooms. These gases, such as ether vapour, ethylene, nitric oxide, and others may be used in such proportions as render the mixture liable to explosion, and it has been necessary to develop a special series of devices, which, if embodied in the equipment of the hospital, will prevent danger from this source. It is evidently necessary to avoid the occurrence of any sparks due to static electricity or to the operation of switches or electrical equipment. Precautions necessary are the effective grounding of all operating room equipment, the ready identification of the contents of compressed-gas cylinders, adequate ventilation, provision for proper humidity of the air, proper construction and installation of all electric light and power cables, outlets and fittings, and precautions regarding electric bell and telephone apparatus, which in some cases has been found liable to produce dangerous sparks.

In the installation of proper equipment for fire protection and prevention the instruction of all employees regarding its purpose and use is of primary importance. Work of this kind is just as necessary as technical improvement in equipment and construction methods.

The public and governmental authorities are gradually realizing how much can be accomplished by adherence to proper standards for safety. The action of those provincial governments who have adopted and are enforcing the use of the Canadian Electrical Code or equivalent regulations, is a case in point. Such policies play an important part in the safety movement which has already resulted in a great lessening of fire hazard, and whose progress will be watched with interest by all engineers.

Report of the Royal Commission on Technical and Professional Services

This report was recently made public by presentation to Parliament, and while there has scarcely been time to judge of its findings as applied to all branches of the Civil Service, there seems a general opinion that its provisions if adopted would mark a distinct advance in the Service's organization. The situation has been clarified by the Commission's definition of what constitutes a technical and professional position, and the report will be of benefit by giving the Government and public generally a knowledge of what professional and scientific service really means.

It is certainly to be hoped that Parliament will take action during the present session on the basis of this well-considered and carefully thought-out document. It is too much to expect that its provisions will not be criticised, but it provides many admirable features and few which have aroused any serious objection. The report simplifies the classification of the technical and professional members of the Civil Service, it recommends what would appear to be a most desirable alteration in the Superannuation Act, and provides a reasonable likelihood of future advancement for the lower grades in the Service.

The immediate salary benefits indicated would largely be in connection with the higher grades, but future benefits would accrue to practically all coming under professional classification.

Since so many of the Civil Servants affected by this report are engineers, it is natural that members of The Institute should be interested in the Royal Commission's remarks as to what constitutes a professional and technical position, a point which has considerable bearing upon the qualifications for membership in The Engineering Institute of Canada and the several Associations of Professional Engineers.

The Commission remarks in part:—

> "The use of the word technical in our terms of reference is obviously beset with difficulty. There is a sense in which an artisan who has served a term of apprenticeship, and become qualified as a journeyman, may fairly be described as a technical man. Yet it is obvious that no line of demarcation drawn for our present purpose, could include such a worker . . . it is the scientific character of so large a part of the work of the Civil Service upon which our attention has been directed.". . .
>
> "A working definition should have reference both to the previous training of the incumbent of a position, and to the duties which he is called upon to perform in that position.". . .
>
> "For a position to be considered as technical or professional, we believe that it should as a rule be

necessary that the holder possess the degree of a recognized university, with specialization in a branch of knowledge generally now regarded as belonging to the professions—as pure and applied science (including forestry), law, statistics, or actuarial science."...

"No definition could permanently be satisfactory, if its application were so rigid as to preclude the admission of occasional special cases."...

"We regard it as essential that the position ... should be such as to demand the use of the technical, scientific or professional knowledge which the incumbent has already acquired by special studies, as distinguished from the practice of a technique which can be learned in the course of employment."...

In these findings it will be observed the Commission deals very clearly not only with the previous training of a technical and professional employee but also with the effect of his professional work upon his status. It is pleasing to note that the report includes in one of its appendices, a resumé of the information furnished at the Commission's request, by the special committee appointed by the Council of The Institute for that purpose.

Publications of Other Engineering Societies

From time to time announcements have appeared in The Engineering Journal regarding the exchange arrangements which exist between The Engineering Institute of Canada and the founder engineering societies of the United States, whereby members of The Institute may secure the publications of the American societies at the same rate as charged to members of those societies. A list of these publications, with the amounts charged, is given below and subscriptions may either be sent direct to New York or through headquarters of The Institute.

	Rate to Members	*Rate to Non-Members*
American Institute of Electrical Engineers		
Journal, single copies	$0.50	$ 1.00
" per year	5.50	10.50
Transactions, per year:—		
Paper	5.00	10.00
Cloth	5.00	10.00

Meeting of Council

A meeting of Council was held on Friday, March 7th, 1930, at eight o'clock p.m., with President A. J. Grant in the chair, and fifteen other members of Council present.

The minutes of the meetings held on February 4th and 12th, 1930, were taken as read and confirmed.

The membership of the following committees were approved:

Finance Committee
Library and House Committee
Legislation Committee
Publication Committee.

The Special Committee on the Publications of The Institute presented an interim report, making certain recommendations, in which the importance of securing more and better papers for The Institute was urged as being a matter which required immediate consideration. The recommendations were considered, but it was felt that before taking action it would be necessary to ascertain the expense involved.

On the nomination of the Executive Committee of the Saint John Branch, it was unanimously resolved that W. J. Johnston, A.M.E.I.C., be appointed councillor for the Saint John Branch to replace the late Mr. E. A. Thomas until the next annual election.

The following committees were re-appointed for the year 1930 with the same membership as last year:

Committee on Policy
Committee on Publicity
Board of Examiners and Education
Honour Roll and War Trophies
Committee on Biographies
Committee on International Co-operation

The Treasurer asked for Council's guidance in preparing the budget for 1930 for submission to Council, pointing out that if provision were made for the same activities as had taken place during 1929 a considerable deficit was likely. After considerable discussion the Finance Committee was asked to submit a draft budget including an allowance for the Plenary Meeting of Council and for the work of certain committees, but omitting certain other activities on the score of economy.

The Secretary submitted a letter to the President from the Hon. Charles Stewart, Minister of the Interior, Honorary Chairman of the Canadian Honorary World Power Conference Committee, which had been presented to the Annual General Meeting, and reported that the necessary publicity had been given to the announcement of this Conference in The Journal, and he was directed to reply to Mr. Stewart that the President would be happy to serve on the committee.

An address to be presented to The American Society of Mechanical Engineers on the occasion of their Fiftieth Anniversary was approved.

Twenty resignations were accepted, and one special case was considered.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

Elections		Transfers	
Members	1	Assoc. Member to Member	1
Associate Members	4	Junior to Assoc. Member	4
Juniors	7	Student to Assoc. Member	3
Students admitted	11	Student to Junior	6

The Council rose at twelve fifty a.m.

OBITUARIES

Edward Prout Girdwood, M.E.I.C.

Deep regret is expressed in recording the death of Edward Prout Girdwood, M.E.I.C., which occurred at Vancouver, B.C. on March 10th, 1930.

Mr. Girdwood was born at Montreal, Que. on September 5th, 1875, and received his education at the Montreal High School and McGill University.

In 1898 Mr. Girdwood was an apprentice in the Canadian Pacific Railway shops at Victoria, B.C. and from December 1898 to January 31st, 1899, was assistant on construction with the same railway, being located at Montreal. He was later for a short time with the Columbia and Western Railway at Brooklyn, B.C., and was for several years on the staff of the British Columbia Telephone Company at Vancouver. Mr. Girdwood went to South Africa with the Canadian Mounted Rifles, and was later located at Pretoria with the South African Constabulary. In 1903-1905 he was with the Durban Municipality Works, Durban, S. A. Returning to Canada, he was on the staff of the Transcontinental Railway for four years, as rodman, topographer, leveller, and instrumentman at Quebec, and as resident engineer at La Tuque, Que. For a short time Mr. Girdwood practised as a consulting engineer in Montreal, and then became resident engineer for the Canadian Northern Pacific Railway at Metchosin, B.C. In 1912 he was resident engineer for the same railway at Duncans, B.C. In 1913 and 1914 Mr. Girdwood was district engineer for the Public Works Department for the districts of Kamloops, Okanagan and Similkameen, in charge of bridges and roads, and was located at Vernon, B.C. From 1915 to 1918 he was overseas with the 48th Battalion, Canadian Expeditionary Forces.

On June 1st, 1918, Mr. Girdwood joined the Water Rights Branch at Victoria, B.C., as engineer, being assistant to the meteorological engineer, dealing with temperature and precipitation and snow fall drainage for the province of British Columbia.

Mr. Girdwood joined The Institute as a Student on April 19th, 1906, was transferred to the class of Associate Member on December 12th, 1907, and became a full Member on November 17th, 1914.

Charles Arthur Millican, A.M.E.I.C.

Members will learn with regret of the death of Charles Arthur Millican, A.M.E.I.C., which occurred on January 23rd, 1930, at St. James, Man.

Mr. Millican was born at Alston, Cumberland, England, on November 23rd, 1861.

From January 1875 to February 1882 he was a pupil with the late Adam Walton, mining engineer. From March 1882 to March 1883 Mr. Millican was assistant to the city engineer of Winnipeg, being in charge of street improvements etc., and in 1883-1884 he was in the office of the Argyle Gold Mining Company Ltd. From June to December 1884 he was assistant to the city engineer of Winnipeg, in charge of street improvements and drainage. For six months in 1886 Mr. Millican was a leveller on location on the Manitoba and Northwestern Railway, and to September 1887 he was assistant engineer in charge of construction on the Red River Valley Railway. In 1887-1888 Mr. Millican was assistant engineer on location and in charge of construction on the Great Northwest Central Railway, and from August to December 1888 he was again on the Red River Valley Railway, this time in charge of construction as assistant engineer on the Portage extension. From December 1888 to December 1889, Mr. Millican was assistant engineer on location and in charge of construction on the Northern Pacific and Manitoba Railway, later entering private practice as a consulting engineer. He served overseas during the war, enlisting in the 90th Battalion, Canadian Expeditionary Force. He was transferred to 3-C Labour Battalion in France and in November 1917 joined the 11th Battalion, Canadian Railway Troops. While in this last battalion, Mr. Millican was in turn private, lieutenant and captain, returning to Canada in December 1918 with the last named rank.

Mr. Millican joined the Canadian Society of Civil Engineers as an Associate Member on January 29th, 1891.

Charles Cesar Leluau, M.E.I.C.

It is with deep regret that we record the death of Charles Cesar Leluau, M.E.I.C., which occurred at Montreal on March 10th, 1930.

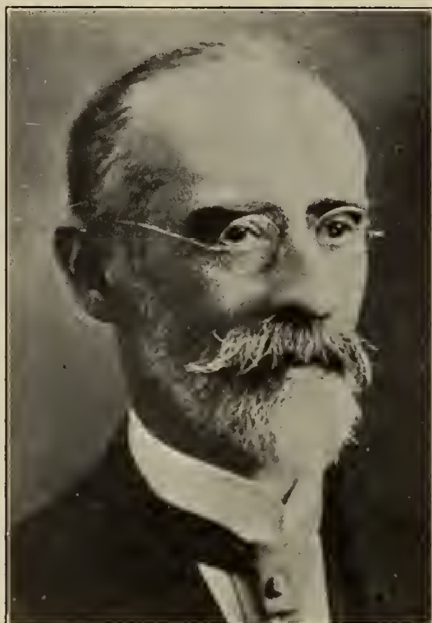
Professor Leluau was born at Hazebrouck, France, on March 8th, 1849. He was a graduate of the Ecole Centrale des Arts et Manufactures, Paris, and before coming to Canada he was engaged for a time as engineer in the French Company Chemin de Fer du Nord, and from August 1880 to July 1895 he was head of an important department in the same company.

Professor Leluau saw active service during the Franco-Prussian war of 1870-1871, being seriously wounded in action, and was awarded the decoration of Chevalier de la Légion d'Honneur for gallantry on the battlefield. The Association des Anciens Elèves de l'Ecole Polytechnique unanimously appointed him an honorary member of their association. The French Government in recognition of his excellent work as a professor bestowed upon him the title of "Officier d'Académie."

He became a professor at the University of Montreal (then Laval University) in 1899, and remained on the university's staff for more than twenty-five years, lecturing on many important subjects, but particularly in physics and hydraulics. He was also secretary-treasurer of the General Railway Signal Company of Canada.

Professor Leluau became a Member of the Canadian Society of Civil Engineers on December 18th, 1903, and was placed on the Life Membership list of The Institute on December 18th, 1928.

CHARLES CESAR LELUAU, M.E.I.C.



HENRY IRWIN, M.E.I.C.

Henry Irwin, M.E.I.C.

The death of Henry Irwin, M.E.I.C., which occurred at Montreal on March 3rd, 1930, removes from the list of The Institute one of its oldest members.

Mr. Irwin was born at Newgrove, county Down, Ireland, on October 27th, 1847. He attended the engineering school of Trinity College, Dublin, from 1866 to 1869, graduating in engineering in the spring of 1870, and receiving two special certificates out of three possible, only one other member of the class also receiving two. These special certificates correspond to honours of other universities. Mr. Irwin was apprenticed to the chief engineer of the Midland Great Western Railway of Ireland from about May 1870 to May 1871, and was assistant to the county surveyor of Antrim county, Ireland, from August 1872 to August 1874.

Coming to Canada in 1874, Mr. Irwin settled in Montreal, and became assistant to Joseph Rielle, a well-known provincial land surveyor. He remained with Mr. Rielle for some years, acquiring much experience in assisting in the planning and laying out of many sections of what are now thickly populated parts of Montreal.

In 1887 Mr. Irwin joined the Canadian Pacific Railway Company as a surveyor in the chief engineer's office in Montreal, becoming assistant engineer in that department in 1901. In 1914 he was appointed right-of-way agent, continuing in that position until 1922, when, although due for retirement, he was retained by the Canadian Pacific as consulting right-of-way agent, holding that position up to the time of his death. Mr. Irwin was a member of the Dominion Land Surveyors and Quebec Land Surveyors. He was also a member of the Civic Improvement League of Montreal.

Mr. Irwin joined the Canadian Society of Civil Engineers as an Associate Member on January 20th, 1887, and was transferred to the grade of Member on May 20th, 1892. Mr. Irwin was always interested in Institute affairs, and represented the Montreal Branch on the Council during the years 1896 and 1897.

PERSONALS

W. E. Seely, S.E.I.C., who was formerly with the MacLaren Dam Company at High Falls, Que., is now in the employ of the Dominion Bridge Company, Ltd., at Lachine, Que.

L. Sosinsky, S.E.I.C., is now on the staff of the Northern Electric Company, at Montreal, Que. Mr. Sosinsky graduated from the University of Manitoba with the degree of B.Sc. in 1929.

M. Sinclair, A.M.E.I.C., has resigned from the position of acting city engineer of Moose Jaw, Sask., to become city engineer of Yorkton, Sask. Mr. Sinclair had been with the city of Moose Jaw's engineering service for eleven years.

Cameron Doberer, S.E.I.C., who graduated from McGill University in 1929 with the degree of B.Sc., and was for a time with the Canada Power and Paper Company at Shawinigan Falls, Que., is now in the employ of Canadian Explosives Ltd. and is located at McMasterville, Que.

M. J. Holm, A.M.E.I.C., who is a member of the staff of the Atlas Construction Company, has been transferred by that firm to West Saint John, N.B. Mr. Holm is a graduate of Copenhagen University, having secured the degree of B.Sc. in 1918.

W. L. Ball, A.M.E.I.C., has accepted the position of resident engineer on the Sunny Brae-Guysboro railway for Canadian National Railways. Since 1926 Mr. Ball has been with Dexter P. Cooper, at Welchpool, Campobelle Island, Charlotte City, N.B.

E. W. Neelands, A.M.E.I.C., has been appointed high-road engineer with the Highroads Commission, St. John's, Newfoundland. Mr. Neelands was formerly with the Department of Lands and Forests, Northern Development Branch, at New Liskeard, Ont.

W. E. Hall, A.M.E.I.C., has severed direct connection with the Avon River Power Company, Ltd., with which concern he has been engaged as construction engineer since 1929, in order to devote his entire time to contracting and private engineering at Windsor, N.S. Mr. Hall was at one time on the staff of the Anticosti Corporation at Three Rivers, Que.

F. T. Boutilier, S.E.I.C., is now on the mechanical staff of the Aluminum Company of Canada, and is located at Arvida, Que. Mr. Boutilier, who graduated from the Nova Scotia Technical College in 1928 with the degree of B.Sc., was for a year and a half in the engineering department of the Dominion Iron and Steel Company Ltd., at Sydney, N.S.

H. B. Brehaut, A.M.E.I.C., is now with the Manitoba Bridge and Iron Works, Ltd., having opened a branch office for that company at Saskatoon, Sask., and being in charge of its interests in that city, adjacent territory and the northern part of Saskatchewan. Mr. Brehaut graduated from the University of Saskatchewan in 1927 with the degree of B.Sc., and subsequently joined the staff of the Canadian National Railways, with which he has remained until the present time.

G. R. Adams, S.E.I.C., has returned to South America, where he is on the staff of the Tropical Oil Company at El Centro, Barranca Bermejo, Colombia. Mr. Adams graduated from Queen's University with the degree of B.Sc. in 1927, and following graduation became connected with Price Bros. and Company, Ltd. at Riverbend, Que. In November of that year he went to Colombia as a member of the staff of the Tropical Oil Company. He returned to Canada in 1929, and has been located at Woodstock, Ont.

Major Alan B. McEwen, D.S.O., A.M.E.I.C., is now in charge of civil engineering work with Canadian Industries Ltd., Montreal. Major McEwen, who was formerly connected with W. I. Bishop Ltd., Montreal, is a graduate of the Royal Military College, Kingston, Ont., and of McGill University, from which institution he obtained the degree of B.Sc., In 1920 he was with Canadian Explosives Ltd., Montreal, and prior to that he was principal assistant to R. S. and W. S. Lea, consulting engineers, Montreal.

M. H. Jones, A.M.E.I.C. who was appointed to the engineering staff of the Ontario Paper Company, Ltd., at Montreal in 1929, has been transferred to Thorold, Ont., as assistant chief engineer. Mr. Jones is a graduate of the Technical College at Cardiff, Wales, of the year 1912. In 1924 he was assistant engineer, pulp and paper machinery, with the Port Arthur Ship Building Company, and in 1928 was resident engineer at the Fort William mill of the Great Lakes Pulp and Paper Company, Ltd., for Backus Brooks Company, Ltd.

W. H. Stuart, A.M.E.I.C., formerly supervisor of hotel grounds and buildings for the Canadian National Railways, Montreal, has been appointed superintendent of facilities, with jurisdiction over buildings and mechanical equipment, and other duties to be assigned from time to time. The appointment covers the sleeping, dining and parlour car department and hotel department, and dates from January 1st, 1930. Mr. Stuart was at one time resident engineer on hydraulics for the Western Region, Canadian National Railways.

H. G. Cochrane, A.M.E.I.C., of the Power Corporation of Canada Ltd., is now located at the Seven Sisters power development at Whitemouth, Man. Mr. Cochrane, who is a graduate of the Royal Military College, Kingston, Ont., was at one time engineer in charge of design and construction of the structural work for the Lethbridge Northern Irrigation District under H. B. Muckleston, M.E.I.C. In 1923 Mr. Cochrane was with the Quebec Development Company, Ltd. at St. Joseph d'Alma, Que. Mr. Cochrane was a member of the executive committee of the Lethbridge Branch for the year 1922-23.

Duncan Kennedy, A.M.E.I.C., is now senior sectional engineer with Rendel, Palmer and Tritton, consulting engineers, in London, England. On coming to Canada in 1924, Mr. Kennedy became engaged on the hydro-electric project at Isle Maligne, Que., with the Quebec Development Company. He later was connected with Messrs. Monsarrat and Pratley on the substructure work of the Montreal South Shore Bridge, and later acted as resident engineer for Robert White and Partners of Westminister, England, on the construction of wharves and jetties at Bharnagar, Para, Kathiawar, India.

J. A. Burnett, M.E.I.C., consulting and appraisal engineer, Montreal, was appointed to make a physical appraisal of the manufacturing plants in the town limits of Lasalle, Montreal, at a recent meeting of the municipal council. In 1922 Mr. Burnett took over the office of M. A. Sammett, A.M.E.I.C. He has had a wide experience with the Royal Electric Company, Canadian General Electric Company, the construction of a large substation for the Montreal Light, Heat and Power Company, the construction of the Montreal and Southern Counties Railway, and the appraisal of all the electrical equipment on the Grand Trunk System for the Government arbitration.

A. S. Williams, A.M.E.I.C., has become electrical designer with the Northwestern Power Company, Ltd. at St. James, Man. Mr. Williams graduated from the University of Manitoba, with the degree of B.Sc., in 1921, and following graduation was demonstrator in physics at that university during 1921-1922. During 1922-1923 he was with the Canadian General Electric Company at Peterborough, Ont. and in 1923-1924 was draughtsman on electrical layouts with the Hydro-Electric Power Commission of Ontario. From April 1924 to the present time he has been chief operator at the Great Falls generating station of the Manitoba Power Company, Ltd.

Victor Stanley Chesnut, A.M.E.I.C., has been appointed assistant engineer of the Saint John Harbour Commissioners, Saint John, N.B. Mr. Chesnut graduated from the University of Toronto with the degree of B.A.Sc. in 1909, and took a post graduate course in 1912. From 1913 to 1917 Mr. Chesnut was assistant resident engineer on the Welland ship canal and in 1917 was for six months assistant engineer on the Bloor street viaduct, Toronto, for Quinlan and Robertson. Later in the same year he was engineer on bridges and culverts for the Munro Construction Company. In 1919 Mr. Chesnut became assistant engineer with McFarlane, Pratt, Hanley Ltd., on concrete grain elevator work, and in 1919 was appointed assistant engineer of the Saint John Drydock and Shipbuilding Company. In 1928 he returned to Messrs. McFarlane, Pratt, Hanley Ltd. at St. Catharines, Ont. as engineer.

Engineer Commander Angus D. M. Curry, M.E.I.C., has taken over the duties of consulting engineer of H.M.C. Dockyard, Halifax, N.S. Commander Curry was born at Newcastle-on-Tyne, England, and received his professional training at the Royal Naval Engineering College, Keyham, England. He came to Canada in 1910, and was commissioned engineer sub-lieutenant in the Royal Canadian Navy, with which his service has been continuous ever since. He was promoted to engineer-lieutenant in 1912 and to engineer lieutenant-commander in 1920. From February 1924 to April 1925 he was in charge of refitting light cruisers and destroyers at H.M. Dockyard, Chatham, England. Subsequently he was assistant to the consulting naval engineer, Department of National Defence (Naval Service), Ottawa, Ont. In 1927 Commander Curry was appointed consulting engineer at H. M. C. Dockyard, Esquimalt, B.C.

J. A. Beauchemin, A.M.E.I.C., has resigned the town managership of Dolbeau, Que., which position he has held since 1927, and is now connected with the Port Alfred Pulp and Paper Corporation at Port Alfred, Que., in charge of the company's municipal affairs, properties and employment. Mr. Beauchemin graduated from the University of Montreal in 1911 and was assistant engineer in the hydraulic division of the Department of Public Works, Ottawa, from 1911 to 1918, when he joined the staff of the Riordon Pulp Corporation, Ltd., at Temiskaming, Que., as assistant to the chief engineer in charge of hydro-electric power investigations. In 1920 he resigned from the Riordon Corporation and became associated with the Donnacona Paper Company, later becoming mill engineer for this company and remaining in that position until 1926. He was then appointed mill engineer on maintenance and construction with the Port Alfred Pulp and Paper Corporation at Port Alfred, to which company he has lately returned.

F. Y. Harcourt, M.E.I.C., who has been district engineer of the Port Arthur and Fort William district for the Department of Public Works, Canada, since 1921, has been transferred by the Department to London where he is to be in charge of the district. Mr. Harcourt obtained the degree of B.A. from the University of Toronto in 1900, and graduated from the School of Practical Science in 1903. In 1903-1905 he was rodman and instrumentman and chief of field

R. de L. French, M.E.I.C.

party with the Ontario Power Company at Niagara Falls, Ont. In 1905-1907 Mr. Harcourt was on the Georgian Bay canal survey as instrumentman. In 1907 he entered the service of the Department of Public Works, Canada, as senior assistant engineer of the Port Arthur district. In 1911-1915 he was district engineer of the same district, and from 1915 to 1919 Mr. Harcourt served overseas, returning to the same position at the end of the war. From 1921 to date he has been district engineer for the Department of Public Works of Canada, of the Port Arthur and Fort William districts. Mr. Harcourt joined The Institute as a Member on May 22nd, 1922, and has taken a keen interest in Institute affairs. He was elected Councillor representing the Lakehead Branch on the ballot which was reported on at the Annual Meeting on February 12th, 1930, and it is most unfortunate that owing to his present move he has been compelled to resign from the Council.

R. de L. French, M.E.I.C., has been appointed engineer for Lucerne-in-Quebec. Thus this vast recreation resort, newly established in the vicinity of Montebello, Que., secures the services of one of Canada's well-known engineers and at the same time retains those of Prof. C. B. Breed, of Boston, as the Community Association's consulting engineer.

Professor French was educated at the Worcester Polytechnic Institute, Worcester, Mass., receiving the degree of B.Sc. in 1905 and that of C.E. in 1908. From April to September 1906 Professor French was associated with the late Malverd A. Howe, a well-known authority on the design and construction of arch bridges. From June 1908 to January 1910, he was assistant engineer with the Commissioners of Sewerage of Louisville, Kentucky, on the design and construction of sixty-five miles of sewers, and from January 1910 to August 1911 he was assistant engineer with the National Concrete Construction Company, Louisville, designing, estimating and constructing reinforced concrete and steel structures, principally buildings.

Coming to Montreal in 1911, Professor French became principal assistant engineer with Messrs. R. S. and W. S. Lea, consulting engineers, and was engaged mainly in connection with water supply, sewerage, and other municipal projects for Montreal, Ottawa, Quebec and other large cities.

Professor French was engineer of the commission appointed by the Dominion Government to devise methods of making the low-grade coals of Saskatchewan available as a domestic fuel, and for three years was a member of the Committee on the Fire Resistance of Roofing Materials of the Dominion Fire Prevention Association, and he has served for some time on the Metropolitan Town Planning Board of Montreal.

Professor French was appointed lecturer in civil and municipal engineering at McGill University in 1911, and was made professor of highway and municipal engineering in 1920.

Professor French is a member of the Corporation of Professional Engineers of the Province of Quebec, the American Society of Civil Engineers and the Canadian Good Roads Association. He joined The Institute in 1918 as a Member and in 1920 was awarded the Gzowski Medal for his paper on "The Design and Construction of Reinforced Concrete Covered Reservoirs."

R. A. C. Henry, M.E.I.C., former Deputy Minister of Railways and Canals, has resigned from that office to become vice-president and general manager of the Beauharnois Light, Heat and Power Company. Mr. Henry graduated from McGill University with the degrees of B.A. and B.Sc., receiving the latter in 1912. Following graduation he entered the service of the Department of Railways and Canals as inspecting engineer, and in December 1913 he was made assistant engineer, which position he held until 1923, when, following the reorganization of the Canadian National Railways, he joined their staff in Montreal as director of the newly established Bureau of Economics, which was set up for the study of railway problems connected with the consolidation and co-ordination of the various lines of railway making up the Canadian National system. In February 1929, following the unexpected death of the former Deputy Minister of Railways and Canals, Major Graham A. Bell, Mr. Henry consented to become Deputy Minister, and he has held that position since that time. Mr. Henry has achieved a reputation throughout Canada and also in the United States as an authority on Canadian railway problems. His work has made him familiar with matters pertaining to canals and water powers, and he is recognized as an authority on water terminal problems.

R. A. C. Henry, M.E.I.C.

ELECTIONS AND TRANSFERS

At the meeting of Council held on March 7th, 1930, the following elections and transfers were effected:

Member

BRIDGES, Frederick, Supt., Government Shipyard, Sorel, Que.

Associate Members

FELLOWS, Howard, B.Sc., (McGill Univ.), asst. chief engr., The Nova Scotia Power Commission, Halifax, N.S.
LeBOURVEAU, Homer Benjamin, B.A., B.Sc., (Univ. of Alta.), asst. engr., Calgary Power Company, Ltd., Calgary, Alta.
LEE, William States, Jr., C.E., (Princeton Univ.), vice-president, W. S. Lee Engineering Corpn., New York, N.Y.
MENGES, Edwin A. H., chief engr., Disher Steel Construction Co. Ltd., Toronto 2, Ont.
STUEWE, William Lafayette, E.M., (Montana Sch. Mines), mech'l. supt. of coal mines, British Empire Steel Corpn., Sydney, N.S.

Juniors

ANDERSON, George Douglas Elphinstone, B.Sc., (N.S.T.C.), elect'l. engr., N.S. Light & Power Company, Halifax, N.S.
BENT, Edgar Delap, B.Sc., (Acadia Univ.), cable engr., cable engrg. lab., Northern Electric Co. Ltd., Montreal, Que.
CLARKE, Thomas Gerard, B.Sc., (N.S.T.C.), professor of engineering, St. Francis Xavier University, Antigonish, N.S.
D'AOUST, Joseph Gilbert, B.A.Sc., (Univ. of B.C.), junior engr., B.C. Pulp & Paper Co. Ltd., Port Alice, B.C.
DAVIDSON, John Knox, B.Sc., (Univ. of St. Andrews), asst. engr., Dominion Bridge Co. Ltd., Montreal, Que.
McDOUGALL, James Lyle, mech'l. engr. and dftsman., Price Bros. & Co. Ltd., Kenogami, Que.
REGAN, Francis Edward, (City and Guilds of London), engr. for Prov. of Quebec, Lancashire Dynamo & Motor Co. of Canada, Montreal, Que.

Transferred from the class of Associate Member to that of Member

McCANNEL, Donald Alexander Roy, B.Sc., (Queen's Univ.), City Commissioner, City of Regina, Sask.

Transferred from the class of Junior to that of Associate Member

INGS, Jasper Harold, B.A.Sc., (Univ. of Toronto), engr., Gatineau Power Company, Ottawa, Ont.
KNAPP, Edward Winslow, B.Sc., (McGill Univ.), elect'l. engr., operation dept., Shawinigan Water & Power Company, Montreal, Que.
VON ABO, Cecil Vivian, B.Sc., M.A., (Univ. of Cape Town), Ph.D., (McGill Univ.), research engr. and district engr., bridges, chief civil engr's. dept., South African Railways and Harbours, Johannesburg, S.A.
WATERHOUSE, George Kerby, B.Sc., (Queen's Univ.), asst. purchasing agent, Aluminum Company of Canada, Ltd., Montreal, Que.

Transferred from the class of Student to that of Associate Member

FINLAYSON, Archie Wallace, B.Sc., (McGill Univ.), squad leader in charge of Falls River power development, B.C., for Power Corporation of Canada, Ltd., Montreal, Que.
MITCHELL, Wallace Murray, B.Sc., (McGill Univ.), constrn. engr., Fraser Brace Engineering Company, Ltd., Sudbury, Ont.
NICHOLL, Henry Lloyd, B.Sc., (Univ. of Man.), sales engr. for Sask., Canadian Westinghouse Company, Ltd., Regina, Sask.

Transferred from the class of Student to that of Junior

BAIN, Archibald Marcus, B.Sc., (Univ. of Man.), M.Sc., (McGill Univ.), struct'l. designer, Dominion Bridge Co. Ltd., Montreal, Que.
COLLINS, George Edward, B.Sc., (Univ. of Man.), res. engr., Good Roads Board, Belmont, Man.
HOLDEN, John Hastie, B.Sc., (McGill Univ.), estimator and designer, Geo. W. Reed & Co. Ltd., Montreal, Que.
KINGSTON, George Harold, B.Sc., (McGill Univ.), elec'l. designer, Alcoa Power Company, Arvida, Que.
MACKAY, Leslie, B.Sc., (Univ. of Man.), asst. res. engr., power development at Slave Falls, Man., for Winnipeg Hydro-Electric System.
ORR, William Winston, B.Sc., (Queen's Univ.), transformer design engr., Canadian General Electric Company, Toronto, Ont.

Students Admitted

CHISHOLM, Donald Alexander, B.Sc., (St. Francis Xavier Univ.), dftsman., C.N.R., Monckton, N.B.
COURTNEY, Alexander Gordon, undergrad., Univ. of Man., 262 Balmoral St., Winnipeg, Man.
EHLY, Lucas Joseph, rodman, Alberta Main Highways, 9327-107a Avenue, Edmonton, Alta.
FORD, Albert Frederick Brome, undergrad., Univ. of Man., 535 Sherburn St., Winnipeg, Man.
HARRIGAN, Mayo Arthur Perrin, undergrad., Dalhousie Univ., P.O. Box 567, Halifax, N.S.
HOOD, George Leslie, undergrad., Univ. of Man., Manitoba College, Winnipeg, Man.
SAVAGE, Palmer Ernest, undergrad., McGill Univ., 154 Ballentyne Ave. No., Montreal West, Que.
SCOTT, Lloyd George, undergrad., Univ. of Man., Manitoba College, Winnipeg, Man.
SMITH, Eugene Lloyd, undergrad., Univ. of Alta., University of Alberta, Edmonton, Alta.
THORN, Richard, mech'l. dftsman., with E. A. Ryan, M.E.I.C., 1188 Phillips Place, Montreal, Que.
WEBSTER, William Beverley, undergrad., Univ. of Toronto, 36 Thorne Crescent, Toronto 10, Ont.

The following Students were admitted at the meeting of Council held on February 4th, 1930.

BARBOUR, Clarence Allen, undergrad., Univ. of N.B., 255 Regent St., Fredericton, N.B.
BLANCHET, Paul Maurice, Grad., R.M.C., undergrad., McGill University, Montreal, Que.
FRASER, Norman Innes, Grad., R.M.C., undergrad., McGill Univ., 470 Prince Arthur St. West, Montreal, Que.
GINGRAS, Francis Percival, undergrad., Univ. of Man., 271 Furby St., Winnipeg, Man.
HAWLEY, Eric Farwell, undergrad., McGill Univ., Ormstown, Que.
LEVERIN, Harald Liecester, Grad., R.M.C., undergrad., McGill Univ., 2044 Metcalfe St., Montreal, Que.
McLEOD, Wilson Churchill, undergrad., N.S. Tech. Coll., 72 South St., Halifax, N.S.
McMORDIE, Robert Campbell, undergrad., Univ. of Toronto, 94 Wright Ave., Toronto 3, Ont.
NATION, Frederick Spencer, undergrad., McGill Univ., 3637 University Street, Montreal, Que.
NELSON, H., dftsman., Vulcan Iron Works, Ltd., Winnipeg, Man.
RODGER, Norman Elliot, Grad., R.M.C., undergrad., McGill Univ., 2044 Metcalfe St., Montreal, Que.
TAIT, Gordon Ewing, undergrad., McGill Univ., 632 Grosvenor Ave., Westmount, Que.
WIEBE, Victor, undergrad., Univ. of Sask., Herbert, Sask.
WILLIAMS, Richard Louis, undergrad., McGill Univ., 159-24th Ave., Lachine, Que.

BOOK REVIEWS

Canadian Trade Index, 1930

Compiled and published by Canadian Manufacturers' Association Inc., Toronto, 1930. Cloth, $6\frac{1}{2}$ x $10\frac{1}{2}$ in., 884 pp., tables, \$6.00.

This is the sixth annual issue of the Canadian Trade Index. The special feature of the 1930 edition is the inclusion of a 54-page special export section, provided by the Department of Trade and Commerce of the Dominion Government, and comprising a summary statement of Canadian progress in commerce, with data designed to aid in the further development of export trade.

The present edition contains an alphabetical and classified list of over 10,000 Canadian manufacturers and their products; a produce section giving the names of producers of a variety of agricultural products; a complete survey of Canadian export trade, besides indicating those firms interested in and prepared to do export trade.

This work is very valuable as a reference aid, and is the only comprehensive book of its kind published in Canada.

Practical Railway Painting and Lacquering (Practical Finishing Series, Vol. 4)

By H. Hengeveld, C. P. Disney and W. J. Miskella. Finishing Research Laboratories, Inc., Chicago, 1929, leatherette, 6¼ x 9¼ in., 242 pp., illus., figs., tables, $3.50.

This book is described as a handbook for railroad men. It is principally concerned with description of mechanical devices which have lately been adopted by the painting trade and is profusely illustrated.

It describes, in a general way, the spray gun and its accessories, sand blasting equipment, mechanical scalers and polishers, etc. The greater part of the book is concerned with the use of the spray gun. With the aid of photographs, the particular forms of equipment best suited for painting and lacquering locomotives, passenger and freight cars, bridges, buildings, etc., are described.

This book should prove valuable to a master painter who wishes to keep up to date in modern painting methods. There are some sections dealing with primers, paints and lacquers but these are not discussed with much detail. One of the authors is a director of a consulting laboratory and a chapter is devoted to describing the tests which this laboratory is prepared to make on paint samples submitted.

Research Chemist,
J. T. Donald & Co., Ltd.,
Montreal.

The Rayon Industry

By Mois H. Avram. D. Van Nostrand Company, New York, second edition, 1929, buckram, 6½ x 8½ in., 893 pp., illus., figs., tables, charts, $12.00.

This book is well named. The accent throughout is on the broad industrial aspects of rayon rather than on the finer technical points of process. The volume is just what is needed for those who wish to familiarize themselves with a general picture of this young prodigy among industries. There is particularly sound and pertinent information for any industrialist who is considering venturing into the field of rayon production, possibly lured into this position by a cursory review of the phenomenal successes of a few of the pioneer rayon producers. Not that the writing is pessimistic in any sense, but it gets down to bedrock on the problems of the industry and its varied and exacting demands.

The book contains an imposing array of statistical information covering all phases of the growth of rayon, production and consumption trends, interrelationship of the various rayons between themselves and other textiles, world wide ramifications of the great producing groups, costs, exports and imports of leading countries, tariffs, etc. Business and industrial organization and economic background are particularly well covered.

As might be expected, the book is written from an engineering viewpoint, and as a result the details of the chemical processes are merely sketched. There is little here for those interested solely in rayon-process technology—a common fault of books and periodicals dealing with rayon.

One wonders why the section on "Control Tests" of the processes was included at all, since the descriptions of methods are so incomplete. Thus in "Determination of Alpha, Beta and Gamma Cellulose" we find the surprising statement: "Alpha cellulose is that modification of cellulose which takes part in the Rayon process," and "Alpha cellulose soluble in caustic solution, but beta cellulose is precipitated by acetic acid, while gamma cellulose remains dissolved." The entire information given on the control of the acid coagulating or neutralizing bath in the viscose process reads as follows: "The strength of the coagulating bath is checked with the hydrometer. The sugar content is determined as follows: The caustic soda is determined by titrating a measured or weighed quantity with normal acid solution using phenolphthalein as an indicator. The amount of sugar present is determined by boiling a measured sample with an excess of standard potassium permanganate solution. The sugar is titrated with oxalic acid." It is perhaps unfair to quote passages which are a contrast to much that is worth while in preceding chapters.

The new edition under review follows two years after the first, and contains a considerable amount of new material, although some of the statistical data is still carried only up to the year 1925, and such promising developments as the Lilienfeld viscose process and the cellulose ether process by the same investigator are conspicuously absent.

The book is recommended as a broad, but in places not too deep, survey of the rayon industry.

CORRESPONDENCE

The Editor of The Engineering Journal

Dear Sir,

Two or three years ago I formed the opinion, which I have strongly held ever since, that the reinforcing of concrete had reached the "Fad" stage. This, I claim, is abundantly shown on innumerable plans, diagrams, sections, descriptions, etc., of works of all kinds shown in the engineering periodical literature of Canada and the United States.

Here is a simple case. A cylindrical column 20 feet high and 2 feet in diameter, of concrete, with the usual amount and style of reinforcing; the cubical contents of such a column is 63 cubic feet. The weight of the reinforcing would be about 600 pounds which at 5 cents per pound amounts to $30.00 or the cost of a yard and one-half or 40 cubic feet of concrete.

If we added this 40 cubic feet of concrete to the column under discussion we could make its diameter about 2 feet 6 inches, and I contend that a concrete column 20 feet high and 2 feet 6 inches in diameter without any reinforcing is a stronger and better column than one 2 feet in diameter with reinforcing.

On page 328 of "Engineering News Record" for February 20th, 1930, there is an interesting case in point; a concrete viaduct in Seattle; columns are 53 feet in maximum height: 3 feet in diameter. The reinforcing, amounting to about 1,000 pounds would cost $50.00, which is the cost of 2½ cubic yards of concrete. If this quantity of concrete be added to the column and the reforcing omitted we should have a column about 3 feet 3 inches in diameter, and I contend that that extra 3 inches in the diameter of such a spindly column is worth far more than the reinforcing.

On page 2 of the advertising section of "Engineering News Record" for February 20th, 1930, there is also a very striking exhibit. The illustration shows "a bulkhead wall ready to receive cast-in-place wall section." That is to say the concrete in this case is subject to either direct vertical compressive strain, or the impact of waves, in either of which cases I firmly believe the very heavy reinforcing shown in the illustration is an absolute waste of money and that a very much stronger piece of work would result from putting the cost of that reinforcing into an enlarged section of concrete.

If the reinforcing in concrete could be so disposed as to take direct or indirect tensible or transverse stress, as in floor timbers or girders, it would be a wise precaution to use it, but this is only possible in one case in five to ten.

Used as it is so freely to-day in retaining walls, dams, piers, abutments, foundations, etc., it is, in my opinion, a sheer waste of money. In these cases the reinforcing either takes no stress at all or a very indeterminate one.

The true inwardness of the matter, I believe, is that the steel interests have "put it over" the engineers all over Canada and the United States. If the makers of steel and the people that handled it commercially can prevail upon an engineer to bury a few tons of it in concrete, where, if it does no good it will do no harm, that is a matter of business, and I am convinced that for every ton of steel that is doing good work as reinforcing in concrete there are a score of tons that are doing no good at all.

Yours very truly,

"CONCRETE"

A. W. P. Lowrie, A.M.E.I.C., Secretary-Treasurer.
H. R. Carscallen, A.M.E.I.C., Branch News Editor.

Things We See

On January 16th, Mr. H. J. McLeod, M.Sc., M.A., Ph.D., professor of electrical engineering, University of Alberta, addressed the Calgary Branch at the Board of Trade rooms on "Things We See," the nineteenth century view of the universe and the new outlook upon nature in the light of twentieth century science. The address was an unusual one for an Engineering Institute meeting, and was very interesting and enjoyable. It is summarized below in some detail.

"The conception of the universe held by scientists toward the end of the nineteenth century is now known to be much more superficial than was thought at that time. Present day research has gone far beyond it and undermined many of its downright certainties.

"In order to understand its position we must recollect that that idea of things was the gradual development from Greek philosophy which had covered the whole range of thought; from Roman law which had organized administration of society; and the Christian religion which contributed the ideal of the universal family.

"Behind the Greek and Roman states had been the desire for security. Greece had achieved it by a policy of isolation, Rome by uniform religious and civil law. The Christian ideal was impossible under the old idea of progress. The Christian church after the fall of Rome abandoned the idea of its founder and fell back on the old pagan ways of accepting truth on authority. They looked back unquestioningly on the fathers who had taught that the world they saw and lived in was a finite universe—a world contained in a finite circumference and ordered on a systematic plan, part of which had been revealed. Salvation was its chief aim.

"The Christian church has been mainly responsible for the new society; but the tenth and eleventh centuries were the golden age of Mohammedanism which spread a civilized stability from China to Spain. And in the twelfth century Latin translations of Arab literature came back to Europe and sowed the seed of the Renaissance.

"Aristotle was still cited as the chief authority in all realms of knowledge. But in the fifteenth and sixteenth centuries progress came to the fore again and thinkers began to look forward instead of back. The new learning was a considerable impetus to this new movement but its chief impulse came from the many voyages of discovery which forced philosophers to take a new view of the universe. Gradually, and against strenuous opposition, the idea began to prevail of an infinite universe instead of a finite. At last Aristotle was laid aside and the new motto prevailed 'Prove all things; hold fast that which is true.'

"In the research which followed, science with mathematics gradually unveiled the mechanism of the universe and gave rise to the stream of inventions which characterized the nineteenth century. Materialism arose as the characteristic philosophy. The predictions which science was able to make were taken as proofs of science and man's mastery seemed secure.

"The system was not yet complete, however. Living things had not been explained nor the mind of man. The purpose of things seemed obscure. But Darwin apparently removed these objections by his discovery that variations may be transmitted and his theory of natural selection of variations. At the beginning of the nineteenth century life was chemical. At the end the living cell was a machine of which biochemistry was well on the way to a solution.

"It was thus the universe appeared in the 1880's. It floated in absolute space and in absolute time, consisted of a definite number of atoms and was pervaded by a strange ether which transmitted stresses and carried light vibrations. Only the details remained to be filled in, so the materialists thought.

"The first of these details to be investigated, however, started the crash of the whole philosophy. Professor Michelson investigated the velocity of the ether with most accurate apparatus. No motion was found. Rutherford and others also opened up a new door by their experiments with radioactivity.

"It took an Einstein, however, to show that the scientific philosophers had been looking for something that did not exist. They felt the world slipping through their fingers, for the old basis of materialism had been quite undermined by the rapid and successive discovery of x-rays, radio, the electron, the quantum theory, relativity, and the structure of the atom. It was, however, the beginning of a clearer understanding of the world out of which will be reconstructed a new philosophy.

"These discoveries all related matter to a series of electrical waves. The idea of this can be seen when a beam of light passes through a prism. It is broken up into a spectrum in which are seen different lines each of which corresponds to a definite wave length of vibration. The beam was not the simple thing it appeared to be but was made up of many of these, each with a different wave length of vibration. A line at the violet end of the spectrum had a frequency twice that of one at the red end.

"Similar characteristics pertain to the phenomena of sound. Middle C has a frequency of 256 per second. Its octaves downward have 128, 64, 32 and 16 vibrations per second respectively. The last is the lowest audible to the human ear. About 30,000 is the highest audible frequency. That is, the ear can hear about 10 octaves, of which the piano comprises the second to the eighth.

"The research of the past fifty years has determined, however, that in regard to light frequencies the scale covers some seventy octaves, of which we know that the spectrum of humanly visible light is the 45th and the x-ray the 65th. Below the 45th are the infra-red rays.

"And thus the conception has arisen that all these phenomena pertain to one enormous scale of 70 octaves, the keyboard of the universe, but so far science gives us no indication of the existence of time or space. We are still unable to prove the reality of the things we see. What a change in our outlook in fifty years! The world is not so simple now; it is no longer one vast machine, and we no longer believe that nature is limited to what we know.

"Science does not tell us the origin of nature or the purpose of the reality behind its laws and symbols. The material has dissolved into the non-material and the sharp distinction between them fades.

"A new civilization lies before us whose philosophy, religion, and art must blend with this background of science. In the panorama of this world we have lived in, we see in the beginning perhaps that a great star swung close to our sun which created a great wave upon it that splashed fire-foam into space and created our earth. The great bulk of matter is still in a firy state.

"By comparison we infer that we live in the dawn of a day just breaking, a day which is to extend to unthinkable length. We ask the meaning and purpose of it. Is life (so rare) merely the accidental outcome of matter and motion, or is it the climax of millions of millions of years of evolution which has also created the suns and systems we see? The answer may be found perhaps in the noon of that day that is breaking. The people of that time will see us in the morning of the world gradually groping our way out of ignorance and superstition toward the truth."

Town Planning

The Branch was given an address on "Town Planning" on January 30th at the Board of Brade rooms, by J. H. Doughty-Davies, A.M.T.P.I.C.

The speaker defined town planning as the scientific and orderly disposition of land and buildings in use and development with a view to obviating congestion and securing economic and social efficiency, health and well being; that is, it is an engineering problem requiring the ability to analyze and elicit basic facts before any definite solution can be reached.

It was brought out that generally a town plan is designed with particular reference to arterial highways and major street requirements, rapid transit, transportation, zoning, public recreation and civic art.

Regarding arterial highways and major streets it was pointed out that in planning these the governing factor is traffic origin based upon development both within and without the city limits. The density of population can be estimated from the topographic conditions in different areas. In deciding on a major street plan a traffic count is made from which the flow of traffic is determined, its maximum density, entrance into downtown districts, and other information. By-pass streets and relief thoroughfares can then be planned and the necessary width of streets determined. A major street should be so located that it is not interrupted by jogs or lack of continuity and should not have excessive grades or sharp curves.

The speaker then took up the subject of rapid transit and showed how by a study of the present street railway system, population, growth, and areas of probable densest population the future needs can be determined and any immediate extensions can be made with the final development in mind, thus causing an immense saving to the citizens.

In discussing "public recreation" which deals with playgrounds for children of elementary school age, larger playing fields for children of high school age, neighbourhood parks, large parks, and park drives, it was pointed out that as a result of many discussions between teachers, play supervisors and other specialists certain standards had been determined. For example, it has been decided that playgrounds for small children should not be more than a half a mile apart. Using the standards decided on for playgrounds, parks, etc., it is possible to reserve sufficient areas for these purposes at a time when land is comparatively cheap.

Under the heading "zoning" the speaker stated that the requirements of the city in its commercial and industrial development are thoroughly investigated and the location of major streets and park drives, street capacities and many other details are carefully considered. Upon these data the boundaries of districts are determined together with the regulations specially applicable to those districts. In regulating the height of buildings in any district, this is limited by the width of streets in that district, experience showing that the bulk of a building is very closely associated with the automobile traffic on the street serving it.

The lecture was followed by considerable discussion as the matter of town planning, especially that part of it dealing with the limiting height for buildings, is a very live issue in Calgary at the present time.

Construction of the Ghost Water Power Dam

H. J. McLean, A.M.E.I.C., production superintendent of the Calgary Power Company, addressed the Branch on "The Construction of the Ghost Water Power Dam," at the Board of Trade rooms on February 13th.

This dam was recently completed for the Calgary Power Company, Ltd., by the Foundation Company of Canada, Ltd. It is situated just below the confluence of the Bow and Ghost rivers about 34 miles west of Calgary.

The speaker described the dam in some detail but in brief the Bow river section is a concrete gravity dam with the power house built on the downstream batter of the dam. The length of this section is 928 feet and the volume of concrete in this and the south sluices and spillway dam is 129,900 cubic yards. The south semi-hydraulic fill dam is 1,140 feet long and contains 800,000 cubic yards. Near the south end of this fill is incorporated the south sluices and spillway dam above mentioned. The north fill dam was placed partly by hydraulic sluicing but mostly by gravel fill with a rolled clay core and contains 300,000 cubic yards.

The maximum head is 108 feet, the effective storage depth is 35 feet, and the net regulated storage 73,700 ac. feet. The dam has created a lake (Gaherty lake) extending 8 miles up the Bow river and about 3 miles up the Ghost river. It has a surface area of 2,855 acres and with the adjacent area will probably be made into a park for use as a summer resort.

The initial installation consists of two 18,000-h.p. vertical Dominion Engineering turbines, one 1,450-h.p. vertical Dominion Engineering station service unit, two 15,000-kv.a. Westinghouse generators and one 1,000-kv.a. Westinghouse station service generator. Provision has been made in the intake dam, and the penstock placed, for a third 18,000-h.p. unit which will be installed later.

The sluice and spillway capacity provided amounts to 150,000 cubic feet per second, giving an ample safety capacity according to the speaker, who estimated the combined maximum discharge of the Bow and Ghost rivers for the past twenty years as 39,000 c.f.s.

The progress of the construction work was explained in detail, being illustrated by an excellent series of lantern slides. The stripping of the site for the south earth fill dam was started on September 7th, 1928, and the whole construction work completed on November 30th, 1929. The first 18,000-h.p. unit was turned over on October 30th, 1929, and power has been generated from October 23rd, 1929.

The lecture and slides were followed with great interest and a large number of questions answered by Mr. McLean afterwards.

The Toronto Waterworks System

The Branch was fortunate enough to be able to persuade Wm. Gore, M.I.C.E., M.E.I.C., to deliver a lecture on "The Toronto Waterworks System" during his brief visit to Calgary recently. Mr. Gore is the senior member of the Toronto firm Messrs. Gore, Nasmith and Storrie, consulting engineers, which has been engaged by the city of Calgary in connection with the waterworks project to be started in the very near future. The meeting was held at the Public Library on the February 20th.

The speaker displayed a large number of very fine lantern slides, which, together with his explanatory remarks, gave his hearers a clear idea of the make-up of the extensive waterworks system of the city of Toronto. The filtration of the supply and the methods used in purifying it to eliminate pollution were described in great detail. Proposed extensions to the system were also detailed.

The lecture proved most interesting, especially in view of the new waterworks system about to be installed by the city of Calgary.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, A.M.E.I.C., Branch News Editor.

(Reported by J. A. M. Galilee, Affil. E.I.C.)

Engineering in Europe

The regular monthly meeting of the Hamilton Branch of The Institute, preceded by a dinner at the Wentworth Arms hotel, was held on Friday, February 21st. The speaker of the evening, Professor R. W. Angus, M.E.I.C., of Toronto University, was introduced by E. H. Darling, M.E.I.C. The subject chosen by the speaker was "Engineering in Europe," which was illustrated by lantern slides.

Owing to ill health two years ago, Professor Angus was granted a year's leave of absence. He spent that time travelling in Europe taking more or less a "busman's holiday." Half of the time was spent on the continent and the other half in Great Britain. It was chiefly the continent which claimed the Professor's attention. The object of the tour was to gain some impressions regarding the comparison of European and American engineering practice. The speaker gave high praise to all the engineers of the different countries wherever he visited, for their hospitality and for their anxiety to show him everything that he wanted to see, as well as to show him some things about which he had not even heard.

The first country to be visited was Holland. This, in the Professor's opinion, was not a country where he might expect much engineering activity, but he was surprised to see at Delft some remarkable experiments being carried out in water channels. The construction of artificial canals and rivers there, on a small scale, is providing the answer to many of the problems which are peculiar to that country.

In Germany, the Professor found many large industrial plants rivalling in size the largest that this country can show. At the A.E.G. works is to be found a bursting pit for turbines, one of the few that are in existence.

In Berlin the Kleinberg power station is quite remarkable. This station generates 300,000-k.w., using pulverized fuel. It consists of three 80,000-k.w. machines and three 10,000 k.w. machines.

At Dresden there is a remarkable peak load storage system. For pumping purposes here there are eight 30,000-h.p. pumps. The pumps are supplied with moveable vanes, resulting in greater efficiency at variable heads.

At Munich there is a famous museum, the Von Dueller Museum, where there is a complete industrial exhibit. The youth of the country is given an opportunity to see the entire processes a product undergoes from the time the raw material is taken from the mine to the packaged article. All kinds of factory processes are explained by working models and diagrams, making an exhibit of the greatest possible value to industrialists.

Many views of hydro-electric undertakings were shown both in Germany and Switzerland. The chief point about these developments was that a relatively small head was utilized and in all these were large collecting dams for peak load use. As well as that arrangements are made for pumping back water during the off peak load. Only the economic conditions of a country could warrant such a procedure.

Both in Continental Europe and in Great Britain the Professor noted that very elaborate experiments are in progress to determine the best practice in any engineering project. For an expenditure of something like $5,000.00 a saving eventually through correct design of very many times that value is thereby saved, and the Professor thought that some such methods might very well be employed in this country.

L. W. Gill, principal of the Hamilton Technical School, in moving a hearty vote of thanks to Professor Angus for his lecture, heartily concurred with the speaker's statement, saying that Europe was now at a position where economics decide the engineering projects and that we in this country, through our wilful waste of natural resources and power, are rapidly coming to the time when we shall be in the same unfortunate position.

Kingston Branch

L. F. Grant, M.E.I.C., Secretary-Treasurer.

On Thursday, February 20th, Mr. C. D. Howe of C. D. Howe and Company, consulting engineers, Port Arthur, gave a very interesting and informative address to the members of the Kingston Branch, on "Grain Marketing and Grain Elevators."

Mr. Howe began by pointing out that the production and marketing of grain constitutes the biggest business in Canada to-day, and indicated the effect of a poor grain crop or of poor prices on the general economic prosperity of the country. The largest competitors of Canada in this commodity are Australia, United States, and the Argentine.

Until 1915 the marketing of grain generally, and of wheat in particular, was entirely in the hands of private dealers. The farmer took his wheat to the nearest one of the numerous small elevators some 7,000 of which are scattered through the Prairie provinces. Here the wheat was weighed, and a price offered by the buyer, this price being based on that quoted in the grain exchanges. Disputes as to weighing or grading could be referred to the government inspection office in Winnipeg. The dealer then sold the wheat. As dealers were, in the main, firms unwilling to carry indefinitely at their own risk all the wheat they purchased, they were obliged to sell wheat at once for future delivery at the Lakehead ports, the buyers being exporters or millers, Canadian or English. At the Lakehead the wheat was finally graded and reached tidewater by Port Colborne, Buffalo, or the Georgian bay ports.

In 1915 the requirements of the allied powers led to an arrangement under which all wheat was purchased by a representative of the Imperial government, who set the price. Two years later this system in turn gave way to the Canadian Wheat Board, which lasted until 1921. While this body operated, the farmer was given an initial payment on delivery of his wheat at the local elevator, and in addition he received a "participation certificate" entitling him to further payments should the ultimate selling price of his wheat warrant it. Originally regarded as worthless by many farmers, these certificates in some cases netted as much as 80 cents a bushel. Indeed the whole operation of the Wheat Board could be considered successful from the farmer's point of view, but the practice of government marketing was not considered sound except under war or other abnormal conditions.

Accordingly, when in the deflation period of 1922 agitation arose for a revival of the Wheat Board, the suggestion was made that co-operative marketing should be substituted, and in spite of some opposition and adverse opinion the Alberta Wheat Pool was formed in 1923, the other provinces joining in 1924. The wheat handled by the pool has grown from 20 per cent of the total crop in 1923 to 52 per cent in 1929. The farmer signs a voluntary contract for five years to sell through the pool all wheat he may grow or otherwise acquire.

The objects of the pool are, first to eliminate the middleman; to curb speculation in wheat and to market the wheat in an orderly manner. Under the system prior to 1915 lack of credit often led to what was virtually dumping. The wheat is sold directly to Liverpool or other buyers and for the first five years of its existence the pool was very successful.

In 1928 every wheat producing country in the world had a big crop, and in view of the probable fall in prices, the pool made an initial payment to producers of only 75 cents a bushel instead of $1.00 as in previous years. Not only the pool but private marketing bodies held wheat, as dumping would undoubtedly have depressed the price below the cost of production. Consequently the world in general and Canada in particular entered 1929 with a much larger carryover than usual. On the other hand reports from other countries indicated poor crops, and the management of the pool felt justified in raising the initial payment again to $1.00. The Argentine crop however turned out to be much better than anticipated, both in quantity and quality. Indeed so high was the grade that the usual admixture of a proportion of Canadian wheat was not needed, making the situation still worse from our point of view. It had been estimated that the Argentine crop would be exhausted in November, but shipments of about 6,000,000 bushels a week are still being made.

Consequently Canadian shipments have been at an alarmingly low figure during the past autumn and winter. Instead of a normal flow of 7,000,000 bushels a week, only about 2,000,000 a week have been shipped, and at the present time that is more wheat in the country than was grown in 1929, some of the previous year's crop still being unsold. The new Argentine crop will be on the market early in April, but reports indicate that the yield will be low.

The question arises as to whether the pool deliberately held up wheat with the object of inflating prices. Due to lack of storage capacity, wheat producing countries other than North America are obliged to market their wheat almost as fast as it is produced, a process which, in times of a large world supply, becomes dumping. Had the pool decided to market all its wheat during the past autumn it would not have been a case of shading the Argentine price, but of entering a price war against a forced seller, which would probably have produced calamitous results.

The situation is unprecedented in Canada because heretofore wheat has been regarded as practically as good as cash, but at the present time the banks have some $250,000,000 invested in a commodity which is not readily marketable. Further, whatever may be the merits or demerits of the Winnipeg Grain Exchange, it proved a ready market for wheat at all times. The operation of the pool has diminished the power of the exchange greatly and it is no longer in a position to dispose of as much wheat as in the past. The situation was aggravated during the past autumn by the existence of a heavy speculative interest, chiefly located in United States, which suffered from the stock market collapse, and which was obliged to sell a large amount of grain with the result of depressing the price further.

Turning to the geography of wheat movement Mr. Howe pointed out the new routes through which wheat finds its way to the consumer. In 1921 the first grain was shipped to Liverpool via Vancouver and the Panama canal. In 1928-29, 100,000,000 bushels went via the Pacific. The opening of the Welland ship canal will undoubtedly result in a saving to the shipper, though the amount cannot be definitely stated yet. The effect of the Hudson Bay Railway will be most interesting to watch.

Concluding his address Mr. Howe dealt with some features of elevator construction.

The number of questions which Mr. Howe was called upon to answer indicated the interest with which his audience has followed his remarks.

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.

The Lethbridge Branch held its usual fortnightly meeting at the Marquis hotel on February 22nd, when C. G. Childe, A.M.E.I.C., gave a talk on "Highways and Byways of the National Parks."

The popular nature of the address made a splendid opportunity for having a ladies night, and the executive's efforts were well rewarded for about ninety people were present for the dinner. During the dinner, orchestra selections were rendered by A. Morgan's orchestra and afterwards pianoforte solos by Miss F. A. Soar and vocal solos by F. G. Teague were appreciatively received.

Mr. Childe in his address discussed the development of the Park roads from the primitive game trails up to the present motor highways, and then led us into the byways by means of motion pictures and beautifully coloured slides, showing many of the wonderful natural beauty spots that have made our National Parks so famous.

Following this an informal dance was held, the music being supplied by Mr. Morgan's orchestra.

MEETING OF MARCH 8TH

The Lethbridge Branch held its regular meeting at the Marquis hotel on March 8th, when the speaker of the evening was Dr. R. Neidig of the Consolidated Mining & Smelting Co., Trail, B.C.

The meeting was preceded by a dinner and musical programme composed of selections by Mr. Morgan's orchestra and vocal solos by Mrs. W. Meldrum and Mr. E. Rannard.

Dr. Neidig, who is connected with the phosphate fertilizer work being undertaken by the Consolidated Mining & Smelting Co., gave a general talk on "fertilizers," outlining the development of ideas in regard to soils and fertilizers from ancient times up till today, when we consider the soil from an agricultural point of view as a dynamic thing in which chemical and bacteriological action is continually going on, varied by climate and tillage conditions.

Modern science has produced fertilizers in much more concentrated forms than were previously known, and much new research has to be done to establish their full utility.

Dr. Neidig outlined the different treatments in use in various parts of the world, showing the great variety of conditions, of soils and climates which determine what fertilizers are most valuable and how they are to be applied. Different applications may be used to promote different qualities such as disease resistance, high yield, high protein content, or quick growth.

In western Canada, fertilization of the wheat growing areas is a comparatively new idea, though it is well established in Australia. The idea is not to replenish an impoverished soil, but to promote more economic production generally.

The Consolidated Mining & Smelting Company has sent out shipments of phosphate fertilizers and in co-operation with the Canadian Pacific Railway, various implement companies and provincial and federal governments, has been carrying out field tests, to provide data for large scale production and application. The results have so far been very encouraging and a large plant is being erected at Trail for the commercial production of highly concentrated fertilizers. Large deposits of phosphate rock are being developed near Fernie, B.C., and the material is shipped to Trail where it is treated. The principal reagent is sulphuric acid obtained from the sulphur dioxide given off in the smelting of sulphide ores. This treatment produces a very concentrated fertilizer known as triple super phosphate.

A large ammonia plant is also being erected for the production of nitrogen fertilizers. Hydrogen is obtained from the electrolysis of water, the oxygen being used for metallurgical purposes. Distillation of liquid air provides the nitrogen supply. Thus with large amounts of phosphate, ammonia and sulphuric acid available, there is scope for a great development in fertilizer production, which will undoubtedly enhance the prosperity of western agriculture, and consequently enrich the whole nation.

It was gratifying to note that the meeting was attended by a large number of technical agriculturalists from various parts of Alberta, who were anxious to hear the first public discussion of the fertilizer question.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

P. B. Motley, M.E.I.C., presented a paper before the Montreal Branch on Thursday, February 20th, dealing with the reinforcing of the Stoney Creek arch bridge of the Canadian Pacific Railway in British Columbia. This paper will be published in full in a later issue of the Journal. Mr. P. L. Pratley, M.E.I.C., occupied the chair.

TRANSFORMER LOAD RATIO CONTROL

On February 27th, C. E. Sisson, M.E.I.C., Canadian General Electric Co., Toronto, presented a paper to the Montreal Branch on "Transformer Load Ratio Control." There are considerably over 100 of these transformers installed, total capacity 5,000,000 kv.a. or more. These transformers are used for interconnecting power systems, allowing generating stations to run with reduced responsibility in regard to voltage regulation. Also phase angle may be shifted by changing ratio. Some of these transformers thave been in use for 5 years, changing taps as frequently as 7 times daily. In general the principal involved is 2 contacts, one of which is closed to the proposed ratio tap, shorting a section of winding through an impedance to limit the current, the first tap then being removed and transferred to the new tap. Operations are carried out in sequence by a motor-driven mechanism. This mechanism may be operated by a hand crank if auxiliary power fails. The largest of these load ratio tap changers is connected externally to the transformer bank by bringing the grounded neutral connection through the tap changer. These ratio changers then operate in series with the main transformer, and may be excited from any local synchronous source of power.

In the discussion the rate of speed involved in changing taps was shown to be approximately 2 minutes per tap, or to work from one end of the ratio change device to the other would involve possibly 20 minutes. Pilot lights indicate position of tap. Mechanism is enclosed in an oil tank external to the main transformer tank. The question of using load ratio change on long lines where independent generators are used was brought up, and it was considered that generator field control is satisfactory in such a case.

J. H. Trimingham, A.M.E.I.C., A. D. Allen, S. B. Brown, A. Gall, John Morse, M.E.I.C., and C. R. Reid took part in the discussion.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.

C. G. Moon, A.M.E.I.C., Branch News Editor.

On February 26th, the Niagara Peninsula Branch held a dinner meeting at St. Catharines to celebrate its tenth birthday and to do honour to Alex. J. Grant, M.E.I.C., who was recently elected to the presidency of The Engineering Institute of Canada.

Many out of town members were present and messages of regret were received from others who were unable to be present.

R. J. Durley, M.E.I.C., and J. M. R. Fairbairn, M.E.I.C., represented Montreal at the head table and spoke briefly, bringing congratulations from Headquarters. Mr. Fairbairn presented the President with the gold badge of The Institute.

E. G. Cameron, A.M.E.I.C., presided and mentioned that the Branch was honoured in having had two Members elected to the presidency within the last ten years—Mr. Grant and Colonel R. W. Leonard, M.E.I.C., Colonel Arthur L. Bishop, A.M.E.I.C., said that he wished to represent Colonel Leonard who, although not well enough to be present, took a great interest in this meeting and desired his congratulations to be conveyed to Mr. Grant.

Alex. Milne, M.E.I.C., and Mr. Gordon Sherk, president of the Rotary Club, welcomed the visitors to St. Catharines, and W. D. Black, M.E.I.C., of Hamilton, responded.

Mr. Grant spoke of the strides which The Engineering Institute had made and the part which it had played in the progress of the Dominion. He referred to the Welland ship canal, with which he has been so intimately connected, and gave praise to the staff for the able assistance which had been given during the construction. The canal would be opened during the coming year and although the cost was greater than the original estimate yet there was reason for it. The index of commodity prices had about doubled since 1913 when the estimate was made and many improvements, not originally contemplated, had been added. When finished it would be a modern waterway in every sense of the word.

During the evening the brief speeches were interluded with songs and orchestral numbers. The local pipe band played and two Scottish lassies danced. Jimmie Rice from Montreal entertained in his unusual manner, Walter McCutcheon from Hamilton ably assisted with some very fine solos and a "good time was had by all."

(Copy of letter contributed)

Dear Cameron:—

Dum vivimus, vivamus! The spirit was willing and the men were weak. It was a good party.

Those of us who came from afar desire to offer a delicate appreciation to the Niagara Peninsula Branch for having combined its tenth birthday festivities with an ovation to the new President of The Engineering Institute of Canada, Alexander Joseph Grant.

Two separate celebrations would have surely constituted a riot.

We met old friends and we made new ones. Prior to the banquet, the Branch, the canal contractors, the boys from Hamilton and Peterborough extended courtesies which also reminded us of old times. During the dinner meeting we enjoyed Jimmy Rice, Jimmy Bond and Walt. McCutcheon, we listened to the speeches with close attention and, when Jack Fairbairn stated that he was proud to present the gold badge to the President because he was Sandy Grant rather than an internationally famed engineer, we pounded on the tables. A contractor leaned over to me and whispered that, although his hair was white, they still called him Sandy because an "extra" always drew forth highly coloured language.

Subsequently we adjourned to another private room and sooner or later retired. And, in the morning—forsan et haec olim meminisse juvabit.

N.B. The correspondent's name was unfortunately illegible but after some trouble, the Branch Editor was able to get a translation of the above Latin phrases which, for the benefit of other illiterate engineers, are somewhat as follows:

(1) Let us enjoy life while we are alive.
(2) At some future date it may be pleasant to remember even this.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

On Thursday, January 30th, Mr. Tom Moore gave a luncheon address on the subject, "Impressions of Japan and the Far East." Mr. Moore is well known in Ottawa and throughout Canada as the president of the Trades and Labour Congress of Canada. He was a delegate to the recent conference of The Institute of Pacific Relations at Kyoto, Japan.

Mr. Moore sketched briefly the objects of the conference, at which there were present delegates from the United States, Canada, China, Manchuria, Australia, and New Zealand, as well as observer delegates from India, Dutch West Indies, Russia and the League of Nations. About two hundred delegates in all were present and it was rather remarkable that the conference was conducted in the English language. However, Mr. Moore's chief remarks were in connection with his own observations of the country and its people. He referred to the extreme courtesy which the delegates experienced, not only in their official relations, but in all their private interviews with the people of the country. The cities, Yokohoma in particular, are in many respects very much like western cities in their streets, means of transportation, facilities for conducting business, etc. The railway system throughout the country is owned by the country, and from Mr. Moore's observations was conducted very efficiently. The countryside in densely populated and intensely cultivated. Nowhere could one see a more efficient system of irrigation.

The conference was conducted in the city of Kyoto, which has a population of about 800,000. In this city one notices the contrast of western and eastern civilizations in a marked degree. Alongside of modern efficient services in many respects and massed production of many commodities, such as textiles, silks, artificial silks, etc., was the presence of the native handicraft occupations. Modern street-cars vie with rick-shaws, modern steam shovels were working alongside hand-barrows, and automobile trucks might be seen in the same street with rows of natives carrying individual burdens.

The Japanese have made efficient and extensive use of electricity, as electric lights are everywhere in evidence. The people themselves are very efficient in their duties, and the workers are beginning to organize themselves for their protection and advancement. It was noticed that communism is endeavouring to make advances among the working classes, but so far this influence has not been felt to any great extent. There is not apparent any great desire to emigrate, as the people have deep-seated affection for their own land and for the traditions of their race. Family traditions and race traditions are a very important factor in the life of the people. The present increasing industrialization of working conditions is tending to break down these old traditions and Mr. Moore considered it very regrettable if all the ancient culture sould be blotted out by the factor system.

The people of Japan do not observe Sunday as a rule, although recognition of it is increasing. However, the first and fifteenth of each month are generally recognized as rest days—the people flocking to the shrines and temples for worship, or to the parks and public playgrounds for recreation.

Westerners find some customs in Japan a little irksome, as for instance taking off their shoes when they go into a house, sitting on the floor when they eat their meals, and eating native meals which often include portions of uncooked meat, fish and other edibles. The houses contain no furniture, such as is to be found in western countries. On the other hand, neither do they contain so many useless nick-nacks as western houses are often cumbered with.

The delegates were entertained wherever they went; these entertainments in many cases taking the form of garden parties. Japan is full of beautiful gardens, the owners of them often taking much more care of them than they do of their houses.

In conclusion, Mr. Moore emphasized the fact that Japan is developing very rapidly into one of the most powerful nations of the world and she has demonstrated her desire to co-operate with other nations on an equal basis in maintaining the peace of the world. The conference at Kyoto had as its object the furtherance of this great aim, and as such has no doubt been of great benefit to the world at large.

Present at the luncheon were Honourable Charles Stewart, Minister of Mines and of the Interior, Honourable Peter Heenan, Minister of Labour, Honourable Jean Knight, Minister from France, Honourable I. M. Tokugawa, Minister from Japan, Mr. A. J. Grant, M.E.I.C., the incoming President of the Engineering Institute of Canada, Dr. C. C. Camsell, M.E.I.C., Deputy Minister of Mines, and H. H. Ward, Deputy Minister of Labour.

Popular Lecture on Talking Motion Pictures

At the Chateau Laurier on the evening of Friday, February 28th, a popular lecture was given under the auspices of the Ottawa Branch of The Engineering Institute of Canada. The speaker of the evening was Mr. O. R. Harvey, manager of the research products department of the Northern Electric Company, of Montreal. This department was formed within the past two years to commercialize new developments in radio, scientific and medical equipment, and sound and talking pictures.

Mr. Harvey's talk was on the development of sound and talking pictures with reference to scientific developments which have led up their present position in the field of popular entertainment. It was illustrated by six reels of films, the apparatus used being a small set, remarkable for its portability. The set was so designed that it could be packed within the space of four medium-sized trunks, and at the conclusion of the lecture it took only a few minutes to pack the entire equipment and transport it to the train for its next journey.

Mr. Harvey's talk traced the development of the motion picture industry from the time some thirty years ago when Thomas Alva Edison first conceived the idea of giving eyes to his phonograph. Various early attempts were made to synchronize sight and sound although the first production of the talking motion picture on a commercial basis took place less than four years ago, when Warner Brothers, small producers in the motion picture industry at the time, put out "Don Juan" with sound effects, in which John Barrymore was the star. This sound picture was looked upon somewhat as a novelty and was only moderately successful; but another one, a talking motion picture, put out in October, 1927, really revolutionized the industry. This talkie was entitled the "Jazz Singer" with Al Jolson as the star. Within a week receipts at the theatre where it was shown were doubled. During the second week they trebled and within two months thereafter thirteen motion picture companies who had dubiously looked upon the early attempts, signed up for the installation of equipment. The result was that the factories manufacturing and installing this sound reproducing equipment were taxed to the utmost, so that it was necessary for them to work their staffs twenty-four hours of the day, a condition which still prevails. It is estimated that five hundred millions have been spent in sound production and reproduction equipment by producers and exhibitors throughout the world.

In Hollywood, old equipment representing millions of dollars in investment was scrapped overnight. The effect upon the motion picture colony was felt in many different ways. As an example, within the space of two months fifteen classes in elocution were commenced in Hollywood in order that the motion picture actors and actresses could perfect themselves in the new art that was required, namely, the art of speaking.

The effect upon the exhibitors themselves was tremendous. It was necessary to install equipment, and in the altering of the interior of their motion picture house, the expenditure of $30,000 or $40,000 for a small theatre was quite usual.

There are, stated the lecturer, approximately 50,000 motion picture theatres in the world of which about 20 per cent are at present equipped to reproduce sound. These sound reproducing motion picture houses extend into 44 different countries of the world, and include quite a number of countries which are considered to be quite backward in other respects.

In Canada there are 225 motion picture houses with equipment to reproduce sound out of a possible 750 theatres. It is estimated that approximately 8,000,000 persons attend the movies in Canada each week.

The recording of the sound in connection with the motion picture industry in done in two ways: on discs or on film. Some producers are still using the disc recording devices, notably Warner Brothers, who introduced sound talking pictures, and the First National.

The disc resembles a gramophone record but rotates more slowly and is synchronized with the picture film so that the operator may start both of them together. In the other method, the film method, an actual picture of the sound is placed upon the film. In taking sound motion pictures by this method two different films are obtained at the same time, one for the picture and the other for the sound. The negative and the picture negative are later printed together on a third film which is used in the projection.

In projecting such a film the film itself is stopped 24 times a second. The sound projection portion of the projecting apparatus is about

$14\frac{1}{2}$ inches below the picture projecting portion, and it could quite readily be believed that for the synchronization and projection of these two elements the skill required in the finest of watch making would be necessary in the manufacture and adjustment of the various working parts. The light beam, for instance, used in the sound projection is from 8/10,000 to 10/10,000 of an inch in width, less than one-third as wide as the human hair. Flutter must be guarded against, and all apparatus, of course, must be rigidly kept in the most perfect working order.

The motion pictures exhibited by Mr. Harvey during the course of his lecture showed the apparatus required in the making of the sound motion picture film. One reel prepared as a cartoon was most ingenious in simplifying the method of explanation, and the members present and their friends evinced in the discussion which followed their keen appreciation of the lecture itself.

Mr. Harvey stated that new developments at present taking place were the introduction of colour pictures and the showing of pictures twice as large in both dimensions as those at present used, the latter giving the illusion of depth, particularly in out-door shots. The lecturer stated that in his opinion, within the next two years all pictures would be in colour and it was interesting to note that in the development of this art a Canadian from the city of Kingston was one of the originators.

A future possible trend is toward the use of television, but at present the apparatus required to effect it is too great for practical application. Perhaps in the course of a few years it will be brought within the realm of practical possibilities.

The chairman of the local Branch, John McLeish, M.E.I.C., presided.

Joint Luncheon With Queen's Alumni

At a joint noon luncheon at the Chateau Laurier on March 13th, arranged in co-operation with the Ottawa branch of the Queen's Alumni Association, Colonel Alexander Macphail, M.E.I.C., professor of civil engineering at Queen's University, gave an address upon the subject of "Charles Darwin." Mr. John McLeish, chairman of the Ottawa Branch of The Engineering Institute of Canada, was chairman at the luncheon, the speaker himself being introduced by A. E. MacRea, A.M.E.I.C., the president of the Ottawa branch of the Queen's Alumni Association.

Professor Macphail delivered a most scholarly address upon the great evolutionist that was listened to with rapt attention. At the commencement he stated that the chief myth associated with the name of Darwin—all great men after their passing had myths associated with their names—was that he was responsible for the theory that man was descended from the ape. Darwin, stated the speaker, never said, believed, or even thought such a thing. He was not gifted in the sense that many other great men have been gifted, but as to whether or not he was a genius, posterity may judge for itself. He was a scientist with the mind of the engineer relying upon his facts and data to speak for themselves.

No subject can be of unbounding interest, stated the speaker, unless it relates to the physical or spiritual welfare of the people. Darwin's work did not relate to the former but to the latter, and to such an extent was this the case that it had given rise to a new word in our language, namely, the word "Darwinism."

Our forefathers, in their conceptions of life, had but a scant six thousand years and a limited space of creation at their disposal. Today, as the result of the investigations of philosophers and scientists we have time extending back into the thousands of millions of years—in fact, so vast, that we have lost track of it—and space so great that there is neither beginning nor end. With such a background it is much easier for us to believe the conclusions in Darwin's great work, the "Origin of Species," published 70 years ago.

The early life of the great evolutionist gave but little promise of his later attainments. At school and university with their standardized curricula, he was by no means a shining success. In fact, these studies bored him and it was with a feeling of relief that he seized his golden opportunity at the age of 23 to become the official naturalist to the famous expedition of The Beagle to the waters of lower South America and the Pacific. This voyage, which took five years, had a great influence on his life and laid the foundation of his later fame.

In 1831 he commenced his first great work, a work which he modestly called an "abstract." So indefatigable was he that he would spend many months of research to arrive at a definite conclusion which he might incorporate into a single sentence. His work and his writing were often carried on in the face of great physical handicap. At times he would suffer from long periods of ill-health, which must have made his work particularly onerous.

The driving power of such a life, stated the speaker, was not ambition, fame, pride, vanity, hunger, or any other of the usual motives which might actuate a lesser man, but simply the pure love of science. His ancestors were yeomen who had about a century before risen substantially to the ranks of the professions and the gentry, but there was nothing in his ancestry to indicate that he should become what he was.

Although Darwin's life was lived in private, so voluminous were his writings and so extensive his correspondence that every incident has been subsequently open to the public like an open page. A list of his works alone would occupy ten pages of ordinary print. The "Origin of Species" was, of course, his greatest life work.

In conclusion, stated Colonel Macphail, "Darwin set up no new standard of morality in the hearts of a nation, nor implanted new ideals in the conduct of domestic life; he did nothing towards enhancing the prestige of the British Empire in every corner of the globe; he founded no empire based on divine rights of kings; he was not in the least concerned with the establishment of responsible or irresponsible government anywhere; his researches did nothing to prevent the loss of human life by disease; he was neither a martyr nor a saint; yet he had a great faith, and did much to convince us that the world is a sane institution, governed by immutable laws, and not the irresponsible dream of a suffering and tormented God."

Peterborough Branch

S. O. Shields, Jr.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

Aerial Mapping

An address by a member of the Canadian Government Air Services has become a much appreciated annual event with the Peterborough Branch On the evening of the February 27th, 1930, A. M. Narraway, M.E.I.C., chief aerial surveys engineer, Department of the Interior, Ottawa, gave a particularly interesting lecture on "Aerial Mapping." S. O. Shields, Jr.E.I.C., acted as chairman for this meeting.

Defining his subject as "the application of the aeroplane and photography to the investigation of the natural resources of a country," the speaker outlined the work being done in Canada. He likened the Canadian plane to the "work horse" rather than the "racehorse," in that it is being put to many useful purposes. During the past 8 years some 340,000 square miles have been surveyed by aerial photography, a feat impossible by other means.

Mr. Narraway exhibited slides of typical planes and camera equipment. Wheels, skies and pontoons are all necessary as well as a canvas canoe, strapped under the plane. The cameras are operated automatically and take some 110 exposures per roll. Stereoscopic pictures in pairs, and vertical pictures are taken. The method of plotting maps from the photographs was described and illustrations of maps so produced were shown.

Aerial photography has many other uses besides map making, such as the forestry (some 35,000 square miles of tree types were located last year), and fire patrol service. Great assistance is rendered in determining the best site for water power developments and the extent of watersheds. Location of transmission lines is much simplified and can be done entirely from the air.

Mr. Narraway described and illustrated how aerial photographs were used to determine geological formations and favourable mineral areas.

Some interesting slides showed how the camera will penetrate water and photograph water channels in an estuary, and contours of the bottom of a lake.

This meeting was largely attended, among the visitors being students of a local flying school. After an active discussion, a hearty vote of thanks to Mr. Narraway was proposed by R. C. Flitton, A.M.E.I.C.

Students' Night

The meeting of March 13th, 1930, was arranged as a "Students' Night" under the chairmanship of W. H. Hooper, Jr.E.I.C. The lecturers, all employees of the Canadian General Electric Company, Limited, were A. E. Jagger, S.E.I.C., and R. L. Morrison, S.E.I.C., both of Vancouver, and graduates of the University of British Columbia, and J. J. Taylor, S.E.I.C., of Edmonton, graduate of the University of Alberta.

Although the attendance was disappointing, keen interest was manifested by those present and the discussion after each paper paid handsome tribute to the appreciation with which the lectures were received.

The Diesel Engine

The first speaker of the evening was A. E. Jagger, S.E.I.C., who presented an interesting and comprehensive paper on the "Diesel Engine," dealing with his subject under the heads of history, cycle of events, materials, construction, fuel, lubrication and air systems, governing and application of the engine.

The solid fuel, constant pressure engine was invented by Dr. Rudolph Diesel in 1892 and a commercial engine of 25 h.p. was built in 1897. During the war, Diesel engine construction received considerable impetus and to-day their manufacture is on an enormous scale. Engines of 8 to 10 cylinders developing 1.700 h.p. per cylinder are now built.

It was explained that the higher efficiency of the Diesel over the gas engine was due to compressing the air to a high pressure and burning the fuel to give a higher mean effective pressure. Both 4 cycle and 2 cycle designs are built, the latter requiring an air compressor for scavenging.

The design and construction of the various parts were next dealt with, and illustrated by means of slides, showing typical Diesel engines of both stationary and marine types. The valve mechanism, fuel and lubrication systems and air compressor were described in considerable detail, as being vitally important to the success of the engine.

In conclusion, the speaker stated that the Diesel engine has been brought to the stage where it enjoys the confidence of companies using prime movers. Motor vessels of all types and sizes are rapidly increasing in numbers, and steam may eventually be entirely superseded for propulsion purposes.

The economy and convenience of the Diesel make it eminently suitable for generation of electric power in many locations. The development of engines of light weight and high speed is permitting the use of Diesels on dirigibles such as the R-101, whose progress will be watched with much interest.

Mr. Jagger's paper was well illustrated with diagrams and photographs, and was followed by considerable discussion.

Power Rectifiers

R. L. Morrison, S.E.I.C., next gave a paper on the theory and application of the "Mercury Arc Power Rectifier." The development of the metal tank rectifier in Europe and America, and some of the difficulties met with and overcome were outlined. Recitifiers are now being manufactured on a commercial basis and with satisfactory operating results. Capacities up to 6,500 kw. at 650 volts and voltages up to 6,000 or 7,000 have been found feasible.

The speaker dealt at some length with the voltage and current wave forms of rectifiers with different numbers of anodes or phases, and also the formulae for voltage and current relations.

It was shown that with 6 or 12 anodes the ripple in the d.c. voltage was reduced to a practical minimum. The advantages of a rectifier in respect to high efficiency were most pronounced at the high voltages, since the losses are almost independent of voltage and load.

Voltage regulation and overload capacity were briefly discussed and it was shown that troubles such as back-firing which had formerly been serious have now been practically eliminated.

The various auxiliaries necessary to the operation of the rectifiers were also described including the vacuum pumps, rotary and mercury types, the vacuum gauge, cooling system, etc.

Forestry in Alberta

"My subject covers a large area" said Mr. Taylor, in opening his interesting talk on Forestry. "It covers an area of 1,500,000 square miles." He spoke intimately of the vast forest reserves of his native province, having at one time been on a survey party at which time he took several photographs from which he made lantern slides. These he exhibited in conjunction with his address which added greatly to its success.

He discussed the duties of the fire rangers which include the cutting of trails, erection of telephone communications between camps and the erection of stop-over cabins and lookout towers.

Their three major duties are preventing of fires, detection and suppression. The first is accomplished by educating the people of the danger of forest fires and of the necessity for conservation of the vast timber resources. Detection includes patrol work by airplanes, a daily patrol of the railroad with speeders and lookout men stationed in the watch towers.

A great point in forestry is being able to recognize fire hazard periods and these are largely dependent on the humidity of the air. One of the latest methods adopted by Price Brothers of Quebec is to measure the moisture content of the "duff" or top soil. It is a method which is meeting with success and which is likely to be adopted by all provinces.

Mr. Taylor also dealt with the control of insect pests which attack standing timber, adding that another menace to forest reserves was fungus diseases.

The aim of the Forestry Service is a system of management which will lead to a sustained yield of timber and the speaker was of the opinion that it should be managed solely by the government and not left to the exploitation of private concerns.

In addition to his own slides Mr. Taylor used some very artistic coloured slides kindly provided by the Department of the Interior.

Saguenay Branch

R. Lanctot, Jr.E.I.C., Secretary-Treasurer.

At Arvida, on Monday, February 24th, at 8.00 p.m., there was a meeting of the Saguenay Branch of The Engineering Institute of Canada, at which about 35 were present, mostly from Arvida. The speaker for the evening was N. D. Paine, A.M.E.I.C., who gave a very interesting address on "Electric Drives for Paper Machines."

Mr. Paine first gave a brief description of a paper machine and its operation; he also pointed out the factors necessitating uniform or closely regulated speeds of the drives of the various parts of the paper machine. He described the sectionalized electric drive for speed differentials, which is a rather modern development of that industry. The speaker then compared the mechanical differential with the electrical one; both control the relative speeds of the driving motors automatically and are quite satisfactory, but, in his opinion, the electrical differential has the advantage because of its cheaper repair and maintenance cost.

The meeting proved very interesting and the paper was appreciated by all.

Saint John Branch

E. J. Owens, A.M.E.I.C., Secretary-Treasurer.

"A sustained yield policy—an allowable cut estimated to be within the annual growth—must be adopted in Canada if the successful industrial life built up on wood-using industries is to be passed on as an asset to the next generation," declared Professor J. Myles Gibson, B.Sc., professor of forestry at the University of New Brunswick, in speaking on forest production, protection and reforestation before a meeeting of the Saint John Branch of The Engineering Institute of Canada, held in the Board of Trade rooms on February 20th last.

Professor Gibson, who is a native of New Brunswick, described the organization and workings of the British Columbia Forestry Service, having spent upwards of 10 years in the Forestry Service on the Pacific coast. He pointed out that few government forestry staffs on the continent have such complete control over the forest and forest lands as the forest branch of British Columbia, and contended that such a service should be established in other provinces of the Dominion which are heavily wooded and where lumber is one of the leading industries, such as is the case in New Brunswick.

In his address he dealt with forestry from the standpoint of the administration of the forest resources in the province of British Columbia, describing the development of the organization from the time it was controlled by two men and a chief ranger down to 1928 when the forestry branch had a staff of 560 employees, 314 of whom were seasonal employees and 246 permanent employees.

Professor Gibson pointed out that the framing of the Forest Act in British Columbia in 1912, following the report of the Royal Commission appointed in 1909 to make an enquiry into timber and forestry, was responsible for the organization and operation of the forestry branch at the present time.

In the organization of this department the natural resources in land, forest and water were placed under the administration of a minister of lands, the present minister of the department being Hon. F. P. Burden, a native of New Brunswick, and a graduate of the University of New Brunswick. The department was divided into four branches—lands, surveys, water and forest.

In dealing with the department of forestry, Professor Gibson made reference to the fact that the present chief forester under whose direction the department functions was P. Z. Caverhill, also a native of New Brunswick and a member of the first graduating class in forestry at the University of New Brunswick. The speaker then described the activities of the various divisions, touching on management, operation, records, surveys, research, trade extension and grazing.

The total forest area of British Columbia is 372,630 square miles, he stated, with 4,000 square miles of water surface.

The organized area of the province, he stated, had been divided into six forest districts, each being in charge of a district forester and several assistants. Each forest district was further divided into ranges, of which there are some 59.

Referring to the surveys division, Professor Gibson mentioned that in 1925 the legislature of British Columbia created a statutory fund for the purpose of developing, protecting and maintaining continuous crops of timber on provincial forests. Eighteen areas, containing approximately 7,000,000 acres, have so far been so dedicated and additional areas are being set aside at the rate of 1,000,000 acres per year, with the object of having 25,000,000 set aside by 1950.

The speaker explained that the forest survey department is at the present time developing a forest cover map of the province on which a provincial stock taking will be based. Vancouver island, an area of 8,000,000 acres, has already been covered and shows an area of 3,703,000 acres of merchantable timber with a total stand of almost 95 billion feet. Forest cover maps, he said, are of great assistance to the administration staffs in both management and operation work.

Professor Gibson touched also on the research work being carried on in British Columbia, and gave some idea of the accurate knowledge being gathered by the forest research division. Research work in British Columbia, he said, is being carried out along two lines—forest production and forest protection.

Trade expansion, he stated, is an essential factor in the life of a province which has commercial forests ready for cutting and whose product must be exported.

In connection with his lecture, Professor Gibson produced photos of some forest scenes and conditions in different phases of forestry work in British Columbia which were flashed on a screen for the benefit of those attending the meeting.

The meeting was presided over by W. J. Johnston, A.M.E.I.C., chairman, who introduced the speaker. A hearty vote moved by C. C. Langstroth, A.M.E.I.C., and seconded by J. A. W. Waring, A.M.E.I.C., was extended to the speaker by the chairman.

Halifax Branch

R. R. Murray, A.M.E.I.C., Secretary-Treasurer.
W. J. DeWolfe, A.M.E.I.C., Branch News Editor.

The February meeting of the Halifax Branch was held on the 20th of the month at the Halifax hotel, chairman W. P. Copp, M.E.I.C., presiding. The meeting was preceded by a supper at which twenty members were present.

In opening the meeting, chairman Copp referred to the election of Prof. F. R. Faulkner, M.E.I.C., as Vice-President of The Institute for this zone and of H. F. Bennett, A.M.E.I.C., as councillor for this district.

Mr. Bennett noted that the chairman of the Saint John Branch, E. A. Thomas, A.M.E.I.C., had died recently and that he had arranged for this Branch to be represented at the funeral.

Chairman Copp then called upon J. S. Misener, M.E.I.C., manager of the Acadia Sugar Refinery at Woodside, N.S., who delivered a very interesting address on "Sugar Refining."

At the conclusion of his address, Mr. Misener invited the members to visit the plant and answered several questions.

For table use, he stated, cane sugar is better than beet root sugar.

Sugar grading was described and it was noted that the product is bought according to sugar content.

The activated carbon method of cleaning sugar is not used very much, being not as good as the char method nor any cheaper.

The reason that sugar does not dissolve during washing is that the water is thrown off centrifugally, about 2¼ millions of lake water per day being used.

A very hearty vote of thanks was tendered to Mr. Misener on motion of K. L. Dawson, M.E.I.C., seconded by H. F. Bennett, A.M.E.I.C.

Mr. D. R. Turnbull, Secretary of Acadia Sugar Refining Company, was called upon and added some very interesting references to Mr. Misener's address. He said carbon had been tried but the quality of product was not as good as from char. He stated that the tropical zone is the natural cane sugar country. The reason for the development of the beet sugar industry he traced to Napoleon's need for sugar for his armies. Beet root sugar is manufactured largely in Europe but not well favoured in this country, being too expensive to produce and needs tariff protection for the industry to live in Canada. Large grained beet sugar is used because of custom of the users but is harder to market than cane sugar.

The Acadia sugar refinery is the second oldest in Canada and the product of refinery is made with every care and very much cheaper than in England. The new machine referred to by Mr. Misener, of which there is not another of quite the same kind anywhere, certainly not in Canada.

Mr. Turnbull, who is an ex-president of the Halifax Board of Trade, made some quite interesting remarks on the economic side of sugar making and manufacturing in general and said that active competition is the cause of labour saving machinery and consequently unemployment. He thought the solution of unemployment lay in methods of distribution, which will take up the number of unemployed.

At the conclusion of Mr. Turnbull's remarks the chairman closed one of the most interesting of recent Branch meetings.

Sault Ste. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer.

The regular meeting of the Sault Ste. Marie Branch was held on February 28th, following a dinner.

Chairman C. H. E. Rounthwaite, A.M.E.I.C., presided. J. W. LeB. Ross, M.E.I.C., gave a short report of the Annual Meeting held in Ottawa. He also reported that Mr. McLachlan, of the St. Lawrence Waterways, was willing to give a paper before the Branch.

The chairman then introduced the speaker of the evening, A. H. Russell, A.M.E.I.C., who spoke on the subject, "Winter Maintenance of Streets and Sidewalks."

An animated discussion followed and a vote of appreciation was tendered Mr. Russell, on motion of C. H. Speer, M.E.I.C., and J. Hayes Jenkinson, A.M.E.I.C.

Before adjourning the chairman announced that the next meeting would be addressed by A. M. Wilson, Jr.E.I.C., on "The Michipicoten Coal Dock."

Toronto Branch

J. J. Spence, A.M.E.I.C., Secretary-Treasurer.
Archie B. Crealock, A.M.E.I.C., Branch News Editor.

On Thursday evening, February 6th, Mr. A. E. Davidson, C.E. transmission engineer of the Hydro-Electric Power Commision of Ontario, gave an address on the construction features of the Gatineau-Toronto 220-kv. transmission line which was erected in 1927 and 1928. The lecture was generously illustrated by lantern slides and moving pictures.

Mr. Davidson told of the location surveys in which the aeroplane played an important part, also the difficulty of finding and getting reasonable terms with the land owners when purchasing the 130-foot right-of-way. The line is 230 miles long, 27 miles being in Quebec. The work consisted of clearing the right-of-way, transporting the material, erection and maintenance of camps about 12 miles apart, placing anchorages, erecting the towers, stringing the conductors and ground wires, removing the camps, equipment and excess materials. While Mr. Davidson apparently regarded such an undertaking as a piece of routine work, his audience, even if not acquainted with the country through which the line passed, could judge by the pictures that everything from open fields to tangled second growth and from swamps to solid rock was encountered.

The right-of-way was kept surprisingly straight considering the nature of the country, so that the number of dead end and angle towers was reduced to a minimum. A novel feature of the clearing of the right-of-way was that most of it was done by the land owners under contract. There are 994 galvanized towers with silicon steel leg angles and structural steel web members. The use of silicon steel reduced the weight of these heavy members of the towers by about one third thereby diminishing the transportation difficulties. The towers are of the single circuit type with the standard towers having a conductor suspended on each side from the overhanging head and the centre conductor strung through the structure. The transposition towers have two conductors suspended from arms on one side of the tower with the third conductor strung through the structure. The towers carry two standard galvanized steel ground wires on the top of the head and a telephone circuit on the tower leg.

The anchorages were of three types, earth, rock and concrete footings; very few of the latter being found necessary. The earth and rock anchors were accurately placed by using setting templates which bolted to the stub angles. The stub angles had groups of extra holes punched in them to provide for considerable adjustment of the tower legs. Several types of side hill extensions were used.

In erection, panels were loosely bolted together and raised. For the upper sections a 30-foot gin pole was slung in cables fastened to the tower legs and as there was no horizontal bracing, the head was raised inside the tower. After the tower was trued up, the bolts were tightened but no burring of the bolt threads to lock the nuts was permitted. The average erection time was one tower per day with a seven man gang.

The conductor is stranded aluminum with a stranded steel core. It is designated as 795,000 circular mils, has an external diameter of 1.1 inches and was shipped on 4,000-foot reels. The stringing was done by teams of horses in some places and by a tractor in others. The tractor pulled up three conductors at once. The joints were made by lapping the steel cores inside of an oval steel tube and twisting it and compressing heavy aluminum sleeves onto the aluminum conductors. A portable hand operated hydraulic press was used for this purpose and the splice is mechanically and electrically better than the cable itself. The conductor was secured to the insulator strings by galvanized malleable iron clamps and a six-foot length of the aluminum cable was secured above the conductor to act as a vibration damper and to protect the conductor in case of arcing from the tower arms.

The moving pictures showed many phases of the construction such as the teaming of material in the winter, erection of the towers and the stringing of the conductors. At the conclusion of the pictures a hearty vote of thanks was moved by Mr. Wilkie and was enthusiastically carried by the members present.

Winnipeg Branch

E. W. M. James, A.M.E.I.C., Secretary-Treasurer.

The Winnipeg Branch held their annual meeting on February 6th, 1930, at which the attendance numbered fifty-two.

The speaker of the evening was Mr. J. C. Burkholder, chief engineer, Canadian National Telegraphs, who spoke on "The Carrier Current."

Mr. Burkholder delivered a most interesting address showing the development of the telegraph as a means of communication, from the state at which twenty-six wires were required for the sending of a single message to the recent accomplishment of sending twenty-four messages simultaneously in both directions over a single pair of wires, by means of the "carrier current."

At the close of the discussion of Mr. Burkholder's address the business of the annual meeting was transacted.

A resolution of sympathy and well-wishing was passed to be expressed to Chairman F. H. Martin, M.E.I.C., whose severe illness has made it necessary for him to spend the winter in California.

The report of the scrutineers showing those elected to office for the year 1930 was then presented as follows:—

Chairman	J. W. Porter, M.E.I.C.
Secretary-Treasurer	E. W. M. James, A.M.E.I.C.
Executive Committee	A. L. Cavanagh, A.M.E.I.C.
	F. G. Goodspeed, M.E.I.C.
	R. W. Moffatt, A.M.E.I.C.
Nomination Committee	J. N. Finlayson, M.E.I.C.
Auditors	J. M. Morton, A.M.E.I.C.
	C. H. Fox, M.E.I.C.
Library and Publications	W. Fulton, A.M.E.I.C.
Legislation and Public Affairs	D. L. McLean, A.M.E.I.C.
Advisory Committee	E. P. Fetherstonhaugh, M.E.I.C.
Remuneration Committee	D. A. Ross, M.E.I.C.
Students' Prize Committee	W. M. Scott, M.E.I.C.
Programme Committee	E. V. Caton, M.E.I.C.
Research and Investigation Committee	Theo. Kipp, M.E.I.C.

Preliminary Notice

of Applications for Admission and for Transfer

March 24th, 1930

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in May 1930.

R. J. Durley, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may includs apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council. be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall he considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for a least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BREWER—HAROLD BYRON, of 169 Strathcona Avenue, Fredericton, N.B., Born at Fredericton, N.B., Aug. 13th, 1907; Educ., B.Sc., Univ. of N.B., 1928; 1928-29, instr'man., munic. and rld. work, field and office, in model townsite, (Arvida); May 1929 to date, hydrographic engr., Dept. of Marine and Fisheries.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Wanted

CHIEF ENGINEER, twenty years industrial construction, production and operation. Structures, equipment, steam, hydro. Experienced in conferences, preliminaries, organizing, preparing plans, estimates, specifications, negotiation contracts. Apply to Box No. 36-W.

CIVIL AND MECHANICAL ENGINEER, aggressive practical engineer, with background of experience in design, construction, maintenance and operation of pulp and paper mill, desires change. Especially qualified to reduce mill costs. Apply to Box No. 53-W.

MECHANICAL ENGINEER, with twenty years experience in design, construction, sales and management desires position of an engineering, commercial or executive nature. College graduate, M.E.I.C., M.A.S.M.E., M.P.E.Q., and formerly chief engineer. Apply to Box No. 92-W.

RETIRED LIEUT.-COMMANDER, Canadian, aged 32, A.M.E.I.C. Specialized in engineering from executive rank. Two years and six months chief engineer marine 31,500 s.h.p. Desires position with manufacturing or business concern in Montreal—management. Apply to Box No. 106-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Opening sought with architects as reinforced concrete designer and engineer; other opening considered. Toronto-Hamilton area preferred. Apply to Box No. 107-W.

Situations Wanted

CIVIL ENGINEER, graduate '26, with fair knowledge of French. Experience as instrumentman on surveys, maintenance engineer on railway construction, and resident engineer on railway construction. Available at once. Apply to Box No. 149-W.

GRADUATE ENGINEER, University of Sask. '25, age 26, desires position. Experience includes one year surveying, one year architectural draughting, three years general construction draughting and superintendence and two years paper mill design and maintenance. Services available immediately. Apply to Box No. 150-W.

ELECTRICAL ENGINEER, B.Sc., E.E., A.M.E.I.C., Canadian, age 29, single, graduate Canadian university 1924. Have been with large power company in U.S.A. since graduation, ten months on sub-stations, remainder of time on design, construction and operation of overhead and underground distribution and transmission system. At present employed by same company. Would like return to Canada. Available on reasonable notice. Apply to Box 236-W.

CIVIL ENGINEER. A.M.E.I.C., graduate, R.P.E.P.Q. Twenty years experience surveying and construction hydro-electric, railways, and paper mills, desires position. Will go anywhere if terms satisfactory. Apply to Box No. 294-W.

INDUSTRIAL ENGINEER, thirty-five years of age, graduate of a well-known university, twelve years experience in design, construction, maintenance and changes in production methods in industrial plants, including several years in pulp and paper industry in complete charge in large mills of all engineering, maintenances, and development work; still engaged; desires to establish new connection. Apply to Box No. 320-W.

Situations Wanted

CIVIL ENGINEER, B.A.Sc., A.M.E.I.C., M.P.E.O., age 37, desires a permanent position as chief draughtsman or plant engineer, preferably in Toronto or district. Seventeen years experience with consulting engineers on industrial, structural and railway work, hydro-electric plants and pulp and paper mills. Some mechanical and electrical experience. Apply to Box No. 332-W.

CIVIL ENGINEER, A.M.E.I.C., Reg. Pro. Eng. Ont. and N.B., age 47, married, twenty years experience in this country; twelve years in Scotland as construction and municipal engineer, specializing in roadway, water and sewer works, desires similar position, available forthwith. Just completed sewer and waterworks schemes for town in Maritime Province. Have also been engaged as engineer and superintendent with contractors on steam shovel excavation, concrete and caisson works for large buildings in Toronto, etc. Apply to Box No. 336-W.

CIVIL ENGINEER, graduate '29, desires engineering position with possibilities of advancement. Work in hydro-electric, construction, municipal, railroad, or mining preferred. Past experience consists chiefly of survey work. Location in western provinces preferred. Apply to Box No. 338-W.

CIVIL ENGINEER, B.Sc., fifteen years experience, including surveying, construction, mining and tunnelling. Available at once. Will go anywhere, but prefer Eastern Canada. Apply to Box No. 346-W.

MECHANICAL DESIGNER, 33 years of age. First class English and Canadian experience (Rolls-Royce, Ford, Platt Bros., G. M. C.) on special machine tool jig and tool designing, maintenance, and production methods; excellent references; desires position. Montreal district preferred. Available immediately. Apply to Box No. 351-W.

Situations Wanted

CIVIL ENGINEER, grad. '29, eleven months on construction, three months on road location, five months in draughting office, desires position on construction or would like to enter draughting office with possibilities in steel and reinforced concrete design. At present employed. Apply to Box No. 352-W.

SUPERINTENDENT, competent electrical superintendent, wishes position with large industrial or power supply company. New construction programme preferred. Experienced in engineering, designing and electrical construction of power houses, sub-stations and industrial control work. Available on short notice. Apply to Box No. 353-W.

ELECTRICAL ENGINEER, graduate McGill Univ. Experience, draughting, checking, short wave radio research, radio operating (ship and shore), demonstrating, electrical measurements and radio laboratories, department electrical engineering; at present demonstrating physics department. Desires position with opportunities, preferably radio work. Location immaterial. Apply to Box No. 356-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., is open for engagement. Twenty-four years general experience both as engineer and as contractor. Has specialized in the construction of wharves, dams, foundations, etc. Apply to Box No. 358-W.

ELECTRICAL ENGINEER, graduate N.S.T.C., Halifax, 29 years of age, two years experience in power transmission and distribution with a large power company in province of Quebec, two years electric test and inspection, W.E. and Mfg. Co., East Pittsburgh, Pa., one year electrical maintenance in large mill. Experience with telephone transmission, substation layout, electrical installation and layout for factories. At present employed. Apply Box No. 361-W.

MINING ENGINEER, graduate, age 32, A.M.E.I.C., ten years experience in design, construction, erection and maintenance of paper mill and mine buildings and machinery. Several years on hydro-electric work in charge of surveys and investigation; desires permanent connection with mining or paper company. Apply to Box No. 362-W.

MECHANICAL ENGINEER, B.A.Sc., Univ. of Toronto 21, A.M.E.I.C., married. Pulp and paper mill maintenance experience: draughting, layout of buildings, machinery and piping, mechanical design. Also experienced in reinforced concrete and steel building design and construction work. Desires position of permanency in plant engineering or maintenance work with reliable organization offering opportunities for advancement. Apply to Box No. 370-W.

CONSTRUCTION SUPERINTENDENT, with twenty-five years experience on hydro-power developments, paper mills and general building construction. Apply to Box No. 372-W.

ELECTRICAL ENGINEER, B.Sc. '23, A.M.E.I.C., experience, estimating pole line, cable and wire layouts, supervising estimates, in charge of cost inventory and appraisal work, in charge of draughting, records and budget control work, instructing engineering principles. Seven years with one company. Four years instructing in electrical engineering at evening classes, desires position along the above lines with opportunities. Best of references. Apply to Box No. 376-W.

ENGINEER, age 30, with experience as railway instrumentman, assistant engineer on erection of large buildings, and mechanical, structural and railway draughting and design, desires position in Ontario. Qualified Captain in military engineering. Apply to Box No. 377-W.

STRUCTURAL DRAUGHTSMAN, age 31, well educated, with experience in designing and supervision, desires a change of position and location. Preferably north western Canada. Apply to Box No. 378-W.

Situations Vacant

STRUCTURAL DRAUGHTSMEN, experienced in detailing steel for industrial plants, city buildings or bridges, for a bridge company located in Winnipeg. Give age, experience, whether married or single, and other particulars to Box No. 474-V.

SALES ENGINEERS. Two experienced industrial paint salesmen wanted by a large paint manufacturing company; one for Toronto City, one for London and Border Cities. Applicants should state fully experience, names of three references. Apply Box No. 497-V.

DESIGNING DRAUGHTSMAN wanted by a large pulp and paper mill, ideally situated. The work will comprise general drawings and details for building construction and alterations. Applicant should be able to design reinforced concrete and structural steel. State age, education, experience, salary desired, and other particulars. Apply to Box No. 503-V.

ENGINEER, wide awake and progressive, preferably technically trained man with several years sales experience, familiar with sanitary requirements of municipal and industrial water systems. Submit with application complete details of education and positions held to date. Apply to Box No. 505-V.

DRAUGHTSMEN. Experienced in A.C. and D.C. machines, switchboard wiring diagrams and station arrangements, industrial control apparatus. State age, experience in detail, and salary expected. Location, central Ontario. Apply to Box 506-V.

GRADUATE MECHANICAL ENGINEER required, preferably single man about twenty-five years of age, with special training, operation, maintenance boiler plant equipment. Preferably junior engineer who has completed apprenticeship course offered by Babcock-Wilcox or other boiler manufacturers. Applicant please state particulars, experience, references, etc. Location Mexico. Apply to Box No. 507-V.

RECENT GRADUATE, in electrical or mechanical engineering, for general industrial work. Work part in office and part in the plant. Must be competent to do transit work and levelling in connection with laying out new building sites. Location, Northern Quebec. Apply to Box No. 508-V.

MECHANICAL DRAUGHTSMAN wanted, with good technical training and acquainted with heavy duty cranes, regulating gates, movable bridges, etc. Not over 30 years of age. Apply, giving full personal particulars and salary expected, to Box No. 509-V.

DRAUGHTSMEN—One or two good draughtsmen familiar with heavy wood mill construction. Acquaintance with gold milling desirable but not essential. State age, education, experience, references, if employed, married or single, salary wanted, and how soon you can report, to Box No. 510-V.

CONSTRUCTION ENGINEER, on hydro-electric power development; capable of taking charge of laying out of work. Reply, stating experience, age and salary. Apply to Box No. 513-V.

MECHANICAL ENGINEER, graduate with three or four years experience in industrial plant maintenance, for metallurgical plant in province of Quebec. Permanent connection for right applicant. Please give complete information. Apply to Box 516-V.

DRAUGHTSMAN, with experience in laying out and designing strutural work, preferably with some mechanical experience. Location near Montreal. Apply at once to Box No. 517-V.

GRADUATE CIVIL ENGINEER, competent to design and estimate reinforced concrete buildings and structural steel. Must be experienced. Knowledge of French preferred but not essential. Good position for right man. Location Montreal. Apply to Box No. 519-V.

SALES MANAGER.—Firm in Eastern Ontario, manufacturing chiefly pulp and paper machinery, requires manager to take direct charge of sales. Apply with references, giving experience and salary expected, to No. 521-V.

RECENT GRADUATE, to assist in office of inspection company. Location Montreal. Apply to Box No. 522-V.

CHIEF DRAUGHTSMAN, Canadian college graduate, with varied experience as to draughting room routines as applied to both civil and mechanical engineering with a good deal of experience in working with tradesmen and salesmen relative to general engineering problems. Apply to Box No. 523-V.

MECHANICAL ENGINEER,—A well known automobile manufacturing company has an opening for a mechanical engineer with several years experience. Automobile experience not necessary. The work is in the engineering department on production, and offers an excellent opportunity for advancement. Apply to Box No. 524-V.

ELECTRICAL ENGINEER, graduate in electrical engineering, good draughtsman, for planning of mechanical equipment in industrial buildings, some experience preferred State age, experience, references, and enclose sample of drawings. Apply to Box No. 525-V.

Volume XIII | Montreal, May 1930 | Number 5

Reinforcement in Place of the Stoney Creek Arch Bridge

P. B. Motley, M.E.I.C.,

Engineer of Bridges, Canadian Pacific Railway Company, Montreal.

Paper read before the Montreal Branch of The Engineering Institute of Canada, February 20th, 1930.

The Stoney Creek bridge is situated on the line of the Canadian Pacific Railway on the eastern slope of the Selkirk range at a point immediately east of the summit, where the famous Connaught tunnel is located, and about 428.5 miles from Vancouver.

It consists of a 336-foot three-hinged arch, on which are supported plate girder track spans which are extended to the abutments at both ends of the bridge, making a structure 486 feet long. There is a curve on the west approach to the bridge, but otherwise it is on tangent, and the distance from track level to bottom of gorge on centre line of bridge is 307 feet.

It was orginally on that portion of the railway commenced by the Dominion Government in British Columbia just before the inception of the Canadian Pacific Railway Company, in 1887 or a little earlier. It formed a part of what was known as the "Onderdonck Contract," Mr. Onderdonck being a noted contractor of the eighties who employed a consulting engineer in New York, Mr. C. C. Schneider—later of international reputation—to design a deck Howe truss bridge of two 200-foot spans and one 100-foot span (approximately), supported on two tall, wooden towers, which, at that time, had the reputation of being the highest wooden structure in the world.

Figure No. 1 shows this structure as it was in 1893, when it became necessary to renew the timber spans.

This was during the chief engineership of P. A. Peterson, Past-President of the Canadian Society of Civil Engineers, who entrusted H. E. Vautelet, M.E.I.C., then a company's assistant engineer, with the task of designing a bridge to replace the old structure. Mr. Vautelet decided upon a 336-foot double-chorded, three-hinged arch, as shown in figure No. 2.

The erection of this 336-foot original steel arch was commenced in the early summer of 1893 and the falsework was completely removed by July, 1894. The method of reconstruction was to fill the gorge with falsework, as shown in figure No. 3, which was so designed that first the lower chord of the arch ribs could be erected upon it. After it was connected up, the web members and upper chord of the arch ribs were erected seriatim. Having completed the two arch ribs and their swaybracing and laterals, the track was supported on the falsework by means of suitable pony bents located between the arch trusses and the track spans. The new steel track spans consisted of lattice girders ranging from 63 feet to 84 feet in length, supported on steel bents. These lattice girder spans were lowered into place by means of gantries and screws at one end, and a small double-boomed derrick car at the other. This work, with the removal of the interlaced timber work, was done between trains without disturbing traffic.

The contract for the manufacture and erection of this original arch bridge was entrusted to the Hamilton Bridge Company, of Hamilton, Ont., who had at that time as their erection superintendent Mr. James Finley, who later achieved considerable reputation as an efficient and successful bridge erector, being responsible for a large number of the creditable pieces of construction in Canada in this branch of engineering during the last thirty years.

A derrick car having double booms was employed for lowering the floor beams framing into the bents carrying the track spans, and this double boom car was understood in 1893 to have been unusual in American bridge practice. It is interesting to note that it is still in service on the Canadian Pacific Railway at Revelstoke, B.C.

A deflection test was made on November 20th, 1893, of the steel structure after it had been swung clear of the falsework. In this test six locomotives of that period were used, which completely covered the 336-foot arch and weighed altogether some 550 tons. The amount of the deflection is not available, but the bridge was considered eminently stiff in service. It is interesting to know that in a recent test, after the completion of the reinforcement, it was only possible to get four modern locomotives over the arch proper to occupy the space which six locomotives occupied in 1893.

The structure presented the general appearance shown in figure No. 4. In comparison with contemporary arches, of which there were only a few in existence at that period, it created favourable comment. As far as is known, it was the only double parallel chorded railway arch in existence with its main hinge pins on its lower chord, in contradistinction to the taper-chorded arch in the Garabit viaduct in France. It was, however, similar to the highway arch at Niagara, except that the latter has its pins located midway between chords.

The structure continued in service from its completion in 1893, accommodating heavier and heavier engines, and

Figure No. 1.—Original Wooden Bridge of 1886.

although as a result various members were overstrained as compared with original designing stresses, yet the limits of good practice in such matters were not exceeded until the summer of 1928, when it was decided to increase the capacity of all the bridges on the mountain subdivision of the Canadian Pacific Railway between Field and Revelstoke, B.C., in order to accommodate new and heavier power. Careful studies were made of these structures, some being reinforced and others completely renewed either in place or on new locations alongside. At Stoney Creek, on account of the desire to avoid the various inconveniences and possible delays both to the bridge replacement and to traffic, it was planned to put the new structure on a location about 40 feet north of the existing one, and use a cantilever deck truss bridge supported on two new piers and abutments. The centre span of this cantilever bridge was to have been 311 feet with a 111-foot flanking span at either side.

However, it was found that on the west side of the canyon a clay fault about 2 feet thick ran down the mountain side at such an angle as to come just under the proposed pier on that side of the opening, and exploratory borings showed that it was impossible to locate the pier entirely clear of it. In addition to this the walls of the canyon, which are composed of soft schist with outcropping ledges of hard rock, afforded no better location for a pier than was occupied by the original bridge. After exhaustive exploration it was decided to abandon the plan of an independent bridge alongside and revert to the original location, the details of which form the subject of this paper.

Figure No. 2.—Original Arch Bridge of 1893.

Cooper's E-60 was decided upon as the loading for the remodelled bridge and a complete investigation was made of the old structure, using this loading, which disclosed the fact that it was entirely feasible to erect new arch ribs outside the existing ones and attach them together in place in such a manner as would equally distribute the new live load between the old and the new ribs. This was accomplished by the use of equalizing beams, on top of which are located the bents carrying the track spans above. In the original bridge the track spans were of such length as to give concentrated loads upon the arch every third panel, except in the centre of the bridge. It was found economical to shorten the track spans to one panel each, except in the centre of the bridge where this was impracticable, and two panel spans were used. In addition to this, the calculations

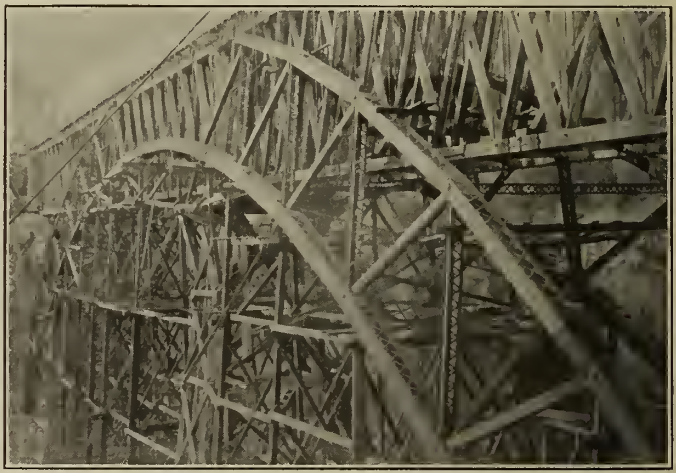

Figure No. 3.—Erection of 1893 Arch.

showed that in the original arch structure the new scheme of loading required some reinforcement in certain members, and this was done as shown in figure No. 4.

The resulting structure, therefore, consists of four arch ribs, attached to one another in pairs by equalizing diaphragms, and of a system of bents so located over the diaphragms that the arch ribs all share the loads equally. There is an exception to this statement in connection with the bents over the end pins. On account of the fact that these are considerably eased of their loading by the shortening of the adjoining spans it was decided for practical reasons to leave these old bents untouched. They are, therefore, slightly out of line as regards the other new bents, but on account of the extra hazard in handling them during erection and the extreme difficulty in avoiding interference with traffic, it was found later that this decision was justified.

There were no serious difficulties in manufacture, the drawings of the old arch ribs being followed closely in fabricating the new ones and the sections and material were, as far as possible, made identical, both as to dimensions and physical characteristics, so as to ensure uniform stiffness in both old and new ribs. The same system of double-flanged thimbles and pins was used as in the old structure. This feature deserves some description, as it formed an important detail in Mr. Vautelet's original design. In the old structure, the lower chord was first erected with thimbles upon a bed of falsework and without, in the first case, a single pin being used. These thimbles were 12 inches in diameter and provided generous bearing surfaces between chord sections. On the finished lower chord were erected the web members and top chords pinned together at all intersections with pins passing through the thimbles, or members, as the case may be, the large main pins of the structure, namely at the skewbacks and centre of span, forming the hinges or turning points of the arch. The wisdom of this arrangement will be apparent, since the thimbles allowed the original lower chord to be erected and swung clear of falsework, if necessary, the pins later taking care of the web members and upper chord.

On these completed arch ribs, after transverse and lateral bracing had been put in, the vertical bents were erected. These were provided with disc bearings at their lower ends and pin bearings at the upper where the track spans rested. The function of these articulated bearings was not actually to rotate in service but to provide good bearing and adjustment to the grade which exists on the bridge, besides tying the track spans together longitudinally. This disc bearing has been used extensively since the construction of the original bridge in Canadian Pacific bridge practice; from many personal experiences during erection the author can testify to its value.

The general features of both the old and the new construction will be apparent from figure No. 4. Broadly speaking, the track spans on the old arch bridge delivered their reactions at six points on the old arch, including the haunches. In the reconstructed bridge, the arch has the reactions delivered to it at thirteen points and the flanking spans have been approximately bisected by new bents located on new substructures provided for the purpose. Thus the structure has been improved, both aesthetically and theoretically, and, while it appears to be broad enough for double track service, this is not a disadvantage, in that it makes for lateral stiffness in service on account of the broad base provided by the widened haunches.

The new vertical bents are located so as to be attached to the loading beams midway between the arch ribs. In the central portion of the arch, however, where no equalizing beams nor bents were necessary, new long double floor

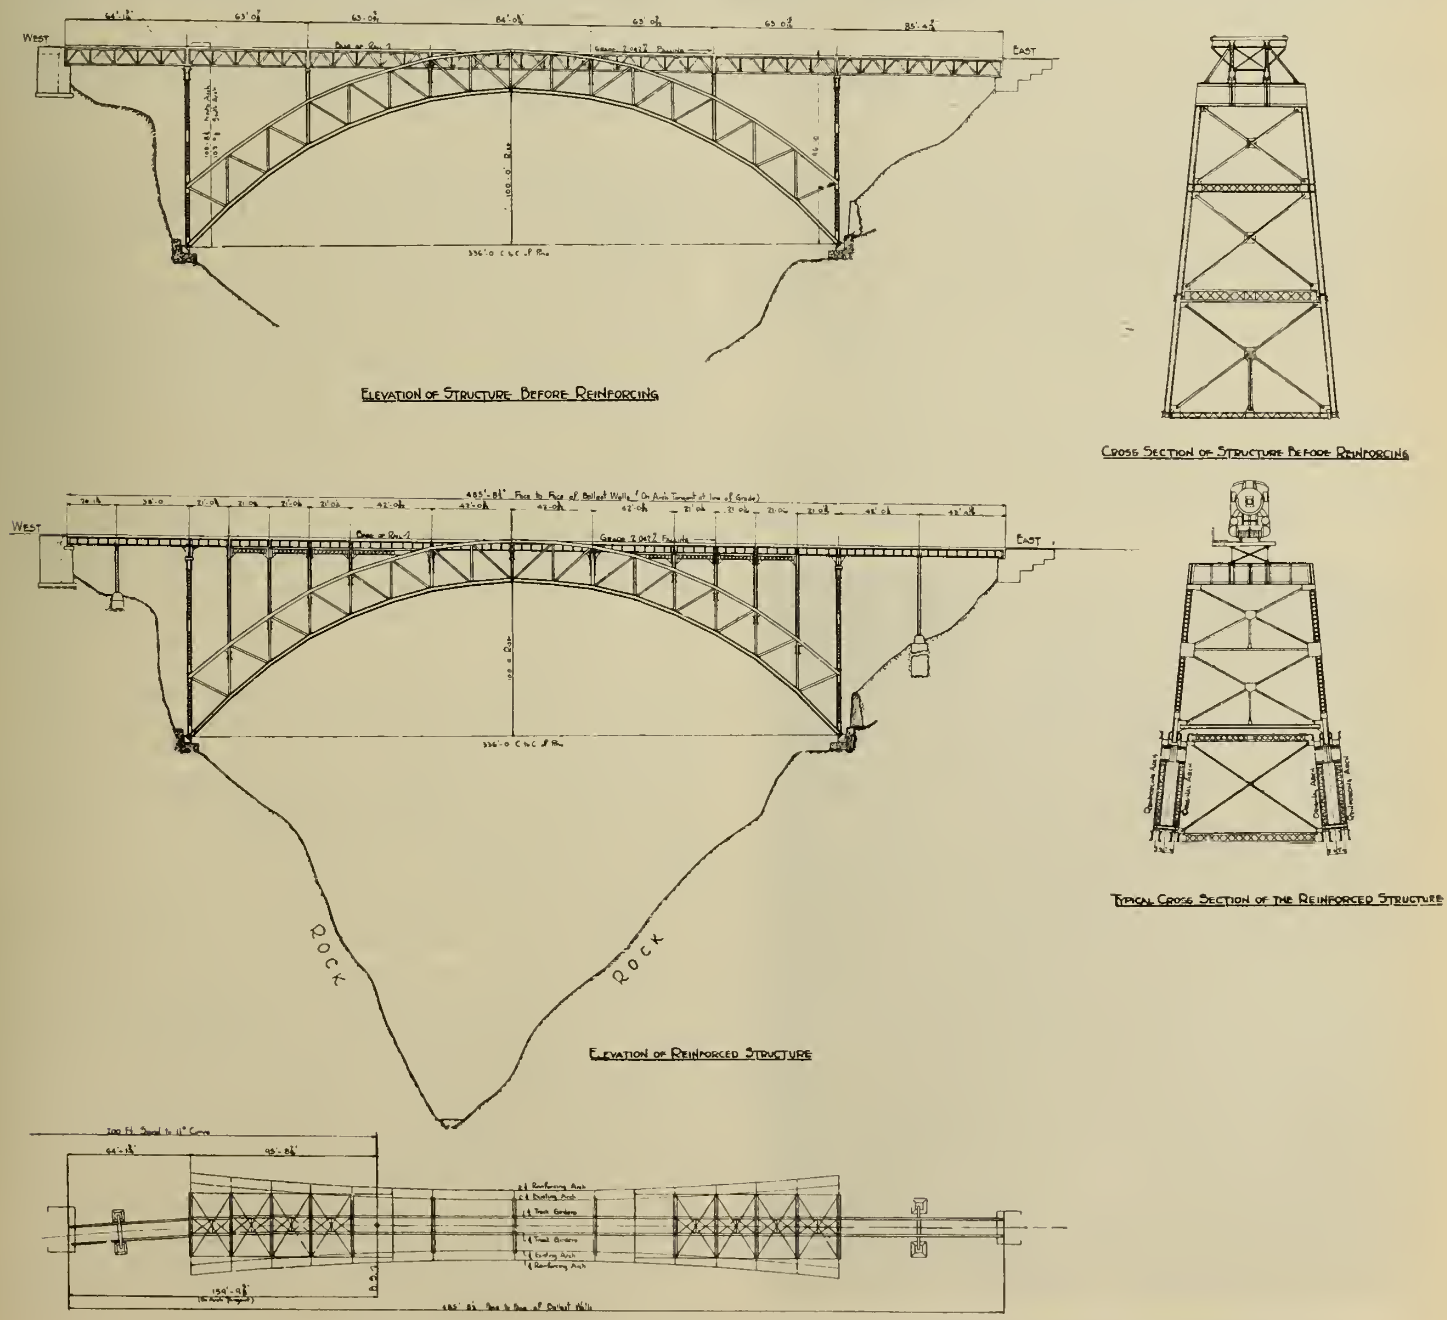

Figure No. 4.—View of Bridge before and after Reinforcement.

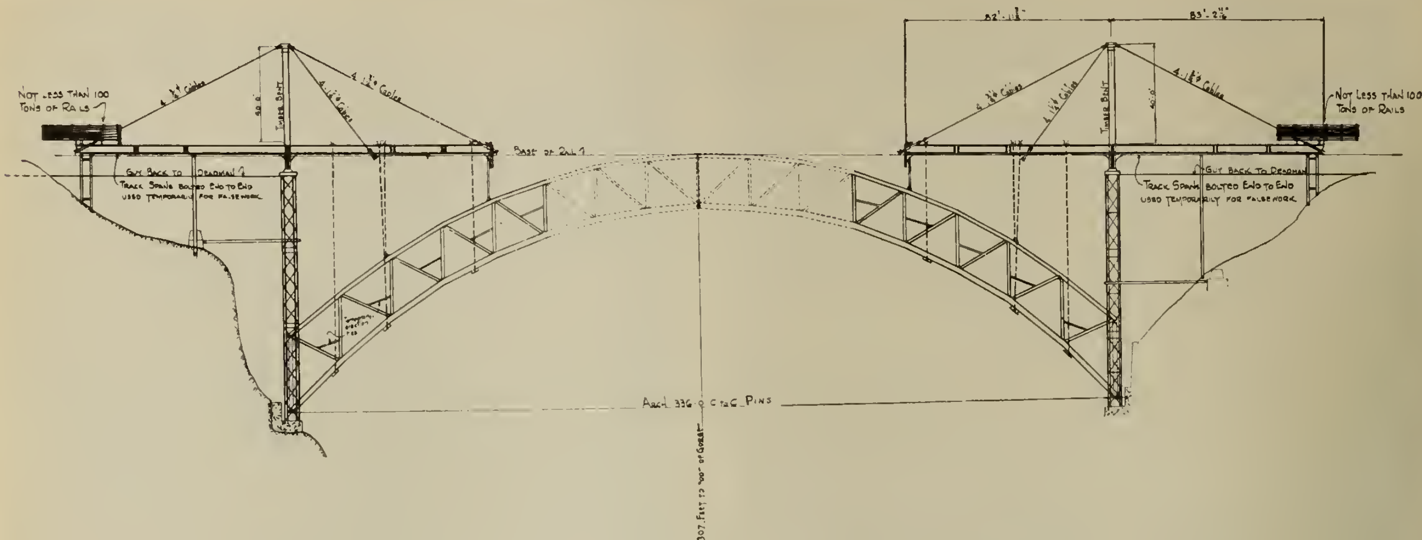

Figure No. 5.—Scheme for Erecting New Arch Ribs by Cantilever Trusses without Loading Old Bridge.

beams are provided which run through the structure, rivetted to both old and new trusses, thus combining floor beams with loading beams.

The track spans themselves are generally equal to the length of a panel, namely 21 feet, except as shown in the centre of the bridge, where they are 42 feet. They are all provided with articulated key bearings at their ends so as to deliver their reactions over the webs of the double floor beams. In order to provide a continuous tie between track spans longitudinally it was felt advisable to put a link and pin connection between the ends of all track spans.

The tractive forces in the new structure are transmitted through lattice struts to the arch ribs themselves.

Having been driven to reinforcing the bridge in place on the main line of a very busy section of the railway, when sometimes fifteen passenger trains had to be taken care of during the hours of daylight when work was possible, naturally the problem of reconstruction resolved itself largely into one of erection methods, which will now be taken up in detail.

Figure No. 6.—Erecting Outer Arch by means of Cantilever Falsework without Loading Old Bridge.

It was not allowable to utilize the old structure for any erection loads, and it was therefore incumbent upon the engineers to so design the work that the arches could be erected by means entirely self-contained and self-supporting.

The scheme decided upon and carried out consisted of a pair of cantilever trusses, counterweighted with old rails at their shore ends, including a wooden tower carried up from a convenient point on the skewback substructure to such a height as to reduce the stresses to convenient limits. (See figure No. 5). The upper chords of these cantilevers consisted of cables, and for the lower chord a series of the new track spans, complete with laterals and brace frames, were bolted together end to end. These were located just above the base of rail and at first extended only three panels out from the skewback panel points. From these plate girder lower chords the panels of the new outer arch truss or rib were suspended by means of suitable wire cables, building out panel by panel, until finally the lower chords and their suspenders had been extended to four panels. There was no further extension from this point, and, instead, the arch ribs were cantilevered out the remaining four panels from each side of the canyon until they met in the centre. It will thus be seen that each of the arch ribs was built out in a self-supporting manner, except for a system of short temporary horizontal struts from the old arch ribs, but otherwise entirely independent of it as far as loading is concerned.

The arch ribs having been thus completed, the work of fastening them together by means of diaphragms or equalizing beams was commenced. Before doing this, however, a system of brackets was erected outside the arch ribs at each vertical, on which was supported, panel by panel, a temporary group of old rails, carefully calculated to provide precisely the same dead load upon the new arch rib as existed on the old. This arrangement is shown in figure No. 8. The effect of this was that the new arches deflected to a point which was considered to be relatively equal to the dead load deflection of the old arches, thus producing conditions which were as nearly as possible theoretically similar in both. Elevations were taken on panel points of the arch ribs as a check, and the similarity of the deflection of the old and the new work was remarkable.

Figure No. 7.—View of Cantilever Falsework, 1929.

There is another feature in connection with these falsework trusses which is worthy of note. As was to be expected, the wire cables stretched considerably during loading. In fact, the upper ones lengthened between six and nine inches, and a system of jacks and jacking beams was provided for adjusting them, which functioned very satisfactorily.

After the arch ribs were coupled up on one side of the bridge, the falsework cantilevers were taken down and re-erected on the other side of the bridge and the same procedure followed in erecting the second arch rib. Progress in the various stages of the work was extremely rapid, and deserves to be placed on record. There were always two gangs working on each portion of the work, one from the east and the other from the west end. The north arch, which was first erected, took fourteen days to couple, and the south one twelve days, and all this in the face of the heavy traffic before referred to. In order to avoid the worst of the traffic the erection crews started work at five a.m. and it was possible to have a somewhat free space of time until about ten a.m. when the usual rush of traffic for the day commenced and continued until five p.m. Some days some extra work was done after this hour, but usually the working day extended from five a.m. to five p.m., with short intervals for meals. The force consisted of upwards of sixty men.

The portion of the work which presented the most difficult problems and needed the most careful preparation commenced after the new arch ribs were erected and the sway and lateral bracing had been reinforced, or renewed, as required. By the plans, the problem resolved itself into a series of operations in which the track was opened, old track spans and bents removed, and new bents and track spans placed. Commencing at the east, or down grade end, after the old wooden deck had been removed, the first 84-foot lattice span was cut apart as to its laterals and brace frames and the two lattice trusses separated to such an extent as to be completely clear of the new work. At the east abutment this necessitated a small amount of temporary cribbing upon which the trusses could rest until, at a more convenient time, they could be entirely removed to the land. The operation of splitting this span made a suitable gap in the work to enable the two single boom derrick cars to place the first two 42-foot flanking spans at the east end, the first land bent having been placed previously. This operation, with the opening and closing of track, removal of old 84-foot span and replacement by the two 42-foot flanking span E-X^1 and X^1-0^1, opening and closing of tracks, placing of ties, rails, etc. took place on June 26th, 1929. Work commenced at five a.m. and track was cleared in good time by ten a.m.

July 1st.—Old 63-foot span removed and spans 0^1-1^1, 1^1-2^1 and 2^1-3^1 put in, together with their bents. Time occupied—five hours.

July 4th.—Old 63-foot span removed and spans 3^1-4^1, 4^1-5^1 and 5^1-6^1 put in, together with their bents and bracing. Time—five hours.

July 8th.—Old 84-foot centre span replaced by new spans 6^1-7^1, 7^1-8, 8-7 and 7-6. Time—five hours.

July 10th.—Old 63-foot span removed and new spans 6-5, 5-4, 4-3 put in, together with their bents and bracing. Time—five hours.

July 15th.—Old 63-foot span removed and new spans 3-2, 2-1 and 1-0 put in, together with their bents, bracing, etc. Time five—hours.

July 17th.—Removed old 84-foot span and put in new spans O-X and X-7. Time—five hours.

This was the final operation involving breaking of track and, as this end of the bridge has some curved alignment on it, there was considerable preparation and many small adjustments to be made during the work, which, however, were completed without delaying passenger trains.

An account of these difficult operations would not be complete without reference to the fact that the seven breaks of track just described involved the removal and transportation along the track of old truss spans, some of the single pieces of which weighed twenty tons. Had there been any failure of tackle or equipment the results would have been serious, it can readily be seen, for the arch trusses and their bracing, and, incidentally, for the traffic of the railway company. It is not too much to say that the men responsible for the organization and erection outfit are to be congratulated on the fact that all this hazardous work was accomplished without mishap to men or equipment.

A deformation diagram (under dead load only) of the trusses indicated that there should be about ⅝ inch deflection at the centre pin. That is to say, the unloaded new arch trusses should have been relatively ⅝ inch higher at their centres than the old ones when first erected, without the dead load which should come to them by reason of the track spans, bents and other attachments. This was realized almost to a fraction by the accuracy of the layout of the skewbacks. It is hardly necessary to point out that it was extremely difficult to lay out this work and to attain precisely the required distance back to back of skewbacks across this 336-foot air line.

As before stated, there were brackets attached to certain panel points of the outer trusses, as shown in one of the slides, on which 115 tons of rails were distributed, this

Figure No. 8.—View showing Temporary Loading of New Arch Ribs with Old Rails before attaching to Old Arch Ribs.

Figure No. 9.—Erecting Track Spans between Trains.

being the estimated amount of the dead load included in the track span, bents, etc. coming to each of the arch trusses. When this dead load was put upon the new arches they behaved identically; that is to say, they deflected an equal amount, namely ⅝ inch as expected by the deformation diagram originally calculated in the drawing office. After deflecting they were securely rivetted together by means of the distributing beams and other details previously decided upon. In order to make sure that the loads were being shared by the trusses as expected a final test was made of the bridge on August 21st, 1929, as shown in figure No. 10, using four of the heaviest engines available, namely,

	Class	Weighing	Total
C.P.R. Engine No. 5768	R-3-c	230 tons	1100 tons
" " " 5900	T-1-a	376 tons	approxi-
" " " 5808	S-2-a	268 tons	mately
" " " 5770	R-3-c	230 tons	

These four engines just about covered the 336-foot arch span, with a slight overlap, and the observed maximum deflections in the centre of the arch were 1-66 inches or 1⅝ inches. While the deflection of the new north arch rib was slightly less, those of the other three were reasonably uniform. It is a fact, however, that the unreinforced arch under ordinary traffic, which was usually composed of double headed engines weighing 230 tons each at a customary speed of 10-15 miles per hour, deflected 2¾ inches, whereas after the reinforcement of the structure the deflection under a standing load of the four engines was only 1⅝ inches.

It is also interesting to note that the aggregate weight of four engines used in the test load of 1929 was almost exactly double that of six engines in 1893.

The field work was commenced in April, 1929, and completed in August, thus occupying less than five months.

The contract for the manufacture and erection of the reinforcing arch ribs, new bracing, and new track spans was entrusted to the Canadian Bridge Company, of Walkerville, Ont., Mr. F. W. Parr being in immediate charge of the work in the field under Mr. Chas. Prettie, superintendent of erection for the Bridge Company, and E. Chorolsky, S.E.I.C., as field engineer.

For the railway company, J. M. R. Fairbairn, M.E.I.C., chief engineer, was responsible for the work as a whole.

The scheme of reinforcing the structure in the manner described was developed and designed in the bridge department of the Railway under the supervision of the author, with A. R. Ketterson, A.M.E.I.C., assistant engineer of bridges, in direct charge.

Discussion

P. L. Pratley, M.E.I.C.[(1)]

Mr. Pratley remarked firstly that the applause indicated a general agreement with his own view that the members present had listened with interest to a most entertaining presentation of a very important piece of bridge engineering. He was sure there would be many members in the audience who would wish to take advantage of the author's offer to answer intelligent inquiries and expand special details. Personally he found a very interesting feature in the references to two famous bridge engineers of the past half century who had been associated with the earlier structures at Stoney Creek, namely, Mr. C. C. Schneider who built the first wooden bridge there, and Mr. H. E. Vautelet who as Chief Engineer was responsible for the original arch construction. They were indeed outstanding men in the profession, and he wished to pay his tribute to his old Chief, Mr. Vautelet, whom he regarded as perhaps the most capable and scientific engineer we had had in Canada, and who had left his mark not only in the vast Canadian Pacific system but also in the Quebec Bridge. The author had shown them some most instructive views of the old arch and the methods of building it, and had followed with equally interesting illustrations of the means adopted for retaining it, while adding new trusses alongside. Doubtless many bridge engineers would find points of interest in the field conditions and the design of the new work, which might now be presented as discussion on the paper.

(1) Monsarrat & Pratley, Consulting Engineers, Montreal.

Figure No. 10.—Official Test, August 21st, 1929.

J. A. McCrory, M.E.I.C.[2]

Mr. McCrory asked the author to outline in a little more detail the means adopted for loading the new arches in order to impress upon them dead-load stresses and deflections equal to those existing in the old.

P. B. Motley, M.E.I.C.[3]

The author replied by recalling the appropriate slides and indicating the bundles of rails applied at the panel points for this purpose.

F. P. Shearwood, M.E.I.C.[4]

Mr. Shearwood complimented Mr. Motley and the Canadian Bridge Company on the successful accomplishment of a very ticklish undertaking. He remarked on the soudness of the principle governing the choice of material and enquired how closely the new steel approached the old in its physical and chemical properties. He also asked whether the duplication of the old detail was so thorough as to involve similar thimbles to those previously used, noting that while these were an essential part of Mr. Vautelet's erection scheme, they would serve no useful purpose in the new arch. Mr. Shearwood made further reference to the work of Mr. Vautelet and the late Mr. Schneider, remarking on the very sound and practical views held by the latter on all matters of bridge construction. He pointed out that Mr. Schneider's specifications were still the basis of the best bridge practice on this continent. A third notable figure who appeared on some of the old views was Mr. James Finley, one of the best known and most widely experienced erection superintendents that this country had ever seen. He was a genius in his line and was still well remembered by many present, although it was now some years since he had joined the great majority.

P. B. Motley, M.E.I.C.

The author in answering the inquiries repeated that the steel was substantially the same in physical properties as that used by Mr. Vautelet. While they had not been able to definitely establish the precise specifications to which the old material had been rolled, they did possess reliable information as to the type of steel being made and used at that time. The thimbles and other details of the old arches had all been faithfully reproduced by the Canadian Bridge Company in accordance with the general understanding to make the new arches as exactly as possible duplicates of the old.

P. L. Pratley, M.E.I.C.

Mr. Pratley then asked whether any difficulty had arisen at the rolling mills in connection with securing the new steel to an old specification, but was advised that no particular trouble had been experienced in obtaining a grade very close to that requested.

R. S. Eadie, A.M.E.I.C.[5]

Mr. Eadie, referring to the loading scheme, asked whether, in view of the fact that the new arch was connected up to the old and participated in carrying the actual dead-load and the train loads before the bundles of rails had been removed, the new arch did not for a time carry practically twice its normal dead-load.

P. B. Motley, M.E.I.C.

The author admitted that this was the case for a short period until the rails could be removed, but that with the trains under careful speed control, the excess load was hardly noticeable. Very few trains passed over until normal conditions had been established.

D. C. Tennant, M.E.I.C.[6]

Mr. Tennant after some general remarks on the classification of engineers and the importance of the Canadian Pacific Railway as a transportation system, enquired whether any actual tests of the old materials had been made with a view to establishing its properties and its metallurgical condition after thirty-six years' service. The answer was in the negative, as Mr. Motley and his staff had not wished to disturb the old structure, even to the extent of replacing lattice-bars or gusset plates from which, conceivably, such test specimens would have been cut. Mr. Tennant also made reference to the economic aspect, alluding to the statement in the paper that an alternative site for a new span had been chosen first and then abandoned. He enquired whether the use of the old span to carry half the track and live-load would not in any event have been the economic procedure, even admitting some increase in the unit erection costs.

P. B. Motley, M.E.I.C.

The author replied that while the method adopted had of necessity been expensive in various particulars, there was quite a satisfactory general economy, having regard to the substructure difficulties that would have arisen if the alternative site had been persisted in.

P. L. Pratley, M.E.I.C.

Mr. Pratley next asked whether any scheme of converting the 3-hinged arch into a 2-hinged arch had been inquired into. He quite realised that the upper chord and web members were light compared to the lower chord, and that any such consideration would have to take account of the actual sections of these members.

A. R. Ketterson, A.M.E.I.C.[7]

Mr. Ketterson rose to explain that any interference with the old arch was considered unwise as, apart from the difference in section of the upper and lower chord, it would have introduced new conditions, whereas the object had been to maintain the same relative stress distribution in the old arch as far as practicable.

F. P. Shearwood, M.E.I.C.

Mr. Shearwood added a further remark on the disparity between the sections of the upper and lower chords, and the consequent unsuitability of the old arch for conversion.

P. L. Pratley, M.E.I.C.

Mr. Pratley stated that the only possible procedure would have been to introduce by jacks a predetermined stress into the top chord, dependent on its figured capacity, as was done at Niagara. He felt satisfied, however, that such attempt at conversion would not have proved of practical value under the circumstances, and it was evident that the better solution was the duplication method actually adopted.

J. W. Seens, A.M.E.I.C.[8]

Mr. Seens, President of the Canadian Bridge Company, offered some observations on the erection work, remarking on the hazardous experiences of the men concerned and the fortunate freedom from accident. He congratulated Mr. Motley on the delivery of a very fine description of the undertaking and moved that the thanks of the meeting be accorded the author in the usual way.

P. L. Pratley, M.E.I.C.

Mr. Pratley then put the vote which was carried with hearty applause, and the author in replying expressed his hope that the members would realise how much he owed his staff, of whom several were present at the meeting, and how much had depended on the co-operation of the contractors. He closed by suggesting that in years to come it would be a matter for legitimate pride to be able to say that one had been connected with this unique and effective piece of bridge engineering at the third construction of the Stoney Creek arch.

Load Ratio Control

C. E. Sisson, M.E.I.C., Works Engineer,
Canadian General Electric Company, Davenport Works, Toronto.

Paper read before Montreal Branch of The Engineering Institute of Canada, February 27th, 1930.

In speaking of the process or operation of controlling load ratio we have in mind changing the voltage ratio of a transformer or transformers without interrupting the load. It is also referred to as "tap changing under load," although with the modern load ratio control equipment described below it will be noted that in shifting from one tap to another, no load is carried by the contacts used, the current having been interrupted on the operating section of the equipment by a circuit breaker of some sort before any movement of the contacts begins.

Application

The applications of this equipment fall into three general classes: (1) control of voltage; (2) control of reactive kv.-a.; (3) control of power flow in loops.

Control of Voltage

The rapid development of the use of electrical energy in industrial processes has given rise to the need of equipment for regulating the voltage applied, without interrupting the current flow. Especially is this true where the voltage range is very great. Such applications are found in electric furnaces, in the electrolytic refining of metals, etc. It has also been found desirable to employ this type of equipment, in order to maintain constant voltages at the distribution end of large systems, although in the case of isolated or independent systems this result can usually be obtained by other means more economical and sufficiently suitable.

Control of Reactive Kv.-a.

By far the most important application of load ratio control is in tying together two or more power systems or stations. It is not so very long since power systems or stations of the same power company were operated entirely independently. However, with the rapidly increasing demand for greater volumes of power, additional stations of the same system were developed and in order to insure reliability of service and improve the load factor, were tied together. Similarly it has been found advantageous to interconnect different systems in greater networks. Such interconnection of stations and systems has brought with it many problems of operation which have created a demand for control equipment other than that already available, for example, field rheostats, synchronous condensers and induction regulators. It is not the purpose of this paper to make lengthy comparison between load ratio control equipment and induction regulators or synchronous condensers except to point out that outside of certain peculiar conditions, the more recently developed equipment has been found more economical so far as space occupied or cost of installation and operation are concerned; and has been found entirely reliable.

When two systems are tied together by an intervening transmission line there are possibly and probably three elements to be controlled:—

(a) The division of energy between the two systems.
(b) The voltage at the busses.
(c) The division of the wattless kilovolt-amperes.

Due to local distribution it is usually desirable to maintain constant voltage on the busses independent of the variation and distribution of the load throughout the system. The adjustment of current between systems is necessary in order to obtain either the maximum economy of operation or the most desirable utilization of equipment. However, when two systems, having their voltages maintained at slightly different levels, are tied together, sufficient lagging current will flow through the reactance of the tie line to absorb the voltage difference in line drop. This lagging current may be highly undesirable especially as it may flow in the opposite direction to the flow of power and thus add to the burden on the generating station.

The division of energy is determined by and can be controlled by the characteristics and regulation of the prime movers. The voltage may be regulated by the field currents, as can also the power factor of the line and the division of wattless current. But while these two quantities may be separately controlled by field they cannot be simultaneously regulated. We, therefore, are compelled to be satisfied with field control of line power factor and one

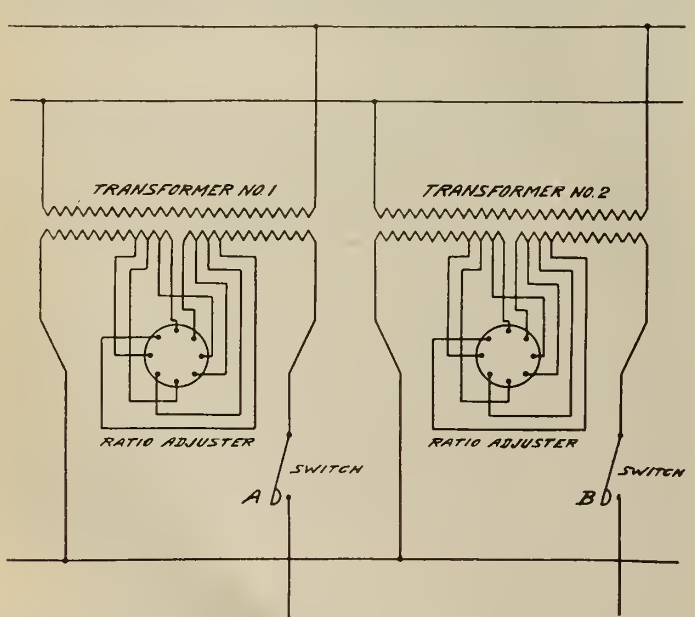

Figure No. 1.—Load Ratio Control using Two Transformers.

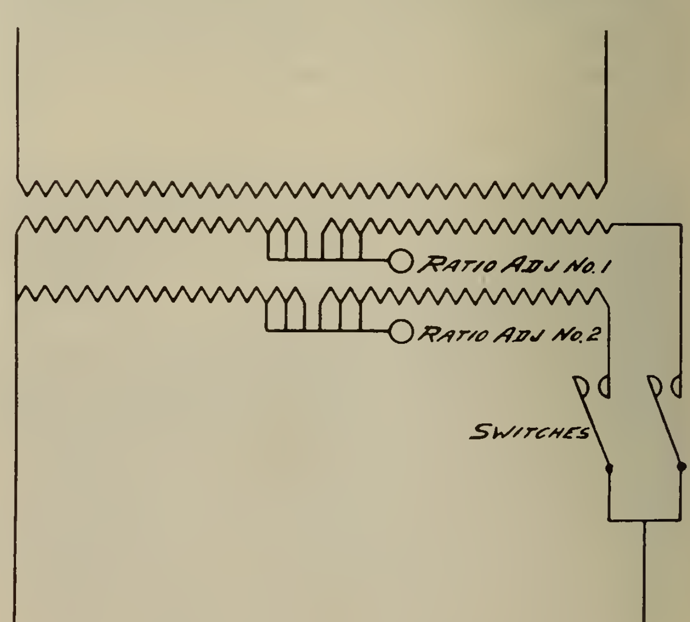

Figure No. 2.—Load Ratio Control obtained by using Two Circuits in Transformer Winding.

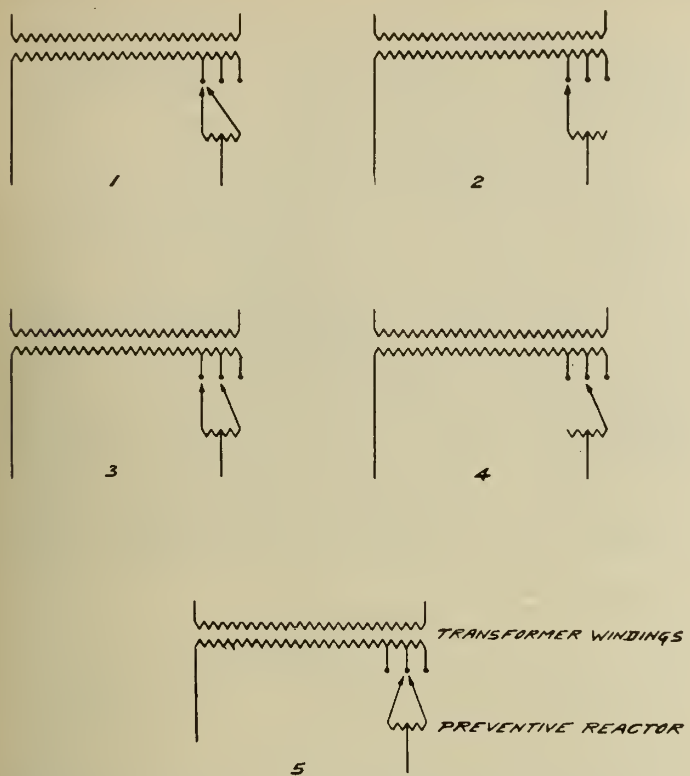

Figure No. 3.—Sequence of Positions for One Change of Ratio.

voltage or of both voltages ignoring the power factor or as a third alternative to introduce some means of assisting the field control. This is accomplished by inserting some variable ratio between the systems, which takes care of the division of wattless current, leaving the voltage control to be taken care of by field regulation. By this means the wattless current may be increased, eliminated or reversed at will, in order to secure the best operating conditions. Inserting such a ratio of transformation in a tie line is equivalent, in its effect on the flow of reactive current, to raising or lowering the voltage on one of the two systems. This scheme can be extended to any number of stations operating on a line, so that by installing one voltage control equipment less than there are stations it is possible to maintain the bus voltage constant at all stations and at the same time obtain the desired current in any part of the line.

Phase Angle Control of Power in a Loop

If, however, we have parallel lines of different characteristics or high voltage loops, a new problem presents itself, in the solution of which the same type of equipment can be employed to provide phase angle control as well as power factor control.

If the currents in the different sections of the two branches of a loop are to be independently variable a resultant voltage will probably exist between the two ends, if the loop is opened. This resultant voltage is the summation of the impedance drops in the different sections, and varies in magnitude and in phase depending upon the variations in the currents in the lines. If the loop is closed a circulating current flows around the loop equal to the voltage between the open ends divided by the complete line impedance. This circulating current alters the total current in different sections of the line and may or may not be sufficient to be objectionable.

If the ratio of the resistance to the reactance in every portion of a loop is the same, and therefore equal to the ratio of the total line resistance to reactance, the currents will divide to give minimum copper losses in the line. This will rarely be found to be the case, but it may be found sufficient and desirable to readjust the lines by the use of reactors. If the line is naturally properly balanced or sufficient adjustment is obtained by the addition of reactors, the necessary flexibility of operation, at minimum line losses, and including local distribution at fixed voltages from each station bus, can be obtained by installing power factor control on the transformers connected to the loop.

However, it may be found that in order to secure the flexibility of current necessary to insure against overloading of parts of the system, such as cables and transformers, phase angle control accompanied by power factor control offers the most satisfactory solution. What is necessary is to introduce into the line a voltage which is always equal to but opposite to the resultant voltage between the ends of the open loop. As this voltage will vary both in value and in phase depending upon how much the currents in the line vary, the control equipment must be adjustable. We, therefore, employ two ratio control equipments, one providing the proper in-phase and the other providing the proper quadrature voltage; these equipments operating independently of each other. It is possible to combine the two into one outfit, arranged, however, to give independent control of power factor and phase angle.

A 20 per cent range in ratio, in the form of 10 per cent boost and 10 per cent buck, when connected in circuit 90 degrees out of phase will give a range in phase angle of approximately 6 degrees each side of normal.

Development of Ratio Control Equipment

Early in the history of transformer design and manufacture the possibility and desirability of placing taps in the winding became evident, and with a growing appreciation of the flexibility of this type of apparatus, there has developed a desire to increase the availability of these taps. The designer, although opposed in general to the addition

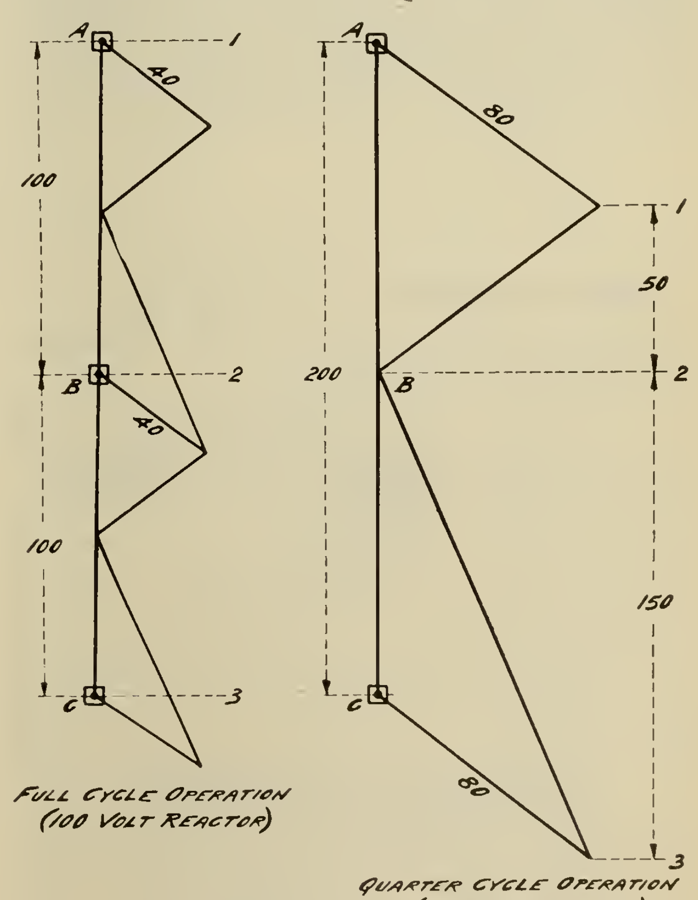

Figure No. 4.—Diagram showing the Voltage Derived during Ratio-Changing under Full Load at 80 per cent Power Factor with a Circulating Current of 60 per cent Full Load in the Preventive Reactor.

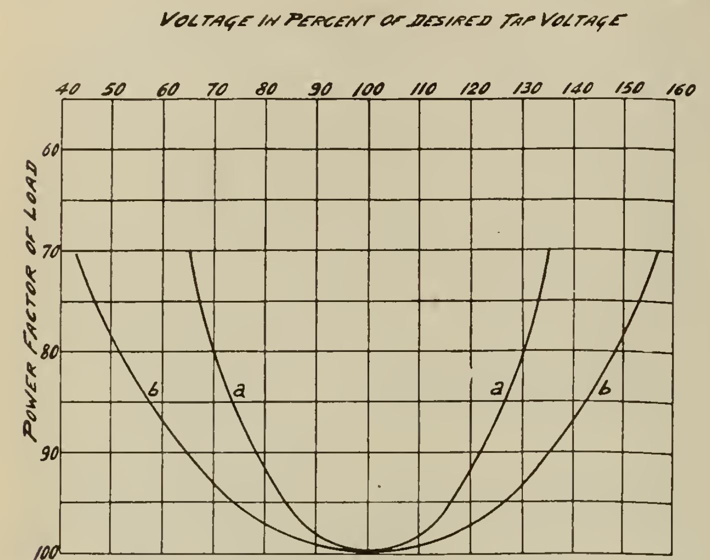

Figure No. 5.—Unequal Voltage Steps Resulting from Quarter Cycle Operation at Full Load.
Curve "aa"—reactor designed for 100 per cent circulating current.
Curve "bb"—reactor designed for 60 per cent circulating current.

of taps in the transformer windings, has long since accepted them as inevitable and reserves any vestige of opposition he may have left, for those cases when some decidedly objectionable features of manufacture would result, if the taps asked for were accepted. In the early development, these taps were brought to a terminal board with movable links for changing connections, it being necessary to disconnect the transformer from service and open the handhole in order to change the ratio. Only average operating conditions were provided for, and changes were seldom made. The necessity for changing taps more frequently, led to the development of the ratio adjuster with its operating handle brought outside of the tank, but

SWITCH CLOSED-O

Figure No. 6.—Method of Obtaining Eleven Ratios from Six Taps Quarter Cycle Operation.

it was still necessary to take the unit out of service during the operation of the tap changer. As the necessity for making these changes became daily rather than seasonal, we were led to the study of ways and means of changing taps without interrupting the load.

It will be recalled that many years ago a device was developed for changing the ratio by means of taps brought to a dial-head which was manually operated at will. The section of winding between taps was short-circuited through a reactance during the transition from point to point. Some similarity will be noted between this scheme and those described below. This scheme was only used in relatively small capacities and since the induction regulator was being developed about the same time and with comparatively small loads to be taken care of, the regulator satisfactorily handled the situation and dominated the field. However, there has been a very rapid increase in the kv.-a. capacity of central stations and simultaneously in transformer banks, with the accompanying natural increase in voltage, which, along with the tendency to connect these

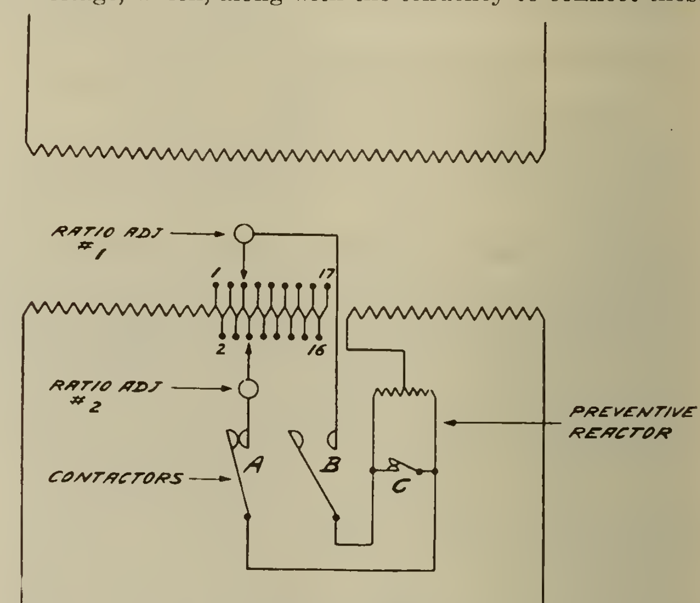

Figure No. 7.—Method of Obtaining Seventeen Ratios from Seventeen Taps.

stations into networks, has given rise to voltage control devices in larger units. In making comparison on a cost basis it will be found that for small loads and lower voltages the induction regulator has an advantage, but the situation is quite the reverse as the capacities, and particularly the voltages to be regulated, become greater. The neutral point from an economical point of view is reached when the capacity of the induction regulators per bank is between 300 kv.-a. and 500 kv.-a. depending upon the voltage involved. There is no definite upper limit to the present type of load ratio control application either of kv.-a., voltage or current, although in some cases, more particularly in tie-in banks, it is necessary to use series transformers and sometimes also exciting transformers to keep within the voltage or current limitations of available or more desirable apparatus. Reference is made to some of these special requirements later.

Theory of Load Ratio Control

Load ratio control, of any type, involves the use of two local circuits capable of carrying the load simultaneously. This permits picking up the load on one ratio before it is dropped from another. Obviously, carrying a load simultaneously on two tap connections would involve a destructive short circuit between those taps unless suitable impedance was introduced to limit the exchange current. All types of load ratio control include such an impedance, either in the form of leakage reactance between special

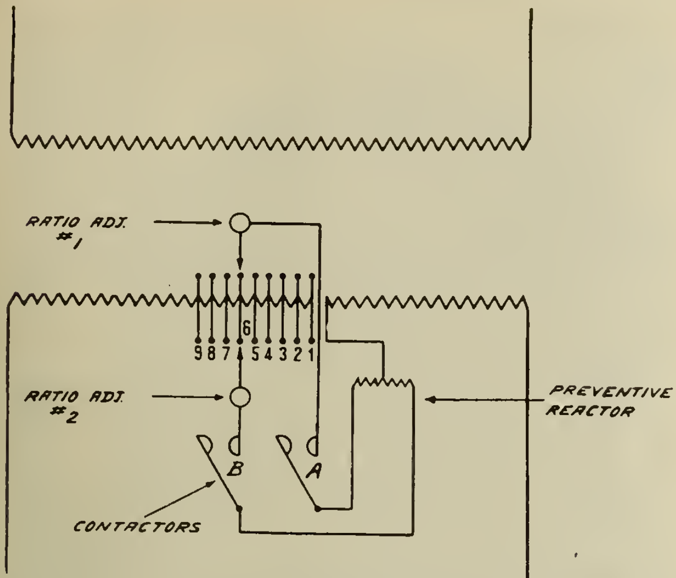

Figure No. 8.—Method of Obtaining Nine Ratios from Nine Taps Full Cycle Operation.

windings on the transformer core, or of a separate iron core reactor.

Perhaps the first method to suggest itself in the consideration of load ratio control was the use of two similar transformers operating in multiple, each equipped with some form of tap changing switch and the two so arranged that each may in turn be cut out of circuit momentarily to permit change of taps, the load being carried by the other during this interval. Such an arrangement is represented in figure No. 1, where transformers Nos. 1 and 2 are operating in parallel, and each is provided with a ratio adjuster. A tap change may be made without dropping the load by first opening circuit breaker *A* which shifts the load from transformer No. 1 but does not remove the excitation, since the high-voltage side is still connected to the line. The ratio adjuster in transformer No. 1 can now be moved to the next position, after which the circuit is again closed. The two transformers are now operating, with unequal ratios, in parallel; and a circulating current which is limited by the inherent reactance of the transformers will flow between them. Next, circuit breaker *B* is opened and the ratio adjuster of transformer No. 2 moved to its next position. When circuit breaker *B* is closed, the two transformers are again operating under normal conditions, but with a changed ratio.

It is important to note that when one of the breakers is open, the voltage which exists across the open breaker is

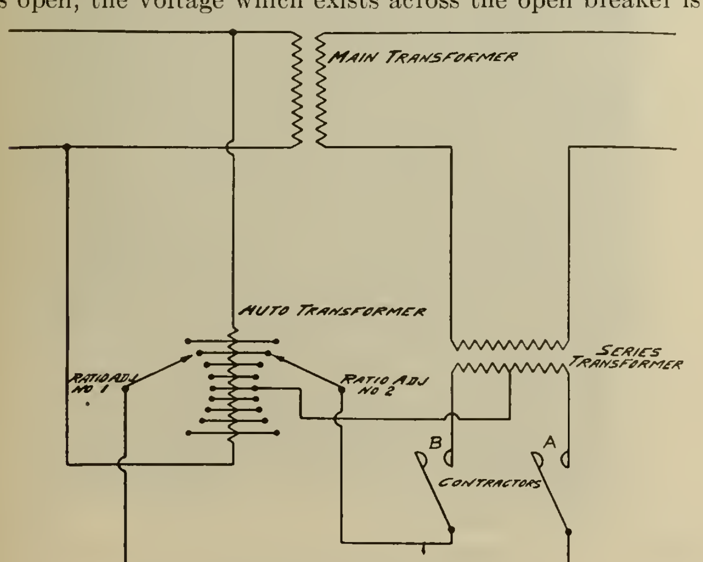

Figure No. 9.—Regulating Transformer.

not the line voltage, but a very small fraction of it, owing to the fact that the disconnected transformer receives excitation from the high voltage side. The greatest voltage which the breakers are obliged to open is equal to that arising from the difference in ratio of transformation of the two transformers plus the impedance drop of the loaded one.

The above method of tap changing is not entirely satisfactory, because the doubling of the load on one transformer, during the switching period, doubles the impedance drop, which results in an undesirable fluctuation in secondary voltage. Thus with 10 per cent transformer reactance at full load, the reactance drop is increased to 20 per cent, which is several times the voltage between adjacent taps.

We turn, therefore, to a single transformer, figure No. 2, which has been designed with a multiple circuit, each circuit, as in the case of the two transformers being provided with a ratio adjuster and arranged so that it may in turn be cut out of circuit. The reactance between the multiple circuits can now be controlled independently of the main transformer reactance, and it can be made small enough to prevent objectionable fluctuations in voltage during the

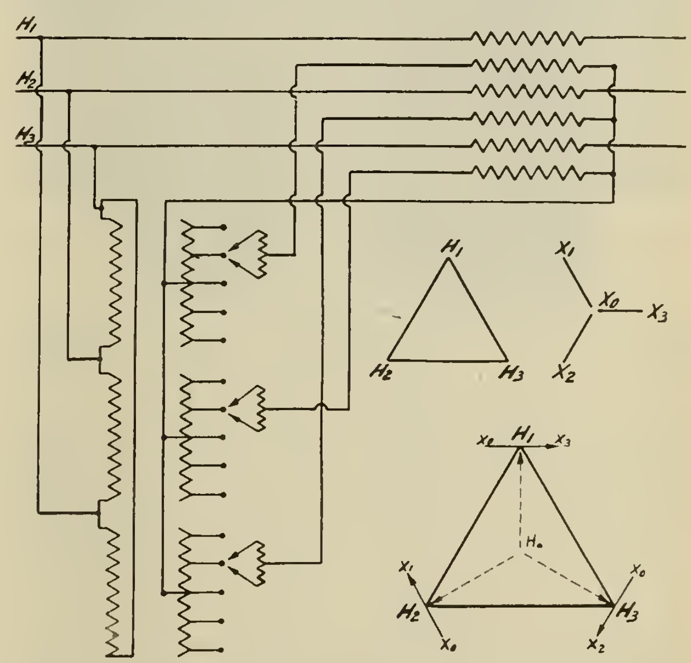

Figure No. 10.—Tap Changing for Phase Angle Control.

process of switching, keeping it at the same time large enough to prevent excessive circulating current.

This method, although in many respects desirable, is also open to two inherent objections. In the first place, it is often the case that the transformer design does not lend itself readily to a multiple circuit without appreciable increase in cost, and secondly, since during the process of switching, transformer full load is momentarily thrown on one half of the winding, in the very remote possibility of the operating motor failing to complete its cycle, this load may be present for a sufficient time to seriously overheat the windings. To provide against this contingency would mean the design of windings with an appreciably greater cross-section of copper, again at a corresponding increase in cost.

The practical consideration, therefore, of these methods has led us, in many cases, to depart from the simple arrangement just described and to adopt an arrangement where only a small portion of the circuit is in multiple. In figure No. 8 is shown an arrangement where the multiple circuit consists only of the ratio adjusters, the circuit breakers and an auxiliary reactance, which has been termed "the preventive reactance," provided to limit the circulating current.

Such an arrangement lends itself, in general, to three

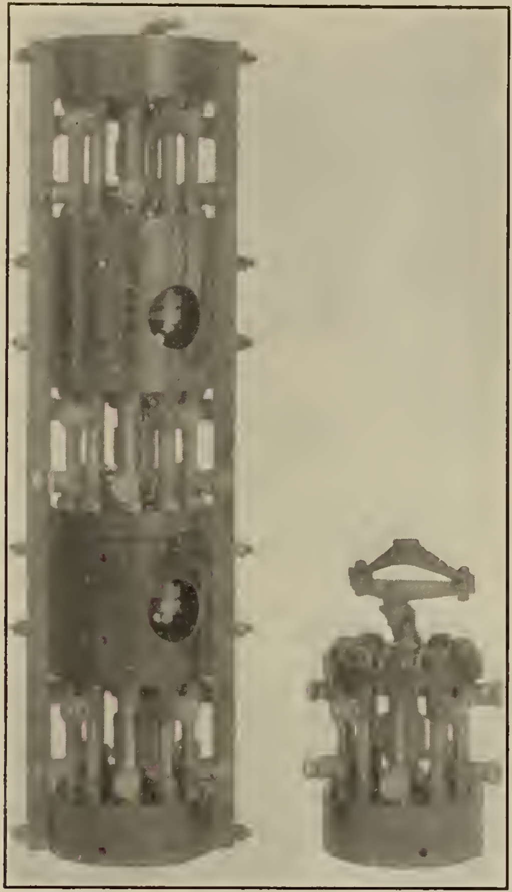

Figure No. 11.—600-Ampere, 10-Point Star Crab Ratio Adjuster—Three-phase Stack and Single Phase.

different schemes of operation which may better be explained by referring to figure No. 3. Here it will be noted that one lead of the transformer is taken from the middle point of the so called preventive reactor. The ends of this reactor are arranged so that they may be connected to any of the several taps, brought from the transformer winding, through some form of tap changing switch. Sketches 1 to 5 indicate the five progressive steps necessary in passing from one tap of the transformer to the next. It will be noted that in steps 1 and 5, both ends of the reactor are connected to the same tap. The reactor is, therefore, short circuited and has no appreciable effect on the voltage obtained from that tap. They are the points of full cycle operation. In either position the reactor core is not excited and does not add any loss to the transformer. These are, therefore, the desirable points of operation, and except perhaps in cases where a very large number of taps are required, are the only operating points used in Canadian General Electric Company apparatus.

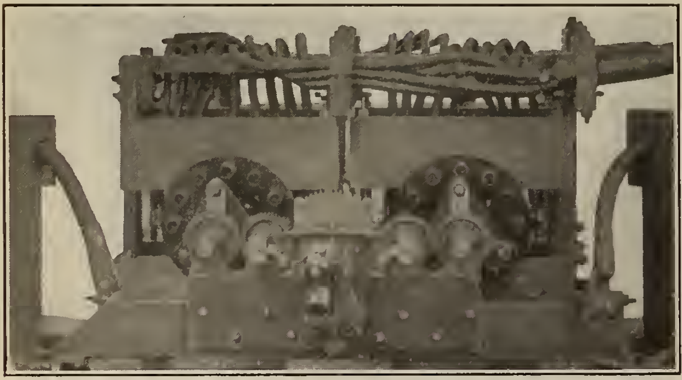

Figure No. 12.—Intermittent Gear and Ratio Adjusters for Load Ratio Control.

Step 3 places the reactor across two adjacent taps of the transformer. The voltage obtained is approximately half-way between that of the two taps. In this position the reactor is fully excited and increases the no load loss and reactive load on the system. This is not a desirable point of operation.

In the case of steps 2 and 4 one-half of the reactor winding is in series with the tap, thus somewhat increasing the regulation drop. Points 2 and 4, therefore, known as quarter cycle operation, should be used only in very special cases. Full cycle operation gives equal steps in voltage at any power factor. Figures Nos. 4 and 5 indicate how far from equal these steps may be in the case of quarter cycle operation.

Perhaps the simplest method of using the preventive reactor in obtaining load ratio control suggests itself in figure No. 6. Here the ends of the reactor are arranged so that they may be connected to the several taps by means of a set of switches which may be operated singly or in pairs in progressing from one tap to the next. Figure No. 6 indicates the various steps used in obtaining eleven ratios from six taps. This method is open to all the objections of quarter and half cycle operation and should, therefore, be avoided.

Figure No. 7 illustrates a method of load ratio control particularly designed to take care of a large number of taps. Here use is made only of the quarter cycle points as indicated

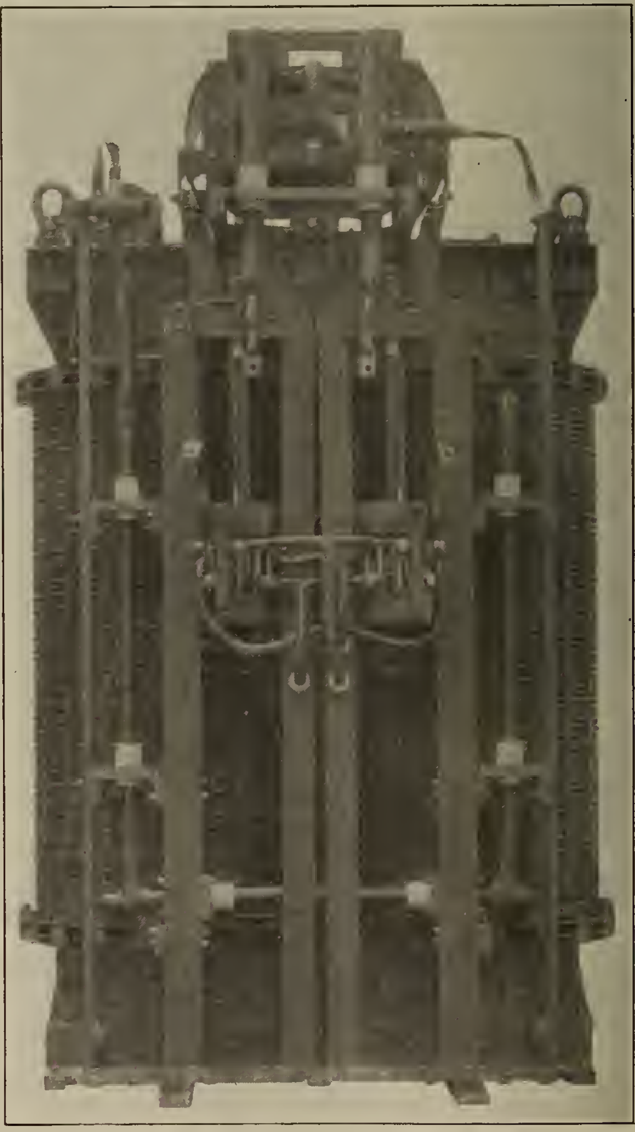

Figure No. 13.—Assembled Core and Coils with Reactor on Top with Type LR-9 Load Ratio Control.

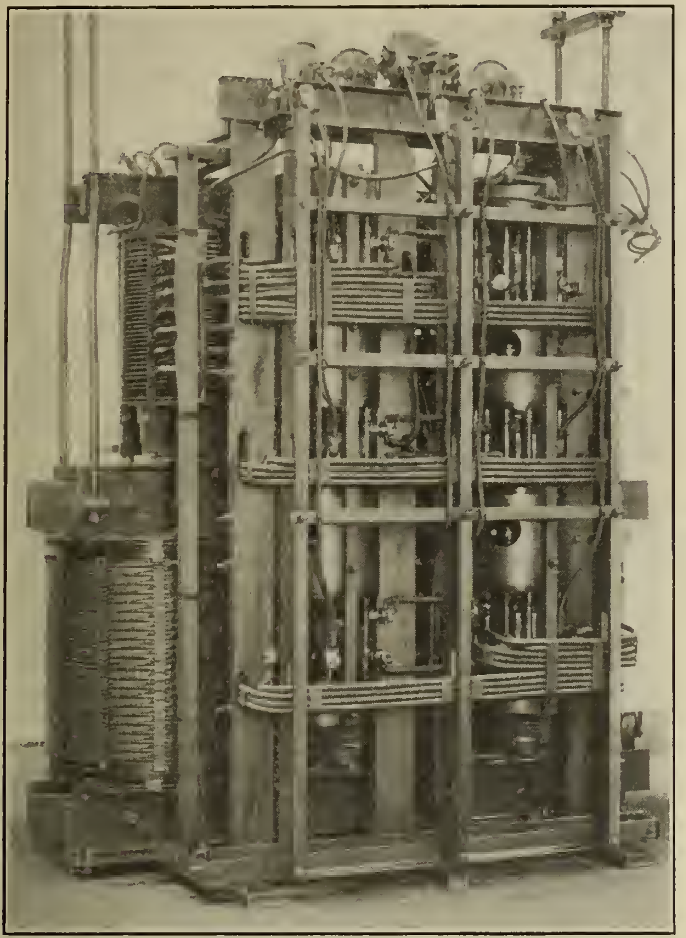

Figure No. 14.—Type LR-9 Load Ratio Control Regulating Transformer—Assembled Core, Coils and Control.

in sketches 2 and 4 of figure No. 3 but the objectionable features of the reactor are to some extent overcome by the addition of switch *C* which short-circuits the reactor on all operating points, this switch being open only during changing of taps.

And now we come to load ratio control in what is

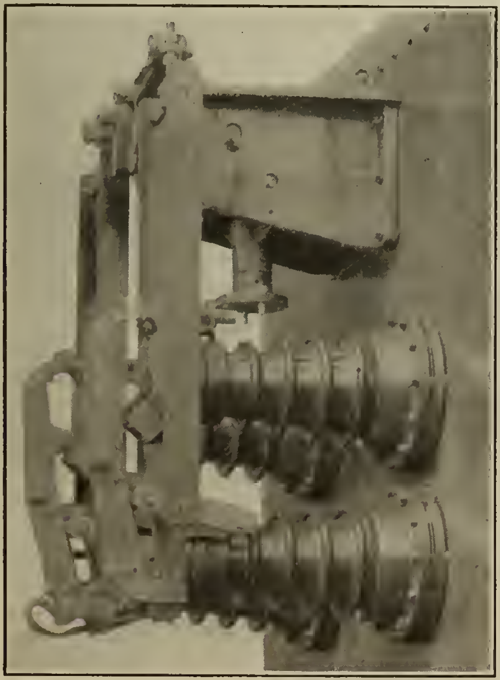

Figure No. 15.—Contactors for Transformer Load Ratio Control, Type LRS-9, 73-Kv.

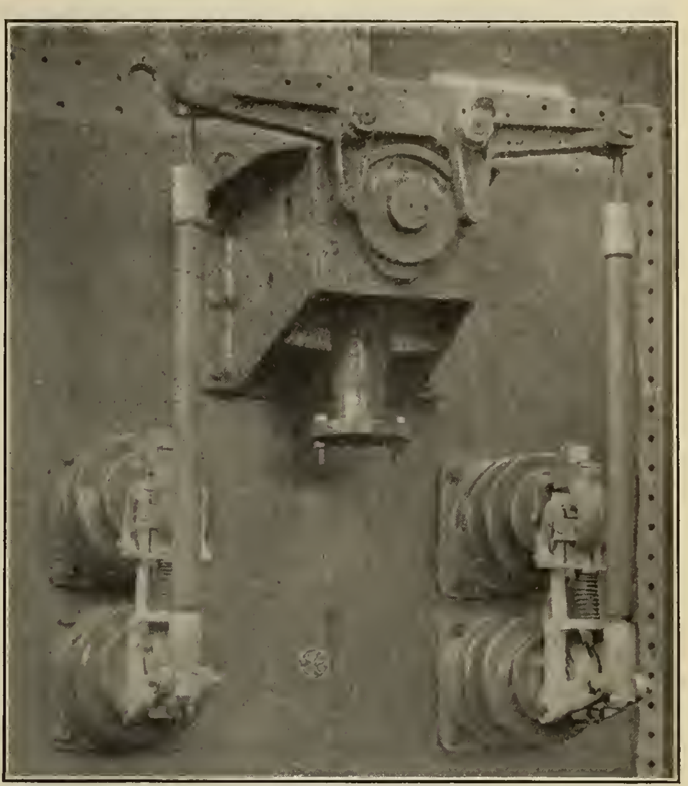

Figure No. 16.—37-Kv., 1,000-Amp., Single-phase Contactors for Type LR-9 Load Ratio Control.

believed to be its most satisfactory form of development in apparatus which makes use only of the full cycle points of operation as indicated at 1 and 5 in figure No. 3. Figure No. 8 is typical of load ratio control as applied to C.G.E. transformers of low and moderate voltage. Here the preventive reactor is connected through contactors to two ratio adjusters, the whole being positively geared to a common driving shaft and designed to complete the cycle shown in figure No. 3 for each change of tap. In changing from tap 6 to tap 5 therefore the following order is followed—

Contactor *A* opens—ratio adjuster No. 1 moves to tap 5—contactor *A* closes.

Contactor *B* opens—ratio adjuster No. 2 moves to tap 5—contactor *B* closes and the cycle is complete.

It will be noted that since both sides of the reactor are connected to the same tap while in an operating position the only voltage which appears across it is due to the leakage reactance between the reactor halves, and this may be made negligible by interlacing the reactor windings. The load current divides equally between the two halves.

Where high voltages are involved a modification of this arrangement is necessary as illustrated in figure No. 9. Here variation in voltage is obtained from an auto-transformer which is designed with a number of taps symmetrically arranged on either side of its centre. This auto-transformer provides excitation through the necessary ratio adjusters and contactors to the primary winding of a series transformer. The cycle of operation is exactly similar to that just described. No preventive reactor is necessary since the primary of the series transformer replaces it. The series winding which may readily be insulated for any desired operating voltage is placed in series with the system and provides the tying link between the tap changing mechanism and the high voltage circuit. The auto-transformer may be excited from the low voltage winding of the main transformer or from any other source which is in synchronism with it; or it may, if desirable, be provided with a separate primary winding designed to take power at any convenient voltage.

Equipment similar to that just described in connection

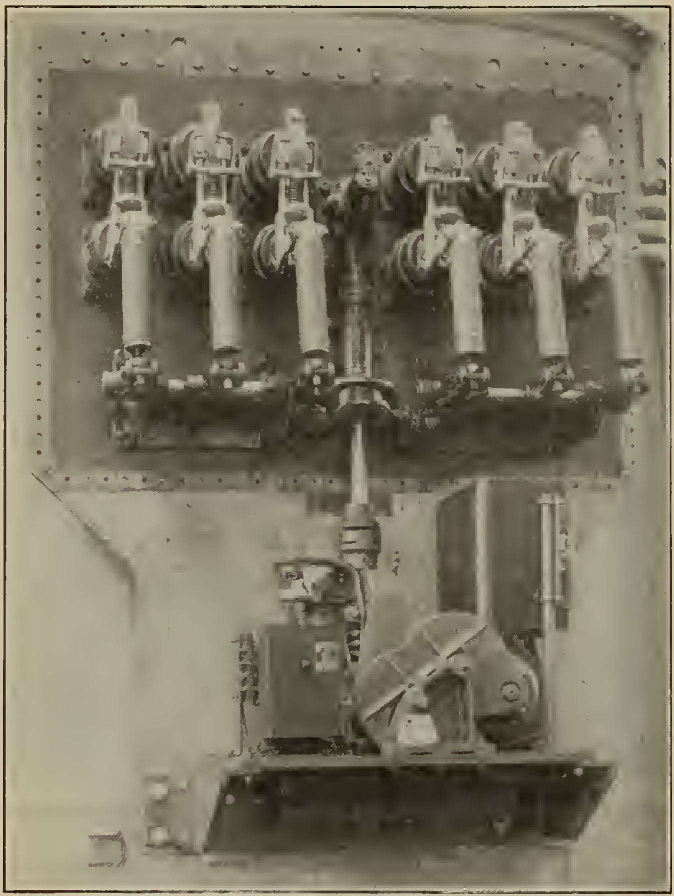

Figure No. 17.—Contactor Panel and Motor Drive for LRT-9-15 Kv., Oil Tank and Motor Housing Removed.

with figure No. 9 may readily be adapted to phase angle control by so interconnecting the auto-transformers with the series transformers that the regulating voltage is at right angles to the system voltage. Figure No. 10 illustrates this equipment when so arranged. It will be noted that the regulating voltage X_0X_1 is at right angles to the system voltage H_0H_2 etc.

Mechanical Equipment

In determining upon standard equipment for load ratio control the following features have been given careful consideration:—

(1) As far as possible standard and proven apparatus should be employed.
(2) This apparatus should be selected so as to provide as wide a range of application as possible with a minimum amount of detailed changes.
(3) The equipment should be made simple of operation and suitable for either hand or remote control.

With these objects in mind the modern equipment consists of:—

(1) Transformers with taps which are by this time thoroughly familiar to everyone.
(2) Two ratio adjusters connected to the transformer taps.
(3) An intermittent gear for operating these adjusters.
(4) Two cam operated oil immersed contactors.
(5) A motor driving mechanism.

The ratio adjusters which may be arranged either for single or three phase are shown in figure No. 11. They are quite suitable for motor drive, and in operation, the driving mechanism turns first one and then the other to an adjacent position, at the same time holding the corresponding contactor open during the movement of each adjuster. It will be noted that these ratio adjusters operate by means of an eccentric, so that with a light torque on the shaft a heavy pressure is placed on the contacts as they wipe into position. The cylindrical bars to which the taps are connected are insulated with herkolite tubes where they pass through the moulded compound head.

Figure No. 12 shows an intermittent gear for driving these adjusters. It is designed to pick up each ratio adjuster in succession without shock and to lock it in position at all other times. There is a universal joint between the gear and the tank wall. Since the number of operations that this equipment is subjected to is not likely to be more than say 3,000 per year, practically no mechanical deterioration takes place during the entire life of the transformer. This intermittent gearing is placed inside of the transformer tank proper. Figure No. 13 shows an assembled core and coils with the preventive reactor, while figure No. 14 shows the interior of a regulating transformer used on high voltage system. It will be noted that both the series and exciting transformers are shown.

Figure No. 15 shows a 73-kv. contactor and figure No. 16 a 37-kv. contactor. They are mounted in a chamber on the side of the tank and are completely immersed in oil, but this oil is entirely separate from that of the transformer proper. Since the taps are changed by the ratio adjusters instead of the transformer tank it is only necessary to have two contactors, one in series with each ratio adjuster. This reduces the number of bushings through the tank wall as well as the voltages in the contactor box. Provision is made for inspecting or replacing the arcing tips, although this replacement will not be necessary, at the most, more than once a year.

The driving mechanism shown in figure No. 17 consists

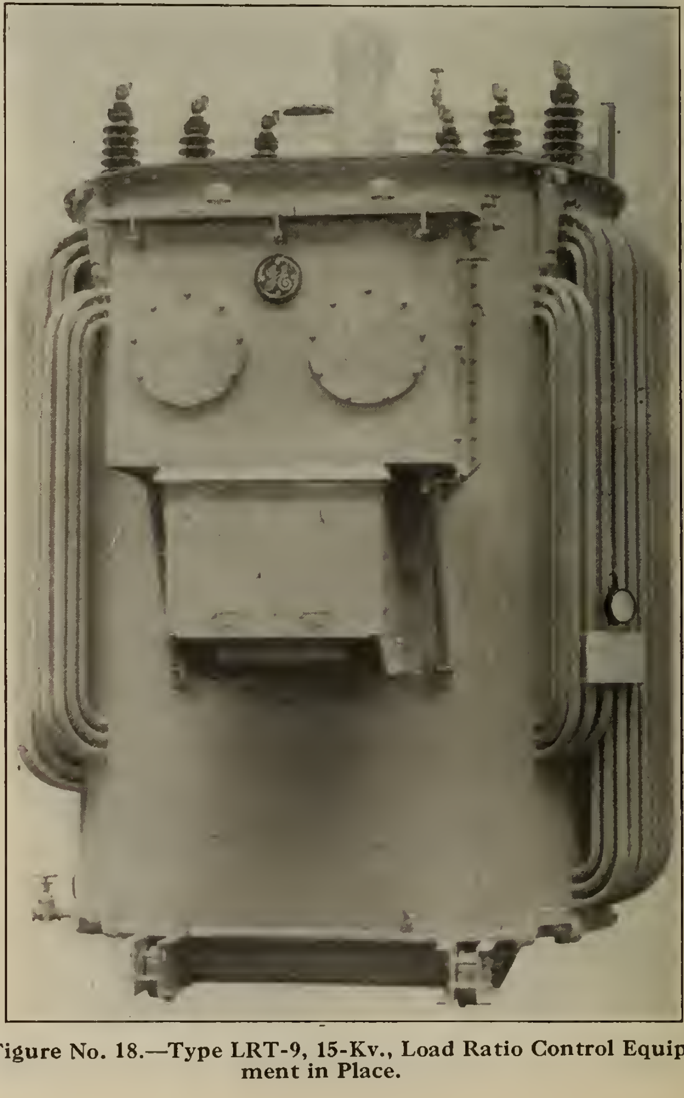

Figure No. 18.—Type LRT-9, 15-Kv., Load Ratio Control Equipment in Place.

of a motor, brake, relay switch, limit switch, drum controller, position indicator and dial switch for remote indication. This mechanism is controlled by means of a pushbutton switch which may be located at any convenient point. Once the motor is started the operation is independent of the operator until a complete tap change has taken place.

Figure No. 17 also shows a combination of contactor panel and motor drive with the heavy steel plate on which the contactors are mounted projected downward so that the motor driving mechanism can be assembled on the same plate, insuring better alignment. However, should it be found that this will carry the motor driving mechanism too high up, the operating mechanism can be lowered and the driving shaft extended. It will be noticed also that this equipment is provided for hand operation.

Figure No. 18 shows the completely assembled equipment, which gives a compact, rugged and entirely reliable piece of apparatus, the necessity and application of which is becoming more and more general.

The author wishes to acknowledge the assistance given by Mr. R. B. Carson, power transformer engineer, Canadian General Electric Company, in the preparation of this paper.

Discussion of Paper on the Fabrication and Erection of the Superstructure of the Montreal-South Shore Bridge by L. R. Wilson, M.E.I.C.[1]

P. L. PRATLEY, M.E.I.C.[2]

Mr Pratley remarked that the paper formed a masterly presentation of the detailed work involved in the fabrication and erection of the bridge superstructure. A good many of the members present belonging to one or other of the branches of The Institute between the St. Clair and the Atlantic where he had had the pleasure of lecturing on the Montreal Harbour Bridge would perhaps remember that he had expressed the hope that some day we would be able to listen to one of the engineers of the Dominion Bridge Company giving a detailed and descriptive account of the operations included in the steel erection on the South Shore Bridge. To-day we were much indebted to Mr. Wilson for his most instructive description of that work. In using the names South Shore Bridge and Harbour Bridge alternately Mr. Pratley was participating in that popular but not particularly profound pastime, adopted by both public and press, of proposing an appropriate patronymic for this product of our prolific profession.

In the erection of such structures as the South Shore Bridge, the public were naturally more impressed by the building of the steel superstructure than by any other phase of the construction. That part of the work was spectacular and for this reason made an appeal. It represented to them the actual spanning of great gaps, the visible process of reaching out to isolated places and the producing of a continuous structure ready to serve them as a highway for their traffic. But he thought the author would agree with him when he stated that in addition, a great and important work was represented in the piers and foundations, which beside supporting the superstructures, had positively to resist the "irresistible" ice pressures to which reference had been made. Several million dollars had been sunk in those foundations, and although the superstructure cost a few millions more, much time, much effort, and much profound engineering study had been consecrated to the varied, serious and fascinating problems which arose in providing the necessary substructures to carry the steelwork described in the paper.

There were many points arising out of the paper which should form the subject of interesting discussion, and he regretted sincerely that the necessary time was not at our disposal to cover these. He desired, however, to point out one or two things that had impressed him in Mr. Wilson's paper.

The author had said, on the very first page of his admirable presentation, that "it is noteworthy to observe that complete agreement was reached in every instance between the engineers and the contractors."

This was no lame statement put in the text simply to suggest that everything was "pie." There had been years of real labour both for the engineers and the Bridge Company as contractors, before arriving at all these agreements, which in their turn had led to the successful erection of this great structure. But it was undoubtedly true that the co-operation offered by the Bridge Company engineers was of the most splendid type. They had given of their time, and of their effort; and possibly something of their profits towards the realization of this steel structure, which was one of the outstanding pieces of bridgework of modern times. It was also true that the "shop practice" achieved in this work surpassed anything yet accomplished in bridge fabrication and erection, particularly in regard to the degree of accuracy obtained both in shop and field.

The author had stated that the design of the bridge was such that there was the very minimum of temporary material left in the permanent structure. This was quite true, and meant of course, that erection conditions were so taken care of in the design that general economy was the result. Mr. Wilson had also mentioned that profiting by the experience at Quebec, the type of main span was adopted with this same idea of convenience in erection and total economy. Mr. Pratley emphasized that where the minimum of permanent material is introduced on account of the temporary erection conditions, definite economy is achieved. In the case considered in the paper practically nothing had been left in the permanent structure that was not required for permanent use, and that he considered that an achievement which deserved to be recorded.

There were admittedly quite a number of details, some of major importance, particularly in the main span, which were contributed by the contractors to the design as built. It should be realized that when putting out the plans for tender, although the designers had to go very carefully into detail and to work out a structure that was practicable of construction and erection, it would be very easy to go too far in that direction. The engineers realized that preparation must be made for the individual disposition of the successful bidder, who would become in due course the responsible contractor. The contractor, in order to make the best use of his own equipment, or equipment with which he is familiar, and in order to bring to bear his own accumulated experience, must make his own complete study of the erection methods and must of necessity control

[1] This paper was presented at the Annual General Meeting of The Institute, at Ottawa, Ont., February 14th, 1930, and published in the January 1930 Journal.

[2] Monsarrat & Pratley, Consulting Engineers, Montreal.

certain features of the design. Several changes were, in virtue of the facts, suggested by the contractors in order to facilitate and improve erection conditions. One such important suggestion was that the height of the main post be reduced. After studies had been made of the effect of such reduction on economy, it was decided to accede to the contractors' request and thus eliminate the need for excess height on their tower traveller, which would only at the most construct a very few panels. The main post was accordingly reduced about 12 feet. Another change effected by the ideas of the contractors was the introduction of an additional panel in the suspended span. It would be noticed from the illustrations and the slides that there are actually seven double panels. There were originally six. Another change was the introduction of two floorbeams at the junction points of the suspended span with the two cantilever arms. From these instances it would be seen that any helpful suggestions received sympathetic consideration, and, if found desirable, were accepted. He would like to tell more of the splendid spirit of co-operation that existed between all those engaged in this monumental piece of work, but time compelled him to close his remarks which he did by again thanking the author for his interesting and instructive paper.

T. W. HARVIE, M.E.I.C.[3]

Mr. Harvie confessed that he had no criticism to offer with regard to this important paper on the fabrication and erection of the steel superstructure of the Montreal-South Shore Bridge, and would only say that he regarded it as a most valuable record of a great work well done. Mr. Pratley had already indicated that Mr. Wilson's paper would be the first of the final authoritative records of this work, and he hoped that the contractors for the substructure, who also carried out their work very meritoriously, and the joint consulting and designing engineers, would feel it their duty to give an account of their labours for the benefit of the engineering profession. Now, although the technical side of such an undertaking was probably by far the most interesting, perhaps the most worrying side was what might be called the "promotion stage." He feared that engineers and contractors alike would be without an occupation but for the "promoter," and was sure that all present who were in any way connected with the construction of the Montreal-South Shore Bridge would cheerfully give that title to the Hon. Dr. W. L. McDougald, who for many years spared no effort in the furtherance of this great project, and gave unstintedly of his time to bring a dream of fifty years to a reality. He was the first man to get the scheme actually going, and all would appreciate that enthusiasm which had resulted in the erection of this great bridge.

Referring to his own function in the enterprise, Mr. Harvie had the privilege of being Chairman of the Advisory Board of Engineers, while at the same time General Manager for the Harbour Commissioners. He was, therefore, the target for the Commissioners, the contractors, and the engineers, particularly his good friend, Mr. Pratley, and in fact for all who cared to shoot, but was glad to say they usually fired blank shot and he had sustained no serious injuries.

That advisory Board consisted of I. E. Vallee, A.M.E.I.C., chief engineer of the Department of Public Works of the Province of Quebec, representing the Province; H. A. Terreault, M.E.I.C., Director of Public Works for the City of Montreal, representing the City; Dr. H. M. MacKay, M.E.I.C., Dean of the Faculty of Applied Science, McGill University; Professor S. A. Baulne, of the University of Montreal, G. H. Duggan, M.E.I.C., as consulting engineer to the Board, and himself, as Chairman, representing the Harbour Commissioners of Montreal. Unfortunately, however, Mr. Duggan, much to the regret of his colleagues, felt it his duty to retire from the Board at a comparatively early stage in the proceedings, and on behalf of the Advisory Board of Engineers Mr. Harvie wished to say how much they appreciated the benefit of his great experience and mature judgment and tender him their thanks for the invaluable assistance he was able to render.

The author and Mr. Pratley had already referred to the friendly spirit which prevailed throughout. Seldom, he believed, had a public work of this magnitude been carried out with such good feeling all round. It would be improper and unjust to close his remarks without paying tribute to the excellent work of the joint consulting and designing engineers, particularly Mr. P. L. Pratley, with whom he had been in the closest contact throughout the whole undertaking. He desired to take this opportunity of thanking him for the great assistance he had given.

C. S. G. ROGERS, A.M.E.I.C.[4]

Mr. Rogers felt that while the author had described the problems met with in the fabrication of this great bridge, he had let us read between the lines the difficulties encountered in its erection. Therein, it seemed to him, lay the value of this paper to all engineers—particularly to the younger generation. Back of all this ease of procedure there had been thoughtful preparation of every step in the whole sequence of seeming simplicity. We admired the man who was sure in his computations of the stresses produced in the members of a complicated bridge structure by equally complicated possible groupings of applied loads. It was possible for such a man to design a finished structure which for its ultimate purpose would be a masterpiece of its kind. On the other hand it was quite possible, perhaps probable, that the structure so designed could never be built (that is from an economic standpoint). And from this extreme of purely theoretical designer, bridge-builders travelled down—or rather up—the long intermediate series to those who possessed the full requirements of theoretical gifts, of knowledge of economic shop processes, of shipping and handling and erection possibilities combined with that careful methodical mind that planned each move and long beforehand was sure that there was a way.

This grouping of engineering gifts was evident as the author's story unfolds.

In studying this paper few would attempt to think of simpler process of erection than those described. Doubtless the engineers responsible for the methods selected could now improve some details. But the outstanding fact of value to all was that careful preparation, detail study of all governing factors, and a complete scheme and programme covering the sequence of all operations had led to the completion of this great structure well over a year before the contract date.

RALPH MODJESKI, M.E.I.C.[5]

Mr. Modjeski wished to congratulate the engineers upon the successful completion of this fine project, and noted that the bridge was most carefully designed, and the whole had been carried out in a very effective and economical manner. There was only one feature which seemed to him subject to slight criticism, namely, that the stone facing of the main piers and abutments had not been carried to the top. He was quite sure that the increased cost would not have been great, and would have paid for itself in the greater durability of the stone masonry over that of concrete.

M. B. ATKINSON, M.E.I.C.[6]

Mr. Atkinson observed that the author was indeed to be complimented on his description of the fabrication and erection of that very fine piece of work, the Montreal-South Shore Bridge, a masterly accomplishment for which the

(3) General Manager, Montreal Harbour Commissioners.

(4) Bridge Engineer, Canadian National Railways, Moncton, N.B.

(5) Consulting Engineer, New York City.

(6) Structural Engineer, Welland Ship Canal, Dept. of Railways and Canals.

engineers and the contractors deserved hearty congratulations of the engineering profession.

The paper did not deal in detail with the general design of the superstructure, and it could be assumed from the general nature of the work described that unsymmetrical members had been compensated to reduce eccentricity as much as possible and all eccentric moments, whether permanent or only occurring during erection, had been fully taken care of. The general design was pleasing to the eye and the treatment of tapering the top chords of the main span was interesting.

He would ask if the timber ties had been specially treated for fire protection and whether the use of non-inflammable material had been considered.

The roadway, although not described, would appear to be of concrete with some kind of paving as a wearing surface and Mr. Atkinson inquired if the use of light weight concrete had been investigated. On the lift spans of the vertical lift bridges over the Welland Ship canal, Haydite concrete had been used for both the sidewalk and roadway reinforced slabs, the roadway having a wearing surface of asphaltic pavement one inch thick. This Haydite concrete, if made out of the aggregate manufactured in Canada, gave concrete weighing under 100 lbs. per cubic foot instead of 150 lbs. per cubic foot for ordinary reinforced concrete. Tests of this concrete had been made at different ages and the following data might be of interest,—

It was interesting to note the experiences met with in the shop in fabricating the silicon steel, and the author had properly laid stress on the necessity of rigid inspection for this material, especially at the mills. Had any excessive brittleness made itself apparent in pieces as they were handled in the shop or field?

He had not noticed any reference to the use of tapered rivets for long grips and therefore presumed that cylindrical rivets were used throughout; had any special care been taken in the heating of the rivets or the quenching of the rivet tips to ensure complete filling of the holes when the rivets were driven? He would also like to know the lengths of some of the longest grips.

The author had stated that the laterals of the main span had holes for 1-inch diameter rivets and that ⅞-inch bolts were used until the holes faired up under load. In this regard Mr. Atkinson would ask whether the bottom laterals had been manufactured to the geometrical dimensions which corresponded to the shapes of the trusses under full, dead and half live loads, so that, under dead load only, the laterals would have an initial draw corresponding to the deformation of the bottom chords under half live load.

The description of the general shop work would show that the same care had been taken with the material for this bridge that was formerly taken in the case of the Quebec Bridge. Had any trouble been experienced when planing the large castings for the main shoes; in other words, did the castings tend to spring as they were being planed, due to internal stress. He would also ask what special precautions were taken for the removal of mill scale before painting, as he understood that at one time the Dominion Bridge Company advocated no shop painting and preferred painting in the field only, after sufficient time had elapsed for rusting the mill scale.

Mr. Atkinson had noted that the pins were painted with oil before shipment and were paraffined before erection, and he would enquire if any attempt had been made in the shop to paint the pins while warm with hot paraffin as he believed that if the paraffin were put on a cold pin it would be easily cracked off, whereas when put on a warm pin, the paraffin would stick to the steel very tenaciously.

Were any special cars necessary for shipment of the members, or were ordinary flat cars used?

From the paper it was evident that the whole question of erection had been thoroughly and painstakingly investigated, and that no necessary expense had been spared to ensure the safety of the structure during every stage of its erection. He noted that various members had lugs attached in the shop for the support of working platforms and would ask if the use was considered of such a flying bridge as was used for the erection of the bottom chords of the cantilever arms of the Quebec bridge.

Regarding the author's statement that the bottoms of the cylinders for the two circular falsework piers were sealed with sand bags by a diver, Mr. Atkinson supposed that these sand bags were placed around the outside of the cylinders, but, if not, and if these bags had been placed inside, he would ask why bags of cement had not been used.

Several of the large travellers used in the work evidently had had to be taken down and re-erected several times for use at various parts of the structure; it would be of interest to know whether special bolts were used and also if they were fitted bolts and what provision was made to prevent the nuts from loosening. Were any special mechanisms used for anchoring the travellers against longitudinal motion and overturning, or was this left to the field forces to take care of and what instructions were issued therefor.

He had noticed that in dismantling the temporary span under the south anchor arm, the members were fleeted back to the anchor pier on suspended tackles so that they could be handled by the traveller situated on the deck approach span. This was presumably necessary on account of the truss members of the anchor arm interfering with the hoisting operations.

He found the information regarding the wedge mechanisms and their use to be of great interest, and would ask what was the maximum pressure contemplated on the lubrite plates, both on the whole area of the plate and on the restricted area of the graphite. He hoped that the author would give a sketch of the pin ends of the structural members at *CU0* and *SL0* with the wedge shoes in place against the pins, as this information was not directly given, or in the case at *CU0*, clearly shown.

The paper brought out the point that close agreement had been found throughout the field operations between the calculated and axial deflections in the various parts of the structure. This had also been obtained in the case of the Quebec Bridge, and demonstrated that in the case of cantilever bridges, if proper care were taken to compute the loading and the effect of details on deformations, the deflections under various conditions of loading could be predicted with reasonable accuracy.

L. R. Wilson, M.E.I.C.[7]

The Author expressed appreciation of the kindly references contained in the discussion on the paper. A number of questions had been raised by Mr. Atkinson which were of such general interest as to warrant a detailed reply.

The permanent roadway construction was, of course, determined by the engineers in collaboration with the Advisory Board after careful investigation of the data available at the time. The railway ties used during construction were not part of the permanent structure, being

[7] Vice-Pres. in charge of operations, Dom. Bridge Co. Ltd.

supplied by the contractor for his own use. In the interest of economy the ties were left untreated.

Regarding the silicon steel, it would be incorrect to suggest that excessive brittleness was found. The characteristics of this material were, of course, sufficiently different from those of medium structural steel as to make silicon steel appear somewhat brittle by comparison. Such characteristics affected shop operations such as straightening, shearing, punching, drilling and planing. Providing proper care was used during these stages, no apparent adverse results were found either in the latter stages of fabrication or in the field.

The maximum grip of shop rivets was 10¾ inches, with a considerable number of about 9¾ inches, tapered rivets being used in these cases. The maximum grip in the field was 6¾ inches, cylindrical rivets being used, but heated with special care. Satisfactory results were obtained with the rivetting although subjected to most rigid inspection.

The answer to Mr. Atkinson's question concerning the length of bottom laterals, was in the affirmative.

The large castings for the main shoes were planed with a roughing cut on both sides first before finishing; this method obviated deformation due to internal stresses. The specification called for one shop coat of paint on all surfaces after assembling; painting of surfaces in contact was not required. The length of time by which fabrication preceded erection made the application of a shop coat advisable. The steel was cleaned thoroughly for painting in the usual manner by brushing, scraping, etc.

The heating of pins in the shop prior to the application of hot paraffin was difficult in practice and somewhat objectionable, particularly as grit, etc., frequently became embedded in the paraffin before the actual driving of the pins. This was true regardless of the care with which the pins were wrapped or packed. It was particularly true at this site where the air was charged with dust, cinders, etc. from the shipping and railway traffic in the vicinity of the bridge. After experience with different methods the most satisfactory results were obtained from that described in the paper.

The use of special cars for shipment of steel to the site was not necessary. The use of a flying bridge similar to

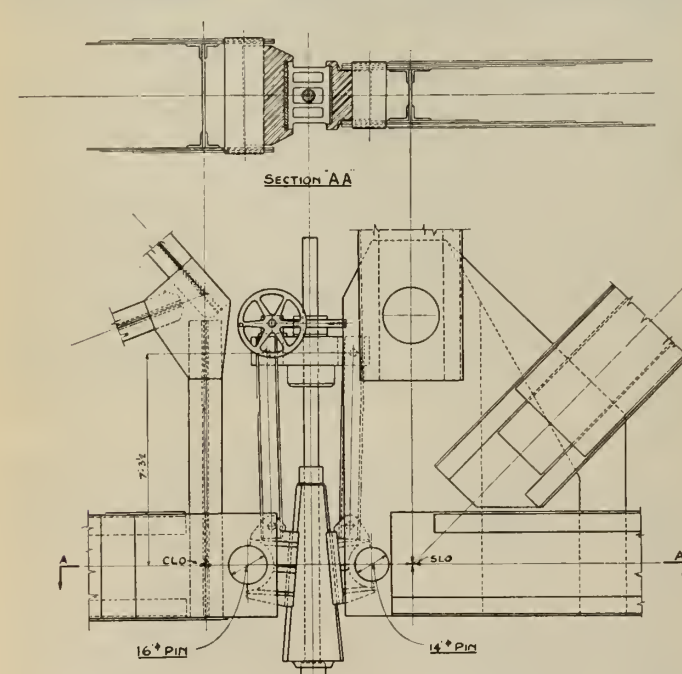

Figure No. 103.—Main Span, Centre Section, Assembly of Wedge Mechanism in Bottom Chord at *CLO*.

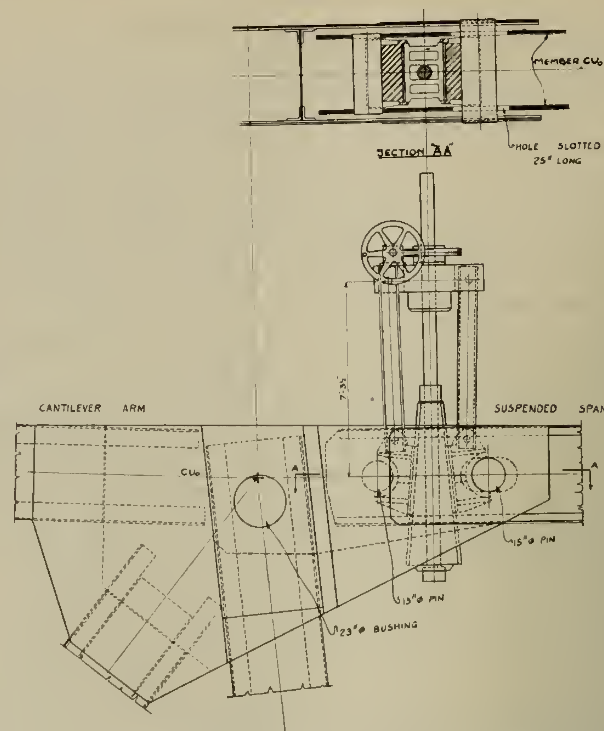

Figure No. 104.—Main Span, Centre Section, Assembly of Wedge Mechanism in Top Chord at *CUO*.

that of Quebec was given careful consideration, but discarded in favour of the use of adjustable tackles for the support of the bottom chord sections as illustrated in figure No. 39 of the paper. The results obtained from the latter were most satisfactory and the equipment was much simpler in every respect.

The cylinders for the falsework piers under the south anchor arm were sealed on the outside with sand bags, thus permitting the internal area to be covered with concrete.

In assembling the travellers, ordinary machine bolts $\frac{1}{16}$ inch smaller than the holes were used. At a few points where heavy stresses occurred, rivets were driven and cut out before dismantling the traveller. The nuts were well tightened at the time of assembly, no further precaution being found necessary. All travellers were provided with special rigging for anchorage against longitudinal movement; the same policy was followed as regards overturning wherever necessary. The instructions issued to the field force were complete as regards the precautions to be taken at all stages, and the field engineers were charged with verifying that the instructions were followed.

The method of dismantling the temporary span under the south anchor arm was dictated by the considerations mentioned by Mr. Atkinson.

To illustrate more clearly the assembly in the structure of the wedge mechanisms used for the suspended span, two additional diagrams had been prepared. Figure No. 103 illustrated the assembly of the bottom wedge at *SU0*, and figure No. 104 that of the top wedge at *CU0*. The maximum average pressure on the lubrite bearing plates was about 2,000 lbs. per square inch on the whole area. The area of the graphite was about 27 per cent of the total area, which corresponded to a pressure of about 7,400 lbs. per square inch on the graphite area if the entire load were taken on the latter.

A feature not illustrated in the diagrams was the method of resisting the twisting action on the mechanism during the operation of the worm drive. In the case of the bottom wedges the cross-head of the mechanism was shimmed snugly between the gusset plates at *SL0* on one side and against a bracket on the opposite side at *CL0*. For the top wedges, a structural frame was securely bolted to the upper side of the top chord and the cross-head shimmed in such a manner as to prevent twisting of the mechanism. The frame also served to carry the working platform.

Discussion of Paper on Water Power Resources of Canada by Norman Marr, M.E.I.C.[1]

G. Gordon Gale, m.e.i.c.[2]

Mr. Gale pointed out that from an analysis of the figures which the author had presented, it would appear that the pulp and paper industry used about one-fourth of the total power development of Canada today, that is, 560,000 horse power installed in their own plants, and about 800,000 horse power purchased from central stations. Including the 400,000 horse power now used for the production of steam, the total used in the pulp and paper industry would represent about one-third of the total power developed. A large proportion of this expansion had taken place quite recently. Notwithstanding this, he believed that the curve which had been projected was quite conservative. There were great possibilities for metallurgical, mining and chemical development, the use of electricity in the home and on the farm was still far from the saturation point, and the estimate of ten million horse power installed in 1940 did not seem excessive.

Within the last six years, 1924-1930,—he selected these years because this period extended from the first to the second World Power Conference,—Canada had increased its installed capacity in a greater proportion than any other country in the world. He was sure that these facts were in the mind of the Hon. Charles Stewart when he addressed the letter to the President which had been read at the morning meeting on Wednesday, and he would suggest that we should do our utmost to assist the World Power Conference Committee in making Canada's participation as representative as possible.

Dr. R. W. Boyle, m.e.i.c.[3]

Dr. Boyle remarked that some years ago, on studying a report of a survey of the requirements of the United States in mechanical power, he had found that the figures for 1920 indicated that every man, woman and child in the United States was using about five horse power to satisfy their mechanical requirements.

Assuming that a man power is one tenth of a horse power, this would mean that every man, woman and child had then available power which was the equivalent of the effort of fifty slaves. Commenting on this survey, a writer had pointed out that the old Greek civilization was based on human slavery, and at one time there were in Athens about one hundred thousand freeman to four hundred thousand slaves, a proportion of four to one. In our days, we had in the shape of mechanical power about fifty slaves to each person, and our mechanical civilization had not yet reached its peak. It was striking to note from the author's curves that if his predictions held good we should have developed in Canada in 1940 about ten million water horse power, at which time the population of Canada would be well over ten millions. Even under these conditions we should have less than one horse power per person. Dr. Boyle therefore agreed with Mr. Gale in believing that all our possible developments would be needed, since even if in time we were to reach an installed capacity of forty-three million horse power, the maximum estimated in the paper, we should not have more than one or two horse power per person. It would therefore appear that all the available water power in Canada would be needed, together with additional energy from other sources, including coal.

Prof. A. F. Baird, m.e.i.c.[4]

Professor Baird inquired whether the author had made any economic studies of the relative cost of small water power plants, as compared with the modern coal installation in similar units? In regard to some of the smaller plants which had been installed in New Brunswick, he had noted during the last year, that the modern powdered coal plant was producing electric energy at a considerably lower rate than the hydro-electric plant, and he would ask if that was a condition peculiar to New Brunswick. The capital cost and fixed charges of the hydro plant were usually high, and perhaps the author could give some data as to other plants throughout the Dominion.

Norman Marr, m.e.i.c.[5]

The author replied that he had no figures in mind, which would bear on that particular question, because each locality was a problem in itself. He might point to the experience of the Calgary Power Company in Alberta, in the centre of the coal fields, where coal could be obtained at a comparatively low rate, but where they still looked to water power, as far as possible, to supply their needs. In fact, in the month of November, regardless of the fact that the Calgary Power Company had taken over a number of steam stations, ninety-five per cent of the energy produced was from hydro stations and many of the steam stations had been closed down.

Prof. A. F. Baird, m.e.i.c.

Professor Baird asked whether the steam plants were modern.

Norman Marr, m.e.i.c.

The author replied that the Lethbridge station was comparatively modern; the Calgary station was modern, and the installation at Edmonton would not be complete until mid-summer, but the problem was essentially a local one. The hydro plant in New Brunswick had been built at a comparatively high rate per horse power, and this was really the essence of the whole matter.

Dr. Julian C. Smith, m.e.i.c.[6]

Dr. Julian C. Smith remarked that in furnishing an up-to-date, comprehensive, and accurate analysis of hydro-electric progress in Canada, and in indicating as he had done so clearly the vital importance of this progress to the basic industries of the Dominion, the author had made a valuable contribution to the records of The Institute. Few engineers realized the vast amount of patient and careful inquiry with subsequent monotonous computational work that was involved in the preparation of such a paper. For all this, but more particularly for the rational presentation of his conclusions, he would offer his personal congratulations.

It was to be hoped that the authorities responsible for financing the excellent statistical work of the Dominion Government, and particularly such specialized diagnosis as that under consideration, understood how very general was

(1) This was paper presented at the Annual General Meeting of The Institute, Ottawa, Ont., February 14th, 1930, and published in the February 1930 Journal.

(2) Vice-President, Canadian Hydro-Electric Corp., Ottawa.

(3) Director, Division of Physics and Engineering Physics, National Research Council, Ottawa.

(4) Professor of Physics and Electrical Engineering, University of New Brunswick.

(5) Chief Hydraulic Engineer, Dom. Water Power and Reclamation Service.

(6) Vice-Pres. and Gen. Mgr., Shawinigan Water & Power Co.

the use made of such data, and how genuinely it was appreciated by the interested business community.

The remarkable and unprecedented extent to which the water powers of the Dominion had been brought into use during the last two decades represented an engineering achievement which was perhaps unparalleled elsewhere. This achievement would be the arresting fact when some future historian reviewed the period in which we were living.

Realizing, from such presentation as the author's, that but a small percentage of our available power resources had yet been harnessed and that we had great reserves of "white coal" still intact, it was impossible to be anything but optimistic as to the continued progress and expansion of Canada.

R. G. Swan, A.M.E.I.C.[7]

Mr. Swan desired to compliment the author upon the striking way in which he had portrayed the development of the hydro-electric industry and its importance in relation to the rapid industrial expansion in Canada.

The subject had been covered so thoroughly and with such a fund of interesting information of a statistical nature that a general discussion of the paper would be somewhat difficult to undertake. He wished, however, to make reference to the terms used by the author in estimating the available water power in Canada.

The basis of flow adopted by the Dominion Water Power and Reclamation Service and used by the author for the purpose of power calculations was expressed in the following terms, with their definitions:

(a) Ordinary minimum flow—i.e., the average, over all the years for which records are available, of the mean flow for the two lowest seven-day periods in each year.

(b) Ordinary six months flow—i.e., the average, over all the years for which records are available, of the mean flow for the lowest seven consecutive days in the lowest of the six high months in each year.

To understand what these flows actually represent in practice it would be necessary to prepare a frequency or duration-of-flow curve for any particular stream or river in order to determine the percentage of total time for which such flows were available. For instance, at first sight one would naturally suppose the "ordinary six months flow" to be a flow that could be depended upon six months of the year for fifty per cent of the total time, whereas the frequency or duration-of-flow curve might show this flow to be available for sixty to even seventy per cent of the total time.

The United States Geological Survey, and nearly all authors on hydraulics, had adopted "percentage of total time" as a term for expressing the availability of run-off and power, and Mr. Swan would suggest that for the sake of uniformity, and in order that such information should be of the greatest practical value not only to engineers but to the layman, interested in the development of power, the term "percentage of total time" should be adopted by federal and provincial departments having to do with the investigation and publication of water and power resources data.

Professor G. J. Dodd, A.M.E.I.C.[8]

Professor Dodd felt that in his paper the author had given a clear and concise review of the statistics of the subject. Behind his figures lay years of work on the part of hundreds of engineers who had surveyed the power to be derived from the important rivers. The country owed a great debt of gratitude to them.

In figure No. 1, the author had shown in graphical form the remarkable growth of the development of water power. According to the Canada Year Book, Canada had 5,371,315 people in 1901, 7,206,643 in 1911 and 8,788,483 in 1921. The estimated population to June 1st, 1929, as given by the author, was 9,796,800. These figures could easily be plotted on the graph, to show how the population had increased alongside the growth in the development of water power, and if the line were projected to 1940, it would appear probable that there will be about 10,900,000 people in Canada in 1940. This would correspond to a development of 10,300,000 h.p., or a total installation of 945 h.p. per 1,000 people.

The graphs also indicated that in the period 1921-1929 the population had increased by a little over a million, whereas the horse power had increased by slightly less than three million. Roughly the growth of the one was three times as fast as the other. One cause for this had been the development of the pulp and paper industry and mining. It was not likely that the former industry would in the near future require very much more power than it was using at present. In mining, however, there undoubtedly would be a great demand for power. This had been foreseen, and already there were developments under construction and others under consideration to meet this demand.

Roughly twenty-five per cent of the total power was now being used by the pulp and paper industries; or 1,437,976 h.p. If we knew exactly how much of this had been developed in the last ten years, we could more safely predict the probable growth of the water power development in the next ten years. Placing this figure at a million h.p., a figure of 9,700,000 h.p. would be arrived at as the probable development in 1940.

Another thing brought out forcibly by the graphs was that the population of Canada did not increase at anything like the same rate as did the development of water power. It would be a wise prophet indeed who could predict the growth of population in any one district due to the installation of a power house there, after looking at these curves.

This valuable paper should draw the attention of people both in Canada and outside to the wonderful possibilities lying in the development of her water powers.

Professor G. H. Herriot, M.E.I.C.[9]

Professor Herriot had read the paper with a great deal of interest, and felt that it contained a wealth of information that could be obtained from no other source. A most striking feature was the astonishing growth of the hydro-electric industry in the brief period of a generation and a half. It was necessary to picture the increase, from an installed capacity of 193,323 horse power prior to 1900, to 5,710,802 installed horse power in 1929, to realize this. The first long distance transmission line was only placed in service in 1898. In these figures the story was but sketched in outline.

The establishment of the Dominion Water Power and Reclamation Service by the Department of the Interior of the Federal Government more than twenty years ago had been a most progressive step. The extension of the field covered and the scope of the work of this branch had always kept considerably in advance of the growth of the hydro-electric and reclamation requirements. The information the branch had furnished from time to time in its reports had been of inestimable value to engineers associated with such engineering problems. The paper under discussion was only one of the many valuable additions that our engineering libraries have received from this branch.

To be more specific, he believed that the value of the paper would have been increased, if the author had given not only the installed capacity but also the average operating capacity of the various plants throughout the

(7) Engineer, Water Resources Dept., Shawinigan Water & Power Co.

(8) Asst. Prof. in Civil Engineering and Mathematics, McGill University.

(9) Asst. Prof., Dept. of Civil Engineering, University of Manitoba.

year. In this connection he might cite the Montreal Island Power development, where the installed capacity will be 120,000 horse power, but the year round power development will be only about 65,000 horse power.

He had often felt that the officials of the Water Powers Branch were in a very favourable position to gather data relative to steam-plant electrical production, and it would seem that statistics that would set forth the costs per k.w. hour as produced by the large steam plants in the United States would form a valuable addition to any engineer's library.

In looking over table No. 4, it struck him that while the preponderance of hydro power was developed by commercial stations a large percentage was developed and distributed by municipal stations. The percentage produced by municipal stations in Ontario was extremely high while that in Manitoba was a large figure indeed. Engineers realized that such municipal stations pay no federal income taxes while their municipal payments had probably been tempered by mercy. The consumer in Winnipeg who received service from the Winnipeg Electric Railway Co. while paying the same rate per k.w. hour for his current as if he purchased it from the publicly owned utility, the city "Hydro," was none the less contributing a small fraction of each monthly payment due to the Dominion Government by way of federal income tax. It might be said that since he is paying the same rate, he is not harmed, but the privately owned utility pays the piper. The consumer was none the less paying the shot indirectly and thus contributing more towards the federal income tax from this cause than his neighbour using the publicly owned current. He would ask whether this was fair, or equitable. When we applied this example to the province of Ontario with its extensive production of publicly owned electricity, and considered it alongside of Quebec and British Columbia with their hundreds of thousands of horse power of privately owned utilities, the burden would run up into millions of dollars.

He would urge that the membership of The Institute get behind a movement to have the federal income tax removed from the privately owned companies distributing electricity to domestic consumers.

He might call attention to two outstanding fields for extension, one in the field of consumption of power and the other in the field of increased production current.

In regard to the former of these, it was safe to say that the supply of electricity to the individual farmers throughout the country had not as yet been touched. This great potential demand was still unmet. It might of course be said that the supply to individual farmers scattered throughout the country is uneconomic; but let us not forget that we are living in a progressive age and what is an economic impossibility to-day will be with us to-morrow, and prove quite profitable.

And what of the farmer, who was now awakening to the importance of mechanization. Last year in Canada he purchased more farm tractors and harvesting combines than in any previous year in our history. The need of real flexible power in the farm yard, home and stables of the farmer was far beyond the domestic requirements of the town or city home. The farmer could turn his current to many uses. The lighting of the hen houses might well convince the hen that she had moved to the land of sunshine. The general illumination requirements were common to all the farm buildings. The use of current for power purposes would be applicable to such duties as pumping water, operating the mechanical milker, the turnip and feed cutters, the fanning mill, the churn, the washing machine, etc., in fact, the uses to which such flexible power might be put on the farm seemed almost unlimited.

In regard to the field of increased production of current he need only point to the fine work of the Quebec Streams Commission, who by means of storage dams had been able to regulate the flow of water to give practically a constant supply throughout the year, thus materially increasing the available all year power. Work of this nature might well change the complexion of a hydro development from an economic blunder into a justifiable development.

Looking at the maps of the transmission lines in the several provinces of the Dominion it seemed evident that the field for the extension of hydro-electric power is still practically unlimited. Portions of our provinces had as yet scarcely been touched by the life giving current. Picturing all that this implies, could we fail to have confidence in the future of this great industry.

N. Marr, M.E.I.C.

The author in reply observed that Mr. Swan in his comments had drawn attention to the basis of flow adopted by the Dominion Water Power and Reclamation Service and used in the paper for the purpose of power calculations, viz,—"ordinary minimum flow" and "ordinary six-months flow." Mr. Swan had pointed out certain advantages in the "percentage of total time" basis which had been adopted for the purpose of power estimates by the United States Geological Survey and others, suggesting that this method should be followed by federal and provincial agencies having to do with the investigation and publication of water and power resources data.

In detailed studies of the power resources of any river where adequate records of flow are available the value of the "flow duration curve" and the "percentage of total time method" was fully recognized, but for a country of the extent of Canada with a multitude of streams in territory remote from ready means of communication on which stream flow records are either fragmentary or entirely lacking, a method of this precision was found difficult of application. Accordingly the Dominion Water Power and Reclamation Service and the various provincial organizations with which it co-operates in making an inventory of the country's water-power resources, had adopted the more general method on the basis of "ordinary minimum flow" and "ordinary six-months flow". The advantages of this method were briefly as follows:—

The flow factors could be quickly determined from a series of flow records and might, furthermore, be readily revised as new records became available.

The two conditions of flow indicated approximately the low and high limits of the capacity of any power site and an estimate on this basis gave a very fair indication of the limits of a country's resources.

The definitions themselves, "ordinary minimum flow" and "ordinary six-months flow" were self-explanatory and did not create an impression of too-great accuracy such as would be given by a definite percentage-of-time definition, which precision would be in no way warranted in a large proportion of the power sites estimated, because of a lack of fundamental stream flow data.

In brief the two bases of "ordinary minimum flow" and "ordinary six-months flow" provided a common measure for comparing the power values of sites on rivers upon which very complete run-off data were available, with sites on rivers upon which the run-off data available were incomplete, fragmentary, or entirely lacking.

Keeping in mind that the primary purpose of these estimates is to indicate the approximate limits of a country's, a district's, or a river's resources, the method adopted was considered more applicable to existing conditions in Canada than one which would indicate a greater degree of precision. Such estimates were simply indicative of power possibilities, as, when the actual development of a site is contemplated or determined upon, an exhaustive analysis of all the run-off records available, in conjunction with the reservoir and regulation possibilities, was always essential as an initial investigatory study, quite irrespective of the manner in which the power estimates might have been tabulated for statistical purposes.

The Registration of Professional Engineers in Canada

The relations of The Engineering Institute of Canada with the various Provincial Associations of Professional Engineers are the subject of real interest to our members, as was clearly shown by the active discussion on this question which took place at the recent Annual Meeting in Ottawa.

The fact that The Institute was instrumental in originating the associations gives them a claim on the good offices of The Institute, and the endorsement given at our Annual Meeting to the recommendations of the report of The Institute's committee, which has for three years being studying the possibilities of co-ordination, indicates that the activities of the associations will continue to receive the encouragement and support of the members of The Institute.

Among the provinces where the most effective recognition has been secured for the principle of the registration of professional engineers, British Columbia and Quebec are prominent. In certain others, legislation, while more or less effective, has not put into the hands of the associations such extensive powers as in the provinces named.

The degree of success which the associations have attained in the different provinces is naturally dependent on the extent of the powers given them by their respective provincial legislatures.

The Association of Professional Engineers of the Province of British Columbia, with a definite policy and well organized secretariat, has made marked progress in obtaining general recognition of the legal functions of the association. Its council early realized that systematic training is necessary for all who would become members of the profession, and has prescribed a definite programme of training and examinations which covers the cases both of applicants who have taken a university course and those who are gaining their professional experience in offices or in engineering works.

Somewhat similar and equally effective action as regards registration and education has been taken by the Corporation of Professional Engineers of the Province of Quebec, and, indeed, the policy outlined above is carried out by all the associations to the extent permitted by their respective legal authorities.

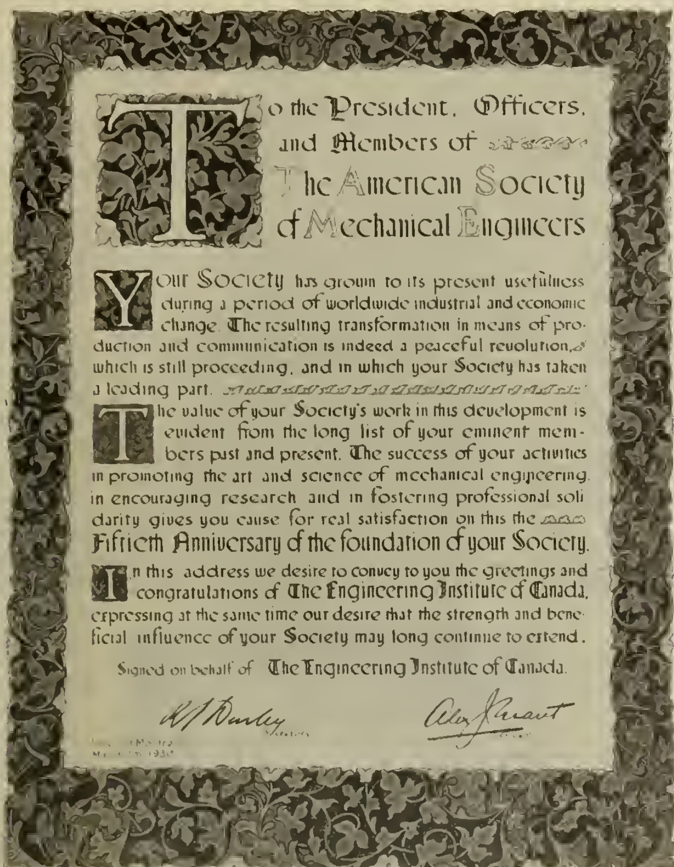
It is gratifying to note that Saskatchewan, the only province, with the exception of Prince Edward Island, which has not hitherto had a registration act upon its books, has now made good this omission. The "Engineering Profession Act 1930 (Saskatchewan)" has just received assent, and goes into force on the 1st day of May. It establishes the Association of Professional Engineers of Saskatchewan, and gives that association power to regulate the profession in the province. The act follows generally the lines of the more effective provincial enactments and definitely establishes the principle of the registration of professional engineers in Saskatchewan.

In Alberta also, it is understood that the powers given to the Alberta Association by its original act and amendments have been consolidated and revised by a new "Engineering Profession Act 1930 (Alberta)" which provides more effective legislation in that province. All who are interested in the development of professional legislation for engineers will welcome these signs that within the last few months a real advance has been made in Canada in the general recognition of the principle of registration.

The Fiftieth Anniversary of the American Society of Mechanical Engineers

The Institute has had many opportunities of welcoming to Canada sister societies from the United States. In 1923 the American Society of Civil Engineers held its semi-annual meeting in Montreal; in 1925 the fall meeting of the American Society of Civil Engineers took place in the same city, and this year the summer meeting of the American Institute of Electrical Engineers will be held in Toronto. Such events enable The Institute to express its appreciation of the cordial relations which have always existed between engineers of all branches of the profession in Canada and their brethren in the United States, but a special occasion was afforded this year by the invitation of the American Society of Mechanical Engineers to send delegates to its Fiftieth Anniversary ceremonies in New York, Hoboken and Washington. These have just taken place, and President A. J. Grant and Past-President C. H. Mitchell were The Institute's official representatives, while others of our members attended as delegates from other scientific bodies. The Council of The Institute prepared and presented an address of congratulation, a photograph of which is shown here, and it was a source of real gratification to assist in celebrating the fiftieth year of such an important body as the American Society of Mechanical Engineers.

The commemoration brought together eminent engineers from all parts of the world. Those from Japan



To the President, Officers, and Members of The American Society of Mechanical Engineers

Your Society has grown to its present usefulness during a period of worldwide industrial and economic change. The resulting transformation in means of production and communication is indeed a peaceful revolution, which is still proceeding, and in which your Society has taken a leading part.

The value of your Society's work in this development is evident from the long list of your eminent members past and present. The success of your activities in promoting the art and science of mechanical engineering, in encouraging research and in fostering professional solidarity gives you cause for real satisfaction on this the Fiftieth Anniversary of the foundation of your Society.

In this address we desire to convey to you the greetings and congratulations of The Engineering Institute of Canada, expressing at the same time our desire that the strength and beneficial influence of your Society may long continue to extend.

Signed on behalf of The Engineering Institute of Canada.

and South America rubbed shoulders with their confrères from Britain and Canada. A salient feature was the realization by those participating, that the engineers of all countries and of all branches of the profession have the same high ideals and are animated by the same desire to work for the common good.

The impressive services in the Cathedral of St. John the Divine; the dramatic pageant at the Stevens Institute, reviewing the work of the engineer; the array of celebrities in Washington at the welcoming assembly, the official dinner, and the convocation for the conferring of honours, all these left a profound impression upon our representatives, who came away convinced of the great effect of such gatherings in furthering international amity and concord.

The American Society of Mechanical Engineers are to be congratulated upon a celebration which was worthy of such an occasion.

Past-Presidents' Prize 1929-1930

Members of The Institute of all classes are reminded that papers for the second competition for the Past-Presidents' Prize must be received by the General Secretary prior to June 30th, 1930, and that the subject prescribed by Council is "The Engineering of Aviation." An announcement, giving the rules under which the prize is awarded, and directions to be followed in the preparation of papers, was published on page 286 of The Engineering Journal for March, 1930. The value of the prize is one hundred dollars, and the competition affords to our members an opportunity of contributing a noteworthy paper to the records of The Institute, and of winning one of the highest distinctions in the gift of The Institute.

Meeting of Council

A meeting of Council was held at eight o'clock p.m. on Friday, April 11th, 1930, with President A. J. Grant, M.E.I.C., in the chair, and nine other members of Council present.

The minutes of the meeting held on March 7th, 1930, were taken as read and approved.

At the invitation of Council, Past-President H. H. Vaughan, M.E.I.C., was present, and after a discussion on the work of the Committee on the Relations of The Institute with the Provincial Associations of Professional Engineers, during which Mr. Vaughan expressed his views on the subject, it was unanimously resolved to request Mr. Vaughan to accept the appointment as chairman of the committee in succession to S. G. Porter, M.E.I.C. In accepting this appointment Mr. Vaughan felt that the solution of the various problems concerning the committee would gradually develop, and hoped that he would have the unanimous support of Council in the policy adopted.

It was noted that the Association of Professional Engineers of New Brunswick had appointed a committee to consider the question of closer co-operation between the various provincial associations and The Engineering Institute.

A question having been raised as to the interpretation of the rules for the award of the Gzowski Medal, the matter was discussed, and it was decided to appoint a small committee under the chairmanship of Vice-President T. R. Loudon, M.E.I.C., to consider these rules and to report to Council as to any notes which might usefully be added to them as an aid in their interpretation.

The membership of the Papers Committee, as submitted by the various branches of The Institute to date, was noted as follows:

T. R. Loudon, M.E.I.C.	Chairman
M. Dwyer, A.M.E.I.C.	Cape Breton Branch
L. H. Robinson, M.E.I.C.	Moncton Branch
H. R. Wake, A.M.E.I.C.	Saguenay Branch
E. Wilson, M.E.I.C.	St. Maurice Valley Branch
P. E. Jarman, A.M.E.I.C.	Montreal Branch
J. J. Traill, M.E.I.C.	Toronto Branch
H. A. Lumsden, M.E.I.C.	Hamilton Branch
C. G. Moon, A.M.E.I.C.	Niagara Peninsula Branch
H. J. Coulter, Jr.E.I.C.	Border Cities Branch
W. S. Wilson, A.M.E.I.C.	Sault Ste. Marie Branch
J. W. D. Farrell, A.M.E.I.C.	Saskatchewan Branch
H. F. Bourne, A.M.E.I.C.	Victoria Branch
P. H. Buchan, A.M.E.I.C.	Vancouver Branch

The examiners for the Students' and Juniors' Prizes, as submitted by the chairman in the various zones, were approved as follows:

Zone A	Vice-President C. J. Mackenzie, M.E.I.C.,	Chairman
	Councillor C. H. Attwood, A.M.E.I.C.,	Winnipeg
	Councillor E. Stansfield, M.E.I.C.,	Edmonton
Zone B	Vice-President T. R. Loudon, M.E.I.C.,	Chairman
	Councillor R. L. Dobbin, M.E.I.C.,	Peterborough
	Councillor W. L. Malcolm, M.E.I.C.,	Kingston
Zone C (English)	Vice-President W. G. Mitchell, M.E.I.C.,	Chairman
	Councillor H. Cimon, A.M.E.I.C.,	Quebec
	Councillor J. A. McCrory, M.E.I.C.,	Montreal
Zone C (French)	Vice-President Geo. R. MacLeod, M.E.I.C.,	Chairman
	Councillor B. Grandmont, A.M.E.I.C.,	Three Rivers
	Councillor O. O. Lefebvre, M.E.I.C.,	Montreal
Zone D	Vice-President F. R. Faulkner, M.E.I.C.,	Chairman
	Councillor H. F. Bennett, A.M.E.I.C.,	Halifax
	Councillor W. J. Johnston, A.M.E.I.C.,	Saint John

The membership of the Committee on Classification and Remuneration of Engineers, as submitted by the chairman, was approved as follows:—

J. L. Busfield, M.E.I.C., Chairman
R. A. C. Henry, M.E.I.C.
P. S. Gregory, M.E.I.C

On the nomination of the Executive Committee of the Lakehead Branch, it was unanimously resolved that

D. G. Calvert, A.M.E.I.C., be appointed councillor for the Lakehead Branch until the next annual election, to replace F. Y. Harcourt, M.E.I.C., who had resigned owing to his removal to London, Ontario.

During discussion on the location to be selected for the Annual Meeting for 1931, a letter was presented from the Executive Committee of the Montreal Branch proposing that that meeting should be held in Montreal. This proposal was accepted with appreciation.

A letter was also submitted from the Executive Committee of the Toronto Branch stating that conditions in 1932 would be favourable and that it was hoped that the Annual meeting of 1932 would be held in Toronto. This was noted, and the Secretary was directed to thank the Toronto Branch for their offer which was accepted subject to later confirmation.

A communication was presented from Major-General A. G. L. McNaughton, M.E.I.C., drawing attention to the desirability of some action by The Institute which would be of benefit to those members who are interested in aviation and radio engineering. The letter welcomed the formation of an Aeronautical Section by the Montreal Branch, and expressed the hope that this example would be followed by other Branches, but General McNaughton felt that some further action than this was very desirable, and that the question should receive the attention of Council. After discussion the matter was referred to a small committee of members interested in these special branches of engineering with a request to make such recommendations to Council as may facilitate progress in the desired direction.

The Secretary submitted a copy of the Bill of the Saskatchewan Legislature incorporating the Association of Professional Engineers of Saskatchewan, and coming into effect on May 1st, 1930. He was directed to write and congratulate the members of The Institute in Saskatchewan who had been instrumental in obtaining this legislation.

The Secretary reported that a letter had been received offering the facilities of the New Zealand Society of Civil Engineers to Institute members passing through or visiting Wellington, New Zealand, and he was directed to express Council's appreciation of this courtesy, and to inform the Society that reciprocal privileges would willingly be granted.

The Secretary presented a list of over-age Students and Juniors who have not replied to three notifications that they are over-age and should apply for transfer to a higher class in The Institute. He was directed to submit these names to the Branches concerned, advising that unless some action is taken within sixty days their names will be removed from the membership list of The Institute.

Nine resignations were accepted, one reinstatement was effected, two life memberships were granted, and a number of special cases were considered.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

Elections	
Member	1
Associate Member	6
Juniors	5
Students admitted	30

Transfers	
Assoc. Member to Member	3
Junior to Assoc. Member	4
Student to Assoc. Member	4
Student to Junior	3
Student to Affiliate	1

The Council rose at one fifty-five a.m.

OBITUARIES

William Pearce, M.E.I.C.

The death of William Pearce, M.E.I.C., which occurred at Calgary, Alta., on March 3rd, is recorded with much regret.

Mr. Pearce was born on February 1st, 1848, in Dunwich township, Elgin county, Ont., and was educated at the county grammar school at St. Thomas, Ont., later attending the University of Toronto.

He specialized in surveying and spent the major portion of his life in western Canada. Between 1874 and 1881 he was engaged on surveying meridians and parallels in Manitoba and the Northwest Territories, and in 1882 he was appointed inspector of Dominion Land Agencies, being appointed superintendent of mines for the federal government in 1884. These duties caused Mr. Pearce to traverse most of the country between the Red river and the Rocky mountains; and between the international boundary and latitude 57. In 1898-1901 he was chiefly engaged in the

William Pearce, M.E.I.C.

adjustment of railway land grants. From 1901 to 1904 Mr. Pearce was inspector of surveys for the Dominion government, and at the end of that period he left the service and entered the employ of the Canadian Pacific Railway Company, in connection with the administration of their lands in the west. Mr. Pearce was always an enthusiast on the possibilities of irrigation development wherever feasible in western Canada, and he promoted the Calgary Irrigation Company. It was in no small measure due to his pronounced views on such matters that the Canadian Pacific Railway Company decided to proceed with such undertakings on a very large scale.

Mr. Pearce was always very much interested in statistics and the compilation of data of all kinds, and along these lines he did most valuable work for the Canadian Pacific Railway. He was a man of broad vision and retentive memory, and visualized the wonderful possibilities of the undeveloped resources of the Canadian west.

His life was an active one, and no one knew western Canada better than he, as he had been closely associated with its development since he first went to Winnipeg in 1874. He was one of the pioneers who helped to map out the west, to develop its resources and to shape its destiny.

The valuable services Mr. Pearce rendered were deeply appreciated and valued by the government and by the Canadian Pacific Railway, and at all times he gave his best efforts to the city of Calgary which had been his home since 1887. To know him was to admire him, and the memories of his active and useful life, his intrinsic worth, and the depth of his human kindness will long be remembered by a host of friends scattered from coast to coast, and far beyond the boundaries of his native land.

Mr. Pearce became a member of The Engineering Institute of Canada on October 14th, 1913, and was subsequently made a Life Member.

John James York, M.E.I.C.

Deep regret is expressed in recording the death of John James York, M.E.I.C., which occurred at Montreal, Que. on April 8th, 1930.

Mr. York was born at Lacadie, near St. Johns, Que., on June 12th, 1861, and commenced his engineering career by serving a six years apprenticeship in heating and ventilation.

In 1881 Mr. York entered the engineering department of the St. Lawrence Sugar Refineries, Montreal, and remained with them until 1894, when he left to take charge of contracts for the Garth Company. In 1895 he became superintendent of the Montreal Board of Trade Building, and in 1900 he returned to the St. Lawrence Sugar Refineries as chief engineer, later being appointed general works manager.

Mr. York was a prominent Mason, and at the time of his death was a 32nd degree Mason, belonging to the Mount Moriah lodge, No. 38 A. F. and A. M.. Montreal. He had many other interests, and was a past-president of both the Verdun Protestant hospital and of the Homeopathic hospital, Montreal, being one of the founders of the latter institution. He was also Boy Scout Commissioner for the east-end of Montreal, as well as a member of the advisory board of the industrial branch of the Y.M.C.A.

Mr. York was a Member of the American Society of Mechanical Engineers. He joined The Engineering Institute of Canada as an Associate Member on April 19th, 1906, and was transferred to the class of Member on June 21st, 1921.

George William Thompson, M.E.I.C.

Deep regret is expressed in recording the death of George William Thompson, M.E.I.C., which occurred at Westmount, Que., on April 1st, 1930.

Mr. Thompson was born at Belleville, Ontario, on August 11th, 1877, and received his education at the Belleville High School and the Ontario Business College.

In 1898-1899 he was engaged on electric wiring etc. with the Montreal Electric Company, and in 1899 returned to Belleville where he carried on a wiring contracting business for three years. In 1902-1904, Mr. Thompson was with the Lachine Hydraulic and Land Company as assistant to construction superintendent on overhead lines and underground conduits and cables. In 1904-1906 he was assistant to the construction superintendent on overhead lines and underground conduits and cables, both construction and maintenance work, with the Montreal Light, Heat and Power Company. In 1906-1908 he was engaged on the construction of electric light and incinerator plants for the city of Westmount for Messrs. Ross and Holgate, and in 1908-1913 Mr. Thompson carried on the

GEORGE WILLIAM THOMPSON, M.E.I.C.

work of superintendent of the Westmount light and power department, during which time he laid out and constructed complete underground conduit and ornamental street lighting systems. In 1913 Mr. Thompson was appointed general manager of the city of Westmount, which position he held up to the time of his death.

Mr. Thompson joined The Institute as a Member in 1921.

PERSONALS

C. H. Pigot, S.E.I.C., has joined the staff of the Beauharnois Construction Company at Beauharnois, Que. Mr. Pigot graduated from McGill University in 1926 with the degree of B.Sc.

H. P. Rust, M.E.I.C., has become connected with Cramp-Morris Industrials, Inc., of Philadelphia. Mr. Rust was formerly with Messrs. Harper and Taylor, engineers, of the same city.

Ernest China, A.M.E.I.C., who since 1922 has been assistant engineer with the Highways Department of Saskatchewan, at Regina, Sask., has been appointed district engineer for the same department at Weyburn, Sask.

J. W. MacDonald, A.M.E.I.C., who since 1928 has been chief engineer with the International Petroleum Company at Talara, Peru, S.A., has now returned to this country and is with Imperial Oil Refineries Ltd., at Sarnia, Ont.

Harold F. Abbott, S.E.I.C., who was formerly in the office of R. G. Gage, M.E.I.C., Canadian National Railways, Montreal, is now with the Beauharnois Construction Company at Beauharnois, Que. Mr. Abbott graduated from McGill University in 1928 with the degree of B.Sc.

Captain E. H. Harrison, M.E.I.C., of the Anglo Persian Oil Company Ltd., Abadan, Persian Gulf, has returned to England on leave, and for the next five months will be located at Oxford. Captain Harrison was engaged on engineering work in Manitoba and British Columbia for some time prior to going overseas in 1915.

R. H. Findlay, A.M.E.I.C., who was formerly with the Dominion Bridge Company Ltd., at Lachine, Que., is now mechanical engineer with the Riverside Iron Works Ltd., Calgary, Alta., which firm was taken over by the Dominion Bridge Company in 1929.

N. R. Crump, S.E.I.C., who since June 1929 has been with the Canadian Pacific Railway Company, is now night roundhouse foreman at Sutherland, Sask. He was former fitter in the Weston shops at Winnipeg, Man. Mr. Crump graduated from Purdue University at Lafayette, Indiana, in June 1929, with the degree of B.Sc. in mechanical engineering.

H. T. Melling, A.M.E.I.C., formerly with the city of Edmonton, Alta., and the city of Regina, Sask., light and power departments, also Canadian representative for Messrs. Willans and Robinson, Ltd., of England, is now located in New York, N.Y. and is connected with the engineering department of the New York Edison Company, on the inspection and construction of their new East River station.

Major E. L. M. Burns, A.M.E.I.C., is now district engineer officer for Military District No. 5, Quebec, Que. Major Burns is a graduate of the Royal Military College, Kingston, of the year 1915, and spent three years on active service during the late war. He has just returned from Quetta, India, where, for the past two years, he has been attending the Staff College.

S. B. Wass, A.M.E.I.C., terminal engineer with the Canadian National Railways, who was transferred from Toronto to Montreal at the beginning of the current year, has been appointed terminal engineer at Montreal, with jurisdiction over the railway's development in Montreal, including the construction of new lines, grade separations and all operations with the exception of the new passenger terminal itself.

H. A. Mackenzie, M.E.I.C., formerly chief engineer of the mechanical engineering department of the Jamma and Kashmir government at Baramulla, India, is now with the Paterson Engineering Company (India) Ltd., at Calcutta, India. Mr. Mackenzie has been in India since 1907, having gone to that country as assistant superintendent of dredging for the Jamma and Kashmir government; he was made superintendent in 1909.

F. V. Seibert, M.E.I.C., is now connected with the Canadian National Railways, being superintendent of the Department of Natural Resources, Manitoba and Saskatchewan, and is located at Winnipeg, Man. Mr. Seibert, who graduated from the University of Toronto in 1912, with the degree of B.A.Sc., was formerly supervisory mining engineer with the Department of the Interior, at Ottawa, Ont.

W. S. E. Morrison, A.M.E.I.C., Lieutenant-Commander (E) R.C.N. (retired) is now service engineer with the Foster-Wheeler Corporation of New York, N.Y. Commander Morrison was for some time located at the R.C.N. Barracks at Esquimalt, B.C. and was promoted to Lieutenant Commander (E) and appointed to the Canadian destroyer Champlain in 1928. In 1929 he was connected with the Combustion Engineering Corporation Ltd., Montreal.

C. E. Fraser, A.M.E.I.C., formerly township engineer of Birchcliff, Toronto, Ont., is now engineer for the McNamara Construction Company, Ltd. at Toronto, Ont. Mr. Fraser graduated from Queen's University 1916 with the degree of B.Sc., and from 1916 to 1919 was overseas with the Canadian Engineers, being demobilized with the rank of Captain. From 1919 to 1922 Mr. Fraser was assistant engineer of the county road department of the united counties of Stormont, Dundas and Glengarry, Ont.

P. E. Cooper, A.M.E.I.C., a member of the staff of the Canadian International Paper Company, has been transferred from Dalhousie, N.B. to Gatineau, Que., where he is resident engineer. Mr. Cooper, who graduated from McGill University in 1923, with the degree of B.Sc., has been with the Canadian International Paper Company for several years. Following graduation he was for three years with the Singer Manufacturing Company.

H. R. McClymont, A.M.E.I.C., formerly electrical and mechanical engineer and principal assistant with Messrs. Kerry and Chace, Ltd., Toronto, is now on the staff of McMaster-Jacob Engineering Company, Ltd., Toronto. Mr. McClymont came to this country in 1911 from England, and until 1916 was engaged with Siemens Company of Canada, as chief construction engineer for western division and later for all Canadian territory. Mr. McClymont has been with Messrs. Kerry and Chace since 1916.

E. G. Ryley, A.M.E.I.C., has been appointed general sales manager of the Truscon Steel Company of Canada, Ltd., Walkerville, Ont. Mr. Ryley received his degree of B.Sc. from McGill University in 1914, and since graduating has been associated with the above company in various capacities, except for the time spent on war service. Following the war Mr. Ryley rejoined the company as manager at Calgary, and has progressed rapidly to his present position.

E. L. Baillie, Jr.E.I.C. is at present on the staff of the Imperial Oil, Limited, at Halifax, N.S. Mr. Baillie graduated from the Nova Scotia Technical College in 1926 with the degree of B.Sc., and was at one time professor of mathematics and later professor of engineering at the St. Francois Xavier College, Antigonish, N.S. He joined the staff of the Nova Scotia Power Commission at Halifax in July 1929, and in November of the same year became a member of the staff of the Department of Highways, in the same city.

J. A. Creaser, A.M.E.I.C., has joined the staff of the National Cement Company, at Montreal, Que. Mr. Creaser graduated from McGill University in 1914 with the degree of B.Sc. and in May of the same year became attached to Kennedy Bros., of Montreal, as chief foreman on water works and sewerage installation. Mr. Creaser was overseas with the Canadian Expeditionary Forces from 1915 to 1919, being a staff captain of the 3rd brigade of Canadian Engineers from June 1918 to the time of demobilization. From 1919 to the present time he has been construction engineer with the Canada Cement Company.

T. S. Scott, M.E.I.C., who since 1922 has been with the city of Niagara Falls, Ont., as city engineer and later as city manager, has resigned that position to become town engineer of Port Colborne, Ont. Mr. Scott graduated from Queen's University with the degrees of B.A. and B.Sc., and for a time was professor of civil engineering at that university. In 1924, rather than accept his resignation, the city council of Niagara Falls gave Mr. Scott a leave of absence in order that he would be free to take charge of the development of a tract of land some 25 miles square in area, lying south of St. Petersburg, Florida.

J. F. Plow, Jr.E.I.C., has been appointed assistant to R. J. Durley, M.E.I.C., general secretary of The Institute, at Montreal, Que. Mr. Plow graduated from the Royal Military College at Kingston, Ont., in 1921, and in 1921-22 was a student at McGill University in civil engineering. From 1922 to 1925 he was vice-president of B. Plow and Company, Ltd., manufacturing stationers and printers. From 1926 to the present time Mr. Plow has been with Price Brothers and Company, Ltd., at Riverbend, Que., being first in charge of the records department, and since 1927, assistant engineer in the mechanical department.

J. F. Plow, Jr.E.I.C.

W. H. DeBlois, m.e.i.c., who since 1924 has been manager of the chemical division of the Mond Nickel Company Ltd., Montreal, Que., is now with Canadian Industries, Ltd., at Toronto, Ont. Mr. DeBlois graduated from McGill University in 1901 with the degree of B.Sc. and following graduation was, until 1903, head chemist of the Nichols Chemical Company at Capelton, Que., and from 1903 to 1908 was with the General Chemical Company, as assistant superintendent at Camden, N.J., superintendent at Pulaski, Va., and assistant superintendent at Edgewater, N.J., and Bayonne, N.J. From 1908 to 1924 Mr. DeBlois was superintendent of the Nichols Chemical Company at Sulphide, Ont., and from 1924 to date he has held the position which he has recently resigned.

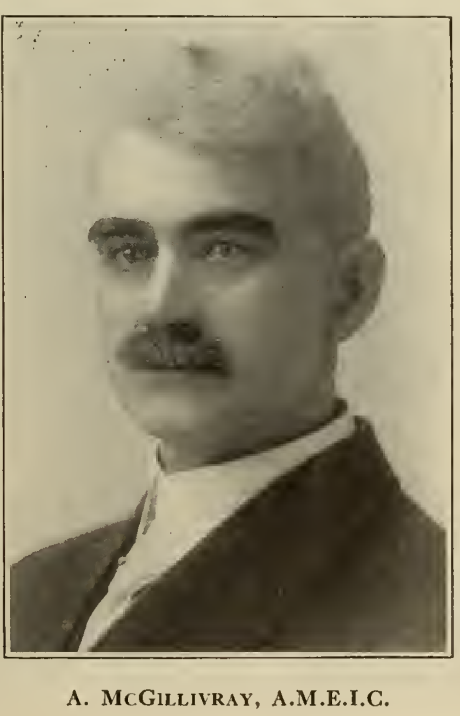
A. McGillivray, a.m.e.i.c., has been appointed Deputy-Minister of Public Works of Manitoba. Mr. McGillivray, who was formerly Highway Commissioner, Department of Public Works, Winnipeg, has been associated with the provincial public works of the government of Manitoba for the past twenty-five years, at first on land drainage work, and for the last sixteen years on good roads work as highway commissioner and chairman of the Good Roads Board. Mr. McGillivray was previously engaged in railway work, having been on location and construction with the Canadian Pacific Railway in British Columbia and with the Canadian Northern Railway in Manitoba. He takes considerable interest in Institute affairs, and in addition to acting as chairman of the Winnipeg Branch, also represented that Branch on the Council for the years 1927 and 1928.

R. S. Baker, a.m.e.i.c. is in private practice as a consulting engineer on bleacheries, equipment and methods, and is located at Ottawa, Ont. Mr. Baker was formerly with Messrs. Alex. Fleck, Ltd., Ottawa, Ont. Following his service overseas Mr. Baker was appointed engineer with the Wayagamack Pulp and Paper Company at Three Rivers, at which time he was engaged on construction work in connection with the woods operation. He was for a time located at Smooth Rock Falls, Ont., with the Mattagami Pulp and Paper Company, Ltd., on the construction of a hundred-ton bleaching plant for the company, and later joined the staff of the Riordon Pulp Corporation at Temiskaming, Ont. as research engineer. Mr. Baker later became mechanical research engineer for the Canadian International Paper Company at Temiskaming.

F. C. Green, m.e.i.c., has been appointed surveyor-general of British Columbia. Mr. Green is a native of Saint John, N.B., where he was gold medalist at the Saint John Grammar School. After graduation in 1893 from the University of New Brunswick with the degrees of B.A. and C.E., Mr. Green spent some years as resident engineer on railway construction in New Brunswick, and the state of Maine, going to British Columbia in 1897, where as senior partner in the firm of Green Bros., Burden and Company, he has since been engaged in a general engineering and surveying practice. Mr. Green has twice filled the important position of president of the Corporation of British Columbia Land Surveyors, and acted for many years on their executive, during which time he was associated with the drafting of various acts in which the profession was particularly interested. Mr. Green has always been actively interested in Institute affairs, and was chairman of the Victoria Branch in 1924, and in 1926 represented that Branch on the Council of The Institute.

G. H. Burbidge, m.e.i.c., formerly senior assistant engineer of the Department of Public Works, at Port Arthur, Ont., has been appointed acting district engineer. Mr. Burbidge graduated from the University of Toronto in 1905 with the degree of B.A., and from McGill University in 1909 with the degree of B.Sc. From June 1909 to September 1910, Mr. Burbidge was assistant topographer with the Geological Survey of Canada, and from September 1910 to June 1911 he was a demonstrator in the surveying department at McGill University. From June to December 1911 he was engaged on the subdividing of townsites for a Manitoba land surveyor. In January 1912 he entered the service of the Department of Public Works of Canada, as assistant engineer. In 1916-1917 Mr. Burbidge was a lieutenant with the 120th city of Hamilton Battalion, and with the Canadian Engineers. Returning to the Department in 1917, he was appointed district engineer for the district of Manitoba.

E. S. Miles, a.m.e.i.c., was recently appointed resident manager for the tunnel division of the Rayner Construction Ltd., Toronto, contractors for the intake tunnel and clear water tunnel in connection with the duplicate water supply system for the city of Toronto. Mr. Miles graduated from



A. McGillivray, A.M.E.I.C.

the University of New Brunswick in 1904, and in September of that year he entered the service of the Department of Public Works, being engaged for three years on a survey of the Georgian bay canal. From May 1906 to May 1907 he was first assistant engineer on the Georgian bay canal survey, in charge of a field party doing general survey work. From 1907 to 1910 Mr. Miles was engineer in charge of construction of the St. Andrews lock and dam on the Red river and in 1911 he was appointed supervising engineer for the department at Ottawa. Mr. Miles left the department to become resident engineer for O'Brien, Doheny, Quinlan and Robertson on Section 3 of the Welland ship canal, but early in 1918 all contracts were cancelled on account of the war and work suspended until early the following year. In 1918 Mr. Miles became manager of the Matane Lumber and Development Company, Matane, Que., but returned to the Welland ship canal in 1921. In 1924 he became engineer for A. W. Robertson Ltd., general contractors, on Section 8 of the Welland ship canal, at Port Colborne, Ont., and has been with that company up to the present time.

E. A. Cleveland, M.E.I.C., commissioner of the Greater Vancouver Water Board, and H. B. Muckleston, M.E.I.C., consulting engineer, Vancouver, have been appointed by the Vancouver city council to investigate the power possibilities of the Cheakamus watershed.

Mr. Cleveland was born at Alma, N.B., in 1874, and received his engineering education at the University of Washington, where he was a special student during 1907. He was first engaged on railway location work in New Brunswick, but since 1890 has been located in British Columbia where he has had extensive experience in engineering works. Mr. Cleveland resigned as comptroller of water rights for the province of British Columbia in 1926, to become commissioner of the Greater Vancouver Water Board. He is also chairman of the Vancouver and Districts Joint Sewerage and Drainage Board.

Mr. Muckleston was born at Kingston, Ont., in 1873, and was educated at Trinity College School, Port Hope, Ont., and the Royal Military College, Kingston, graduating from the latter institution in 1894. Mr. Muckleston was for a number of years in the employ of the Canadian Pacific Railway Company, and later was chief engineer of the Lethbridge Northern Irrigation District at Lethbridge, Alta. Early in 1924 Mr. Muckleston entered private practice as a consulting engineer in Vancouver, and later in the same year he became affiliated with Dr. J. A. L. Waddell, M.E.I.C., of New York city, on the design and supervision of construction of bridges in Alberta and British Columbia.

K. B. Thornton, M.E.I.C., appointed General Manager Montreal Tramways Company

K. B. Thornton, M.E.I.C., formerly assistant general manager of the Montreal Tramways Company, was recently appointed general manager of the Company. In 1893 Mr. Thornton was connected with the Royal Electric Company and the Montreal Light, Heat and Power Company, and for twelve years was intimately associated with the construction, operation and other engineering details of the power systems of these two companies. From 1905 to 1911, he was with the operating department of J. G. White and Company of New York, occupying the following positions: 1905-06, resident engineer and manager, Nassau Light and Power Company, Roslyn, L.I., N.Y.; 1906, assistant manager, operating department, J. G. White and Company, New York city; 1908-09, resident engineer and acting manager, Portland Electric Company and affiliated companies, Portland, Maine; in 1910 he was appointed advisory engineer to the Canadian Light and Power Company, Montreal, and the following year became chief engineer and general manager of that company, and also of the Montreal Public Service Corporation, in this capacity having full charge of the operating organization of both companies, and of all design for new construction and plant extension. Mr. Thornton also acted as consulting engineer to the Montreal Tramways Company. In January 1925, he was appointed assistant general manager of the Montreal Tramways Company.

K. B. Thornton, M.E.I.C.

Mr. Thornton joined The Institute as a Student on January 4th, 1894, and was transferred to Associate Member on March 16th, 1899, and to Member on November 23rd, 1920. During the years 1921-22 and 23 he was on the Council of the Institute and was vice-president representing Zone C in 1925-1926.

ELECTIONS AND TRANSFERS

At the meeting of Council held on April 11th, 1930, the following elections and transfers were effected:

Member

GENTLES, Allan Summerhayes, B.Sc., (McGill Univ.), manager, Pacific Division, Dominion Bridge Company, Limited, Vancouver, B.C.

Associate Members

COOKE, Norman Logan, B.Sc., (N.S. Tech. Coll.), principal, St. Patrick's Mechanic Science School, Halifax, N.S.

CRASE, George H., B.C.E., (Univ. of Michigan), district sales manager, Horton Steel Works, Ltd., Toronto, Ont.

CUMMING, James Deans, B.A.Sc., (Univ. of Toronto), manager and owner, General Wrecking Company, Detroit, Mich.

FARMER, Rupert Whitley, B.Sc., (McGill Univ.), engr., Montreal Light, Heat & Power Cons., Montreal, Que.

HAWTHORNE, Donald J., Sterling Clock Company, Inc., La Salle, Ill.

STUART, Kenneth, Major, D.S.O., M.C., asst. director of military intelligence, National Defence Headquarters, Ottawa, Ont.

Juniors

BARNETT, Henry Edgar, B.Sc., M.Sc., (Univ. of London), test dept., Can. Gen. Elec. Co. Ltd., Peterborough, Ont.

HUMPHRIES, George Edward, engrg. staff, Riter Conley Co., Pittsburgh, Pa.

POTTINGER, Alexander, B.A.Sc., (Univ. of B.C.), elect'l. dftsman., Canadian Westinghouse Co. Ltd., Hamilton, Ont.

SHERWOOD, Charles Max, B.S. in C.E., (Rose Polytech. Inst.), asst. engr., Can. Engrg. & Contracting Co. Ltd., Hamilton, Ont.

WILLIAMS, Edward Clifford, (City and Guilds of London), students' test course, Can. Gen. Elec. Co. Ltd., Peterborough, Ont.

Transferred from the class of Associate Member to that of Member

FORD-SMITH, Percy, president and gen. mgr., Ford-Smith Machine Co. Ltd., Hamilton, Ont.

REDFERN, Wesley Blaine, B.A.Sc., (Univ. of Toronto), vice-pres. and sec. treas., James, Proctor & Redfern, Ltd., Toronto, Ont.

WILSON, John S., B.A.Sc., (Univ. of Toronto), gen. mgr., Dryden Paper Co. Ltd., Dryden, Ont.

Transferred from the class of Junior to that of Associate Member

DOWNES, Michael Augustine, B.Sc., (McGill Univ.), asst. engr., Technical Service, City of Montreal, Que.

MITCHELL, Frank Leslie, B.Sc., (McGill Univ.), Abitibi Power & Paper Co. Ltd., 80 University Avenue, Toronto, Ont.

POWELL, Morley Vincent, B.A.Sc., (Univ. of Toronto), Can. Gen. Elec. Co. Ltd., Peterborough, Ont.

TOOKER, Guy Langrishe, asst. engr., roads dept., engrg. dept., City Hall, Vancouver, B.C.

Transferred from the class of Student to that of Associate Member

BINNS, George Frederick, B.Sc., (McGill Univ.), asst. factory engr., Imperial Tobacco Company of Canada, Ltd., Montreal, Que.

BUZZELL, Henry Walter, B.Sc., (McGill Univ.), bridge designer, Harrington & Cortelyou, consltg. engrs., Kansas City, Mo.

JOHNSON, William James, B.Sc., (McGill Univ.), res. engr., at Halifax, N.S., for John S. Metcalf Co. Ltd., Montreal, Que.

KATZ, Morris, B.Sc., M.Sc., Ph.D., (McGill Univ.), chemist for National Research Council of Canada re Trail Smelter Smoke Investigation, Northport, Wash.

Transferred from the class of Student to that of Junior

BLACKMORE, Cyril Leslie, B.Sc., (McGill Univ.), elect'l. engr., Deer Lake power house extension, International Power & Paper Company, Deer Lake, Nfld.

JONES, J. H. Mowbray, B.A.Sc., (Univ. of Toronto), res. engr., Mersey Paper Co. Ltd., Liverpool, N.S.

OLEKSHY, Mike Dmytro, (Univ. of Alta.), instr'man., Alberta Main Highways, Edmonton, Alta.

Transferred from the class of Student to that of Affiliate

MATSON, Bruce Cook, B.A.Sc., (Univ. of Toronto), engr., Innerkip Lime & Stone Co., Woodstock Ont., and sales engr., Maloney Supply Co., Toronto, Ont.

Students admitted

AYER, Thomas Haliburton, (Undergrad., N.S. Tech. Coll.), 22 Harvey Street, Halifax, N.S.

BAKER, John Arthur, (Undergrad., Univ. of B.C.), R.R. No. 1, Eburne, B.C.

BARCLAY, Guy, (Undergrad., Univ. of B.C.), Sugar Lake, via Lumby, B.C.

CAMPLONG, Lloyd William, quantity engr., Fraser Brace Engineering Co. Ltd., Copper Cliff, Ont.

COSSER, Walter Geoffrey, (Undergrad., McGill Univ.), 3592 University St., Montreal, Que.

CRASTER, James Edmund, (Undergrad., Univ. of B.C.), Vernon, B.C.

DAYNES, Joseph Henry, B.Sc., (A.C.G.I.), test work, Can. Gen. Elec. Co. Ltd., Peterborough, Ont.

DOHERTY, Thomas Harry, (Undergrad., Univ. of B.C.), 309-12th St. East, North Vancouver, B.C.

DUNHAM, Charles Burton, (Undergrad., Univ. of B.C.), 4205-11th Ave. West, Vancouver, B.C.

FRASER, Ralph Percy, (Undergrad., Univ. of Man.), 107 Tache Ave., Norwood, Man.

GONZALEZ, George Albert, (Undergrad., McGill Univ.), 435 Grosvenor Ave., Westmount, Que.

GONZALEZ, Luis Carlos, (Undergrad., McGill Univ.), 435 Grosvenor Ave., Westmount, Que.

HANLY, John Bruce, (Undergrad., Univ. of Toronto), 78 Grosvenor St., Toronto, Ont.

HRENNIKOFF, Alexander, (Undergrad., Univ. of B.C.), University of British Columbia, Vancouver, B.C.

JAGGER, Albert Edward, B.A., B.A.Sc., (Univ. of B.C.), Student, Can. Gen. Elec. Co. Ltd., Peterborough, Ont.

JOST, George Barber, (Undergrad., McGill Univ.), McGill University, Montreal, Que.

LAING, David Alexander Shearer, (Undergrad., McGill Univ.), 218 Redfern Ave., Westmount, Que.

LATTA, William S. B., (Undergrad., Univ. of B.C.), 4453-12th Ave. West, Vancouver, B.C.

LIND, Walter J., (Undergrad., Univ. of B.C.), 4509-9th Ave. West, Vancouver, B.C.

LOCKE, Charles William Evans, (Undergrad., Univ. of B.C.), 554 Rithet St., Victoria, B.C.

MACDONALD, Ernest Gordon, (Undergrad., Univ. of Man.), 89 Canora St., Winnipeg, Man.

MADSEN, Christy, (Undergrad., Univ. of B.C.), 1936-6th Ave. West, Vancouver, B.C.

MATHESON, John Gordon, B.A.Sc., (Univ. of Toronto), test dept., Can. Gen. Elec. Co. Ltd., Peterborough, Ont.

MEIKLE, James Barton Ross, (Undergrad., Univ. of Man.), 61 Kennedy St., Winnipeg, Man.

MELLOR, John Harold, (Undergrad., McGill Univ.), 619 Belmont Ave., Westmount, Que.

NESBITT, Lyman M., (Undergrad., Univ. of B.C.), 4453-12th Ave. West, Vancouver, B.C.

NICOLAISEN, Juncker Zelo, B.Sc., (Univ. of Durham), dftsman., Can. Gen. Elec. Co. Ltd., Peterborough, Ont.

SHIELS, Thomas, (Undergrad., Univ. of B.C.), 1761 Williams St., Vancouver, B.C.

SWANNELL, Lorne Forster, (Undergrad., Univ. of B.C.), 4715-4th Ave. West, Vancouver, B.C.

WHEATLEY, Eric Edmund, (Undergrad., McGill Univ.), 657 Belmont Ave., Westmount, Que.

Inaugural Meeting of the Aeronautical Section of the Montreal Branch

Tuesday, April 8th, marked the beginning of a new phase in The Institute's development, in the inaugural meeting of the newly formed Aeronautical Section. D. C. Tennant, M.E.I.C., chairman of the Branch, presided and after giving a short address dealing with the aims, objects and constitution of The Institute as a whole, introduced the chairman and vice-chairman, J. L. Busfield, M.E.I.C., and Prof. C. M. McKergow, M.E.I.C., respectively. Following a few remarks by Mr. Busfield, the Chairman then called on the speaker for the evening, J. A. Wilson, A.M.E.I.C., director of civil aviation in the Department of National Defence at Ottawa.

Mr. Wilson congratulated the members of the newly formed section on the step which had been taken and referred briefly to the interest taken by the various Branches of The Institute in aviation matters in the past. He then went on to stress the importance of engineering in all its branches to the continued progress of aviation. Some of the work already accomplished was referred to in the development of the Rolls Royce-Schneider cup engine; the lighter-than-air machines, R.100 and R.101; the modern air port; the mooring mast, etc.

The foundation of the new section was declared by Mr. Wilson to be a very happy incident, and with the support of the engineering profession, he felt that the development of aviation as a means of rapid transportation would make marked progress, and without taking anything from the other established methods of transport.

The following letter was received from G. J. Desbarats, M.E.I.C., Deputy Minister of National Defence, Ottawa:

> "Please extend to the Executive of the Montreal Branch of The Engineering Institute of Canada congratulations of this Department on the forming of an Aeronautical Section of The Institute in Montreal. The attitude of The Institute towards aviation has been invariably helpful and the formation of a special section in Montreal will bring The Institute into still closer touch with aeronautical engineering.
>
> The Department is very gratified to know that the growing importance of aeronautics is now being given official recognition and we will always be ready to assist the new branch in any way we can.
>
> May I, as one of the senior members of The Institute, who has always taken an active interest in its affairs and has also been closely connected with the administration of aviation for many years, express my personal good wishes and pleasure in the formation of the new branch."

A telegram, reading as follows, was also received from A. G. L. McNaughton, M.E.I.C., Chief of General Staff, Department of National Defence, Ottawa:—

> "Best wishes for success of aeronautical section Montreal Branch Enginering Institute of Canada in important work which it can carry out in keeping Canadian engineers in touch with developments in the air. Assure you full co-operation Officers National Defence Headquarters concerned in aviation matters."

Lt.-Commdr. A. Pressey, R.C.N., who is the officer in charge of mooring at the St. Hubert airdrome, spoke briefly on the problems encountered in mooring large dirigibles to their masts and explained in some detail the method followed in making them fast.

In conclusion F. C. Laberge, M.E.I.C., moved a very hearty vote of thanks to the speakers on behalf of the meeting.

De Laval Steam Turbine Company, Trenton, N.J., have just issued a new booklet entitled "Successful Canadian Pumping Stations." This booklet, containing twenty-eight pages, illustrates, describes and lists on a map Canadian pumping stations equipped with De Laval pumps.

Canadian Ingersoll-Rand Company, Ltd., have recently issued a new 38-page bulletin entitled "The Oil Electric Locomotive", which describes by general information, operating data and costs, graphs and drawings the Ingersoll-Rand oil electric locomotive. Copies will be gladly sent upon request to the Company at 10 Phillips Square, Montreal, Que.

BOOK REVIEWS

Flood Flows

A Study of Frequencies and Magnitudes

By Allen Hazen. John Wiley & Sons, New York, 1930, buckram, 9¼ x 5¾ in., 199 pp., figs., tables, $4.00.

This book will be welcomed by all hydraulic engineers, for it makes available to them the results of the experience, investigation and analyses of the question of flood flows by the well-known consulting engineering firm of Hazen & Whipple over a period of more than twenty years. "The object of the work," to quote the author, "is to gather in one compact presentation those methods previously published that seem most helpful, some of the basic data arranged in convenient form for reference; to add here and there some scraps of information not elsewhere easily obtainable; and to mix in a little of the author's philosophy in regard to the interpretation of the data and the application of the results."

Every hydraulic engineer is called upon at times to estimate flood flows in connection with works he is about to design. In many cases a review of the flow data for the stream and a study of all records of high water marks will provide the basis upon which to estimate the biggest flood of which there is evidence in the past, and the engineer will thereupon adopt designs providing a substantial factor of safety and will feel reasonably secure. While this method is entirely satisfactory when the consequences arising from an even greater flood than provided for will not be particularly serious, something a great deal more scientific is required when the cost of protection is high or when the consequences of failure will be disastrous. Any engineer can amplify this statement out of his own experience.

The book under review deals exhaustively with the whole question of flood estimation, and can be recommended as being of great interest to those engineers who are regularly dealing with problems of this kind. To the engineer suddenly confronted with the necessity of making a flood study, Mr. Hazen has provided most valuable guidance.

J. T. Johnston, M.E.I.C.,
Director, Dominion Water Power & Reclamation Service, Ottawa.

Wasser-Kraft-Jahrbuch 1928-29

Fourth Annual Volume Water Power Year Book; published by G. Hirth Verlag A. G., München, Herrnstrasse, 1929, cloth, 6 x 9 in., 487 pp., illus., diagrs., tables, R.M. 22.

The fourth volume of this well-known annual contains over thirty articles which naturally deal particularly with the European aspect of water power engineering. It is admirably prepared, and is well worth study by those sufficiently familiar with the German language.

The first section contains papers treating principally of the development and installation of water powers, and gives a description of the present position as regards hydro-electric power development in Austria, Italy, France, Norway, Finland, Iceland and Greece. These are followed by a series of articles on the legal and other regulations governing the development of water power in those European countries where this has been most complete, and there is a sketch of the various hydrographic institutions in Europe with a number of papers on hydrometric investigations and their relation to the design and operation of water power installations.

The third section of the book treats of technical problems relating to the development of water powers, and includes a very interesting and informative paper on the aesthetic considerations which should govern the designers of power station buildings in their relation to the natural beauties of the surrounding landscapes. The record of a series of measurements of the stresses in the material of the penstock of a power development working under a head of nearly 400 metres is of considerable interest.

The fourth and concluding section of the volume, dealing with turbine machinery, contains an excellent summary of the progress of turbine design in the United States and Canada up to 1929, a paper by a Swedish engineer on the erosion of turbine blades and an account of recent experimental work on the resistance of various materials to corrosion, all of which will repay study.

The cavitation problem is treated mathematically, and other theoretical papers relate to shaft-vibration and similar topics connected with turbine and governor design.

The whole volume gives an admirable presentation of the situation in Europe to-day as regards this important branch of engineering work.

BRANCH NEWS

Border Cities Branch

R. C. Leslie, A.M.E.I.C., Secretary-Treasurer.

(Reported by H. J. A. Chambers, S.E.I.C.)

The regular monthly meeting of the Border Cities Branch was held on February 14th.

Orville Rolfson, a.m.e.i.c., the chairman, introduced Prof. N. L. Badger, professor of chemical engineering at the University of Michigan, who addressed the meeting on the subject of "The Use of Diphenyl as a Heating Medium."

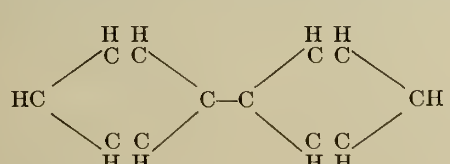
The speaker prefaced his address by a few remarks concerning the profession of the chemical engineer, defining the chemical engineer as one experienced in the design and operation of chemical plant or apparatus and concerned with the unit operations of evaporation, distillation, crystallization, crushing, drying, etc.

The speaker stated that the chemical engineer is not a composite chemist and mechanical engineer, but one who is definitely concerned in carrying out the unit operations of the chemical plant. The profession being young is not hampered by the empiricism of the older professions and consequently attacks its problems from an almost purely philosophic standpoint.

The development of diphenyl gave ample evidence of this attack. In 1917 the search for the ideal heat transference medium in the operation of evaporation was fostered by Socerson Evaporator Company of Chicago.

Of the many mediums for accomplishing this end, necessary vapour had proven hard to handle and extremely injurious to the health of workmen, direct heat was wasteful, and superheated steam had a low heat transference coefficient. The physical characteristics of the ideal medium had been decided upon, a substance possessing high latent heat, high heat transference coefficient, stability up to 800° F. and to operate as a saturated vapour with continuous performance, and non-injurious to health.

Four years ago diphenyl was selected for these tests. At that time it was a rare chemical used by the Eastman Company's research department at Rochester,—a colourless crystalline substance having the structural formula:—



Contrary to the usual behaviour of such large molecules, diphenyl did not break up when subjected to high temperatures.

In 1917 it retailed at $27.00 per pound. Subsequent researches and methods of manufacture have reduced this cost to $0.40 per pound. The bulk of the commercial market substance is produced by the Federal Phosphorus Company of Alliston, Alabama, and is made by passing benzol vapour over hot nickel gauze as a catalyst.

Of the many uses to which diphenyl may be put, the speaker cited the following commercial installations,—

Processing of lubricating oils.
Evaporation of caustic solutions.
Heating and processing of tars, asphalts, roofing papers, shingles, etc.
Replace direct coke fire under copper kettles in varnish and printers' ink manufactures.

All these uses are awaiting the design of the practical boiler in order to make them economically feasible and research is now being made to this end.

Research has been made in detail in the evaporation of caustic solutions. The design of the diphenyl boiler embodies torch welded joints inasmuch as the electric weld, though strong mechanically, is not tight since it includes scale, and diphenol acts as a reducer. Diphenol dissolves rubber and grease and hence pipe joints are designed with pump packing and are kept water-cooled. The caustic solution circulates in nickel pipes since it has a corrosive effect on unprotected iron.

Solid 99 per cent caustic is produced at a temperature of 725° F., which is greatly beyond the critical temperature of steam. Under similar circumstances, by using steam, only a 50 per cent solid solution could have been attained, the remainder of the process being carried out by direct fire would be slow and imperfect.

At atmospheric pressure the melting point of diphenyl is 159° F., the boiling point 499° F. and the critical temperature 980° F. The diphenol boiler is 65 per cent efficient and diphenyl has a heat transmission ability one hundred times greater than that of steam. The research programme contemplates using diphenyl as a fluid for prime movers. An installation would need no replacement, the losses are negligible, it operates in a closed system, the first cost is the last.

A lively discussion followed,—Messrs. Burns, Fletcher, Thoresen and Coulter taking part.

It was moved by F. Stevens, m.e.i.c., seconded by H. Thorne, m.e.i.c., that a hearty vote of thanks be conveyed to Prof. Badger.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.

J. R. Dunbar, A.M.E.I.C., Branch News Editor.

At a meeting held in the Hamilton Technical Institute on March 19th, 1930, R. E. Smythies, m.e.i.c., of the Lincoln Electric Co., Toronto, gave an address on "Recent Developments in Electric Arc Welding."

In opening, the speaker summed up the advantages of electric arc welding as a means of producing stronger, lighter and cheaper products than by the use of castings or rivetted work.

The first electric welder in Hamilton was installed in 1913 at Dominion Foundries.

Slides were shown illustrating direct connected motor generator welding sets, both single and double. In the case of the double type, one driving motor is placed in the centre, between two generators. These two generators can be used independently by two different operators, or may be paralleled by convenient switches, for use on heavy welding, up to about 600 amperes demand.

These welding outfits are supplied in portable style on trucks, or on stationary bedplates, as may be required. Gasoline engines may be used for driving, instead of electric motors, for use in the field. As might be expected, these welding equipments are constructed practically entirely of welded steel.

Slides were then shown of various classes of welded structures, both during construction and after completion, including domestic heating-boilers, high pressure stills, hydraulic power plant penstocks, long pipe lines for water or oil, the Detroit River tunnel, heavy machinery, structural steel buildings, etc., etc. Figures were given showing a two million dollar saving in constructing a 90-mile 5-foot diameter pipe line in California, in addition to the continuous saving due to the prevention of water leakage.

The penstocks at the Queenston plant were electric welded. Automatic welding machines are now in use on pipe lines, tanks, automobile rear axle housings and other forms of quantity production, thus reducing costs and making for uniform welding.

In heavy machine making, it frequently costs less to make the machine of parts welded together than the cost of development and pattern making alone would amount to in the case of making the parts of castings. As a rule welding eliminates practically all of the machining which would be necessary in the case of castings. In the case of a pedestal illustrated, made of welded steel to take the place of a cast iron one, the welded pedestal weighed 520 lbs. and cost $114.00 against the cast pedestal weighing 1,950 lbs. and costing $242.00.

Regarding the old objection to welded steel on the ground of lack of rigidity, the speaker assured the meeting that it could be made as rigid as castings, and still be lighter, cheaper and stronger.

Regarding the strength of welds, results of tests were shown, indicating that weld metal is stronger than the main body of steel. For example, where the steel had a strength of 60,000 lbs. the weld stood 70,000.

One factor in obtaining good uniform welds is the use of a flux, generally in the form of a coating around the welding rods. Another factor is the use of welding rods and current in proportion to the thickness of metal being welded.

Mr. Lumsden occupied the chair and Mr. Munson moved a vote of thanks to the speaker for his excellent address.

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.

The annual meeting of the Lethbridge Branch was held in the Marquis hotel on March 29th, preceded by the usual dinner and musical programme which consisted of vocal solos by R. S. Rannard and Wm. Meldrum and orchestral selections by Morgan's orchestra.

The Secretary-Treasurer, Wm. Meldrum, A.M.E.I.C., read his report which showed a slight decrease in attendance and membership during the year.

The retiring chairman then announced the results of the elections for Chairman and Executive Committee as follows:

Chairman: C. S. Clendening, A.M.E.I.C.
Executive: R. Livingstone, M.E.I.C.
N. Marshall, M.E.I.C.
N. H. Bradley, A.M.E.I.C.
R. F. P. Bowman, S.E.I.C.

The newly-elected chairman, Mr. Clendening, then took the chair and introduced a general discussion on the policy of the Branch for the coming year, in which nearly all the members took part, and expressions of opinion were freely made which will be of value in determining the nature and extent of the year's activities.

Councillor G. N. Houston, M.E.I.C., gave a short talk in regard to some of the matters which have come before Council recently.

A vote of thanks to the retiring executive was then unanimously adopted after which the meeting adjourned.

London Branch

F. C. Ball, A.M.E.I.C., Secretary-Treasurer.
Jno. R. Rostron, A.M.E.I.C., Branch News Editor.

The February meeting of the Branch was held on the 26th in the Public Utilities Commission board room, twenty-four members and guests being present.

The speakers for the evening were W. G. Ure, A.M.E.I.C., city engineer of Woodstock, and F. W. Farncomb, M.E.I.C., London, their subjects being "Land Surveying in Western Ontario" and "Early Surveys in the District of London" respectively.

Mr. Ure in his opening remarks made a comparison between engineering and surveying. The former was a broad term which embodied so many branches and the latter was very definite. The qualifications required by the Ontario Land Surveyors Association were exclusive and thorough, both as to training, apprenticeship and final examination, the latter generally being considered "stiff." In western Ontario it is safe to say that the ratio of engineers to surveyors is about 10 to 1.

As to the employment of a qualified surveyor by an individual preparing a plan and description and duly registering it, the speaker thought it was well worth while. There was nothing to prevent the owner doing it himself, but experience had shown that trouble was likely to ensue when the other fellow on the other side of the boundary came along. He could point to a large number of defective descriptions in the Registry Office as a result of which many people were living on the wrong property and endless trouble, annoyance and expense was often the outcome.

In some of these cases the Statute of Limitations came into play which, while it gave no title to the land appropriated in error by one owner, it prevented the other owner taking action.

The speaker cited many amusing cases of the various complications which had arisen during his experience and he recommended the employment of a qualified surveyor if the prospective owner wished to preserve peace and harmony with his neighbours.

Two plans, were shown, the one illustrating what is known as the "single front" system and the other the "double front."

In the single front system the measurements of the lots were taken beginning at the town line and along the front of each concession road and the lot lines were run straight through from one concession road to the next and parallel to the town line. As it was impossible for two surveyors to make the same measurement for any distance over stumps, fallen trees, uneven ground, etc., and with the old style of link chains, jogs were inevitable at the intersection of the concession and side roads.

In the double front system, however, the measurements were taken along the centres of the concession roads and the lot lines were run in opposite directions, and parallel to, the town line half through the concessions, causing the jogs to take place at the blind line or centre of the concession.

The speaker concluded with some interesting remarks concerning the fees paid to the surveyors of those days (the Surveyor General himself only receiving 15/- (fifteen shillings) a day) and their methods of marking their lines and points by blazing trees and the use of wooden stakes and stumps.

Mr. F. W. Farncomb stated that the earliest survey of the London district, Middlesex, was first recorded by Governor Simcoe in 1793. The speaker traced the Governor's journey, starting from Niagara Falls on the 4th of February, 1793, through the southern part of western Ontario and finally to this district.

A note of additional interest was added to Mr. Farncomb's remarks by the fact that he had in his possession several diaries written by some of these pioneer surveyors (one of these being by Major Little-Hale) which were handed round for inspection and perusal. From these one learned that there was something else besides surveying to occupy the attention of the surveyors such as the Commissariat, sickness, etc. Some of these diaries gave somewhat of an insight into the trials and hardships as well as the accomplishments and achievements of these pioneer surveyors.

A description of the staff and compass used in those days was given. Mr. Farncomb also gave some interesting reminiscences of his own when he was engaged in surveying in Algonquin park in his younger days.

The city of London was surveyed by Colonel Burwell in 1828 and in 1853 city engineer Peters was instrumental in establishing stone monuments below the surfaces of the streets at the intersection of their centre lines. Many of these are in existence today and form the legal basis of all street lines etc., but on the other hand many of them have been removed and not replaced during excavation for sewers and other work.

Both speakers were much appreciated and an animated discussion followed each address. Cordial vote of thanks were accorded them.

Railway Construction Through the Yellowhead Pass

The regular monthly meeting was held on March 19th in the Public Utilities Commission board room and the chairman of the Branch, W. G. Ure, O.L.S., A.M.E.I.C., conducted the meeting, twenty-two members and guests being present.

W. R. Smith, A.M.E.I.C., vice-chairman of the Branch, was the speaker and his subject was "Railway Construction through the Yellowhead Pass." His address was illustrated with many views taken in this picturesque country.

Mr. Smith prefaced his remarks by stating that his paper contained an account of work, experiences and observations which came within the scope of a resident engineer. Out of ten years spent in railway construction work the three years spent in the vicinity of the Yellowhead remained in his memory as the most interesting. He also wished to acknowledge the courtesy of the Canadian National Railways to whom he was indebted for many of the views shown.

In November 1909 he was instructed to take a party of eight men and supplies to mile 80 of the Mountain Division—204 miles west of Edmonton—and carry out the duties of resident engineer and also to make any revisions of location necessary. They had their supplies loaded on five flat sleigh racks and it took them three weeks to chop their way through to their destination.

The work was constructed on a maximum grade of 4/10th of one percent, a maximum curvature of 6 degrees or radius of approximately 955 feet, also 0.02 was allowed for compensation in grade per degree of curve so that the grade on a 6° curve would be only 0.28.

Searle's spirals were used as easements on all curves over 2°.

Embankments were 16′ in width up to 18′—cuttings were 22′ in width allowing for shallow ditches 3′ in width by 1′ deep at each side. Rock cuttings were 20′ in width. Earth slopes were calculated at 1½ to 1 while rock quantities were figures at ¼ to 1 slope.

The first duty of a resident engineer is to see that the right-of-way is cleared and then run check levels and establish bench marks. Then pick up the location centre line and re-run the alignment according to the location map supplied. Curves must close at the tangent points to 3/10 of 1 foot otherwise they must be re-run and the errors found and corrected.

It is then the duty of the engineer to list all structures required, bridges, culverts etc., and send it in to the divisional engineer. In the meantime temporary wooden structures are employed which are afterwards filled in or removed.

In the meantime the instrument man is busy cross-sectioning cuts and fills and the evenings are spent calculating quantities.

In cross-sectioning the slope was often as steep as 60° and the method adopted for obtaining the horizontal distances was by calculating them from the measured distances along the slope by the medium of the trigonometrical functions of the vertical angles obtained by the use of an Abney hand level. To obtain these measured distances the rodman had to be lowered by a rope. In many cases this work was done above boiling rapids where a slip would be fatal.

It is often necessary to divert mountain streams by means of rock filled cribs and these diversions are sometimes a cause of much anxiety to the engineer.

Slope chaining by means of the Abney level with clinometer attachment was found to be speedy and accurate. The method was to give the sloped tape all the support possible and then read the actual vertical angle, sighting along the tape.

Temperature had to be taken into account when using the steel tape. In re-running curves it was possible the temperature might vary as much as 20° from the time it was first run.

The speaker said he wished to pay tribute to some of the older engineers who trod these trails in the seventies. The Yellowhead has an elevation of only 3,718 feet and is one of the lowest in the Rockies. The reason why Lord Strathcona and Sir Sanford Fleming did not make use of this wonderful pass when they were consolidating the provinces by the building of the C.P.R. is that they decided to keep near the boundary in order to hold the south country from the greed of the republic to the south.

At Moose lake on the British Columbia side of the pass a very old stump was found shaped in the form of a pyramid. On one of the blazed sides was the following inscription:

Party No. 15
Bench Mark No. 572—1873
Elev. 3418.25

and on the back of the stump—Sanford Fleming.

The elevation was only 10 feet different from ours and the location was not a foot off our centre line.

A hearty vote of thanks was accorded to the speaker.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

On the evening of February 6th, A. H. Harkness, M.E.I.C., of Toronto, described in some detail the structural and engineering problems connected with the construction of the Sun Life building on Dominion square, Montreal.

Some idea of the magnitude of the work was given by Mr. Harkness in the following statistical description. "The old portion of the building has a frontage of 144 feet on Metcalf street on the west, 139 feet on Mansfield street on the east and abuts on Dorchester street with a depth of 214 feet. The new portion extends to the north between Metcalf and Mansfield streets 284 feet, making the size of the entire building 214 feet by 429 feet.

"The building will be twenty-six storeys, including three duct floors and a pent house, above the ground floor, rising to a height of about 390 feet above the sidewalk level. There are three basements, the lowest one being 40 feet below the sidewalk level. The total floor area of the building, omitting duct and pent house floors, is approximately one million square feet or about twenty-three acres.

"The new portion is equipped with twenty-eight passenger elevators and one freight elevator in the central service area as well as a second freight elevator off the lane at the north. The building will have accommodation for about 10,000 employees. The general dining rooms or cafeterias will provide meals for 8,000, and practically the whole of the sixth floor is given over to this purpose. There are, in addition, seven dining rooms for different classes of employees. In the north wing there is an assembly hall 63 by 126 feet with gallery and stage, on the eighth floor, a basket-ball court or play room, 59 by 127 feet, on the eighth floor and bowling alleys on the tenth floor for men and women.

"The construction of the new part of the building is being carried out in three parts. The easternly half of the new extension up to the eighth floor was started during the summer of 1927 and is now nearly completed and partly occupied. The westerly half was started during the winter of 1928-29, and is now enclosed. The tower portion from the eighth floor is now started, the steel being erected to the thirteenth floor. It is expected to have the tower portion enclosed by next winter."

Mr. Harkness pointed out that as compared to some of the large buildings recently constructed or now being constructed in the United States, the structural engineering on the Sun Life building can not be considered as offering much out of the ordinary. There were, however, some problems in the offsetting of columns, the arrangement of the new steel framing in relation to that of the old section of the building, the reinforcing of these old columns and beams to take increased loads, the shoring up of old columns to take new bases and footings, that are not met with in entirely new buildings. Mr. Harkness discussed some of these difficulties, showing by means of slides and diagrams the ingenious methods used in overcoming them.

D. C. Tennant, M.E.I.C., of the Dominion Bridge Co. Ltd., added a few words to the remarks of Mr. Harkness. Confining himself to the problems relating to steelwork erection, he gave some figures of the steel tonnage in the building. The original section had 1,930 tons, the second 1,325, the large back portion 9,645, while the tower will have 6,100 tons. This added to the 840 tons in the power house on the east side of Mansfield street makes the total tonnage 19,840 tons.

F. P. Shearwood, M.E.I.C., occupied the chair and among those who took part in the discussion was Mr. Cook of the firm of Cook & Leitch, general contractors for the building.

Climatic Cycles

In a very interesting address before the Montreal Branch at their regular weekly meeting on March 6th, Mr. A. Strieff, consulting engineer of Jackson, Mich., demonstrated a method which he has developed of predicting stream flow and showed the apparent relationship that exists between climatic and sun-spot cycles.

In introducing his subject, Mr. Strieff gave a résumé of research work that has been devoted to the investigation of climatic changes and the theories that have been developed, many of which, as he pointed out, are highly controversial. There have been many attempts made to correlate meteorological data and the solar cycles but without satisfactory results and the conclusion has been that "because cycles in temperature, pressure and rainfall are largely obscured and surpassed in amplitude by local and momentary changes, they are of no practical use in meteorological work."

"This conclusion of practical meteorology has been transferred sine qua non to engineering, although the conditions are modified to such extent in hydrographic data that the situation is completely reversed. Here secular amplitudes occasionally surpass the amplitudes of local and momentary changes and, far from being obscured by the latter, are often visible by mere inspection of the record. On account of this more favorable proportion between the secular and the fortuitous momentary amplitudes the chances for a successful elimination of controversy are more favourable in the application of climatic sequences to hydraulic engineering than to weather service."

"Weather service deals largely with momentary values and changes. The task of hydraulic engineering is the control and conservation of water, hence it deals largely with cumulative values. Precipitation is collected on large drainage basins and partially runs off. Part of the runoff is accumulated in lakes and storage basins. The storage quantities and water elevations represent a repeated accumulation and by this cumulative process small secular differences, unimportant for weather service but sustained over long periods, become great and important effects."

Mr. Strieff first applied his method to the flow of the Ausable river in Michigan, records of which were available extending over a number of years, and found a remarkable correspondence between the curve he derived and the Bruckuer Cycle of Wolf Numbers. Since then he has applied his method to the flow curves of other rivers with uniformly satisfactory results. By means of a series of summations and differentiation he eliminates the fortuitous elements of the hydrographic record and obtains a smooth curve the trend of which is known and the future value of which can be estimated with remarkable accuracy.

Upon conclusion of Mr. Strieff's address, Mr. C. R. Reid of the Shawinigan Water & Power Company and Mr. Trimingham of the Southern Canada Power Company remarked that they have been following with a great deal of interest the work that Mr. Strieff has been doing and called attention to the value to hydro-electric companies of forecasting stream flow.

Upon motion of Prof. E. Brown, M.E.I.C., the Chairman thanked the speaker on behalf of the Branch.

Student Section

On Thursday, March 13th, two very excellent papers were presented before the Montreal Branch by the Student Section. The first was given by Mr. Arthur Piché, entitled "Welded Airplane Structures". Mr. Piché dealt with the various applications of welding in the construction of aeroplanes at the present time, at the same time tracing the developments of these applications and indicating the tremendous importance which this art now plays in the fabrication of present-day machines.

The second paper was given by Mr. Rolland Rouselle, the subject being "The Problems in Long Distance Telephones." At the conclusion of Mr. Rouselle's paper a special moving picture film was shown through the courtesy of the Bell Telephone Company of Canada.

Road Building

The Branch was addressed on March 20th by E. L. Miles, M.E.I.C., of Lindsay, Ont., engineer of highway development for the county of Victoria, on the subject of "Road Building." In his paper, Mr. Miles traced briefly the historical development of road building from earliest times extending back as much as one thousand years before the famous King Tut. In these ancient times, roads were made of stone and were very thick. Drainage was not thought of but excavations were made about four feet deep and five or six feet wide and filled with carefully sized stones. Frost conditions were of course unknown in the tropical regions then inhabited and traffic was slow. Furthermore the work was done by slaves at practically no cost to the governments so that while some of these roads exist to the present day their methods cannot be applied to our problems of modern road construction. Many of these problems have arisen out of the development of the motor car and highway construction is forced to keep pace with the latter from year to year.

Some indications of the extent of highway development in Canada were given in the figures presented by Mr. Miles. The total allotment of $20,000,000 given by the federal government under the Canada Highways Act of 1919 had all been paid to the provinces concerned by 1928 and of the 8,737 miles of road under agreement, 8,105 miles were actually built and 563 miles were under improvement. In this same connection the Ontario Highway system and the methods of financing same were explained.

In conclusion Mr. Miles dealt with the trend of highway construction indicating the points of traffic density at which improvements became necessary and recounting the many benefits both economic and social arising out of a properly organized system of highway development.

J. A. Lalonde, A.M.E.I.C., occupied the chair and H. S. Van Scoyoc, M.E.I.C., moved a hearty vote of thanks to the speaker for his very interesting paper.

North Toronto Sewage System

A very interesting paper on the North Toronto Sewage System was presented before the Branch by George Phelps, A.M.E.I.C., assistant city engineer of the City of Toronto, on March 27th.

The design and construction of the main trunk sewer were dealt with in considerable detail and slides were shown illustrating the various phases of the work as it progressed. The North Toronto system required approximately four years for its completion and cost in the neighbourhood of $10,000,000. The natural slope across the North

Toronto district is from northwest to southeast and several natural watercourses had to be incorporated in the system. These were carefully gauged for a number of years and studies of rainfall and runoff were also made, in order to obtain accurate data on which to base the design of the main trunks. Owing to the profile of the territory in question a great deal of the main trunk section had to be placed at considerable distances below the surface and as this involved tunnelling in wet sand and clay some very interesting engineering problems arose.

Practically all of this work was done in compressed air and in the beginning there were no governmental regulations covering such conditions. However, in a short time, proper rules were drawn up and full provision made for the proper handling of men under competent medical supervision. An age limit of 35 was set for all workers and under a pressure of 22 pounds a man was not allowed to work more than two 4-hour shifts per day.

The majority of the sewer construction was carried out in brick but a certain amount was done in concrete when it was found more economical to do so.

The sewage from the North Toronto system is being handled at present by old disposal plant but as it is out-of-date plans have been prepared for its replacement at an early date.

At the conclusion of Mr. Phelps' paper a considerable amount of discussion followed, Messrs. T. J. Lafrenière, M.E.I.C., W. S. Lea, M.E.I.C., J. G. Caron, A.M.E.I.C., and D. C. Tennant, M.E.I.C., taking part. The thanks of the meeting were conveyed to the speaker by Geo. R. MacLeod, M.E.I.C., who presided.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

"Canada, a Land of Opportunity" was the subject of an address delivered before the Branch on February 20th, by C. H. Wright, B.Sc., M.E.I.C., district manager and engineer of the Canadian General Electric Co., Halifax. The meeting was open to the public and was held in the City Hall, the Council Chamber being taxed to capacity. F. O. Condon, M.E.I.C., presided.

Mr. Wright's address dealt with the minerals, water powers, agricultural and forest products of Canada, and was a most instructive and comprehensive survey of the physical assets of the Dominion.

Perhaps the most interesting point stressed by the speaker was the fact that there is no section of Canada that has not been abundantly blessed by nature either in mineral resources or products of the soil. The ore deposits controlled by one Canadian Company alone, exceed in value those of the Saar valley, the economic and real cause of the great war.

A vote of thanks was tendered Mr. Wright on motion of G. C. Torrens, A.M.E.I.C., seconded by G. E. Smith, A.M.E.I.C.

Two motion pictures were then shown, first "The Iron Mule," a humorous take-off on the early steam locomotive, and, second "Power," showing the construction and operation of the recent developments in steam and oil-electric locomotives.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.

At Niagara Falls on April 10th our members assembled to hear John Murphy, M.E.I.C., of Ottawa tell of his recent trip to the World Engineering Congress, Japan.

Mr. Murphy spoke briefly of the history of this interesting country, "Nippon, the Land of the Rising Sun"—as the Japanese call it.

In 1868, said Mr. Murphy, the doors of Japan had been finally opened to the world. Japanese students were scattered all over the universe. They attended high schools and universities. They took apprenticeship courses in great works of every conceivable character. These students, now mature experts in their respective spheres, are today the backbone of Japan's progressiveness. She is, so far as manufactured things are concerned, absolutely self-sufficient. Her initiative powers are illustrated in many power plants where, side by side, her own machines are in operation—exact duplicates of those first obtained in other countries.

Japan has a population of some 63,000,000 although her territory is only three times as great as the combined areas of Nova Scotia and New Brunswick. Since the era of modernization these people have acquired a feeling that they are perhaps a trifle superior to the rest of the world and were quite shocked when the United States prohibited further immigration.

Over-population, the need of finding work for the men and women, prevents the adoption of many labour-saving machines but where power is actually needed it is skilfully and economically employed. Fifty thousand horse power is used for pumping water to the rice fields. Japan's water power development totals 2,500,000 horse power—with as much more arranged for. There are steam plants aggregating 1,500,000 horse power. The largest hydro-electric development is in Korea—190,000 k.w.

Tokyo is a city of 2,500,000 population with a similar number within hailing distance. Since the earthquake it has been modernized in many respects with wide boulevards, fine stone and concrete buildings and some 527 bridges. $23,000,000 were spent on bridge construction within five years. Five hundred million dollars have been spent on the reconstruction of Tokyo, the national capital.

The Engineering Congress met between the dates of October 28th and November 10th, 1929, in the Parliament buildings in Tokyo. Including ladies, there were 300 delegates from the United States, 100 from the United Kingdom, and 4 from Canada. The total registration exceeded 3,000. Nine hundred papers were prepared and the organization which controlled the presentation of this enormous mass of knowledge was perfect.

Japanese "secretaries" had, in advance, made synopses of all the papers and had merged the synopses into "groups for discussion." The secretaries read their "reports" at the openings of the sessions and "discussions" followed. All the proceedings were in English. Occasionally a Japanese engineer used his native tongue and, then, his statement was translated into English. At no session attended by Mr. Murphy was any statement translated into Japanese although the chairmen always asked the audiences if they wished for a Japanese translation.

English is compulsory in the schools. The railway stations have their English names conspicuously posted. The traffic signs on the streets bear the words "stop" and "go"—in addition to the Japanese characters.

The four Canadian delegates sailed from Vancouver on October 17th of last year and were received with the utmost courtesy by the Japanese customs officials (who passed their luggage without any inspection) and by the Canadian diplomatic representative, the Hon. Herbert Marler, and Mr. James Langley, the Minister of Japan, and the Trade Commissioner, respectively.

Although not on the agenda, Mr. Murphy had brought with him some moving pictures depicting the formation of frazil ice and some of the remedial measures used in Canada. He was promptly given a place on the calendar. It appears that there are frequent ice troubles at Japanese northern power stations.

Three major resolutions were adopted at the Congress. First looking towards a world-wide organization or federation of engineers; secondly regarding government subsidies to control and remedy floor conditions; and thirdly, some united action for uniform and safe design or construction of dams and an investigation of their internal stresses and hydrostatic uplift.

The announcement by Mr. C. W. Stone of Schenectady that a new thyratron tube had recently been perfected which would transform a.c. to d.c. current, or vice versa at practically no loss and that it would revolutionize power transmission, created considerable interest. A trial with 20,000 volts, 100 amperes, resulted in an efficiency of 99.94 percent.

Many very beautiful lantern slides illustrated his talk. He also took the unusual but extremely thoughtful course of congratulating the lantern operator upon his skilful handling of these slides. The operator was overcome.

Harry M. King, M.E.I.C., and A. L. Mudge, M.E.I.C., both brother electricians, were allowed by Chairman Cameron to express the gratitude of the Branch.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

The Engineer and Industry

The place of the engineer, particularly the mining engineer, in industry and his contribution toward the welfare of the general public was the subject of a noon luncheon address by G. C. Bateman, secretary of the Ontario Mining Association, before the Ottawa Branch, on the April 10th at the Chateau Laurier.

The mining industry, stated Mr. Bateman, had been somewhat retarded of late but had by no means gone to pieces; it was basically too sound for that. This industry, in common with other basic industries, sometimes suffered from causes originating outside itself, relating to the disposition on the part of some to capitalize the cupidity and gullibility of the general public in their desire for large financial returns. In spite of what others may think or say, the mining industry does not depend for its advancement or enlargement upon the mining broker, but rather upon new discoveries, new areas being opened out and new developments. These have recently been all too few.

The broker, however, does have an important part. In this age of specialists his part should be that of a security merchant rather than that of a promoter. In the matter of the promotion of properties, also, mining is too big to cater to practices that cannot be approved; if the industry is to advance, higher standards in the matter of financing must prevail.

Mr. Bateman also gave it as his opinion that there are too few engineers who take part in public, municipal, and civic affairs. This is often due to the engineer's desire to concentrate upon his own particular job as the one important thing in life; or sometimes in the case of the impermanently placed engineer upon the diffidence he has in inserting himself into the affairs of the permanent residents of a community. As a result, municipalities have often suffered through a lack of most valuable aid that engineers could have given.

The mining engineer in the past has been looked upon as a roving individual but this has been gradually righting itself, partly on account of natural evolution, and partly on account of the develofment in many places of large propositions which have assured a longer life in their utilization. Big business is also coming to recognize more and more that engineers can fit into the administrative, as well as the purely technical, part of industrial organizations and engineers are accordingly beginning to find places as executive heads and upon boards of directors of large business firms, banks, public service corporations, etc.

The matter of research is also one which is taking a more and more important part in industry. In United States it has been stated that advancement along technical industrial lines has been due in a large part to the close contacts maintained between the technical schools and colleges and the large industries. This has unfortunately not been true to such a great extent in Canada, but the condition has been gradually righting itself in our own country. In this connection, the speaker touched upon the work of the Technical Service Council, an organization conceived by engineers and of which the director and secretary is an engineer.

Today, there is a greater diversification in the products of industry than formerly, so that less and less of the country's prosperity depends upon any one industry alone. It is well that this is so, as the effects of failure are thereby minimized in any one line as, for instance, in Canada at the present time in connection with the inadequate marketing of her wheat crop. However serious that may be, it is not as serious as it would have been a few years ago. The mining industry in Canada is, with the exception of agriculture, the leading industry in the country. In Ontario metals in excess of one billion dollars in value have been produced, and there is an assured future in sight for several times this amount. The annual production in Ontario is one hundred million dollars and in Canada over three hundred million dollars. In northern Ontario alone fifty million dollars a year is paid out in wages and in supplies and a lesser sum of twenty-seven million dollars in dividends.

The new spirit of confidence which slowly began to permeate Canada after the Great War did not originate solely through a realization of the possibilities of the thinly settled southern sections of Canada. There was associated with it a thought of the future possibilities of the vast area lying beyond the frontier. In a realization of those possibilities the engineer has taken and will continue to take a greater and greater part.

The life of the engineer, concluded the speaker, is truly one of romance and adventure. He goes out into the waste places and makes them productive. He brings to the development of the resources of a region his vast experience and by his contribution removes much of the drudgery, much of the human toil from labour, with the result that the world is made a much better place in which to live. He, with his wider vision and with the resources of science which are at his disposal, adds greatly to the sum of human happiness of the people of the world today.

The Technical Service Council

The work of the Technical Service Council in its endeavour to further the collaboration of science with industry and to stem the exodus of technically trained Canadians was outlined at a noon luncheon address at the Chateau Laurier on March 27th, by Lt.-Col. R. E. Smythe, B.A.Sc., D.S.O., M.C., director and secretary of that organization. The chairman, John McLeish, M.E.I.C., presided.

Col. Smythe in his opening remarks stated that the Technical Service Council was so far an experiment only, intended to cover a period of about three years in its endeavour to see what can be done toward bridging the gap between industry and education. The amount estimated as necessary to cover the expenses of the organization for this period of time was subscribed by a number of Canadian industries, to whom an appeal was made. When it has been expended, the matter will come up for further arrangement, if the experiment will then appear to have justified itself. Regarding this latter, there would seem, however, to be little doubt.

The Council has four objects: first, to retain for Canada young Canadians educated along technical and scientific lines; second, to bring graduates of universities and technical institutions into practical contact with Canadian industry; third, to submit to universities the recommendations of industry concerning scientific courses; and fourth, to aid industry in their technical and scientific employment problems.

In commenting upon the efforts put forward by the Council in conformity with these objects, the lecturer quoted a number of interesting figures relating to the subject. Thus, of the entire class who graduated in 1923 from the faculty of applied science of the University of Toronto, some 240 strong, there were 24 per cent who left Canada. In 1925, there were 27 per cent, and in 1926, there were over 20 per cent. Also, from a census taken five years after graduation of the technically trained graduates from another university there were 25 per cent in professional work, 41 per cent in the general industrial field, 16 per cent in commercial life, 4.5 per cent in financial pursuits and the rest in governmental and other types of work.

During the past two decades or so a great change has come over the engineering profession. Then it was the usual thing for graduates in civil engineering from technical universities to equal the total number of graduates in all other engineering branches. At the present time the graduates in civil engineering are only about 21 per cent of the total. Those in mechanical engineering average about 35 per cent, in electrical engineering 21 per cent, in chemical engineering 14 per cent, in mining 8 per cent and in metallurgical work, 3 per cent.

At the close of Col. Smythe's talk, a short period was taken up in discussion.

Peterborough Branch

S. O. Shields, Jr.E.I.C., Secretary.

Ball and Roller Bearings

An address on the above subject was given before the Branch on March 27th, 1930, by Mr. Runge, general superintendent of the S. K. F. Company. The speaker was introduced by V. S. Foster, A.M.E.I.C., chairman for this meeting.

He first outlined the development of the S. K. F. Company which now has 24,000 employees and factories in many countries.

The prime requisite in the manufacture of anti-friction bearings is extremely pure material, and nearly all the steel in S. K. F. bearings is made from Swedish iron, well known for its high quality.

Mr. Runge described and illustrated by slides the various types and forms of S. K. F. bearings and their application, and then proceeded to cover in detail the manufacturing processes.

In the manufacture of balls the material used is steel containing approximately one per cent carbon and chromium content is .40 to 1.60 per cent. The use of chromium produces more uniform hardening. The first operation in the manufacture of balls is cold pressing or cold heading as it is more commonly known. The material is fed into the machine from wire coils, cut off the desired size and the machine is capable of making 350 balls per minute ranging from ½ to ⅜ inches in diameter. Balls over one inch diameter are hot pressed and it is very important to have the correct annealing in the wire. Slugs are cut off and fed into a furnace then come through automatically and are placed in the dies.

Following this process is the normalizing or annealing operation. Balls then go through the filing machine which like all other machines in the factory is of special design made specially by the S. K. F. Company for their own particular needs.

Going through another machine the balls are roughed up to an accuracy of 5 to 6 thousandths of an inch, after which they are placed in tumbling barrels containing water and emery. They now begin to approach some degree of accuracy and absolute roundness. The lining used for these barrels is rubber which was found most suitable after many tests with felt, wood and steel. The next stage in the manufacture is to the grinding machine composed of a very fine abrasive wheel. Another grinding after this in a slower machine is undertaken and the secret of accuracy is that the balls go through this operation so many times.

After grinding comes the hardening process; the balls are placed in special gas furnaces going in at the cold end and gradually working their way through to the maximum temperature after which they are immersed in a water tank for quenching. After quenching it is very necessary to draw back in oil at 350 deg. C. to relieve strains. Then back to the tumbling barrels for eight hours to take off the carbonised surface of the ball, then again to the grinding machine, for twelve to twenty hours of slow grinding under heavy pressure. The ball comes from this machine with an accuracy plus or minus of ½-10,000th part of an inch.

Balls are then inspected for surface finish by specially trained girls who look for fine cracks, soft spots and surface marks. The girls wear gloves so that the balls are not marked by the moisture of the hands, thus ensuring proper inspection.

The manufacture of the rings was also shown on the screen and conformed in the main to that adopted in the manufacture of balls. After hardening the rings are tested on a special magnetic machine to guarantee uniform hardness. The tester is similar to a radio set and is very satisfactory.

About 28 per cent of the factory employees are inspectors. Cleanliness observed in all operations in the manufacture of ball bearings is a remarkable feature. All slides bore out the speaker's statement in this respect and in the final inspection department all the employees are attired in white uniforms while the air is all filtered and changed every five minutes.

Before packing bearings are immersed in filtered oil and wrapped in grease paper prior to being placed in stock.

A vote of thanks was accorded the speaker by Ross L. Dobbin, M.E.I.C., who voiced the opinion of the gathering by commenting on the excellence of the address.

Toronto Branch

J. J. Spence, A.M.E.I.C., Secretary-Treasurer.
Archie B. Crealock, A.M.E.I.C., Branch News Editor.

On the evening of Thursday, February 20th, 1930, the regular meeting of the Toronto Branch was held in the mining building of the University of Toronto. The speaker of the evening was Mr. A. W. Sime, technical engineer of the International Petroleum Company, who delivered a talk on "The Petroleum Industry."

Mr. Sime's lecture was indeed a very interesting one as he described the ramifications and the varied contacts of the petroleum industry and the indispensable part played by the engineer in the growth of this industry and the tremendous possibilities for his future activity. So embracing is the industry that the widest possible definition of the word "engineer" is necessary as every possibly type of practical man; every shade and grade of engineering trained man; as well as the geologist; the surveyor; the designing and erecting engineer be he civil, mechanical, electric or hydraulic; the chemist; the chemical engineer and the technical man who studies application of products are all found within the industry.

Mr. Sime outlined the beginning of the industry and the great development that has taken place all within the space of a lifetime—three score years and ten. Following on he described the various operations in their logical sequence, viz.—search, production, transportation, refining, distillation and application. In the search for oil Mr. Sime drew an interesting picture as he stated that the search for oil paralleled the search for other of nature's riches found in the ground, notably the search for gold with its possible accidental discovery, the rushes to a particular locality, the tremendous activity and the feverish excitement. The search for oil leads the prospector to work in mountainous regions, in dense tropical jungles, amid the palm groves, or on arid deserts of the south or the snowy plains of the north. In general the discovery of oil has been of spontaneous generation but here and there have been examples of more ordered, efficient and calculated search. In other words some fields bear the marks of the engineer. The men who blaze the trail are the geologists without whom no large modern producing company could hope to succeed. The geologist decides the location, advises as to the amount of preliminary work to be done, directs the sinking of the test holes. If the field to be tested is in an inaccessible part of the world the burden then falls largely on the surveying, constructional and mechanical engineers. The metallurgical engineer and the designing engineer are called upon when drilling starts as drilling apparatus and steels have to be used in holes that are at times from 6,000 to 8,000 feet in depth. The transmission of power in the rotary system through a 4½-inch pipe to the cutting edge at these great depths calls for intensive study and research work. The same is true of the cable tool method where the heavy bits are alternately raised and suddenly lowered to chew their way through by percussion. Following this Mr. Sime proceeded to describe the other troubles in drilling, the actual striking of gas or oil when pressures at times as high as 3,500 pounds per square inch are encountered. The next problem described was that of temporary storage reservoirs and the reduction of waste in storage and transportation as well as the removal of saline water which is some times found with the oil.

The transportation of the oil to the refinery is one of the greatest importance. The most common methods are pipe line, ocean going tank steamer or railroad tank car. For pipe line transportation it is necessary to make reconnaissance surveys of available routes and detailed estimates of the cost. With all the legal and engineering detail it corresponds to the construction of a new railroad. Mr. Sime stated that on this continent there are approaching 100,000 miles of pipe line from 4 inches to 12 inches in diameter forming a veritable network on the map. The relay pumping stations are usually located from 30 to 40 miles apart and pressures as high as 800 to 900 pounds are used for pumping purposes. The volume of oil carried by pipe lines runs much more than half a billion barrels per year, some of which is moved only a few miles while a large quantity is pumped 1,700 miles from oil field to refinery. The sea-going oil tanker is of modern design and equipment and the tonnage runs up to 25,000 tons, with ability to discharge her cargo of over 100,000 barrels and be away inside of 24 hours.

The refinery was next described by Mr. Sime. The refining process to express it in as few words as possible. is one of separation and purification. In the refining process they are always striving for higher yields, for closer uniformity of product and higher quality. All these have kept the refining engineer inventive, resourceful and extremely busy. At the conclusion of his address Mr. Sime showed a series of pictures describing the various activities of the industry.

A very hearty vote of thanks was tendered to the speaker for his interesting address.

Meeting of March 6th.

"Signaling, Its Relation to Speed and Safety of Railroad Operation" was the title of an interesting talk which was delivered on Thursday, March 6th, 1930, to the members of the Toronto Branch of The Engineering Institute by Mr. S. J. Turreff, assistant resident manager of the Union Switch and Signal Company of St. Louis, Mo.

In his lecture Mr. Turreff first dealt with the reasons which led up to signaling, the most modern branch of the railway field and then dealt with the purpose which it serves in American transportation. As always "necessity became the mother of invention" and the growth of signal systems began due to the undesirability and expense of stopping trains to permit trainmen to throw switches or flag crossing lines. The first signal systems were those consisting of a series of levers from which wire or pipe lines extended to switch operating mechanisms and fixed wayside signals. As time went on telegraph train orders and time tables were used exclusively for the spacing of trains. Following this came the automatic block signal which was made possible through the invention of the track circuit by Dr. William Robinson in 1879. The purpose served by the automatic block branch of signaling is to permit the operation of a greater number of trains within a given territory with as great a degree of safety as possible, when depending entirely upon the human element operating the train. Later developments in the signaling art have been developments of the general principles previously established by the interlocking and automatic systems, and always with similar objectives.

Continuing, Mr. Turreff gave a detailed description of the various systems in use to-day including cab signals and train control, centralized train directing system and electro-pneumatic car retarder in use in hump yard operation.

Following the lecture motion pictures were shown which illustrated clearly the two systems receiving the greatest attention from railroad officers to-day, namely, the centralized train directing system and the electro-pneumatic car retarder system.

Mr. Turreff's address and the motion pictures were thoroughly enjoyed by all and a vote of thanks was tendered to the speaker for his address and the showing of the pictures.

Annual Meeting

The annual business meeting of the Toronto Branch was held on the evening of Thursday, April 3rd, and was attended by a goodly number of the Branch members. In the absence of T. Taylor, M.E.I.C., the chair was occupied by L. W. Wynne-Roberts, A.M.E.I.C. The minutes of the last annual meeting were read and duly adopted. Following this the reports of the chairmen of the various committees were received. From these it was evident that the Toronto Branch is exceedingly active and that the membership is growing. J. W. Falkner, A.M.E.I.C., and L. A. Badgley, A.M.E.I.C., who were appointed auditors, reported that the books were in excellent condition. The scrutineers, Messrs. McMaster, Ferris and Dunbar, having completed the counting of the ballots, submitted their report to the chairman who announced the following members elected.

Chairman	J. J. Traill. M.E.I.C. (acclamation)
Vice-Chairman	C. S. L. Hertzberg, M.E.I.C.
Secretary-Treasurer	J. J. Spence, A.M.E.I.C.
Executive Committee	J. W. Falkner, A.M.E.I.C. (2 years)
	F. B. Goedike, A.M.E.I.C. (2 years)
	A. B. Crealock, A.M.E.I.C. (2 years)
	G. H. Davis, M.E.I.C. (1 year)

Mr. McCarthy then escorted Mr. Traill to the chair and in his remarks Mr. Traill thanked the members for their support. He stated that though it was customary to discontinue the meetings at this time, he was arranging for one more meeting in the month of April which he believed would prove of genuine interest and that further information would be sent to all members as soon as details were completed. The meeting closed with a vote of thanks to the auditors and scrutineers.

Joint Meeting

On the evening of Thursday March 20th, 1930, the Toronto Branch of The Engineering Institute of Canada held a joint meeting with the Association of Professional Engineers of the Province of Ontario. The meeting was an open one and ladies were invited. The speaker was Mr. B. R. Value, executive engineer representing Messrs. Parsons, Klapp, Brinckerhoff and Douglas, consulting engineers, Detroit, Michigan. The subject of Mr. Value's address was "The Design and Construction of the Detroit and Canada Tunnel." That the subject was a very interesting one was evidenced by the splendid turnout and all expectations were fulfilled as Mr. Value's lecture was most intresting and was thoroughly appreciated by all present.

Saint John Branch

E. J. Owens, A.M.E.I.C., Secretary-Treasurer.

Picturing a prosperous future for Canada in general and for the Maritime provinces in particular, C. H. Wright, M.E.I.C., president of the Halifax Board of Trade, addressed a meeting under the auspices of the Saint John Branch, Engineering Institute of Canada, in the Board of Trade rooms, March 20th. W. J. Johnston, A.M.E.I.C., chairman of the Branch presided, and there was a large attendance.

Mr. Wright gave much first hand information concerning different parts of the Dominion. During the last three years he had made two trips to western Canada.

Saint John, he said, along with Halifax, was among the greatest ports of Canada, and he predicted a prosperous future for both. The Dominion was second in the world in water power development per capita, with 9,000,000 horse power or one horse power per person, with possibilities for 33,000,000 horse power more. In the development of this additional power there would be a necessary expenditure of $90,-000,000, according to the pace set during the last two years. This water power development was saving 100,000 tons of coal daily for Canada, and the speaker mentioned the advantages of water power particularly in Ontario and Quebec, where there is no coal found.

Referring to mineral developments in Canada he pointed out that Canada took first place in the production of nickel and asbestos, second place in cobalt, third place in gold and silver, fourth place in lead and copper and sixth place in zinc. In connection with zinc half the total zinc produced in Canada went to Japan, which country consumed three per cent of the world's supply. There had been seven and a half billion dollars worth of minerals discovered in Canada which amounted to $700.00 per capita, and at present Canada's mineral production amounted to $5,000,000 each week with Canadian mineral production rapidly increasing.

In agriculture the Dominion had produced $1,000,000,000 annually, and the speaker mentioned the great wheat pool of western Canada, which he claimed was doing a business of $1,000,000 daily, and next to the Dominion government was doing the largest business in Canada.

He also touched on the annual income from forestry products, logs, firewood, pulpwood and pulp and paper, which totalled $400,000,000 annually.

Canada takes second place in export and world trade per capita, and he pointed out that of the agricultural products, Canadians were consuming 99 per cent of their egg production, 93 per cent of the bacon production, 95 per cent of the poultry production, 97 per cent of the lamb production, 99 per cent of the cheese production and 85 per cent of the beef production.

After speaking of the resources of British Columbia, Mr. Wright considered the Prairie provinces, pointing out that in Alberta, Saskatchewan and Manitoba the production of wheat had amounted to 270,000,000 bushels last year. The Peace river district with its 47,000,000 acres of rich black soil, and present population of 60,000 people, which was growing at the rate of 20,000 annually. In 1929 new homesteads taken up numbered 5,000 in this district, and the motor licenses for the same year numbered 2,500. He predicted that in 10 years this district would be capable of producing 100,000,000 bushels of wheat annually, if there was a demand in the world for such a large increased production.

Dealing with Nova Scotia, he stated the coal and steel industry was as important to that province as the pulp and newsprint industries were to New Brunswick. In touching on the various industries of the sister province he made particular mention of the apple production of the Annapolis valley and the fishing, the newsprint and tourist industries, pointing out their individual importance to the economic welfare of the province. Speaking of the province of Prince Edward Island he told of the potato growers there receiving an increase of $5,000,000 for their potato production last year.

Of New Brunswick he told of an increase of $7,476,000 in 1929 field crops over 1928, and of the great strides being made by the pulp and newsprint industry with still greater development to follow. In this connection the whole northern part of the province had been converted from a land of stagnation to a land of marked activity by the paper industry development there.

Referring to the tourist revenue received by New Brunswick, Mr. Wright asserted that good roads and more good hotels would result in the $15,000,000 revenue received last year being doubled in the next few years. In conclusion he pointed out that the Canadian National Railways in 1929 spent $2,500,000 on capital expenditure in the Maritimes, and $30,000,000 on regular maintenance and operation, while the Canadian Pacific Railway had spent $2,500,000 on capital expenditures. The C.N.R., he said, had left with the British Empire Steel Corporation in 1929, $14,000,000, and the C.P.R., $4,750,000. In the last 18 years the C.P.R. has given Besco $50,000,000 worth of business. This, he said, is what transportation means to the Maritime provinces.

Mr. Wright was complimented on his address by F. M. Sclanders, commissioner of the Saint John Board of Trade, who briefly touched on conditions in the Maritime provinces as well as in western Canada, where he had spent many years.

A vote of thanks, moved by F. P. Vaughan, M.E.I.C., and seconded by G. G. Murdoch, M.E.I.C., was extended to the speaker by the chairman.

Joint Meeting

A joint meeting of the Saint John Branch of The Engineering Institute of Canada and the University of New Brunswick Engineering Society was held in Fredericton on April 4th.

H. L. Campbell, President of the University of New Brunswick Engineering Society, welcomed the guests and then turned the meeting over to W. J. Johnston, A.M.E.I.C., who spoke for a few minutes on the aims and objects of The Engineering Institute of Canada. He then introduced the speaker of the evening, F. P. Vaughan, M.E.I.C., who read a paper on "High Potential and High Frequency Apparatus" and also did a number of experiments. The apparatus used in this connection was later donated to the University of New Brunswick by Mr. Vaughan.

He stated that while the production of high potential and high frequency currents for the use of condenser discharge is not new, they are rapidly becoming of commercial importance and are used very extensively today in wireless telegraphy and telephony, the testing of high voltage insulators and lightning arresters, the production of ozone and nitrogen, X-ray work, high frequency furnaces, the electro culture of plants, and when properly used and applied to electro therapeutics have produced some remarkable results.

Alternating currents met with in commercial use are of relatively low frequency. When the frequency is from 1,000 to 100,000 they are called high frequency currents and when the frequency rises to a million or so they are called electric oscillations.

We are concerned with an alternating current of very high frequency which consists of separate groups of alternating currents, each group beginning with the same amplitude but damping down more or less rapidly to zero and after a short period of time beginning again. These are known as damped electric oscillations. The rate at which the amplitude dies away in each train is called damping. A train of very few oscillations is called a highly damped train and over 100 a feebly damped train.

Until quite recently there were but three practical methods by which high frequency currents could be generated. One of these methods employed an alternating current generator of special construction, having a very large number of stator pole pieces and the rotor drives at a very high rate of speed, 10,000 to 20,000 r.p.m. The maximum frequency obtainable by this method is about 100,000 cycles per second and includes machines of this type developed by Nikola Tesla, R. A. Fessenden and E. F. W. Alexanderson, whose latest machine is rated at 200 k.w., the rotor of which weighs 3½ tons and has a speed of 2,100 r.p.m., the whole machine weighing 12 tons and has a frequency of 22,000 cycles per second. The results to be obtained by this method are by means of a very extensive machine although they undoubtedly possess great advantages in radio telephony.

Another type of high frequency alternator, operating on the principle of electrical resonance, has been developed by Dr. Goldschmidt, which generates radio currents at frequencies from 30,000 to 75,000 cycles per second.

The second method is by means of the direct current arc, when an ordinary arc is shunted by a suitable inductance and capacity, sustained oscillations are set up in the circuit. This method produces a persistent or undamped wave and has been successfully developed by Duddell and Poulsen and is used successfully for wireless telegraphy and telephony.

The latest development for the generation of undamped oscillations is the thermionic vacuum valves, such as the General Electric Company pliotron oscillators, being a highly exhausted two or three element valve of enlarged dimensions.

The third and most well-known method of producing high frequency currents, due to Lord Kelvin, but better known by the experiments of Nikola Tesla, is by the discharge of a condenser, the same being charged to a high potential and discharged through a circuit having inductance and low resistance, a train of oscillations being set up at every discharge of the condensers. It is necessary to arrange the circuit for the production of the trains of damped electric oscillations by condenser discharges so that the inductive circuit is in service with the condenser. This usually consists of a transformer containing no iron, called an air core transformer. Two circuits are wound one over the other and high insulated from each other. One of these is called the ordinary, the other the secondary. The primary circuit is arranged in series with a condenser and spark gap, this being the circuit in which the oscillations are set up by the discharge of the condenser. The oscillations in the primary induce other oscillations in the secondary, and if the secondary has a greater number of turns than the primary the secondary voltage will be greater than the primary in the following ratio. If the two circuits, that is the primary and secondary, are more or less widely separated or loosely coupled and tuned in resonance, the damping being negligible, the ratio of transformation is determined entirely by the capacities in the two circuits, but when the circuits are close together or closely coupled, but not tuned in resonance, the ratio is determined by the relative number of turns in the two circuits.

Current is applied to the apparatus at a voltage of 110 volts. This first passes through a variable inductance, which is in series with the primary of the transformer and in some cases serves to limit the current supplied. The transformer consists of a core type transformer having a primary and secondary wound on each leg. The primary of 110 volts supplied to the primary is stepped up to ten or twelve thousand volts, due to the difference in the ratio of the number of turns on the two coils. The secondary circuit is hunted with a variable condenser which is in series with a spark gap and the primary of the oscillations increasing to many thousands of volts.

The discharge across the spark gap is practically a short circuit across the secondary terminals of the transformer and if this arc is not suppressed or broken up, there will not be a true oscillatory discharge in the condenser circuit or at best only a weak one, for the reason that as the arc discharge holds, the secondary terminals of the transformer are reduced in voltage and not until the arc is destroyed that the spark gap can build up a sufficient difference of potential to give a fresh charge to the condenser. The inductance and capacity of the secondary systems also influence the number of discharges obtainable during an alternation. The less the inductance and capacity of the condensers connected to any given oscillator, the greater the number of discharges obtainable per second and likewise if the inductance and capacity of an oscillator be reduced, the rate of sparking will be increased. When the gap is long more energy is stored up in the condenser but as it is only charged once or twice per half cycle the total available energy may be less than when a short gap is used. With a short gap the charging and discharging takes place many more times per half cycle although not as much energy is stored up in each charge. The length of the spark gap is determined by the type of service required. If we require long sparks from the secondary of the high frequency transformer or oscillator, the spark gap in the condenser circuit should be long; but when a high effective current is required the gap should be short. If, however, the gap is made too short, a flaming arc will occur in place of a long bright spark and no oscillations or only weak ones are set up for the reasons as stated before. On account of the exceedingly high frequency of the oscillatory discharge of the condenser the inductive effects are remarkable, considering the small quantity of electricity stored in the condenser.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer.

Annual Meeting

The thirteenth annual meeting of the Branch was celebrated by a banquet at the Kitchener hotel, Regina, on the evening of March 21st, 1930. H. R. Mackenzie, A.M.E.I.C., Chairman of the Branch, presided over the gathering which numbered thirty-eight.

The Chairman opened the meeting by proposing a toast to The King, after which the following guests were introduced:— J. B. Hamilton, a former member of The Institute and formerly of Estevan, Sask., H. B. Brehaut, A.M.E.I.C., now of Regina, but until recently with the C.N.R. at Saskatoon, Sask., E. S. Carpenter, a graduate in engineering from the University of Saskatchewan and son of H. S. Carpenter, M.E.I.C., W. G. Dyer, B. W. Sewell, and Dr. J. S. Huff, Commissioner of Education for Saskatchewan.

J. R. C. Macredie, M.E.I.C., of Moose Jaw, Sask., sent his regrets at his inability to attend the meeting.

The report of the Legislation Committee was presented by the Chairman of that committee, P. C. Perry, A.M.E.I.C. The report indicates that the Engineers Bill now before the Legislature of Saskatchewan has reached the final stages and is expected to receive its final reading soon. The thanks of the meeting were tendered Mr. Perry and his committee, also H. R. Mackenzie, A.M.E.I.C., Chairman of the Branch, and to Hon. A. C. Stewart, Minister of Highways, and Mr. G. Bennett, M.L.A., for their efforts in bringing this Bill to the present stage.

The report of the Papers and Library Committee was presented by the Chairman of that Committee, Stewart Young, A.M.E.I.C. The meeting passed a vote of thanks to this committee for the excellent work which they had performed during the past year.

The report of the Executive Committee was presented by the Secretary-Treasurer, R. W. E. Loucks, A.M.E.I.C. This report shows the Branch to be in a healthy condition with a total membership approximately the same as for last year.

The scrutineers Messrs. Harry Jones, S.E.I.C., and G. G. Fitzgerald, A.M.E.I.C., reported the election of officers as follows:—

Chairman—Prof. W. G. Worcester, M.E.I.C., University of Saskatchewan, Saskatoon, Sask.
Vice-Chairman—D. A. R. McCannel, M.E.I.C., City Commissioner, Regina, Sask.
Executive—(2 years)—
J. M. Campbell, A.M.E.I.C., Moose Jaw.
D. A. Smith, A.M.E.I.C., Regina.
R. A. Spencer, A.M.E.I.C., Saskatoon.
Nominating Committee—
R. N. Blackburn, M.E.I.C. (Chairman), Regina.
A. M. Macgillivray, A.M.E.I.C., Saskatoon.
H. R. Mackenzie, A.M.E.I.C., Regina.
H. McIvor Weir, M.E.I.C., Saskatoon.
G. M. Williams, A.M.E.I.C., Saskatoon.

Messrs. O. Inkster, A.M.E.I.C., and C. D. Lill, A.M.E.I.C., were elected as auditors for the ensuing year.

H. S. Carpenter, M.E.I.C., on behalf of the Branch presented a gold membership badge to M. B. Weekes, M.E.I.C., a past Chairman, in token of their appreciation of his services to the Branch. Mr. Weekes suitably thanked the Branch for the action taken.

J. R. Reid, A.M.E.I.C., who is now living in Regina was introduced to the meeting and spoke briefly. Messrs. H. G. Phillips and W. E. Denley, A.M.E.I.C., spoke on behalf of the highway engineers who will shortly be leaving Regina to take charge of the newly organized districts in the province.

The business of the meeting was interspersed by songs rendered by Mr. Forbes Roberts accompanied by Mr. Dickenson.

Address By Dr. J. S. Huff

Dr. J. S. Huff, Commissioner of Education for the Province of Saskatchewan, gave a very interesting address on the new curricula for secondary or high schools. He stated at the outset that this was his first public utterance outlining the scope of the new curricula now in course of preparation by educational experts of the province, covering 'teen age children and which it is hoped will be ready for introduction into the schools by September 1931.

In framing the curricula Dr. Huff stated that the social and economic needs of the individual as they are interpreted by the experts will be the sole basis of fixing the various courses of study, regardless of anything that has been or now is in existence.

He stated that there should be no break in a child's 12 year course of study taking him through the public and secondary schools, but that the first six years of his course should train him to speak, read, and write English with accuracy and precision and with some degree of fluency and that he should have mastered the number relations necessary in the ordinary business of life. In the following three years the individual should have an opportunity of expanding into fields of observation and scientific record that have to do with the common professions of the people of the province.

The new curricula will be founded on three basic principles: the development in the pupils of health and happiness, the economic and social efficiency including citizenship and character training, and recreation or the employment of leisure hours for the enrichment of life. In the secondary schools the child should have an added opportunity to explore possible life vocations, and for this purpose courses have been designed relating them to the needs and environment of the child. Agriculture, the basic industry of the province, will be given prominence in the new course of study, which will also include studies in geology and those subjects related to the development of the natural resources of the province.

In the new curricula plans have been made for preparing the pupils for the vocations of life under four headings:—

1. For entrance to teacher training schools.
2. For entrance to technical schools.
3. For entrance to university arts courses.
4. For entrance to business and commerce.

In all these courses the number of subjects will be materially reduced from the number now prescribed. As the pupil advances he will be given more optional subjects and fewer compulsory ones. Provision will be made to allow bright pupils to combine two courses, such as the teacher training course and university matriculation.

Dr. Huff concluded his address by stating that the framing of the new curricula is a scientific matter and must be founded on public opinion. He made a plea to the engineers of the province to aid the department in cultivating public opinion in harmony with the scientific plans of the experts.

In the discussion which followed the engineers voiced their approval of the new curricula which they felt would place our schools on a much higher plane than in the past.

Report of Executive Committee

To the members of the Saskatchewan Branch, The Engineering Institute of Canada:

Your Executive Committee respectfully submits the following report covering the conditions of the Branch and its operation during the past year:

The membership is 118 as compared with 121 reported at last annual meeting, and is made up as follows:—

Honorary Members	1
Members	16
Associate Members	78
Juniors	6
Students	10
Affiliates	2
Branch Affiliates	5
Total	118

The Executive held seven meetings for the transaction of Branch affairs. There were six regular meetings of the Branch and one special meeting—this latter taking the form of a dinner dance to which the ladies were invited. Ladies night proved to be an enjoyable and highly successful event.

Our Councillor, D. A. R. McCannel, A.M.E.I.C., attended the Plenary Meeting of Council at Montreal in October last, and gave the Branch a full report of matters dealt with at that meeting.

Special matters referred to the Executive were dealt with by that Committee and in some cases by the Branch at the regular meetings. As you are aware, the Executive passes upon and makes recommendations on all applicants for admission and transfer within Saskatchewan, and a number of these were dealt with. The question of securing legislation incorporating the engineers in Saskatchewan has been one of the important events of the year. This matter has been handled mainly by the Legislation Committee.

In May 1928, H. S. Carpenter, M.E.I.C., was elected to the senate of the University of Saskatchewan for a term of three years as a representative of the Saskatchewan Branch of The Engineering Institute of Canada. The privilege of having a representative from this Branch on the senate was granted on the request of the Branch Executive.

We are honoured in having Prof. C. J. Mackenzie, M.E.I.C., Dean of Engineering at the University of Saskatchewan, as Vice-President of Zone A for another year. Dean Mackenzie has served on several important committees of The Institute during the past year.

The annual scholarship of $50.00 offered by the Branch to the most deserving student in the graduating class in engineering at the University of Saskatchewan was awarded to Mr. B. P. Scull of Saskatoon, Sask.

The average attendance at the Branch meetings has been 34, exactly the same as for last year. Each meeting has been preceded by a banquet. The programme, as arranged by the Papers and Library Committee, has resulted in considerable interest on the part of all members in attendance. Your Executive is highly satisfied with the general interest displayed in the affairs of the Branch.

Attached hereto is the financial statement for the year, showing revenue and expenditure, also assets and liabilities. This statement has been examined by your auditors. Although no Branch assessments have been levied since 1925 the assets show a surplus over liabilities of $615.63 being an increase of $4.89 over the surplus shown last year. Accounts payable this year are $18.56 as against $21.84 last year. Branch News produced a revenue of $36.98. The meetings have been practically self-sustaining.

On behalf of the Executive,
R. W. E. Loucks, A.M.E.I.C., *Secretary-Treasurer.*

Financial Statement 1929-30

Revenue

On hand from 1929	$255.07	
Headquarters rebates	280.05	
Branch dues	18.00	
Branch News	36.98	
		$590.10

Expenditure

Office expenses	$ 52.39	
Meeting expenses	73.10	
Honorarium	130.00	
Scholarship	50.00	
Sundries	30.90	
Bank balance	253.71	
		$590.10

Assets

Bank balance	$253.71	
Est'd. Headquarters rebates 1930	271.20	
Est'd. Headquarters arrears	99.28	
Est'd. Branch Dues 1930	10.00	
Furniture and library	50.00	
		$684.19

Liabilities

Scholarship for 1930	$ 50.00	
Accounts payable	18.56	
Surplus	615.63	
		$684.19

This is to certify that we, your auditors, have examined the books and vouchers of the Saskatchewan Branch, The Engineering Institute of Canada, and believe the above statement represents the correct financial position of the Branch.

(Signed) David D. Low, Jr.E.I.C.
W. H. Hastings, A.M.E.I.C.
Auditors.

Sault Ste. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting of the Sault Ste. Marie Branch was held in the Y.W.C.A. rooms on March 28th. A. M. Wilson, Jr.E.I.C., of the lands department of the Algoma Central Railway, read a paper on "The Construction of the Michipicoten Coal Dock."

In introducing his subject Mr. Wilson gave a brief account of the reasons for building a coal dock at Michipicoten. Paper mills, railways and mining operations are large consumers of coal in the districts of Algoma, Cochrane, the western part of Sudbury and the eastern part of Thunder bay district. To provide cheaper transportation for this coal which is brought by boat from the northeastern United States the Algoma Central Railway decided to develop the already partly developed Michipicoten harbour as a coal dock. This greatly reduces the rail haul as previously this coal had to be transshipped at Sault Ste. Marie.

Michipicoten harbour was developed originally about 1900, to serve the iron mines and is connected to the main line of the railway by a branch. The old dock was demolished in 1928 and in the winter of 1928 and 1929 a survey of the harbour was made, soundings being taken through the ice. Rock was found at depths of from 22 to 55 feet. It was then decided to build wooden cribs to be sunk five feet below the dredged channel. These cribs, and the space immediately behind them, were filled with iron ore waste which was obtained from a nearby source. The remainder of the fill, an area about 300 feet wide and 500 feet long and triangular in shape, was filled with gravel obtained from a high bank alongside the track about seven miles distant. The dock top was built on a continuous line along the top of the cribs and tracks laid on the raised fill behind the dock front. On the runways of the coal bridge 100-lb. C.P.R. section rail was laid. The coal bridge is a rope trolley steam operated type, the framework being of rugged steel construction. It is designed to unload stock, reclaim and load out bituminous coal at the rate of 500 net tons per hour.

A vote of thanks was tendered Mr. Wilson by Messrs. A. H. Russell, A.M.E.I.C., and W. S. Wilson, A.M.E.I.C.

Following Mr. Wilson's paper L. F. Harza, M.E.I.C., consulting engineer of Chicago, who is associated with the Algoma District Power Company, gave a talk on "The History of Dam Construction" or "Types of Dams." Mr. Harza illustrated his talk with blackboard sketches.

Earth, loose rock, masonry, and the largest concrete dams are of the gravity type. Earth dams well packed and containing some clay are as tight or tighter than concrete dams. It is now customary to put drain pipes in the lower toe to take care of any seepage. They are built as high as 250 feet.

Hydraulic filled earth dams originated west of the Rockies. Properly constructed the hydraulic-filled gives the tightest dam known.

In rock-filled dams the main fill consists of rock. A masonry wall is put on the face and this topped with a concrete slap. This type is used where it is hard to get concrete material.

Lately several new types of dams are being designed to compete with the gravity dam in order to cheapen the cost. Such a one is the Coolidge dam, a modified multiple arch dam, called a dome dam. Difficulties arise due to shrinkage, setting and compression which all tend to shorten the arches which factors all have to be taken care of in the design.

A vote of thanks was tendered Mr. Harza by F. Smallwood, M.E.I.C., seconded by all present.

Victoria Branch

K. M. Chadwick, M.E.I.C., Secretary-Treasurer.

On Friday, March 28th, The Victoria Branch of The Engineering Institute of Canada held a most successful dinner and smoking concert at Hamsterley Lake Side (near Elk lake), when some forty members and guests were present. The chair was occupied by Patrick Philip, M.E.I.C., ably supported by the Honourable F. P. Burden, Minister of Lands, J. E. Griffith, M.E.I.C., Deputy Minister of Railways, and J. P. Forde, M.E.I.C., district engineer of the Dominion Public Works.

Mr. Philip referred to the activities of the profession, laying stress on the desirability of the amalgamation of The Engineering Institute with the various provincial societies of the Professional Engineers, on which problem committees of both organizations are now engaged.

He paid a compliment to the committee responsible for such a successful evening and recommended that a similar gathering should be held quarterly each year. This success was attributed chiefly to I. C. Barltrop, A.M.E.I.C., O. W. Smith, M.E.I.C., H. F. Bourne, A.M.E.I.C., Chairman of the local Branch, and K. M. Chadwick M.E.I.C., Secretary of the local Branch.

Following Mr. Philip's speech Bob Webb led the gathering in community singing. Hon. F. P. Burden proposed the toast of "The Profession," and spoke of the need of the engineer in the development of the country. He also reviewed the work of the many and varied branches of engineering which members of the profession were called upon to undertake.

J. P. Forde, M.E.I.C., spoke of the good work done during the late government's regime by Hon. Messrs. Pattulio and Sutherland, late Minister of Lands and Minister of Public Works, in raising the status of the profession in the public mind, which good work was being carried on by the present ministers, Hon. F.P. Burden and Hon. N. S. Lougheed.

An excellent musical programme and sketch followed, the efforts of Messrs. Bob Webb, Frank Allwood and G. Ingledew being much appreciated. Musical accompaniment was ably provided by Percy Fletcher. A most enjoyable evening was terminated by the singing of "Auld Lang Syne."

The Steel Company of Canada, Limited has just issued a new booklet, which contains 12 pages with illustrations, explaining the advantages of "Stelco Scale Free Pipe."

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Wanted

CHIEF ENGINEER, twenty years industrial construction, production and operation. Structures, equipment, steam, hydro. Experienced in conferences, preliminaries, organizing, preparing plans, estimates, specifications, negotiation contracts. Apply to Box No. 36-W.

CIVIL AND MECHANICAL ENGINEER, aggressive practical engineer, with background of experience in design, construction, maintenance and operation of pulp and paper mill, desires change. Especially qualified to reduce mill costs. Apply to Box No. 53-W.

CIVIL ENGINEER, graduate '15, with railroad, roads and municipal experience, desires spare time work in evenings and Saturday afternoons. Speaks French and English. Neat draughtsman. Apply to Box No. 55-W.

MECHANICAL ENGINEER, with twenty years experience in design, construction, sales and management desires position of an engineering, commercial or executive nature. College graduate, M.E.I.C., M.A.S.M.E., M.P.E.Q., and formerly chief engineer. Apply to Box No. 92-W.
