The General Secretary announced the result of the recent ballot on the proposed amendments to Sections 44 and 51 of the By-laws. (See p. 299 of this issue.)

The President gave a general outline of the relations with the various Provincial Associations with special regard to the Dominion Council. He also described a very successful joint dinner which had been held on April 22nd in Toronto between the Council and Past-Presidents of The Institute and the Council and Past-Presidents of the Association of Professional Engineers of the Province of Ontario, and mentioned some of the expressions of appreciation which had come from various officers of the Provincial Association and from others interested in the welfare of the engineering profession. He thought that this dinner had prepared the way for further conferences leading to closer co-operation between all organized engineering bodies in Ontario.

Councillor Newell, as chairman of the special Committee on Professional Interests, made a report on the activities of his committee dealing with the Professsional Associations in Nova Scotia, New Brunswick, Manitoba and Saskatchewan. Negotiations with these provinces were proceeding satisfactorily, and he was hopeful that a satisfactory basis of co-operation would be reached in due course. The tremendous majority by which the members of The Institute had approved of the enabling By-law No. 76 was an indication that members were anxious to see a closer relationship brought to pass in all the provinces.

The status of the Nova Scotia negotiations was discussed at great length, and it was unanimously agreed that the present difficulties regarding authority for an appropriate agreement could and would be cleared away. The President emphasized that as far as the Institute was concerned, its policy and its practice was to encourage the closest possible constructive co-operation with the Associations, at the same time to refrain from forcing or pressing negotiations faster or further than might be desired by the respective associations.

Strong representations were made for a widespread dissemination of the proceedings of Council in order that branch executives might be better informed. Council was urged to consider at its next regular meeting the advisability of authorizing the General Secretary to send copies of minutes to all branch chairmen.

Mention was made of the progress report of the Committee on Membership and Management. In view of the pressure of time, it was decided that the report be considered by the local branches, and their comments forwarded to Headquarters.

Many expressions of appreciation were made in reference to Mr. R. J. Durley's services as General Secretary. Great regret at his retirement was indicated.

An intersting discussion took place on the report of Past-President Shearwood dealing with the supply of and demand for technically trained men. The President reported the action of the Toronto meeting, and described what had been done since that time towards capitalizing on the suggestions contained in the report. Professor McKiel commended the report strongly, and stated that this was one of the most important subjects that the Institute could consider.

As the date for the submission of names for the Sir John Kennedy Medal had passed, the President announced the five names which had been sent to Headquarters with branch recommendations. It was agreed that the five names, with a history of their achievements, should be sent to all members of Council.

The President outlined the developments leading up to the World Power Conference which was to take place at Vienna on August 25th, 1938, and stated that council would we glad to accredit any corporate member who desired to attend.

The Council rose at three forty-five p.m., to attend the President's reception, which was held in the main lounge of the hotel.

Annual Meeting in Ottawa 1939

At the Council meeting in Toronto on April 22nd the invitation of the Ottawa Branch was accepted and the annual meeting will be held in that city at a date which is not yet determined. It is expected that it will take place at the end of January or early in February.

One of the principal features of this meeting will be the presentation of papers and discussions on Western Water Problems. G. A. Gaherty, M.E.I.C., is chairman of the committee and has already arranged with several of the outstanding experts for the preparation and presentation of papers on the various phases of this important topic. It is expected that members and public officials from the Prairie Provinces and from Ottawa will take a very active part in this part of the annual meeting. A list of papers and speakers will be published shortly.

OBITUARIES

Frederick William Caldwell, M.E.I.C.

Deep regret is expressed in placing on record the death of Frederick William Caldwell, M.E.I.C., at his home in Schenectady, N.Y., after several months' illness.

Mr. Caldwell was born at Lawrence, Mass., on November 12th, 1875. He was graduated from the Massachusetts Institute of Technology in 1899 with the degree of S.B. Going to Schenectady in 1902, he began a connection with the General Electric Company which lasted twenty-five years. During this time he was in the office of the vice-president of the company, in charge of engineering and manufacturing. His duties were of an executive nature in general engineering. In 1928 he came to Montreal where he remained until 1934, practising as a consulting engineer. He then returned to Schenectady and continued his practice. In 1935 he became a member of the New York State Planning Board.

Mr. Caldwell joined The Institute in 1929 as a Member.

Major John Cormack Craig, D.S.O., O.B.E., M.E.I.C.

From Scotland comes word of the death of Major John Cormack Craig, M.E.I.C., in Edinburgh on April 30th. Major Craig was born at Aberdeen, Scotland, on July 10th, 1874, where he received his early education at Robert Gordon's College. In 1900, after ten years' apprenticeship with Hall Russell and Company, shipbuilders and engineers, and with the city engineer, Aberdeen, Major Craig was appointed assistant resident engineer on the Aberdeen sewage works. Three years later he became engineering assistant to the city engineer of Westminster, London.

In 1905 Major Craig was appointed resident engineer of the Public Works Department of Straits Settlements. During the years from 1905 to 1913 in which he held office, he was in charge of the construction of ferro concrete lighthouse Straits of Malacca and harbour extension works Penang.

In 1914 Major Craig came to Canada and was on the staff of the Pacific Great Eastern Railway at Vancouver. In the fall of that year he received his commission as lieutenant in the 6th Field Company Engineers. In 1915 he became captain of the 1st Canadian Pioneers and in 1916 major chief engineer and 2nd in command of the 9th Canadian Railway Troops until September 1918, when he became assistant director of construction, light railway section. He was awarded the Distinguished Service Order and was mentioned in despatches three times. Following the war he remained in the Old Country until his appointment in 1922 as assistant chief engineer, Gold Coast Harbours, with headquarters at Accra. Later he was located at Seccondee, Gold Coast Colony, West Africa.

In 1927 Major Craig left Aberdeen for British Guiana as director of public works at Georgetown. In 1931 he returned to British Guiana for another term of duty. At the completion of this term he returned to Scotland where he resided until the time of his death.

Major Craig joined The Institute in 1916 as an Associate Member becoming a Member in 1919.

His Grace the Duke of Devonshire, K.G., P.C., G.C.M.G., LL.D., Hon.M.E.I.C.

His Grace the Duke of Devonshire, whose death occurred on May 5th, 1938, was born on May 31st, 1868. He received his education at Eton and Trinity College, Cambridge. From 1891 to 1908 he was a Member of Parliament for Derbyshire West. From 1900 to 1903 he served as Treasurer of H.M. Household and from 1903 to 1905 Financial Secretary to the Treasury. His Grace served as a Civil Lord of the Admiralty from 1915 to 1916. With his fine reputation gained in local affairs and affairs of the state, his appointment as Governor-General of Canada in 1916 was a fortunate one for Canada. His term of office included the last two years of the Great War and continued until 1921. During this eventful period the Duke of Devonshire exerted himself on behalf of every patriotic cause.

In 1917 His Grace shared in the national celebration of the golden jubilee of Confederation and took part in the inaugural ceremonies of the opening of the Quebec bridge. In 1919, as Governor-General, he took a leading part in the ceremonies attending the laying of the foundation stone of the Memorial Tower of the new Parliament Buildings at Ottawa by the Prince of Wales.

The Duke of Devonshire became an Honorary Member of The Institute on March 20, 1917.

David Howard Fleming, M.E.I.C.

Members of The Institute will learn with regret of the death of David Howard Fleming, M.E.I.C., who died April 9th in Toronto. Mr. Fleming was born at Pelee Island, Essex County, Ont., on April 1st, 1888. He received his education at Windsor Collegiate and later at the University of Toronto from which he was graduated in 1913 with the degree of B.A.Sc. After graduation he became assistant to the city engineer at St. Catharines, Ont., and later was connected with the engineering department of the City of Toronto. In 1919 Mr. Fleming became town engineer of Owen Sound, Ont. This position he held until 1924 when he joined the firm of A. W. Connor and Company, consulting engineers, in the capacity of municipal engineer. In 1929 he became consulting engineer for Layne Canadian Water Supply Company, Toronto. From 1931 he was in private practice as consulting engineer in Toronto.

Mr. Fleming joined The Institute in 1912 as a Student, becoming an Associate Member in 1916 and a Member in 1936.

Edwin Albert Forward, M.E.I.C.

Members of The Institute will regret to learn of the death of Edwin Albert Forward, M.E.I.C., in Montreal, on April 30th. Mr. Forward was born at Iroquois, Ont., on October 23rd, 1870. He received his early education there, later attending the School of Practical Science, University of Toronto, from which he was graduated in 1897 with honours. From 1898 to 1904 he was engaged on construction of the 14-foot enlargement of the St. Lawrence canals, at the Galops, Morrisburg, Farrans Point and Cornwall sections.

In 1905 to 1906 he took part in the preparation of survey and estimates for the Georgian Bay ship canal and then took charge of construction of a lock and curtain dam on the Red river, Manitoba, until 1909.

In 1910, Mr. Forward associated himself with Messrs. Quinlan and Robertson of Montreal, general contractors, and for ten years was connected with construction works of importance including, Transcona railway shops, Trent and Welland canals, power dam at High Falls on the Du Lièvre, St. Charles river and harbour improvements at Quebec, the building and outfitting of vessels.

From 1919 to 1921 he was engaged on various valuation cases including the Grand Trunk arbitration case, and in the latter year established a consulting practice. He remained in private practice until 1926 when he entered the firm of Robertson and Janin, Iroquois, Ont. In 1931 he came to Montreal to the firm of Angus Robertson Limited as chief engineer.

Mr. Forward joined The Institute as Associate Member in 1900, transferring to the class of Member in December 1911.

Harry Donald Macaulay, A.M.E.I.C.

The death of Harry Donald Macaulay, A.M.E.I.C., occurred in Montreal on May 14th, 1938. Mr. Macaulay was born in Saint John, N.B., on August 2nd, 1888, and here received his early education. After following a course in civil engineering at the University of New Brunswick, Fredericton, N.B., he began his railway work as rodman on the Boston and Albany Rail Road in 1909. In 1910 he became rodman then instrumentman on construction and valuation work with the Chicago and North-Western Railway. While in the United States Mr. Macaulay continued to study civil engineering and took a post graduate course at the Wisconsin University. Mr. Macaulay entered the employ of the Canadian Northern Railway in 1912 and as resident engineer remained here for a year. From 1913-1914 he acted as transitman on location with the St. John and Quebec Railway.

Mr. Macaulay contributed in no small measure to the development of his native port. In 1914 he became assistant engineer in the Federal Department of Works, Saint John Harbour staff. He worked on the design and construction of the Beacon Bar wharves and on the Courtenay Bay development and later on the harbour-front survey.

When the Saint John Harbour Commission was formed Mr. Macaulay became a member of the staff and afterwards served on the National Harbours Board. He left the latter position in the fall of 1937 to go to Port Alfred, Que., to take the position of resident engineer of the Saguenay Terminals Limited for the Aluminum Company of Canada. He held this position until he became ill and fourteen days later died.

Mr. Macaulay joined The Institute as an Associate Member in 1919.

Joseph Baermann Strauss, M.E.I.C.

The death of Joseph Baermann Strauss, M.E.I.C., occurred on May 16th in Los Angeles. Mr. Strauss was born in Cincinnati, Ohio, on January 9th, 1870, and was graduated from the University of Cincinnati in civil engineering in 1892. He returned to the University two years later as instructor in the College of Engineering. From 1897 to 1899 he was designer in charge of the Sanitary District of Chicago.

In 1904, after two years' practice as consulting engineer in Chicago, Mr. Strauss formed the Strauss Bascule Bridge Company in which we held the positions of president and chief engineer. This company devoted itself to the preparation of plans and specifications for bascule and lift bridges of his design. Between the years 1904 and 1921 approximately 220 of these bridges, representing a money value of $30,000,000, were built in the United States, Canada and various parts of the world. In the designs of these bridges the bascule bridge reached the largest limits in size and weight which had been attempted up to that time. Mr. Strauss was thus the originator of five types of the Strauss trunnion bascule bridge which is standard throughout the world. He also originated two types of lift bridges and invented a type of portable searchlight used by the United States and Russian Governments in the Great War.

Mr. Strauss was also designing engineer for the Arlington Memorial Bridge across the Potomac river at Washington, D.C., and consulting engineer for the Port of New York Authority on the George Washington Memorial Bridge. He will be remembered in Montreal for his work as engineer for the Jacques Cartier Bridge. His reputation was made world-wide by his design of the Golden Gate Bridge at San Francisco. He received the degree of D.Sc. from Cincinnati University.

He joined The Institute as an Associate Member in 1909 becoming a Member in 1921.

PERSONALS

Members will be interested and concerned to hear of the illness of Secretary Emeritus R. J. Durley, M.E.I.C. Mr. Durley underwent a serious operation on May 16th, the outcome of which the doctor reports to be perfectly satisfactory. It will be many weeks, however, before he will be able to leave hospital. Any communications for Mr. Durley addressed to the Institute will be put into his hands without delay.

Members of the Institute everywhere will be pleased to know that recognition of the services of President Challies during the period of his public service at Ottawa, has been made by the Professional Institute of the Civil Service of Canada, in the form of an Honorary Membership. The citation on the certificate reads as follows:

> "In recognition of conspicuous services rendered by him to the Institute in that he was chiefly responsible for proposing that an institute of professional civil servants of Canada be established, took the initiative in its formation and served upon the provisional executive during the organization period; thereafter, he at at all times promoted the interests of the Institute as a member of the Hydraulic-Reclamation Engineers Group until his resignation from the public service in 1925."

(Signed) J. Clement Beauchamp,
President.
C. Sweet,
Hon. Secretary-Treasurer.

G. J. Desbarats, Hon.M.E.I.C., formerly Deputy Minister of National Defence, and Mrs. Desbarats celebrated the fortieth anniversary of their marriage on May 17th. In the evening they held a dinner party when their entire family were present. The Institute joins with their many friends in offering congratulations, and expresses the hope that they may enjoy many more anniversaries together.

Past-President A. J. Grant, M.E.I.C., of St. Catharines, has been visiting throughout the winter in the Barbados. He was present at the dinner given by the Niagara Peninsula Branch to the President on May 13th, looking very fit after his vacation.

J. G. Sullivan, LL.D., M.E.I.C., was honoured by the American Railway Engineering Association at its thirty-ninth annual meeting in Chicago, by his election to honorary membership. Mr. Sullivan is a prominent figure in both The Engineering Institute of Canada and the American Railway Engineers Association, being a past-president of both organizations. His contribution to the science of engineering and to the benefit of the Institute was recognized in the awarding of the Sir John Kennedy Medal to Mr. Sullivan in 1937. This is the highest honour which the Institute can confer.

C. A. Robb, M.E.I.C., Professor of Mechanical Engineering at the University of Alberta, was a very welcome visitor at Headquarters on May 19th.

J. D. Sylvester, S.E.I.C., is another Edmonton member who is spending some time in Montreal. It was an interesting coincidence that Professor Robb and Mr. Sylvester should happen to come to Headquarters at the same time. It is pleasant for the Headquarters staff to see out-of-town members meeting in this way under the Headquarters roof.

John A. Stiles, M.E.I.C., of Ottawa, chief executive commissioner of the Boy Scouts Association in Canada, was awarded the "Silver Buffalo for Disinguished Service to Boyhood" at the National Scout Council's 28th annual meeting May 14th.

Norman B. Wilson, M.E.I.C., a partner in the firm of Wilson and Bunnell, consulting engineers, Toronto, has been retained by the city of Edmonton to prepare a comprehensive survey of the city's transportation set-up.

G. P. Wilbur, A.M.E.I.C., manager of sales, Ontario Division of the Dominion Bridge Company, Toronto, was recently elected president of the Canadian Institute of Steel Construction.

Archibald Cox, A.M.E.I.C., has accepted the position of master mechanic and construction engineer with the Crow's Nest Pass Coal Company, Limited, Michel, B.C.

David Boyd, A.M.E.I.C., who has been with the Canada Car and Foundry Company as welding engineer, has been transferred to Fort William, Ont., as works manager of their plant there.

Robert M. Hardy, M.Sc., A.M.E.I.C., assistant professor of civil engineering at the University of Alberta, was another welcome visitor at Headquarters. He was particularly interested in sounding out the employment situation in the Montreal district in order that he might be in a better position to advise the Edmonton graduates. He has been very active in Institute affairs, serving for some time as Secretary-Treasurer of the Edmonton Branch.

D. C. Tennant, M.E.I.C., has recently been appointed engineer to the Ontario Division of the Dominion Bridge Company and will be located at Toronto. Mr. Tennant has been connected with the Dominion Bridge Company since 1900 having entered the company after his graduation from Toronto University with the degree of B.A.Sc. with honours. He served as Councillor of The Institute from 1931-1933.

L. G. Scott, Jr.E.I.C., who has been located at Winnipeg, has been transferred by the Hudson's Bay Company to Edmonton, Alta.

K. Y. Lochhead, Jr.E.I.C., is now with the Hudson's Bay Company Retail Store in Vancouver, B.C., having been transferred from Winnipeg, Man.

The Council of the Association of Professional Engineers of British Columbia announces the appointment of Mr. J. C. Oliver, B.A., B.A.Sc., as Registrar of the Association. Mr. Oliver graduated from the University of British Columbia in 1927. He took up his duties as Registrar on May 1st.

John T. Dyment, A.M.E.I.C., who for the past year has been with the Department of Transport as aeronautical engineer in the Aeronautical Engineering Branch has accepted a position with the Trans-Canada Air Lines in Winnipeg in the same capacity. Mr. Dyment was graduated from the University of Toronto in 1929 with the degree of B.A.Sc.

J. Donald Rice, S.E.I.C., is now engineer in charge of the geological office of the International Petroleum Company, Limited, Negritos, Peru, S.A. After graduating from McGill University in 1935 with the degree of B.Eng., Mr. Rice was connected with the Foundation Company of Canada, Montreal, for a year. He then entered the Canada Car and Foundry Company Limited, Montreal, remaining with this Company until March of this year.

Edgar T. J. Brandon, A.M.E.I.C., chief electrical engineer of the Hydro-Electric Power Commission of Ontario, on April 25th celebrated thirty years' service with the commission. Mr. Brandon has the distinction of being the second longest service employee on the staff. He began his connection with the Commission in 1908 on design and construction.

George MacLeod, A.M.E.I.C., was recently made district engineer at Salmon Arm, British Columbia, by the Department of Public Works. Mr. MacLeod was formerly general foreman in the Departmental office in New Westminster, B.C.

ELECTIONS AND TRANSFERS

At the meeting of Council held on May 20th, 1938, the following elections and transfers were effected:

Members

HODGSON, Ernest Atkinson, M.A., (Univ. of Toronto), Ph.D., (Univ. of St. Louis), chief, Division of Seismology, Dominion Observatory, Ottawa, Ont.

HORNBACK, Michael Edwin, B.Sc. (Civil), (Univ. of Miss.), 2535 Montclair Ave., Montreal, Que.

THRUPP, Frederick Edward Milan, Dipl. Ing., (Tech. Univ. of Darmstadt, Germany), manager for Canada and Newfoundland for the Buell Combustion Co. Ltd., of London, England, Hamilton, Ont.

Associate Members

CHARLES, Robert Simpson, Jr., B.A., (Amherst College, Mass.), field engr., International Water Supply Ltd., London, Ont.

HUTCHEON, Neil Barron, B.Sc. (Mech.), M.Sc., (Univ. of Sask.), asst. professor in mechanical engineering, University of Saskatchewan, Saskatoon, Sask.

MacGILL, Elizabeth Muriel Gregory, B.A.Sc. (E.E.), (Univ. of Toronto), M.Sc. in Engrg., (Univ. of Mich.), asst. engr., Fairchild Aircraft Ltd., Longueuil, Que.

MUSGRAVE, Arthur Stanley Gordon, B.A., B.Eng. (Civil), (Trinity College, Dublin), municipal engr., Oak Bay, B.C.

Juniors

HARSHAW, Francis Norman, B.Sc. (Civil), (Univ. of Sask.), transmitter operator CFQC, Saskatoon, Sask.

KRENDEL, Conrad John, B.Sc. (Civil), (Univ. of Man.), University of Manitoba, Fort Garry, Man.

MALBY, George Thomas, B.Sc. (Civil), (Univ. of Man.), engr., Saguenay Power Co. Ltd., Arvida, Que.

PIERCY, Walter J., B.Sc. (E.E.), (Univ. of N.B.), underground electrn., McIntyre Gold Mines, Timmins, Ont.

PORTER, LAWSON BARDON, (Univ. of N.B.), asst. engr., National Harbours Board, Saint John, N.B.

*STEAD, Harry G., chief dftsman., E. Leonard & Sons Limited, London, Ont.

WHITEWAY, Lorne Bruce, B.Sc. (E.E.), (N.S. Tech. Coll.), Stellarton, N.S.

Transferred from the class of Associate Member to that of Member

ELDERKIN, Karl O., B.Sc. (Mech.), (McGill Univ.), engr. for John Stadler, M.E.I.C., consltg. engr., Montreal, Que.

KINGSTON, Thomas M.S., B.A.Sc., (Univ. of Toronto), city manager-engineer, Chatham, Ont.

Transferred from the class of Junior to that of Associate Member

*GRANT, Eric, 3645 Jeanne Mance Street, Montreal, Que.

HORTON, Everill Blackwell, B.A.Sc., (Univ. of Toronto), designing engr. and dftsman., Price Bros. & Co. Ltd., Riverbend, Que.

LEBLANC, Jules, B.A.Sc., C.E., (Ecole Polytechnique, Montreal), B.Sc. (Elec.), (Mass. Inst. Tech.), asst. chief engr. for Provincial Relief Work, District of Montreal, Ministry of Labor, Montreal, Que.

*MOFFAT, Alexander Robertson, (Queen's Univ.), chief surveyor of underground workings, Lamaque Gold Mines Ltd., Bourlamaque, Que.

WRIGHT, Noel Nithsdale, B.Sc., (Univ. of Illinois), sales engr., Ferranti Electric Limited, Montreal, Que.

Transferred from the class of Student to that of Associate Member

MACDONALD, John Ernest, B.A.Sc., (Univ. of B.C.), constrn. foreman, West Kootenay Power & Light Co., South Slocan, B.C.

Transferred from the class of Student to that of Junior

BENJAFIELD, John F., B.Sc., (Queen's Univ.), field engr., Foundation Company of Canada, Cornwall, Ont.

JOHNSON, James Richard, B.Eng., (McGill Univ.), asst. chief engr., Dominion Rubber Company, Montreal, Que.

JORDAN, Jack McLean, B.A.Sc., (Univ. of Toronto), 205 Wychwood Ave., Toronto, Ont.

McMANUS, Leslie Harold, B.Sc., (Univ. of Alta.), instructor, University of Alberta, Edmonton, Alta.

McMATH, Andrew A. B., B.Eng., (McGill Univ.), i/c Pulp and Paper Engrg. Dept., Canadian Ingersoll Rand Ltd., Sherbrooke, Que.

Students Admitted

ACKHURST, William Hall, (N.S. Tech. Coll.), 113 Henry St., Halifax, N.S.

BRYDGES, Robert James, B.Sc., (Univ. of Man.), P.O. Box 303, Souris, Man.

BUCHANAN, Arnold Amherst, (McGill Univ.), 3472 Montclair Ave., Montreal, Que.

DEAN, Maurice Ferguson, (Dalhousie Univ.), 142 9th Ave., Lachine, Que.

MEAGHER, Robert Douglas, B.Eng., (McGill Univ.), 571 Island Park Drive, Ottawa, Ont.

SNYDER, Robert Bertrum, B.Sc., (Univ. of Sask.), Lashburn, Sask.

WHITE, Clifford Hubert, B.Sc., (Univ. of Man), 337 Arlington St., Winnipeg, Man.

The following Students were admitted at the meeting of Council held on May 1st, 1938:

HOUGHTON, James Scott, B.Eng., (McGill Univ.), 730 Upper Belmont Ave., Westmount, Que.

RONCARELLI, Joseph Angelo, B.Eng., (McGill Univ.), 1429 Crescent St., Montreal, Que.

*Has passed Institute's examinations.

Elizabeth M. G. McGill, A.M.E.I.C.

Moncton Branch Dinner to Presidential Party

Standing—C. J. Letterick, Prof. F. L. West, M.E.I.C., A. R. Bennett, V. C. Blackett, A.M.E.I.C., Sec.-Treas., H. A. Fuller, G. E. Smith, A.M.E.I.C., C. W. Milton, N. B. Eagles, S.E.I.C.

Seated—Councillor F. Newell, President J. B. Challies, G. L. Dickson, A.M.E.I.C., General Secretary L. A. Wright, Prof. H. W. McKiel, M.E.I.C., J. A. Godfrey, C. S. G. Rogers, A.M.E.I.C., E. A. Cummings, Murray Wilson, S.E.I.C.

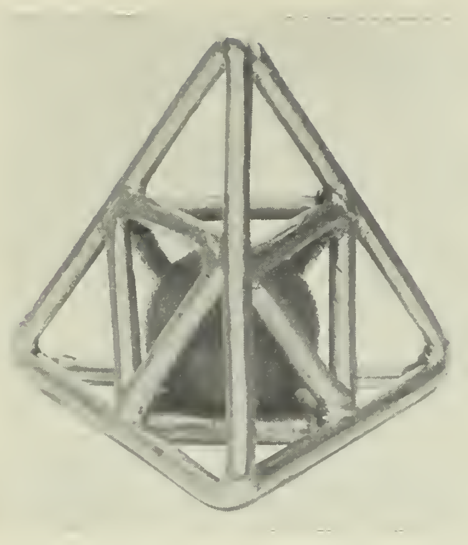
Saint John Branch Entertains the President and His Party

Seated at head table—G. A. FitzRandolph, G. Stead, M.E.I.C., S. Hogg, A.M.E.I.C., President J. B. Challies, Maj. W. H. Blake, A.M.E.I.C., Councillor F. Newell, General Secretary L. A. Wright, C. C. Kirby, M.E.I.C., J. D. Geary.

Standing—G. A. Vandervoort, A.M.E.I.C., V. S. Chesnut, A.M.E.I.C., C. N. Wilson, J. T. Turnbull, A.M.E.I.C., J. P. Mooney, A.M.E.I.C., G. G. Murdoch, M.E.I.C.

E. J. Owens, A.M.E.I.C. is seated at the end of the table to the left with C. T. Nisbitt, W. D. MacDonald, F. P. Vaughan, M.E.I.C., R. T. A. Moore, J. E. Warner, and F. A. Patriquen, JR.E.I.C., to his left and C. D. McAllister, R. E. Beeth, A. R. Crookshank, M.E.I.C., H. R. Logie, G. N. Hatfield, A.M.E.I.C., J. H. McKinney, A.M.E.I.C., and John Reed to his right.

Seated at table to the right—Norman Britain, A.M.E.I.C., H. P. Lingley, JR.E.I.C., Gordon Dow, S.E.I.C., J. R. Freeman, M.E.I.C., T. S. Moffat, A.M.E.I.C., A. A. Turnbull, A.M.E.I.C., and J. N. Flood, A.M.E.I.C.



The New Equilateral Tetrahedron

A photograph of an ingenious paper weight which was used by a past-president of The Engineering Institute of Canada, in his short speech at the memorable joint dinner of the Councils of The Institute and The Association of Professional Engineers of Ontario, held in the Royal York hotel, Toronto, on the evening of Friday, April 22nd, 1938. He appealed to all the various engineering organizations of the country to unite in some kind of all embracing organization, whatever its form might take, to enclose within it the whole engineering profession, loosely knit together with some freedom of internal movement. He likened the twenty triangles of the chromium plated copper framework to The Engineering Institute, the Dominion Council, the Provincial Associations and other organizations, and the loose manganese bronze ball enclosed within, to the profession in its entirety.

CORRESPONDENCE

The Editor,
The Engineering Journal.

Dear Sir:—

I desire to make the following statements in answer to Mr. R. M. Hardy's letter appearing in the issue of May 1938 (p. 253), in criticism of an article by myself entitled "A Statical Determination of the Reactions at Points of Contra-flexure in the Columns of a Steel Mill Building Bent Due to an External Wind Load" which appeared in the February, 1938 issue (p. 109).

The computations necessary to obtain the numerical values of the reactions require only one setting of the slide rule and the values are read off directly, knowing the length of the vector. The scale for all vectors is the resultant load divided by the length N and in this example the value of the right hand reaction is the scale multiplied by the length NB, which equals 9,000 divided by 2.4 and multiplied by 1.1. The value of the left hand reaction $= 9{,}000 \div 2.4 \times 1.5$.

The unit wind loads are for a wind velocity of 100 mi. per hr. The pressures produced on the different parts of the bent are with one exception in accordance with the Fifth Progressive Report of Sub-Committee No. 31, Committee on Steel of the Structural Division of the American Society of Civil Engineers. This report, under the heading "Wind Bracing in Steel Buildings" appeared in Proceedings of the American Society of Civil Engineers, March, 1936. The one exception is the unit load used for the windward slope of roof. A unit load of 5 lb. per sq. ft. pressure was used whereas for this roof — slope 25.5 degrees — and openings assumed the unit load on windward side would be almost zero. This value being so different from present specifications I was afraid of being misunderstood; moreover, a pressure load illustrated the example to better advantage.

The assumption that the windward column takes sixty percent of the total shear is directly in accordance with the distribution of shear in horizontally loaded two post rigid bents as determined by the "Cross" and "Slope Deflection" methods.

The assumed position of the plane of contra-flexure in the columns as located above the column base a distance of one-third the height to the knee brace connection is based on the fact that in actual construction the columns are only partially fixed at the base. This assumption is on the side of safety, for to assume contra-flexure as at half the height to the knee brace connection would be for the condition of a perfectly fixed base.

Yours very truly,
W. J. Smither,
Associate Professor of Structural Engineering, University of Toronto.

Toronto, Ont.,
May 20th, 1938.

The American Society of Mechanical Engineers Alleghenies Student Conference at Toronto, May 2nd and 3rd, 1938

The following report was prepared by Professor W. G. McIntosh in response to a request from the editor. The Journal is always pleased to give publicity to any activity that tends to enlarge the education or improve the welfare of the student engineer.

While the Student Branch organization in the A.S.M.E. is of comparatively recent origin, the present enrolment is about 4,000 at about 110 colleges which are divided into 9 groups for the purpose of holding annual conferences.

The Alleghenies group (Group III) comprises branches at the following colleges—University of Akron, Bucknell University, Carnegie Institute of Technology, Case School of Applied Science, Catholic University of America, University of Cincinnati, George Washington University, Johns Hopkins University, University of Maryland, Ohio Northern University, Ohio State University, Pennsylvania State College, University of Pittsburgh, University of Toronto and West Virginia University.

The meeting at Toronto was the fifth for this group, the previous meetings being held at Pittsburgh, State College Pa., Washington, D.C., and Columbus, Ohio. The Student Branch at the University of Toronto was represented by a large delegation of students at all except the first conference.

The organization work for this conference was carried out by student committees under the general chairmanship of Mr. Vernon M. Parrish, an undergraduate student, who was also chairman of the Student Branch here during the past year.

The most important features of the Conference were the Technical Sessions held on Monday and Tuesday mornings. The first session opened with an address of welcome by President Cody which was very much appreciated by the students and members of staff of the visiting colleges. Nine papers were presented by undergraduates from as many colleges in competition for five prizes of $50, $25, $10, $10 and a pocket slide rule. The judges, Mr. Ellis of the Ontario Research Foundation, Mr. Nagler of the Canadian Allis-Chalmers Co., and Mr. Rude of the British American Oil Co., gave very high praise for the excellence of the papers.

At a banquet Tuesday evening, Dr. Harvey N. Davis, President of Stevens Institute of Technology and President of the A.S.M.E. for 1938, presented the prizes to the winners. Mr. James B. Purdy, Ohio State University, received first prize for his paper on "Air Conditioning for Railway Passenger Cars." Mr. Robert J. Rock, Case School of Applied Science, received second prize for his paper on "The Air Streamlining of Ocean Ships." Following the presentation of the prizes, Dr. Davis addressed the gathering, which numbered about 190, on "Some Phases of the Engineer of the Future," emphasizing the human aspects of the work of the engineer.

The committee arranged for the inspection of the University laboratories and the Ontario Research Foundation by the visitors from other colleges and also for a number of plant visits on Monday and Tuesday afternoons; in the latter they had the co-operation of the industries in the Toronto district.

With a view to creating more and better friendships between the members from the various colleges the social activities were given considerable prominence. Group meals in the Great Hall of Hart House, swims in the pool before breakfast, a smoker and entertainment Monday evening, and a dance at Hart House Tuesday evening as a final wind-up of the conference were arranged by the committee with the co-operation of the staff at Hart House. At the dinner Monday evening, Dean Mitchell, M.E.I.C., and Professor Angus, M.E.I.C., each gave a very interesting coffee talk.

As an indication of the enthusiasm of the student members for these conferences I may be permitted to give a few examples. Two years ago 33 U. of T. students travelled to Washington, a distance of about 550 miles each way. Last year 25 University of Toronto students attended the conference at Columbus, a distance of about 425 miles, and spent the balance of the week visiting the University of Michigan, General Motors Proving Grounds, Chrysler Research Laboratory, the Packard and Ford plants and Greenfield Village. This year Ohio State University had an attendance of 33 students who travelled about 425 miles, Case School of Applied Science 24 students who travelled about 300 miles, and the University of Maryland 13 students who travelled about 550 miles. The travelling in most cases is done in private automobiles and the necessary cost to each student would probably not average more than about $12 to $15. To create additional interest, the Ontario Section donated a "man-miles" cup for annual competition. The cup was presented for the first time this year, the winning college having about 15,000 man-miles to its credit, by Professor F. V. Larkin, Director of Mechanical and Industrial Engineering at Lehigh University and representative of the Committee on Relations with Colleges at the conference.

As a further indication of the interest of the students the attendance at the technical sessions was about 180 and 160 on Monday and Tuesday respectively from a total registration at the conference of 201 of whom 155 were students and staff from colleges to the south.

The conference next year will be held at Case School of Applied Science, Cleveland, Ohio.

While the effects of such conferences are no doubt many, from my observations of the first four of this group, and my intimate connection with this the fifth conference, I believe they can all be summed up under the heading of "training the young engineer for future responsibility in society activities." This training is broad and varied, involving the organizing and carrying out of the many details which go to make a conference successful; financing all functions on a very limited allowance from headquarters and with no reserves upon which to call; the handling of a technical meeting involving the presentation of papers and the discussions of same; experience in presenting papers and meeting the discussion as gained by the speakers; the promotion of social intercourse and the intermingling of delegates; and last, but by no means least, the mixing of students from different colleges, exchange of ideas, the broadening of enlarged acquaintenceship, and the valuable friendships frequently made.

World Power Conference

Notice has been received of the Vienna Sectional Meeting of the World Power Conference to be held from August 25th to September 2nd, 1938, at Vienna. The absorption of Austria by Germany necessitated a few changes in the details of the conference, but the meeting will take place as originally arranged and the technical programme remains unchanged.

Canadian participation is confined to two papers for the Section on Energy for Agriculture.

1. "Agriculture in Canada" by Dr. C. F. Wilson, Dominion Bureau of Statistics.
2. "Electric Energy in Agriculture in the Province of Ontario" by R. T. Jeffery, Hydro-Electric Power Commission of Ontario.

So far we have not been informed of any delegates in Canada who will attend the conference, but if any of our members plan to be there, the Institute will be very pleased to recommend them to the Canadian Management Committee of the conference as accredited delegates.

A few copies of the detailed programme are available and may be secured from the General Secretary.

The International Electrotechnical Commission—Canadian National Committee

Originally formed in 1906, in London, as an outcome of an International Electrical Congress held in the United States in 1904, the I.E.C. has the object of furthering international co-operation in electrotechnical industry, with a view of obtaining uniformity in such matters as nomenclature, methods of testing and rating, and electrical standardization in its broader aspects.

The work is carried on by more than twenty advisory committees each dealing with a specific subject and composed of delegates of the various countries interested therein. These delegates are appointed by the national committees, of which there are now some twenty-two. The Plenary meetings of the Commission are in fact a kind of world parliament of electrical technologists and are held triennially.

The original Canadian Committee of the International Electrotechnical Commission was maintained for years under the Chairmanship of John Murphy, M.E.I.C., of Ottawa, to whom the continuity of this organization is largely due. After some years, during which the Committee was the responsibility of the Department of Trade and Commerce and, later, of the Canadian Engineering Standards Association, it was felt that the function of maintaining this organization and service should come under the direct auspices of the National Research Council. Accordingly, the old Committee wound up its affairs in order that the National Research Council could take over.

Early in 1937 the National Research Council organized its Associate Electrical Committee to function also as the Canadian Committee of the International Electrotechnical Commission. On this Committee are representatives of the Electrical Industries and Utilities, Electrical Departments of the Universities, Government Services and the National Research Council. The Council appointed Dr. R. W. Boyle, M.E.I.C., as Chairman and A. J. Grant, M.E.I.C., as Secretary. Thus far, two Technical Panels have been organized and have begun their work. A Panel on Nomenclature, Symbols, Units, Electrical Measurements and Instruments acts under the Chairmanship of Professor V. G. Smith of the University of Toronto, with Mr. J. S. Johnson of the National Research Council as Secretary, and there is a Panel on Aluminum Conductors, under the Chairmanship of A. S. Runciman, A.M.E.I.C., Shawinigan Water and Power Company, with Mr. A. J. Grant, National Research Council, as Secretary (*pro tem.*). The President of the National Research Council is a member ex officio of the Associate Committee and all subsidiary committees.

The new Canadian Committee will be represented and make its submissions to the International Electrotechnical Commission for the first time at the coming Triennial Plenary Conference to be held in England in June 1938. An invitation has been received for direct representation, and arrangements have been made for the Secretary of the Committee to proceed to England as its representative.

BRANCH NEWS

Edmonton Branch

F. A. Brownie, A.M.E.I.C., Secretary-Treasurer.
J. W. Porteous, Jr.E.I.C., Branch News Editor.

The final dinner meeting of the Edmonton Branch for the 1937-38 season was held at the Macdonald hotel on April 21st, 1938. As the main item of business, a new executive committee was elected for the ensuing year with W. E. Cornish, A.M.E.I.C., as Branch chairman.

Chairman J. D. Baker, M.E.I.C., then introduced the speaker of the evening, A. W. Haddow, A.M.E.I.C., Edmonton City Engineer, who presented a very interesting paper under the title "An Amateur Tries to Understand the Weather."

Mr. Haddow introduced his subject by pointing out that it is only since the development of the telegraph and the radio that weather has been studied on a world-wide basis rather than as a purely local phenomenon. He then outlined the various theories to account for the major movements of air masses on the earth's surface. It can be shown that the forces which act on the atmosphere due to the earth's motions and shape, together with the effect of the sun's energy, produce the prevailing winds as we know them.

Mr. Haddow then described the effects of these air movements and proceeded to a discussion of local weather conditions in Alberta. He concluded by correlating moisture and temperature conditions with the vegetation found in various parts of the world.

The discussion which followed indicated the general interest and timeliness of Mr. Haddow's subject in view of the important problems now being attacked with regard to drought and agriculture in Western Canada.

Hamilton Branch

A. R. Hannaford, A.M.E.I.C., Secretary-Treasurer.
W. W. Preston, S.E.I.C., Branch News Editor.

Why Bridges?

In an address enhanced with humour, R. K. Palmer, M.E.I.C., Chief Engineer of the Hamilton Bridge Company, discussed the question "Why Bridges?" before the Hamilton Branch at its meeting in McMaster University on May 10th, 1938. Mr. Palmer stated that the purpose of bridges was obviously to surmount barriers. He pointed out that bridges and roads were developed about the same time, because gaps along the roads had to be bridged before the roads could be opened for through traffic.

Any bridge, he continued, should possess structural efficiency and beauty of appearance. It is comparatively easy for the engineer to write specifications to guarantee that bridges will have the necessary strength, conveniences and durability, but writing a specification for beauty is exceedingly difficult. Beauty is art and depends on the designer's emotions rather than his mathematics. The surroundings at the bridge-site have considerable influence on the appearance of the bridge.

To make bridges beautiful, the speaker urged designers to select the most suitable materials. Every material has a particular place in a structure and any substitution would offend the spectators. Concrete has a pleasing appearance when it follows curved lines. Its massiveness gives one a feeling that there is great compressive strength in concrete, but when it is used in tension or bending, one is apt to be dissatisfied. On the other hand steel is the proper material where there is tension, and it alone is suitable for long-span bridges. Mr. Palmer then asked for unity of appearance. He deplored the use of both concrete spans and steel spans in the same bridge. He condemned, especially, the use of different materials for the hand-railings, and the use of concrete when fixed up to imitate cut stonework.

Throughout the lecture Mr. Palmer illustrated his remarks by referring to local bridges. His outstanding example was the high level bridge at the western entrance to Hamilton. This structure was awarded the second prize in the annual A.I.S.C. competition for bridges built in North America. Its beauty is increased by four pylons at the ends of the bridge and on each side of the roadway. Without them the motorist would pass over the bridge without knowing it was there, but by their presence he realizes that he is passing over something unusual.

Mr. Palmer was introduced by H. A. Lumsden, M.E.I.C., and at the close of his address called on Major V. S. Thompson, A.M.E.I.C., designing engineer at Hamilton Bridge Co. Mr. Thompson described briefly how recent designs had been influenced by aesthetic considerations. By substituting rocker bents for towers, and curved portals for straight ones, mazes of intersecting lines have given place to graceful curves and beauty.

The concluding part of the programme featured two motion pictures loaned by the Bethlehem Steel Co. and shown by their representatives, W. W. Martin of Hamilton, and W. R. Harris of Toronto. The first reel, entitled "The Manufacture of Structural Steel Shapes," gave the story of steel from the mine to the finished products. The second picture showed the "Erection of the Golden Gate Bridge" at San Francisco.

W. J. W. Reid, M.E.I.C., was chairman and attendance 175. W. L. McFaul, M.E.I.C., moved a vote of thanks to the two speakers, the two projectionists and also to Chancellor Whidden and Dr. Burke of McMaster University for their kindness to the Hamilton Branch. Refreshments were served following the meeting.

Kingston Branch

R. A. Low, A.M.E.I.C., Secretary-Treasurer.

A general dinner meeting of the Kingston Branch was held in the Students Memorial Union, Queens University, on March 1st, 1938.

A short business meeting followed the dinner, with Major H. H. Lawson, M.E.I.C., chairman of the Branch, presiding.

Following the meeting, members made an inspection tour of the new Sanitary and Highway Laboratory, Queens University. Dr. W. L. Malcolm, M.E.I.C., professor of Sanitary Engineering at Queens University, conducted the tour, explaining the operations of the many different methods of sewage and water treatments available in the laboratory, and giving brief outlines of many active or projected research problems. The many discussions throughout the evening showed the keen interest of all those present.

A hearty vote of thanks to Dr. Malcolm for his instructive discourse was moved by E. C. Goodman, A.M.E.I.C.

The second public meeting of the Kingston Branch was held in Sir Arthur Currie Memorial Hall, Royal Military College, on April 17th. In addition to the members of The Institute, many students from both Queens University and the Royal Military College were present.

The speaker of the evening, Mr. Robson Black, Vice-President and Manager of the Canadian Forestry Association, was introduced by the chairman, Major H. H. Lawson, M.E.I.C., of the Kingston Branch.

Conservation: A First Charge on Patriotism

Mr. Black brought forcibly home, by statistics, the vast amount of wastage of this country's forest wealth. He also referred to the wholesale slaughter of wild life, with the resultant disappearing of many valuable species. Such an attitude on the part of Canadians, if pointed in other directions, would result in the practical disappearance of other resources. Unlike the resources of a mine, the resources of a forest was not alone in cubic content of wood but rather in its capacity, under scientific direction to reproduce itself or its most desirable species in maximum volume and with a maximum rate of growth.

The speaker pointed out that 92 per cent of the forest resources of Canada were public-owned. The greater part of these forest lands were unfit permanently for agriculture, but their one highly desired service to the nation was in their valuable contribution of timber. The authority of the state was absolutely essential for the proper regulation of any public-owned natural resource.

Mr. Black presented interesting data on conservation measures adopted in Finland, Switzerland and other European countries, where often the whole of the national estate was under an economic plan and the right to exploit natural resources ended where it failed to coincide with the interests of society. The speaker stressed the fact that large numbers of thoughtful Canadians have become persuaded that the resources of this country were no longer the affairs of learned societies alone, but the immediate and demanding concern of this generation. He closed with an appeal to the younger man to give leadership to the cause of conservation, and urged that immediate action should be taken to awaken Canadians to their duty. A series of films on conservation completed the programme.

A vote of thanks to Mr. Black for his interesting and instructive address was moved by Gentleman Cadet Hyman of Montreal, seconded by K. N. Campbell, Queens University.

Prior to the address, Mr. Black was guest of honour at a dinner held at the Badminton Club, other guests including the Commandant of R.M.C., Brigadier Matthews.

At the conclusion of the lecture, the guests and members were entertained at the R.M.C. Senior Staff Mess by the chairman, Major H. H. Lawson, M.E.I.C., and Lt.-Col. Leroy Grant, M.E.I.C. Members were given a much appreciated opportunity of discussing various aspects of the problems of conservation with Mr. Black.

Lakehead Branch

H. Os, A.M.E.I.C., Secretary-Treasurer.

The regular monthly dinner meeting of the Lakehead Branch was held at the Royal Edward hotel, Fort William, April 13th, 1938.

The chairman, G. R. Duncan, A.M.E.I.C., welcomed the members and guests, and requested those present to introduce themselves by standing in turn giving name and employment.

The following three members, J. M. Fleming, M.E.I.C., P. E. Doncaster, M.E.I.C., and H. P. Sisson, Affil. E.I.C., were elected to act with G. H. Burbidge, M.E.I.C., and H. G. O'Leary, A.M.E.I.C., previously appointed by the Executive, as a Nominating committee to draw up a slate of officers for election at the annual meeting in May. Mr. G. H. Burbidge was elected chairman of the committee.

F. C. Graham, A.M.E.I.C., read a resolution, made by the Executive committee of the Branch and edited by J. M. Fleming, M.E.I.C., recommending Hon. C. D. Howe, Hon.M.E.I.C., Minister of Transport, for the Sir John Kennedy Medal. Mr. Graham moved that the resolution be adopted as read, Mr. O'Leary seconded it and the motion was carried unanimously. J. Antonisen, M.E.I.C., spoke in support of the motion and expressed his pleasure at this effort to give recognition to Mr. Howe for his outstanding services to the engineering profession.

Mr. P. E. Doncaster brought up the question of amendment to By-laws No. 44 and No. 51, and spoke very strongly in favour of changing them as recommended by Council. David Boyd, A.M.E.I.C., urged that the amendments to the by-laws should be approved by the membership. He stated that the elected Executive committee of the Montreal Branch had been powerless for years due to existing by-law No. 51 of The Institute. He lauded the work of the ex-officio members of the Montreal Branch for the work they had done for that Branch and The Institute at large, but stressed the fact that they could, under the present conditions, run Branch affairs and also Institute affairs to suit their own interests without due regard to the opinions and interests of the younger members elected to Council.

S. E. Flook, M.E.I.C., introduced the speaker of the evening, D. B. Armstrong, A.M.E.I.C., of the Dominion Bridge Company. Mr. Armstrong spoke on "Pre-stressing and Erection of the Island of Orleans Bridge," showing slides to illustrate his lecture. Mr. E. Smith moved a vote of thanks to the speaker and Mr. Doncaster seconded the motion. Due to the lateness of the hour, there was no general discussion of the many interesting subjects introduced by the speaker during his lecture.

Forty-one members and guests were present.

Lethbridge Branch

E. A. Lawrence, S.E.I.C., Secretary-Treasurer.

The annual meeting of the Lethbridge Branch was held on Saturday afternoon, March 5th, 1938, at which the Secretary's annual report was read and adopted. The financial statement showed a satisfactory improvement in the Branch's affairs. The retiring chairman, J. M. Campbell, A.M.E.I.C., expressed his appreciation of the Branch Secretary, E. A. Lawrence, S.E.I.C., and thanked the various committees for their efforts. He then vacated the chair in favour of the incoming chairman, R. F. P. Bowman, A.M.E.I.C.

The Lethbridge Branch held a dinner meeting at the Marquis hotel on Saturday evening, March 12th, at which the members entertained their ladies. During the dinner orchestral numbers were rendered by Mr. Geo Brown Sr. and his orchestra, followed by vocal solos by Miss Eastabrook and Mr. Geo Brown Jr.

The speaker of the evening was Pilot-Officer Wilson Donaldson, R.A.F., who addressed the meeting on "Training for the Royal Air Force." Mr. Donaldson described the procedure of applying for a short service commission and the many tests and examinations involved, followed by an interesting description of the methods in vogue in England. His experiences in England and Iraq as a pilot of heavy bombing planes were told in a very interesting and homorous manner.

A hearty vote of thanks was moved by C. S. Clendenning, A.M.E.I.C., for Mr. Donaldson's address.

London Branch

D. S. Scrymgeour, A.M.E.I.C., Secretary-Treasurer.
Jno. R. Rostron, A.M.E.I.C., Branch News Editor.

The regular monthly meeting of the Branch was held on April 26th, 1938, in the Officers' Mess, Richmond Street Armouries, London, Ontario, through the kindness of Lt.-Col. Veitch, A.M.E.I.C. Two talking films, sponsored by the Imperial Oil Company, were shown.

A. O. Wolff, M.E.I.C., chairman of the Branch, presided and in his opening remarks he welcomed those members of military units who were present and said that the thanks of the meeting were due Lt.-Col. Veitch for the use of the officers' quarters.

He also said that a joint meeting would be held between the Grand Valley Group of Registered Professional Engineers and the London Branch of the E.I.C. at Brantford toward the end of May and it was hoped that as many members and others of the Branch as possible would attend. All were heartily welcome.

Mr. Wolff then pointed out that the thanks of those present were due the Imperial Oil Company for the movie exhibition which was now to be shown and introduced Mr. Howard of the Imperial Oil Company.

The first film was called "The Long Road," its object being to show the rapid growth and improvement and use of the motor car and other locomotive traction right from the days of Watt and Stephenson to the present day.

The first locomotives and later the first motor carriages and cars were shown. Amusing scenes were given of the days when all power driven units on the road must be preceded by a man with a red flag and so on through all the stages up to the present day facilities of traction. All modern transportation units were shown in full operation on the railways and highways, in cities and at the race tracks.

The second film was named the "Inside Story," and dealt mostly with lubrication. From the days of the first refining of petroleum in 1859 the industry had never stood still. Scientific research had been going on all the time so that wonderful improvements had been made. If a 1938 car were operated with 1928 gas and oil the results would be found to be very inferior.

This film gave views of various refineries and depicted scientists at work in their laboratories, also showing the elaborate and delicate machinery used. It showed how the "knock" was eventually taken out of the motor which for a long time was thought to be of mechanical origin but was found at last to be in the explosion of the gasoline and was duly corrected.

Many times magnified views of bearings, cylinders, etc., were shown and the action of the lubricant therein. This was particularly the case with the cylinders where the action of the oil and the piston rings was very clearly shown and described. All kinds of gears were shown and the necessity of using the right grade of oil was stressed. Particular attention was also drawn to the proper consideration of temperature and speeds in the selection of the proper oil.

The films throughout were beautifully clear and steady.

A vote of thanks to the representatives of the Imperial Oil Company present was moved by R. S. Charles, seconded by Major Andrewes, A.M.E.I.C., and unanimously carried.

About 31 members and guests were present, and questions were asked and answered by the company's representatives.

Montreal Branch

E. R. Smallhorn, A.M.E.I.C., Secretary-Treasurer.

Trans Island Motor Highway

The Executive committee of the Montreal Branch called a special general meeting on May 9th for the purpose of discussing the location of the western portion of the proposed Trans Island Motor Highway. It was their wish to obtain a general discussion and as much information as possible concerning the proposed routes other than the Metropolitan Commission scheme, and particularly if possible to hear an elaboration of the reasons in favour of a location south of the tracks nearer to the Lake Shore summer resorts. There have been committees appointed by the Executive at various times during the past few years to endeavour to gather and present such information in case the Branch might be put in the position of expressing an opinion on this question. Up to the present it has not been easy to get such data.

For this meeting the Hon. F. J. Leduc co-operated whole-heartedly and delegated Mr. Martineau and Mr. Racicot, two engineers in his department, to explain fully the views of the Provincial Roads Department. This they did very capably and satisfactorily.

Other engineers especially invited included Mr. H. A. Terreault, Chairman of the Town Planning Commission, and all the engineers who were members of the Board appointed by the City of Montreal about ten years ago, to survey and report on this question. Mr. Terreault opened the meeting by explaining very clearly the background and technical investigation which had resulted in the so-called Metropolitan Commission scheme. Mr. Paul A. Beique also contributed a concise and clear resumé of the work of the engineering commission. Mr. Gordon McL. Pitts also spoke generally in favour of the Central Island scheme.

The meeting proved to be one of the largest of the year and evoked such interest that active discussion continued until 11 p.m. when a resolution was adopted by a large majority of those present approving the location of the western access to the city north of the tracks rather than to the south.

Lectures on Economics

A series of lectures on economics has just been concluded. Such a series has been carried on for the past four years under the auspices of the Papers Committee. Each year they have been given by Dr. D. M. Marvin, economist, of the Royal Bank of Canada, Montreal, who has shown a keen interest in the activities of the group and who has devoted a great deal of time to the preparation of the necessary lecture material and to the answering of questions.

In order to obtain proper continuity, the attendance at lectures has been restricted each year to those subscribing to the whole course although the invitation was extended to all members of the Branch. No rigid routine of subject-matter has been adhered to, as the lectures have not been in any way an elementary or technical study of economics itself, but rather discussions of business and business conditions associated with engineering and allied activity and the discussion of such conditions from the economic view point. To provide background, some of the earlier lectures dealt with the fundamentals of economics.

The series during this past winter season consisted of eleven lectures dealing with the present world situation in general; the present irregularities in financial and business stability, etc. One evening was devoted to an informal talk by Miss Aryness Joy who is head of the Statistical Bureau in Washington, who was visiting Montreal in connection with her work.

Dr. Marvin is internationally known as an economist, but it is less well-known that he studied and taught psychology for many years. These qualifications and his keen interest in engineers and engineering have made this activity of the Montreal Branch extremely interesting and the twenty-three members who participated feel that an opportunity of very great value has been afforded to the membership of our Branch.

Typical of the activities of this group is the present arrangement that two lectures will be held during the summer; one at the end of July and one at the end of August to discuss economic developments at that time; it being felt that these few months are a period of pronounced financial and economic change.

Niagara Peninsula Branch

G. E. Griffiths, A.M.E.I.C., Secretary-Treasurer.
J. G. Welsh, S.E.I.C., Branch News Editor.

On May 13th, 1938, the Niagara Peninsula Branch of The Institute terminated another very successful season of activities with a dinner meeting at the Hotel General Brock, Niagara Falls, Ontario, with Chairman L. C. McMurtry, A.M.E.I.C., presiding.

The Branch was highly honoured by the presence of the President of The Institute, J. B. Challies, M.E.I.C., and the General Secretary, L. Austin Wright, A.M.E.I.C. Mr. Challies gave a few words of praise to the Canadian engineers with regard to their hydro-electric achievements which are so splendidly illustrated in the Niagara District. He stated that the European plants excelled the Canadian developments in but one manner, and that was in their aesthetic treatment.

Mr. Wright placed himself high in the respect of the listeners with his few pointed remarks. After a few interesting words from Mr. Anderson, M.P.P. for Welland, the retiring chairman, Mr. McMurtry, thanked the assembly and his executive for the splendid way in which all had co-operated during the past season.

Mr. McMurtry then called upon the chairman elect, C. G. Moon, A.M.E.I.C. The executive for the ensuing year was introduced and the reappointment of Mr. Griffiths as Secretary-Treasurer was heartily endorsed by all those present.

W. R. Manock, A.M.E.I.C., the Niagara District's new Councillor to The Institute, introduced the speaker of the evening, Mr. A. E. Hay, sales manager of the Pratt & Lambert Company. In a very sincere, exceedingly interesting and humorous manner Mr. Hay spoke in his own inimitable way of "The Essentials of Life," pointing out that labour, perseverance and service were the true essentials.

The meeting was taken to a still greater degree of perfection by the achievements of past-chairman G. E. Woods as maker of "Manhattans."

Saturday afternoon a few members of the Branch joined the Buffalo Engineering Society in a luncheon and a trip through the new sewage disposal plant of the City of Buffalo. The plant was in the final stages of completion and with a large number of very competent guides the afternoon was very profitably spent.

Ottawa Branch

R. K. Odell, A.M.E.I.C., Secretary-Treasurer.

Parking in Ottawa

At an evening meeting, held at the lecture hall in the National Research Laboratories on April 12th, 1938, Robert M. Simpson addressed the members on "Parking in Ottawa." Mr. Simpson had been acting as Survey Director of the Citizens Parking Committee of Ottawa, an organization which had recently completed an investigation of the car parking situation in the city, and had prepared a comprehensive report.

The speaker explained some of the findings of the committee. He stated that Ottawa's effort was the first comprehensive parking survey ever made in Canada although one was subsequently completed in Vancouver. To carry out the survey, the assistance of 240 men who were on the relief rolls was utilized to obtain the detailed information required. These men, for an area of about a third of a square mile in the business centre of the city, obtained comprehensive data relating to traffic movement on certain days during the fall of 1937.

One thing which the survey revealed was the large number of people who walked to work in the city of Ottawa. There were, as a matter of fact, about three times as many people walking to work in Ottawa as in any other city of comparable size in America. After 9.30 a.m. also, there were many more motor vehicles in the district than parking spaces provided for. This overloaded condition of the city streets was no doubt largely responsible for the number of violations of parking ordinances noted by the enumerators.

According to the count, at one time over 41 per cent of all the motor cars parked in the downtown section were violating one or more of the traffic ordinances, such as by parking in no parking areas, by overtime, by being too near corners, by double parking, by being close to hydrants or otherwise by improper parking. Incidentally, for 1937, out of the total number of parking infractions noted by the police, less than 6 per cent resulted in prosecutions. No doubt the tendency toward this condition of congestion will be more intensified in the future, as more people are supplied with cars. In 1920, for instance, there was one car for every 22 people in the city whereas in 1937 there was one for every 7 people. By 1950 it is estimated there will be about one car for every 6 people. Another interesting point brought out by the survey was that while the average motor car is travelling over the down town section, 68.93 per cent of the time is taken up in actual motion, 22.08 per cent in waiting for cross traffic, 7.78 per cent for street cars to load and unload, 1.04 per cent in delays due to the improper parking of automobiles and 0.16 per cent of the time in waiting for pedestrians to get out of the way.

A. K. Hay, A.M.E.I.C., in leading off with the discussion, stated that as a result of the survey some recommendations had been brought forward from the advisory committee, one of which was that a straight fine of one dollar be imposed for every traffic law violation, such fine to be without additional costs if paid within 48 hours, otherwise the regular rates would prevail. Such a course would engender a greater respect for traffic regulations and militate against their abuse.

Other discussion followed. One of the recommendations was that parking meters be installed in the downtown area and much of the time of the discussion was taken up with this suggestion.

Seismology

At the noon luncheon April 21st, Dr. E. A. Hodgson of the Dominion Observatory gave an address on "Seismology," which included a short account of the routine and present-day research trends in this science.

The survey of land for oil bearing strata was one of the off-shoots of seismological science of recent years, according to Dr. E. A. Hodgson. Using seismographs it was possible to locate underground oil sources through a study of the records obtained upon the recording instruments. A small party of men can by this means cover from two to three square miles of territory in a day. Equipment costs about $30,000, lasts about two years, and requires an expenditure of from $3,500 to $4,000 per year to operate.

Dr. Hodgson briefly outlined the development of the science of seismology since the establishment all over the world about 43 years ago of a series of stations for the study of earthquakes. Recording instruments may vary in weight from one pound to 20 tons. Nowadays they are more sensitive than formerly and may be electrically controlled instead of mechanically controlled. Although he has been a student of seismology for 25 years, Dr. Hodgson stated, he has actually studied earthquakes themselves and their effects upon the ground only on two different occasions.

Another study bearing upon the science is that of the design and construction of buildings to resist the devastating effects of earthquakes. Scientists have tried to determine just what it is about earthquakes that actually cause devastation and to introduce elements into building design so as to obviate the possibility of such destruction. He instanced the case of a hotel in Tokio where such considerations had been taken into account in its construction with the result that it had survived many earthquakes where even the ornamental parts of the hotel had not suffered. In California much attention has been paid to building construction from this point of view. Specifications can be made up whereby at an additional cost of 10 per cent over usual costs of construction, buildings can be made earthquake free. The additional cost can be saved on reduced insurance premiums in about ten years.

W. F. M. Bryce, A.M.E.I.C., local chairman, presided.

Sunspots

An address on "Sunspots" was given at the noon luncheon, May 5th, by Dr. Ralph E. DeLury, of the Dominion Observatory. Dr. DeLury of late years has devoted an increasing amount of attention to the effects of solar variations on terrestrial phenomena, and his talk dealt largely with fluctuations in physical, organic and economic phenomena as related to the eleven-year sunspot cycle.

Years of research and investigation on the part of physicists and scientists generally have revealed remarkable similarities between the cycles of sunspot activity and other trends, according to the speaker. By the use of graphs and diagrams he showed how the curve of sunspot activity over a period of years was closely approximated by the curve of marriages, of commodity prices, of tree growth, and of many other happenings, even to the number of influenza cases. As Dr. DeLury explained it, whatever type of precipitation follows as a direct result of sunspot activity has a definite bearing upon life itself.

Although the average sunspot cycle is about eleven years, the definite prediction of crops ahead cannot be made as yet but one would expect the prairie crops to be at their best when the solar activity was at a minimum. A very long series of records and much further study would be necessary if one wished to arrive at any definite conclusion in this regard. At the present time the sun has just passed through a period of maximum activity and appears to be going on towards a minimum phase.

By making use of fine grained plates sensitive to violet and blue light, photographs of the sun's disc now reveal much more character than those taken formerly by plates using yellow light. The shape and nature of the spots and large bright faculae themselves are more readily observed, as well as the radial streamers that may be given off indicating their rotating or vortex nature. The spots are, according to the speaker, comparatively stable, and often last longer than a complete rotation of the sun or more than 25 days.

Much can also be learned regarding the sunspots from a study of their spectra. Analyses of these undertaken at the Mount Wilson Observatory revealed that spots are magnets and close pairs are usually of opposite polarity. Variation in the frequency of the Northern Lights appears to follow that of the sunspots, lagging one year behind.

As an indication, also, that the sunspots may have an effect upon other bodies than the earth, there appears to be a relationship between the intensity of the spots and the size of the snow-capped areas on the planet Mars, and the brightness of Encke's comet.

Ultra violet light, emitted strongly by the high-level faculae, ionizes the upper atmosphere of the earth in variable amounts producing electromagnetic fluctuations and inducing variations in haziness and cloudiness with the other meteorological pulsations in the sunspot cycle.

W. F. M. Bryce, A.M.E.I.C., chairman of the local branch, presided.

Peterborough Branch

W. T. Fanjoy, A.M.E.I.C., Secretary-Treasurer.
J. L. McKeever, Jr.E.I.C., Branch News Editor.

At the regular meeting of the Branch held on April 14th, 1938, the guest speaker was Mr. A. G. Scott, chief lubrication engineer of the Imperial Oil Company Limited. Instead of addressing the meeting himself Mr. Scott brought with him two talking films. The first of these was a travel film, being the record of a motorized expedition through Central Africa from French Morocco to Nairobi. This picture gave an interesting account of the customs of the various native tribes through whose territory the expedition passed, and was much appreciated by the Branch.

The second and main film of the evening was called "The Inside Story," and gave a graphic account of the lubrication of various types of mechanism, and by means of animated diagrams showed how the lubrication wedge forms between journal and bearings and how this wedge is affected by load, speed and type of lubricant. After the showing of the picture, Mr. Scott was good enough to answer a number of questions put to him by members of the Branch.

Attendance, 58.

The annual meeting of the Branch was held at the Y.M.C.A. on Thursday, May 5th, commencing with supper at 6.30 p.m. Unfortunately the Branch chairman, V. R. Currie, A.M.E.I.C., was still feeling too badly over the recent loss of an appendix to attend, and his place was taken by the past-chairman, H. R. Sills, A.M.E.I.C., After supper, the ballots were counted by scrutineers W. M. Cruthers, A.M.E.I.C., and V. S. Foster, A.M.E.I.C., and the following were declared elected to the executive for 1938-39: I. F. McRae, A.M.E.I.C., B. I. Burgess, A.M.E.I.C., W. T. Fanjoy, A.M.E.I.C., G. A. Cunningham, A.M.E.I.C., A. L. Malby, Jr.E.I.C., B. Ottewell, A.M.E.I.C., and R. L. Dobbin, M.E.I.C. Councillor A. B. Gates, A.M.E.I.C., and Past-chairman V. R. Currie, are, of course, members ex-officio. Following announcement of the new executive, the usual yearly reports from the various officers were heard. In this connection the Branch were very glad to welcome back after his long illness their Councillor, Mr. Gates, who reported on the activities of the Council, with which he had kept in touch by correspondence. The remainder of the evening was spent in various diversions such as bowling, ping-pong and volley-ball, for which prizes were awarded at the close of the meeting by Mr. Dobbin.

Attendance, 42.

On May 19th the Peterborough Branch held a joint meeting with the Foreman's Association of the Canadian General Electric Company in the Legion Hall, the occasion being the showing of two talking films furnished through the courtesy of the Bethlehem Steel Corporation. The first picture showed the manufacture of structural steel shapes at the various plants of the Corporation, the process being followed from the unloading of the ore to the finished rolled product.

The second picture was a pictorial and verbal description of the building of the great suspension bridge over the Golden Gate narrows at San Francisco, for which the Bethlehem Corporation furnished the steel.

Both pictures were viewed with great interest by a large audience and the representatives of the Steel Company were sincerely thanked for bringing them to Peterborough.

Sault Ste. Marie Branch

N. C. Cowie, Jr.E.I.C., Secretary-Treasurer.

The Sault Ste. Marie Branch of The Engineering Institute of Canada held a dinner meeting in the grill room of the Windsor hotel, Sault Ste. Marie, Ont., on Friday, April 29th, 1938.

Following an appetizing dinner, which was served by the hotel staff and enjoyed by the 29 members and guests in attendance, the chairman of the Sault Branch, J. S. Macleod, A.M.E.I.C., presided at a short business meeting. During this period the secretary was instructed by the meeting, on a motion of John L. Lang, M.E.I.C., seconded by Wm. Seymour, M.E.I.C., to write to R. J. Durley, M.E.I.C., Secretary Emeritus of The Engineering Institute of Canada, and to L. Austin Wright, A.M.E.I.C., General Secretary of The Institute, and to convey to the former the regrets of the meeting on hearing that he had found it necessary to resign from his former position as general secretary and to extend to the latter the welcome of the meeting as he takes over the heavy responsibilities Mr. Durley lays down.

Following this business part of the meeting, the members and guests present were favoured by Mr. R. J. Anderson, service engineer of the Dominion Oxygen Co., Limited, Montreal, with an excellent paper entitled. "The Oxygen-Acetylene Process in Industry." In introducing his talk, Mr. Anderson gave a brief résumé of the founding of the various materials used in this process, and an outline of the present day methods and procedures used to produce these materials. He then mentioned the ways this process can and is being used to the economic advantage of several of the industries with which his listeners were familiar. The discussion which followed brought out several uses of this process which were of more particular interest to some of the members present.

The appreciation of the meeting of Mr. Anderson's talk were extended to him on a motion of F. Smallwood, M.E.I.C.

Toronto Branch

J. J. Spence, A.M.E.I.C., Secretary-Treasurer.
A. E. Berry, M.E.I.C., Branch News Editor.

The annual meeting of the Toronto Branch was held at the Military Institute, University Ave., on Thursday, May 12th, 1938. A. U. Sanderson, A.M.E.I.C., occupied the chair. A number of prominent guests were in attendance, including President Challies, M.E.I.C., General Secretary L. A. Wright, A.M.E.I.C., Past Vice-President R. L. Dobbin, M.E.I.C., Peterborough; Vice-President E. V. Buchanan, M.E.I.C., London; James A. Vance, A.M.E.I.C., London; W. J. W. Reid, M.E.I.C., Hamilton, and others.

The activities of the evening started with a dinner, at which an unusually large number were present. Chairman Sanderson in his opening address reviewed the year's activities of the branch, and emphasized the desirability of having all engineers associated with The Institute.

Committee reports were presented as follows:—Secretary-Treasurer —J. J. Spence; Membership—W. E. P. Duncan, M.E.I.C.; Branch Editor—A. E. Berry; Social Committee—N. MacNicol, M.E.I.C., and Press Relations—D. D. Whitson, A.M.E.I.C.

The scrutineers' report on the election of officers resulted in the following executive for 1938-39:

Chairman:	C. E. Sisson, M.E.I.C.	
Vice-Chairman:	A. E. Berry, M.E.I.C.	
Sec.-Treasurer:	J. J. Spence, A.M.E.I.C.	
Committee:	Nicol MacNicol, M.E.I.C.,	H. E. Brandon, A.M.E.I.C.,
	D. D. Whitson, A.M.E.I.C.,	W. E. P. Duncan, M.E.I.C.,
	G. H. Rogers, A.M.E.I.C.,	M. Barry Watson, A.M.E.I.C.
Councillors:	W. E. Bonn, M.E.I.C.,	O. Holden, A.M.E.I.C.
Ex-officio:	A. U. Sanderson, A.M.E.I.C.	

President Challies addressed the meeting and in a most interesting manner discussed the various problems which are now before The Institute, and also reviewed the more recent activities of the executive. The address dealt in vivid manner with the arguments for recognition by all engineers of this national Institute. It was indeed a stimulus and an inspiration to greater attainments by The Engineering Institute.

The guest speaker of the evening was Wilson Woodside, who gave a most enlightening discourse on his observations in Germany, particularly on that country's living conditions and preparations for war.

Presidential Party's Visit to the Cape Breton Branch

Standing—S. C. Mifflen, M.E.I.C., W. C. Risley, M.E.I.C., Y. C. Barrington, A.M.E.I.C., J. H. Fraser, C. M. Anson, A.M.E.I.C., R. F. McAlpine, JR.E.I.C., S. G. Naish, A.M.E.I.C., J. A. MacLeod, A.M.E.I.C., A. B. Blanchard, M.E.I.C.

Seated—L. A. Wright, A.M.E.I.C., A. P. Theuerkauf, M.E.I.C., J. B. Challies, M.E.I.C., F. Newell, M.E.I.C., I. W. Buckley, A.M.E.I.C., F. W. Gray, M.E.I.C., M. F. Cossitt, A.M.E.I.C.

Canadian Living Costs Favourable on Comparison

Rising living costs since 1934 in most important countries add significance to a comparison of recent indices. In 1937, the average cost of living index for Canada was 131; for the United States 147; and for Great Britain 159; according to figures based on government statistics. The average for Canada over a 25-year period to the end of 1937 was 8 per cent below that of the United States and about 20 per cent below that of Great Britain.

James Watt International Medal

The Council of the Institution of Mechanical Engineers awarded the second James Watt International Medal to Mr. Henry Ford on April 22nd. This award, established in 1936 on the centenary of Watt's birth, is made biennially for outstanding achievements in the field of mechanical engineering.

Erratum

The price of "Engineering Law" by R. E. Laidlaw and C. R. Young reviewed in the Engineering Journal, May 1938, page 252, was incorrectly stated as $5.00. The price is $4.00 a copy.

The Empire Exhibition at Glasgow

The British Empire is a group of nations bound together by the ties of sentiment and common interest, and including units of the most diversified races, languages and creeds, all in very widely varying stages of industrial development. The task of bringing the characters, interests and industries of all these nations into focus by the holding of an Empire exhibition is therefore a formidable one, and has not been attempted since the British Empire Exhibition at Wembley in 1924. With improving trade, however, manufacturers are looking for new markets, and the potentialities of the Empire are of particular significance in this connection in view of the unfortunate restrictions which hamper developments in so many foreign markets. The decision to hold a further Empire exhibition in Glasgow this year is, therefore, particularly timely, and it may be hoped that the opportunities which it will afford for an interchange of views and information between those representing the various units of the Empire, in combination with the improved prospects of extra-imperial trade arising from negotiations with foreign nations, will give a marked fillip not only to our home manufacturers, but to those of other Empire countries. It is clearly essential that to be successful, an exhibition of the type visualized must be on an extensive scale, and the Glasgow exhibition, which opened on May 3rd and will remain open until October 29, covers an area little less than that at Wembley, of which the great extent will be remembered by a large proportion of our readers. Actually, the area covered by the Glasgow exhibition is 175 acres, against 216 acres for Wembley, but the chief effect of this difference is to make the present exhibition slightly more compact. It may be said that while full advantage has been taken of the developments in exhibition technique since 1924 to display the exhibits in a more attractive manner, and particularly to utilize the experience recently gained in the construction, lighting and heating of buildings, the two exhibitions are closely comparable in their manner of demonstrating the art, culture and products of the Empire. In view of the progress that has been made in so many directions since the Wembley exhibition, that at Glasgow should prove of even greater interest.

—*Engineering.*

Institute of Metals Award Medal

Sir William H. Bragg, O.M., F.R.S., noted crystallographer and physical chemist, has been awarded the platinum medal which has been established by the Institute of Metals, a leading British scientific organization, in recognition of his outstanding services to non-ferrous metallurgy.

The medal was conferred on Sir William for his achievements in the x-ray examination of metals. He has been a pioneer in the study of the crystalline structure of metals by the refractory method; his findings have been an important factor in the development of modern alloys. He is an Australian by birth and is an honorary member of The Institute.

The medal is a disc of pure platinum, two inches in diameter and weighing 4½ ounces. It is donated by the Mond Nickel Company, Limited, subsidiary of International Nickel, the company which in 1933, in commemoration of the 50th anniversary of the Canadian nickel industry, established a platinum medal for award by the Canadian Institute of Mining and Metallurgy for distinguished contribution to the mining and metallurgical industries of the Dominion.

In recent years Canada has become the world's largest producer of the platinum metals, its output being recovered and refined in the precious metals refinery of the Mond Nickel Company at Acton, a suburb of London. The source of this platinum is the copper-nickel ore of the Sudbury district.

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted after a lapse of one month, upon request.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Situations Wanted

ENGINEER, A.M.E.I.C., Combustion specialist heat balance. Steam, Mechanical. Refrigeration. Office routine. Correspondence. Plant layout. Apply to Box No. 5-W.

PAPER MILL ENGINEER: B.A., B.A.Sc. Married. Age 34. A.M.E.I.C. Ten years experience in paper mill costs, maintenance, design and construction. Now employed as cost engineer in Southern States. Hard worker with excellent references. Available immediately. Apply to Box No. 150-W.

PAPER MILL ENGINEER. If you are willing to pay around $5,000 per year for the services of an engineer, age 36, with twelve years experience in paper mill design, construction and operation, apply to Box No. 482-W.

CIVIL ENGINEER, B.A.Sc., A.M.E.I.C. Married. Experienced in engineering and architechtural design and in supervision, office management, etc., wants to round out experience in the contracting field. Ten years experience since graduation. Present location Toronto. Address Box No. 576-W.

ELECTRICAL ENGINEER, B.Sc. E.E., Age 39. Married. Seven years experience in operation, maintenance and construction of hydro-electric plants, and sub-stations. Five years maintenance and installation of pulp and paper mill electric equipment. Reliable and sober, with ability to handle men. Best references. Any location, at once. Apply to Box No. 636-W.

ELECTRICAL ENGINEER, B.Sc. '28. Two years student apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660-W.

ELECTRICAL AND CIVIL ENGINEER. B.Sc. Elec. '29, B.Sc. Civil '33. JR.E.I.C. Age 32. Experience includes four months with Can. Gen. Elec. Co., approximately three years in engineering office of large electrical manufacturing company in Montreal, the last six months of which were spent as commercial engineer, also experience in surveying and highway work. Year and a half employed in electrical repair. Best of references. Apply to Box No. 693-W.

CIVIL ENGINEER, B.A.Sc. (Toronto '27), age 34, married. Five years railway and construction work as building inspector and instrumentman. Level engineer and on construction of a long timber flume for a pulp and paper mill. Field engineer for a sulphite company, in charge of the following mill buildings, acid, digester, blow pit, barker room, chip storage and acid towers. Available immediately. Apply to Box No. 714-W.

MECHANICAL ENGINEER, JR.E.I.C. Technical Graduate. Bilingual. Married. Experience includes five years with firm of consulting engineers, design of steam boiler plants, mechanical equipment of buildings, heating, ventilating, air conditioning, plumbing, writing specifications, etc. Six years with large company on sales and design of power plant, steam specialties and heating equipment. Available on short notice. Apply to Box No. 850-W.

CONSTRUCTION ENGINEER, Grad. Toronto '07. Experience as resident engineer and superintendent on railroad, municipal, hydro-electric and industrial construction. Intimate with organizing, layout, survey, estimates and costs. Available immediately. Apply to Box No. 886-W.

CIVIL ENGINEER, B.Sc. '29, JR.E.I.C., R.P.E.M. Age 31. Married. Experience includes railway and highway surveys and construction, land and mineral claim surveys, 4 years draughting, structural and hydraulic design, preparation of plans and estimates for hydro-electric development, sewage disposal project, water treatment plant, subway construction, buildings, etc. Experienced in reinforced concrete design including statically indeterminate frames. Also capable of preparing designs in steel and timber. Desire permanent employment, preferably in structural design. Available immediately. Apply to Box No. 1023-W.

ELECTRICAL ENGINEER, B.Sc. '29, age 30. Single. Eight and a half years experience on maintenance, on construction, floorman and operator on hydro-electric system. Desires construction, service, sales or research work. Any location. Excellent references. Apply to Box No. 1062-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

TECHNICALLY TRAINED EXECUTIVE. General experience administrative, organization and management in business and industrial fields, including; business, plant, property and estate management; plant maintenance, modernization, production and personnel; economic studies, company reorganizations and amalgamations, valuations; railroad, highway, hydro, pulp, newsprint, housing, industrial surveys, investigations and construction; B.Sc. degree in engineering, age 49, married, Canadian. Apply to Box No. 1175-W.

CHEMICAL ENGINEER, grad. McGill '34, experienced in meter repairs, control work; and also chemical laboratory experience. Apply to Box No. 1222-W.

CIVIL ENGINEER, B.A.Sc. (Toronto '33), S.E.I.C., age 27. Married. Five years experience includes highway surveys, bituminous and concrete paving, steel and reinforced concrete building construction, instrument work, draughting, cost accounting and estimating and some experience as foreman. Available immediately. Apply to Box No. 1265-W.

ENGINEER SUPERINTENDENT, A.M.E.I.C., R.P.E., Que. and Atla. Age 47. Twenty years experience as engineer and superintendent in charge of hydro-electric, industrial, railroad, and irrigation construction. Specialized in rock excavation and suction dredging. Intimate knowledge of costs, estimating and organizing. Available immediately. Apply to Box No. 1411-W.

CIVIL ENGINEER, graduate 1927, age 34 years, desires position as town engineer. Eight years municipal experience. Location immaterial. Apply to Box No. 1628-W.

CIVIL AND ELECTRICAL ENGINEER, JR.E.I.C. (Univ of Man.). Married. Age 25. Good draughtsman. Four months draughting, one year instrumentman on highway location and construction, inspection and miscellaneous surveying and estimating. Six months as field engineer on pulp and paper mill construction. Prefer electrical or structural design. Available at once. Apply to Box No. 1633-W.

ELECTRICAL ENGINEER, B.Sc. E.E. (Univ. of Man. '37). Age 24. Single. Experience in highway construction as inspector. Also experience in sales work and petroleum refining. Available on short notice. Apply to Box No. 1703-W.

CIVIL ENGINEER, B.Sc. in C.E. '34. S.E.I.C. Age 27. Five years experience, including harbour construction, highway paving, one and a half years paper mill construction, instrument work, draughting, estimating, interested in design. Available on short notice. Apply to Box No. 1737-W.

CIVIL ENGINEER, B.A.Sc. '33. O.L.S. Age 27. Married. One year and a half in charge of power plant construction. Four summers on land surveys and one summer on mine survey work. Also experience in draughting, electrical wiring, and highway engineering. Apply to Box No. 1757-W.

ELECTRICAL ENGINEER, B.E. in E.E., N.S. Tech. Coll. Single. Age 25. Experience in sales, electrical installation, and construction work. Available immediately. Will go anywhere. Apply to Box No. 1758-W.

CHEMICAL ENGINEER, graduate, Toronto '31. Seven years experience in paper mill, meter maintenance, control work and chemical laboratory. Speaking French and English. Location immaterial. Available at once. Apply to Box No. 1768-W.

CIVIL ENGINEER, B.A.Sc., JR.E.I.C. (Toronto '35). Age 24. Experience in structural design, construction and surveying, including one year in South America. Details on request. Apply to Box No. 1784-W.

The Outlook in Constructional and General Engineering

There was again a very considerable expansion in activity in constructional engineering in 1937. Employment at July rose from 31,733 in 1936 to 36,025 in 1937. The latter being an increase of 87.6 per cent compared with the low level of 19,198 reached both in 1932 and 1933. Both the number insured and number in employment are very substantially in advance of pre-depression levels, but the figure for the number unemployed at 4,038 is also considerably above the minimum of 1,857 recorded in 1927. By December, 1937, the number unemployed had fallen to 3,834, but this was followed by an increase in January, 1938, to 4,063.

In spite of a substantially increased production of structural steel, most constructional engineers complained of the difficulty of obtaining adequate supplies of raw material. According to the Building Industries Survey, issued by the Building Industries National Council, the output of structural steel in 1937 amounted to 3,330,000 tons, compared with 3,042,000 tons in 1936 and 2,153,000 tons in 1929. This substantially increased demand was brought about by the combined incidence of rearmament requirements and the considerable recovery in normal activity. The problem of delivery dates was further accentuated by the fact that rearmament work was of a particularly urgent nature, consisting in the construction of new factories and of factory extensions as a preliminary to the actual production of armaments and equipment for the defence services. Specific examples are provided by the shadow aircraft factories and the new munitions factory at Chorley. In connection with the latter, Sir Lindsay Parkinson and Company, to whom the contract was allotted, recently announced that work was being carried out to the value of £300,000 per month.

Some idea of the importance of rearmament work can be obtained from the statement of Sir Thomas Inskip in November, 1937, that fourteen shadow factories had then been erected at a total cost of £8,368,000, including machinery. In addition, over 900 engineering firms had been visited and allocated to the War Office, Admiralty or Air Ministry, in accordance with their qualifications and the ease with which they could take up the manufacture of any particular product. In many cases extensions to capacity were financed by the Government and expenditure on extensions to factories amounted to £8,162,552. These figures do not include factory construction and extensions other than those financed by the Government, nor do they include direct Government expenditure on aerodrome and munition and other factories managed by the Government; the value of the contract for the munitions factory at Chorley, for example, alone amounted to approximately £4,000,000.

The development of flat construction which has been such a feature of recent years continued in 1937. Though most marked in London and the Southern counties, this development is by no means confined to these areas and there has been considerable activity in the construction of working-class flats in several of the Northern industrial centres. There has also been a good deal of flat construction in the seaside towns on the South Coast.

Turning to future prospects on the industrial side, it has already been stated that new factory construction has shown signs of falling off in recent months. This has been attributed to the incidence of N.D.C. and to general uncertainty regarding the future trade outlook. In certain individual categories, demand has been well maintained, and coke-oven construction, for example, continued at a high level.

There is, however, growing support for deferring public works schemes and for drawing up a long-term programme of such projects to be put in hand when industrial activity begins to decline.—*Engineering.*

The Island of Orleans Suspension Bridge; Prestressing and Erection

D. B. Armstrong, A.M.E.I.C.,
Designing Engineer, Dominion Bridge Company Limited, Montreal.

Presented before the Montreal Branch of the Engineering Institute of Canada, October 21st, 1937.

SUMMARY.—An outline of the principles involved, and the methods employed in prestressing the cable strands and suspender ropes for the Island of Orleans bridge; followed by a description of the principal erection features.

Foreword

Construction of the Island of Orleans bridge, across the north channel of the St. Lawrence river some six miles below the City of Quebec, was undertaken by the Provincial Government as an unemployment relief project and the work was spread over a four year period, from 1931 to July 1935.

The bridge measures 5,840 ft. between abutments and the long north and south approaches, each consisting of a series of reinforced concrete girder spans followed by a number of steel deck-truss spans of conventional type, were built under the direct supervision of the Department of Public Works, Quebec. The central portion, 2,370 ft. long, contains a suspension span which, with the two adjoining approach spans, was designed by Messrs. Monsarrat and Pratley of Montreal, consulting engineers, who also supervised the construction of this portion throughout.

Owing to the special purpose of the work it was specified that, as far as possible, all labour and materials must be of Canadian and preferably of provincial origin. This stipulation was largely responsible for the contractor's decision to construct a modern plant for prestressing the long cable strands and suspender ropes, the first plant of the kind to be established in Canada.

Cables and Suspenders

The compositions of the main cable, cable strand and suspender rope are shown in Fig. 1.

The main cable, 10 in. in external diameter, is composed of thirty-seven 1⅜ in. dia. parallel prestressed galvanized wire strands and is built up in hexagonal form, rounded out by cedar filler strips and wrapped with a continuous serving of No. 9 gauge soft galvanized wire. Each strand contains 37 main wires and six filler wires, having a specified gross area (including galvanizing) of 1.12994 sq. in., but the actual area is more nearly 1.17 sq. in. due to a slight over-run in the wire sizes. The pitch of the outer gallery, or layer, of wires was made of opposite hand to those of the core section, in order to neutralize torsional twisting. The strands of successive layers are alternatively of right and left hand lay; the purpose being to create line bearing, instead of point contact, between the wires of adjacent layers.

The suspenders are 1⅜ in. dia. galvanized wire ropes of Warrington construction (i.e., 6 strands of 19 wires each, surrounding an independent wire rope centre composed of 7 strands of 7 wires each), and having a gross area of .9229 sq. in.

Prestressing

The 74 bridge strands were manufactured in a rope closing machine, of sufficient capacity to contain the 43 spools of wire required to make a 2,500 ft. strand, and were stranded in a single closing operation. They were wound on individual wooden reels, having an external diameter of 5½ ft. and a drum diameter of 4 ft. and were delivered to the prestressing plant with sockets attached.

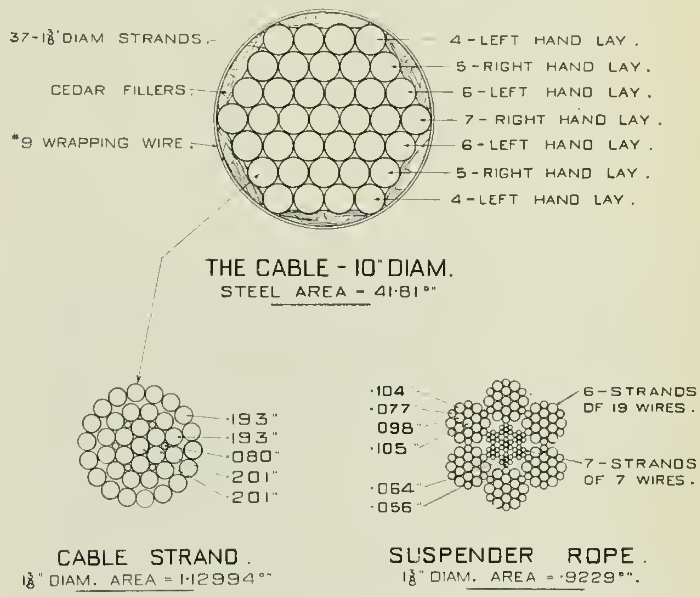

Fig. 1—Cross-sections of Cable, Cable Strand and Suspender Rope.

The prestressing tension, generally specified as 50 per cent of the ultimate strength, is considerably higher than the maximum designed working load but is well under the yield point of the strand. For the Orleans bridge the designed working stress was 83,400 lb., the prestressing load was 120,000 lb. and the minimum allowable yield point was 167,000 lb. per strand.

Measurement of the strands for finished length, and the application of intermediate marks corresponding to the locations of the cable saddles and suspender attachments in the finished bridge, is done immediately following the prestressing. This supplementary operation calls for the exercise of extreme care to attain the required precision, such as in this case, where the extreme tolerance was one inch in 2,468 ft. or approximately 1 in 30,000.

Prestressing Plant

The prestressing plant, a general view of which appears in Fig. 2, is situated on the contractor's property at Longueuil, Quebec, where sufficient land was available to

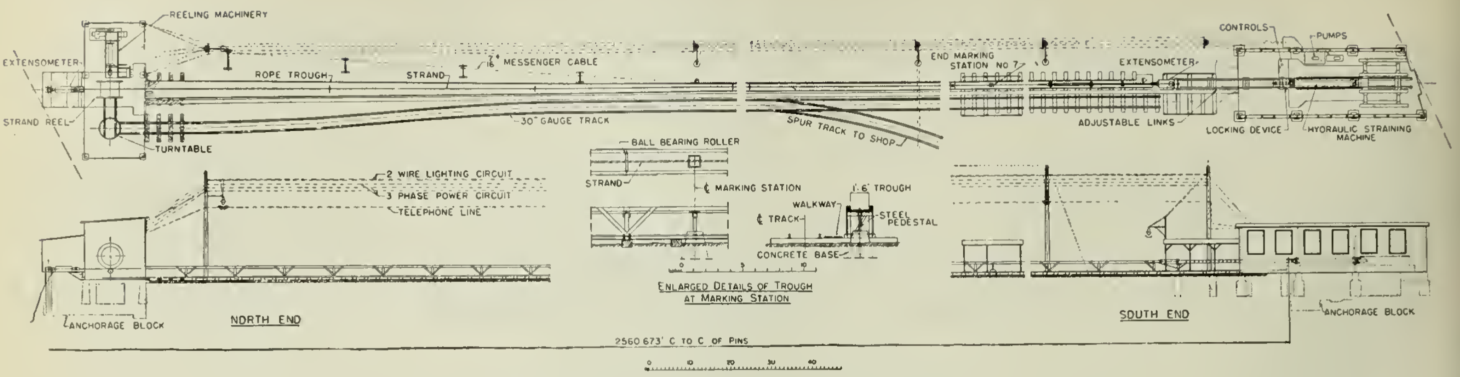

Fig. 2—Prestressing Plant; General Layout.

prestress the strands in a straight length. Adjacent shop buildings, with overhead crane facilities, provided suitable space for the socketing and storage of strands.

At points 2,540 ft. apart, massive concrete anchorages were built, one to serve as a "dead" end anchorage and the other as a base for the hydraulic straining machine.

Between these anchorages the strand was supported, at 50 ft. intervals, on ball-bearing rollers mounted in a continuous shallow wooden through, 18 in. wide. Since the ground was not perfectly level, the trough was built on a slight vertical curve having a maximum offset of 4 ft. from a straight line. At intermediate points where the strand was to be marked, steel marking pedestals, set in concrete footings, were installed in the trough. Paralleling the trough were a walkway, a narrow gauge railway with connecting spur to the shop, and a pole line carrying power, telephone and lighting circuits between the buildings at either end. The entire runway was illuminated by lights spaced at 120 ft. intervals, since the operations could only be carried out at night under favourable temperature conditions.

The strand reel, weighing $5\frac{1}{2}$ tons, was first fitted with an 8 in. dia. shaft, equipped with keyed face plates which were securely bolted to the reel heads. It was then mounted on the special truck and shunted by a yard locomotive to the north end of the plant. Here the truck was turned through 90 deg. on a turntable, and moved into position over a structural steel base located in the line of the trough. The truck was jacked clear of the rails, by operating 4 corner screws, then shimmed and bolted to the base.

Next, the outer strand socket was detached from the reel and connected to a small two-wheeled rubber-tired buggy, carried on the end of a $\frac{7}{16}$ in. dia. messenger cable. This cable, used for unreeling the strand, led up the trough to a sheave located at the far end whence it returned, through idler sheaves mounted on the side of the trough, to a winding drum in the north end building. The drum was operated through a 15 hp. electric motor at an unreeling speed of 100 ft. per min. The reverse operation of reeling the strand was done through the same motor, by disengaging the winding drum and engaging the chain and sprocket driving mechanism on the reel truck. During the unreeling operation it was necessary to apply a slight braking force to the reel shaft, to prevent the strand from overwinding and to counteract a surging action induced by a combination of friction on the trough and elasticity in the 5,000 ft. messenger cable. When the strand was fully unreeled, the sockets were coupled up to 2 load-measuring extensometers, permanently attached to the fixed anchorage girder and hydraulic straining machine, respectively.

Hydraulic Straining Machine

The straining machine is essentially a hydraulic ram with a 12 ft. stroke (Fig. 3). The ram is retractable by means of a push-back piston, and a set of telescoping side bars permits the overall travel of the tail block to be increased to 22 ft.

The ram cylinder is a steel casting 15 ft. 3 in. long, $18\frac{3}{4}$ in. in dia. and $1\frac{3}{4}$ in. thick, mounted on a steel base which is in turn anchored to a concrete block containing 60 cu. yd. The ram is a hollow cast iron cylinder, 16 ft. long, machined to $11\frac{7}{8}$ in. outside and $7\frac{3}{8}$ in. internal diameters. Attached to its head is a trunnion, mounted on wheels that travel on machined rails; its rear end is supported and guided on the push-back piston, a 4 in. dia. shelby steel tube 15 ft. 6 in. long with $2\frac{1}{4}$ in. bore. One end of this piston is affixed to the cylinder head and the other end carries a bronze piston head upon which the ram slides.

The telescopic side bars that connect the ram trunnion to the tail block are bored at one foot intervals to permit free adjustment of the overall length, and for locking purposes. The tail block is mounted on wheels which travel on a machined track set in the rear of the straining machine, and carries the south extensometer on cantilevered supports. An important feature of the straining machine is a device for locking the side bars to the machine base at any position of the ram travel thus making it possible to release the pressure, either to retract the ram for a second stroke or to relieve the pumps during the relatively long prestressing and marking periods. Fluid pressure is applied through two electrically driven triplex pumps, operated singly or in tandem as desired. A needle control valve provides for fine regulation of the ram stroke and a relief valve limits the overall travel.

The machine has a capacity of 165,000 lb. at a working pressure of 1,500 lb. per sq. in. and was subjected to a test pressure of 2,000 lb. per sq. in. A load of 1,000 lb. produced an elongation of about 1 in. in the 2,500 ft. strand, hence it was considered essential to have instruments that would record the load accurately within 200 lb., and for this purpose the extensometers were developed.

Extensometer

Fundamentally, the extensometer simply consists of a steel rod, equipped with sensitive indicators for measuring the axial strains when the rod is subjected to tension.

The rod is composed of a nickel alloy steel, heat treated to give a high elastic limit, without appreciably affecting the ductility. Test coupons which underwent the same heat treatment showed a yield point of 114,500 lb., an ultimate strength of 135,500 lb. per sq. in., with 22 per cent elongation and 62 per cent reduction of area.

The body of the rod which is 56 in. long, was ground to a uniform diameter of 1.595 in., corresponding to 2 sq. in. in cross-sectional area. Its ends were upset before heat treatment, and threaded for the necessary attachments.

Two crosshead blocks are mounted on the bar, at 30 in. centres, by means of adjustable hardened steel points, bearing precisely on the horizontal axis of the rod. Two side bars, 1½ in. deep and ¾ in. thick, pass through vertical slots in these crossheads, being supported in the one on vertical steel points and in the other on small brass rollers, centred in longitudinal grooves cut in the underside of the bars. Dial indicators, reading directly to 1/10000 part of an inch, are mounted horizontally on the outer ends of the side bars, with their spindles located in the plane of the horizontal axis of the bar and bearing against the polished ends of micrometer screws mounted in the rear crosshead.

When the extensometers are not in use the micrometer screws can be disengaged from the spindles to protect the indicator mechanism against inadvertent shocks.

When the rod is under tension the mean of the two indicator readings represents the true axial strain, since the influence of vertical bending is avoided by taking the measurements on the horizontal axis, and horizontal bending strains are nullified by averaging the two dial readings.

The extensometers were calibrated for loads up to 160,000 lb., in an Olsen tensile testing machine, and showed remarkable consistency under repeated loadings. The calibration also served to eliminate possible inconsistencies in the individual characteristics of the indicators. An elongation of .0001 of an inch in the bar is equivalent to 203 lb. tension and it is possible to read loads to within 50 lb., by interpolation, if desired.

The north extensometer was attached directly to the fixed anchorage loading girder by means of a yoke plate provided with vertical and horizontal pins designed to eliminate bending strains. The south extensometer engaged the tail block of the straining machine through a spherical nut, bearing on a spherical seat, to allow correct alignment of the extensometer and strand.

A set of adjustable plate links, carried on 10 in. dia. roller-bearing wheels, were inserted between the south extensometer and strand socket to accommodate small variations in the manufactured lengths of the strands.

Preliminary Studies

Before any bridge strands were actually prestressed, a study was made of the various influences that might affect their finished lengths, and a number of preliminary experiments were conducted. For these experiments four strands, identical in construction to the bridge strands and utilized later as erection footwalk cables, were used.

The several factors which had a bearing, in greater or lesser degree, on the finished strand lengths were as follows: base line chainage, anchorage movement, tension, friction, temperature, reeling, twisting, socketing.

Chainage

The distances between the anchorage blocks and marking stations were chained at night, using a 500 ft. tape that had been previously checked and calibrated by the Department of Standards at Ottawa. Several chainages were made until the probable overall error was reduced to less than $\frac{1}{16}$ in. Incidentally the same engineers using the same tape, made the chainage of the bridge piers, thus personal errors were largely avoided.

Anchorage Movement

Before any strands were prestressed, reference targets were established on each anchorage block. The locations of these targets, under no load and under the full prestressing load of 120,000 lb., were observed by means of transits set at right angles to the line of stress, but no movement whatsoever could be detected.

Tension and Friction

The average tension in the strand was assumed to be the mean between the readings of the two extensometers. This would only be true if the friction on the trough, represented by the difference between extensometer readings, were applied uniformly throughout its entire length and an experiment was therefore conducted to determine if this were so. At that time the strand was supported directly by the wooden trough; the ball-bearing rollers being added later as a result of this experiment.

The strand was first loaded to the specified marking tension of 59,000 lb. and, based on the difference between the extensometer readings, corrections for a uniformly applied friction were computed and applied to the strand at each station. Next, the load was increased about 10,000 lb. then lowered to bring the end mark back to its former position; this operation being done to reverse the direction of the friction. When proportional friction corrections had been computed and applied as before, it was found that these marks, instead of coinciding with the original set, as they should have for a uniform distribution of friction, varied erratically, by as much as one-half inch. It was also found that the quantity of friction varied considerably, being greatest (about 5,000 lb.) when the trough was thoroughly wet, less on a perfectly dry trough and almost nothing when the trough was heavy with dew.

These phenomena led to the introduction of ball-bearing rollers, at 50 ft. intervals, for supporting the strand clear of the trough when under marking tension. The overall friction was reduced thereby to about 2,000 lb. and was found to be very uniformly distributed throughout the length of the trough.

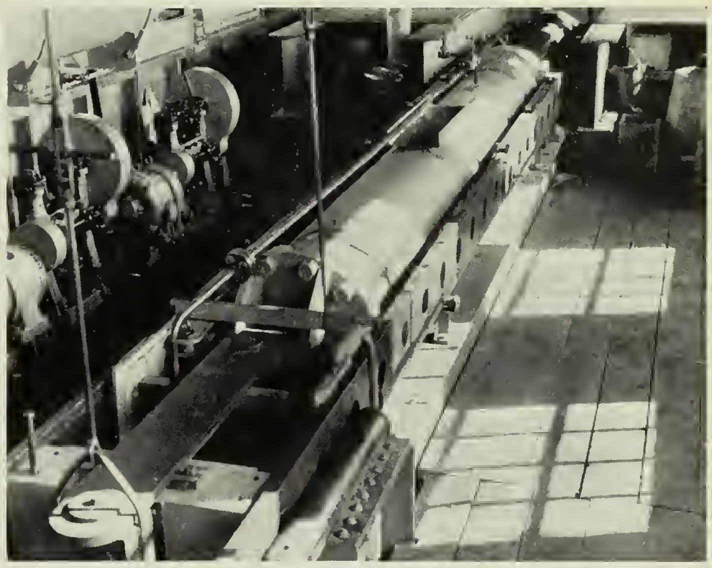

Fig. 3—Prestressing; Hydraulic Straining Machine.

Temperature

All prestressing and marking operations were, of necessity, done at night and work was not commenced until well after sundown, to allow equalization of the strand and trough temperatures. Automatic recording thermometers were installed at intermediate points for determining the general trend of temperatures.

Sensitive thermometers, calibrated to $^1/_{10}$ deg. C., were clamped on the strand near each end and a complete record of temperatures was kept during the prestressing period so that not only the actual temperature, but the rate of change would be known at the time of marking. Temperature fluctuations were generally slight but, when any rapid change occurred, sufficient time was allowed for the strand to absorb the full effect before any marks were applied.

A somewhat interesting experiment was made to determine the relationship existing between the true strand temperatures and the thermometer readings, under various conditions. A strand was stressed and left in the trough for a period of 20 hours commencing at 4 a.m. and ending at midnight, during which time the thermometers and extensometers were read at short intervals. Changes in the strand tension were translated into corresponding temperature changes, through the common relationship that

$$\delta = \frac{PL}{AE} = WTL, \text{ whence } t = \frac{P}{AEW}$$

(t = temperature, P = pull, A = strand area, E = modulus of elasticity and W = coefficient of expansion).

The results of this study are shown in Fig. 4 and led to the conclusions that:—

1. It would be utterly impracticable to measure and mark the strands accurately in sunlight.
2. Measurements should not be made in hot weather until two hours after sundown.
3. Under normal night conditions, the strand would absorb temperature changes fully within 30 min.

Reeling

Several strands were unreeled a second time and were re-measured to determine the influence of reeling after prestressing. The strands in every case were found to have shortened, but by variable amounts ranging from 3/8 in. to 2 3/8 in. It was also found that the modulus of elasticity remained unaffected when the strand was reloaded, up to 80,000 lb., but beyond this point the modulus fell off and by the time the full prestressing load of 120,000 lb. was reached the strand had stretched to its original prestressed length. As the normal bridge design stress was only 75,000 lb., an arbitrary amount of 2 in. was added to all standard strands to compensate for reel shortening.

Two special strands, however, that were to be used as guides for erecting the cables, and four others, marked for locating the suspender ropes in the bridge, were reeled in after being prestressed and then unreeled for marking so that errors from reeling would be eliminated. Further investigation showed that the strand lengths were not affected by a second reeling operation.

Twisting

In some former instances, fabricators and erectors have found it difficult, if not impossible, to prevent strands from twisting during and after prestressing, thus altering their length. The Orleans strands were so constructed that the torsions of the inner and outer galleries were almost perfectly balanced and no trouble from twisting occurred.

From the time the outer socket was removed from the reel until it was re-attached after prestressing, the sockets were positively restrained and this procedure was also followed during erection so that not a single twist occurred in any of the 74 strands.

Socketing

When delivered for prestressing, the strands were equipped with permanent sockets on one end and temporary sockets on the other. As tension was applied, the zinc cones bedded down in the socket baskets and by the time the marking tension of 59,000 lb., i.e. the average dead load stress in the bridge, was reached the total slip amounted to 1/8 in. An allowance of this amount was therefore made for subsequent slip under load, when the strand was cut and re-socketed to exact length.

Prestressing Strands

The sequence of operations in prestressing a bridge strand is as follows:—

After being connected up, the strand was subjected to an initial load of 10,000 lb., a reference mark was established on the strand at the end station (No. 7) and the thermometers were attached. The tension was then increased to slightly more than the minimum specified prestressing load of 120,000 lb., where the strand was locked up for 30 min. For about 10 min. the load fell off slowly, indicating a readjustment of the wires, or structural stretching, but after decreasing about 1,500 lb., no further change occurred. The strand was then unlocked and the tension reduced by 10,000 lb. stages until all load was off, changes in the strand length being recorded at each stage for the calculation of the modulus.

Tension approximating the marking load of 59,000 lb. was next applied and the strand was again locked. Corrections for differences between the normal and actual temperatures, and tensions, were calculated with the aid of ready reference tables, and the strand was marked accordingly with pencil, at each marking station. The tension was then increased some 10,000 lb. and lowered again to about the marking load, this operation being done to reverse the direction of the friction. Temperature and pull corrections were again computed and applied to the strand. The mean between the first and second set of marks at each station was deemed to be the correct location, with friction eliminated, of the permanent mark.

The permanent marks consisted of fine black lacquer lines around the strands with heavy black bands painted on either side for ease in location in the field. A series of red marks were also applied, at about 6 ft. intervals, to the upper face of the strand throughout its entire length, in order that any subsequent twisting could be detected and rectified. The strand was then re-reeled and returned to the shop for cutting and socketing.

The 1 3/8 in. diameter suspender ropes were fabricated by the manufacturer in a single length of 11,600 ft. and then cut into five suitable lengths for prestressing. In prestressing them it was found necessary to maintain the specified prestressing load of 75,000 lb. for at least three hours before all stretching ceased. The suspenders were measured off under a marking tension of 24,000 lb., using a steel tape standardized at the normal design temperature of 60 deg F., hence only corrections for pull and socketing allowance had to be provided. Friction and reeling corrections were disregarded since their influences on the suspenders, the longest of which was 236 ft., were negligible.

Cutting points were established by notching the wires with a hack-saw, and each length was painted with its identification number and an intermittent red stripe in the same manner as the strands.

Cutting and Socketing

The strand was firmly seized with wire at three points on either side of the cutting mark, and was then cut by means of a power driven hack-saw, equipped with a tungsten steel blade, since the high carbon steel wires were of almost tool steel hardness.

Sockets were clamped in a special stand, located 16 ft. above the shop floor, designed to ensure a straight lead and to maintain the strand and socket in perfect alignment. The strand was secured in long vertical clamps, adjustable by a rack and pinion device for locating the strand correctly with respect to the socket. Every care was taken in brooming and cleaning the end of the strand, the socket was preheated to about 300 deg. F. by blow torches and was then filled with molten zinc poured at the carefully controlled temperature of 850 deg. F. During the pouring process, the sockets were vibrated by hammers to dislodge air pockets and were then left to cool undisturbed for 20 minutes.

Tests

The engineer's specifications called for laboratory tests to determine the modulus of elasticity, yield point and ultimate strength of both the strands and suspender ropes, the ultimate strength of sockets and the adequacy of the socketing methods.

Twelve prestressed strand specimens were tested for modulus, yield and ultimate strength, and twelve others for ultimate strength only. Readings were made over a specified length of 100 in. by means of sliding extensometers with scales graduated to 1/100 of an inch. The 24 strand

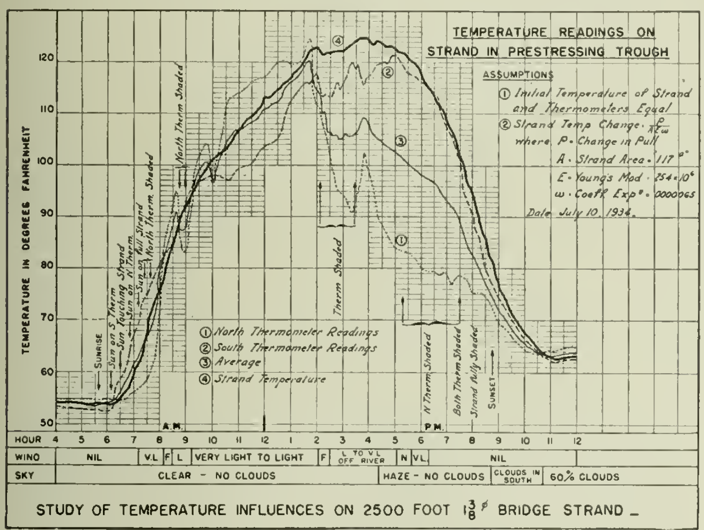

Fig. 4—Temperature Study on 2,500 ft. Bridge Strand.

tests indicated a remarkably close range of uniformity and a much higher strength than specified.

In one of these tests an interesting demonstration was had of the intimate bond that exists between the layers of wires in a strand. It was found that a single internal wire (slightly defective due to piping) broke at three separate points and at different stages of loading, before the strand failed as a whole; which would indicate that despite the initial breakages, the wire was prevented from slipping by the clamping action of the outer wires.

Four suspender specimens were also tested around a sheave of 12¼ in. inside diameter. When a load of 300,000 lb., the limiting capacity of the local testing machine, failed to produce ultimate failure, two specimens were broken at Toronto, in the one million pounds capacity machine of the Department of Mines. Failures occurred at 324,800 lb., and 325,600 lb., respectively, about 82 per cent of the value of the two parts of rope in direct tension.

Two suspender sockets were attached to short pieces of bridge strand, linked together, and tested to destruction. Failure occurred at 203,700 lb., through one pinhole at a point approximately 120 deg. from the back of the pinhole. The sockets had a guaranteed strength of 90 tons and the failure was undoubtedly accelerated by pronounced bending in the 1⅞ in. dia. connecting pins, which had a permanent central deflection of ¼ in.

Strand specimens were also socketed and tested to destruction, and in every case the socketing proved adequate, the only effect being that the zinc cones bedded down about ½ in. under the ultimate load.

PART II. ERECTION

The anchorage steel was erected during the course of the anchorage pier construction, early in the summer of 1934.

The main programme, however, commenced with the setting of the north tower bases on September 20th, 1934, and continued with only minor interruptions due to bad weather, throughout the winter and into mid-summer of the following year.

Cold and blustery weather severely hampered the cable erection, but this disadvantage was ultimately offset by the ease with which the suspended span steelwork was handled from the ice, with the result that the total erection costs were probably no greater than if all work had been done during the summer months.

Chainage

The absence of any suitable locations for establishing triangulation stations and a base line close to the site made it necessary to measure the central span by direct chainage.

This was done by means of a piano wire stretched over the ice, in the early spring of 1934, before any of the six central piers had been built. The measurement was therefore made between the last approach span piers, a distance of 2,670 ft., or practically one-half mile.

The piano wire was fixed at one pier, supported on four intermediate trestles set on the ice, and passed over a bicycle wheel (a practically frictionless sheave) on the far pier, with a 20 lb. weight suspended from the end to maintain a constant tension in the wire. When weather conditions became favourable, and the supports were brought level by the rising tide, reference points were established on each end of the wire.

The wire was later set up over level ground with all governing conditions duplicated, and the distance between the end reference marks was chained and corrected for temperature differences. This measurement was used for locating the six central piers and was proved by subsequent observations to be extremely accurate.

Anchorages, Cable Bents and Towers

The anchorage steel was transported on scows, directly from the contractor's dock in Lachine, to the site where a floating derrick was used to erect it in the partially built anchor piers. Each anchorage unit was assembled to its previously located centre lines, brought to correct elevation by means of special adjustment screws provided in the base plates, concreted in, and its position re-checked to assure that no displacement had occurred.

The cable bents were erected by deck travellers, after the latter had completed erecting the 238 ft. approach spans. After being assembled, the bents were tilted shorewards on their pins to bring the saddles 10 in. back of their normal locations, where they were securely shored and tied to the ends of the approach spans.

The tops of the main piers were bush-hammered and ground to provide perfectly level seats for the tower bases, the accuracy of this work being checked with a 12 ft. straight-edge and a sensitive hand level, containing the bubble from a surveyor's level, and made especially for the purpose.

The tower steel arrived at the site on scows and the first section, comprising bases, posts and bracing, was erected by the Quebec Harbour Commission's 50 ton capacity floating crane. This crane also placed the frame of the creeper traveller in its first position, attached to the tower, after which a smaller derrick scow was utilized for assembling the traveller derrick and mounting its hoisting engines on the pier.

The creeper traveller shown in Fig. 5 consisted of a structural steel frame, 47 ft. by 27 ft. in plan and 18 ft. deep, surmounted by a 20 ton capacity stiff-leg derrick, with 60 ft. boom. The frame was suspended by long pin-connected link plates, bolted to the tower splices, and was held in contact with the tower by means of adjustable yokes that encircled each tower post. The traveller weighed

42 tons and, when boomed up, its centre of gravity lay 3 ft. beyond the tower face, but when making the heaviest lifts from a scow on the far side of the pier, the combined load was practically centralized on the tower, so that at all times its overturning influence was small. The traveller was "jumped" from one splice to the next by means of nine part hoisting tackles, hung from outrigger brackets, bolted to the topmost splice holes. Two 9 by 10 hoisting engines were installed on the pier for operating the derrick and for raising the traveller, respectively, but it was found advisable to substitute a larger 10 by 12 engine for the latter operation owing to the large amount of sliding friction developed.

During erection the post splices tended to remain open on the outside faces, due to the inward inclination of the posts, and the fact that the post sections were fabricated slightly longer than normal to compensate for dead load compression, whereas the bracing members were of true geometric length. This difficulty was overcome by the use of temporary splice bars, having groups of holes, matching those in the two sections to be connected but spaced ¼ in. closer together than normal. Drift pins brought the joints perfectly tight and after the surrounding rivets were driven the temporary bars were replaced by permanent splice plates. Riveting scaffolds were suspended below the traveller frame and all riveting followed closely behind the assembly.

After completing the tower erection, the traveller placed the main cable saddles in their initial positions, offset 21 in. towards the shore, and mounted a 5 ton capacity guy derrick, with 20 ft. mast and 30 ft. boom, on the centre of the top strut. The derrick was guyed to the ends of the strut and to outrigger timbers, bolted across the strut and anchored down to the tower bracing. The traveller was then lowered to the pier and dismantled.

Catwalks

Temporary light wooden walkways or "catwalks" were installed immediately after the completion of the second tower (Fig. 6). These catwalks were located about 3 ft. below the initial position of the main cables and extended from pier to pier, each being carried on two 1⅜ in. dia. strands that were, in turn, supported in temporary saddles attached to the sides of the main tower and cable bent posts.

The strands were anchored to rods embedded in the anchor pier, by turnbuckles having a 30 in. runout, so that later the catwalks could be slackened off as the main cables deflected under the weight of the suspended structure, a deflection that amounted to 11 ft. in the central span.

The reels containing the catwalk strands were first mounted on a scow and after the strand sockets had been connected at one anchorage the scow was towed across the river at slack water, and the strands unreeled. As each pier was passed, slings were attached to the strands and when the far anchorage had been reached and the sockets at that end connected, the strands were hoisted by the tower derricks, placed to their designated marks in the saddles and clamped to prevent displacement.

Next, a light timber and steel cross-bridge was hoisted at one tower, attached to the four strands by hookbolts, and lowered by tag lines as far as it would slide towards the centre of the main span.

The wooden walkway sections, which were prefabricated in units 10 ft. long, and stored on the main piers in early December before the river ice formed, were then hoisted to the tower tops, hook bolted to the catwalk cables and lowered concurrently in the central and side spans and on the back stays. As soon as the cross-bridge became accessible it was worked down to the centre of the main span, where it served as a combined strut and crossover between the catwalks. Additional timber cross-struts were installed at the quarter points of the main span and at the middle of the side spans.

The posts and braces provided on each walkway section, and attached to them by single bolted connections, were next upended and made ready to receive the hand lines. The latter were ⅝ in. dia. ropes, hung from tower to tower under their own weight to provide initial tension, and then hook bolted to the walkway posts.

Storm cables, single ¾ in. dia. ropes in the form of inverted catenaries directly below each catwalk and bridled to the catwalk cables, were provided in the central span only. Their ends were fixed to the base of one tower and were connected to the other by means of running tackles, to allow free movement under temperature changes, but counterweighted to maintain a constant tension of 5,000 lb., in the rope.

Shortly after the catwalks were erected they were subjected to a strong gale, during which their behaviour became a matter of much interest. Under the action of the wind, which blew diagonally from the south east, the main span catwalks drifted approximately 8 ft. laterally, accompanied by a very slight and slow vertical motion. In the north side span, however, they swung rapidly to and fro through an arc of nearly 180 deg., midway between the end- and mid-supports. The oscillations were of a periodic nature, delivered severe longitudinal impulses to the cable bent and in turn appeared to be amplified by the spring in the lashings that tied the cable bent to the approach span.

Fig. 5—Creeper Traveller Erecting Tower.

The turnbuckles on the lashings were tightened as much as possible in an endeavour to dampen the oscillations and, whether due to this action or not, the catwalks steadied down within 20 min. and additional cross-struts were immediately installed at the quarter points of each side span. No further trouble of this sort was experienced during the many periods of high wind that followed.

Main Cables

The 74 strand reels were delivered by scow before winter set in, and were stored on the base of the north anchor pier until required. Unreeling stands were set up on the pier and the strands were hauled across in pairs, one to each catwalk, by means of ¾ in. dia. lines operated from a hoisting engine located on the south anchor pier. The leading socket was carried in a light sheet-steel "torpedo" which was guided by a man to prevent fouling or twisting. Signal men, stationed at telephones on the tower tops and at both anchor piers, were in direct communication with the engine runner so that when necessary the operations could be stopped instantly.

The first two strands to be erected were the special guide strands. After being unreeled and connected to the anchorages, the strands were lifted by means of the tower derricks, assisted by gin poles at the cable bents, and placed in the saddles with their marks carefully adjusted to the scribed centre lines on the saddles. As previously stated, the saddles were all offset definite amounts towards the shores, their temporary positions being the predetermined points at which the unloaded strands should be supported in order to have balanced horizontal components at the towers and equal tensions on either side of the cable bents, under a temperature of +15 deg. F.

Checking of the guide strand setting involved a rather elaborate series of field observations which, on account of the unfavourable weather, took nearly three weeks to complete. It was necessary to determine the true positions of the four tower saddles, the four cable bent saddles and the elevations of the five sag points for each strand and, to be of any value, the observations had to be made when the structure was not exposed to sun or wind, and when the temperature was steady.

From a comparison of the results of this survey with a set of prepared charts, showing the correct sag elevations for a wide range of temperatures combined with variations in span lengths, the required adjustments of the strand were found.

The sag elevations in the central span were read by means of a level, mounted on one tower, which was first lined in on a target set at the same elevation on the far tower and then rotated to read on a level rod projected downwards from the strand, through the catwalk. Transits were set up at fixed points, and elevations, on the outer ends of the approach spans for reading the side span sags. The telescope was first sighted on a target at a known elevation on the tower, to fix the vertical angle, and was then rotated horizontally to read on a vertical rod held on the strand at the middle of the side span. The elevation of the line of sight at this point having been calculated in advance, the sag elevation was quickly determined from the rod reading. The backstay sags were taped directly from timbers, set at a fixed elevation above the strand and cantilevered from the approach span trusses.

Mining transits were used for locating the positions of the tower saddles, the transits being set on the main piers, at points, offset from the tower axis, on the centre line of bridge. After sighting on a central target on the far pier, the telescope was rotated horizontally through 90 deg. then transited to read on horizontal target rods clamped to the top strut of the tower. The cable bent saddles were located directly by means of plumb bobs.

A complete set of observations took about 2½ hr. for a party of six men, and on more than one occasion the work was rendered useless by the sun's appearance before all readings could be completed. It is interesting to note in this connection that, after the strands were finally adjusted, an examination of the original marks applied at the prestressing plant indicated that just as satisfactory results would have been obtained by setting the strands to these marks and then equalizing for any small differences in sags. This procedure would undoubtedly have saved much time, and should be entirely practicable on future

Fig. 6—General View of Catwalks.

occasions where due care has been taken with the preliminary preparations.

After the two guide strands were finally adjusted and re-checked, erection of the remaining strands got underway. Each layer of strands was set slightly high in all spans and the individual strands were then slackened down to their final positions by means of clamps and adjusting turnbuckles, attached temporarily to the saddles, and by easing off the end adjustment bolts. To prevent the strands from slipping in the saddles, the partially completed cables were clamped down to the saddles by wooden blocks, excepting while strands were actually being placed, and, to preserve them in their proper relative positions, light wooden frames were lashed around the strands at intervals of 200 ft. These frames were replaced by heavier wooden template frames as soon as the cable acquired sufficient mass to support them without causing appreciable local deflections.

On several occasions, for short periods, operations had to be suspended when the combination of wind and sub-zero temperatures became unbearable and once, following an unseasonable thaw, thick ice formed on the strands, and had to be removed by scraping and beating with hardwood sticks, before additional strands could be erected. The cables were finally completed on January 28th, seven weeks after having been started, and strangely enough the weather immediately moderated and was ideal for all later work.

The caps were firmly bolted on the cable bent saddles and all lashings and shores were then removed from the bents. The cable bands were assembled on the cables, being located by the marks placed on the suspender guide strands during prestressing.

The bands were found to be slightly large for the finished cable, due to the facts that their internal dimensions overran slightly and that an allowance of $\frac{1}{16}$ in. had been made for "build up" of the cable, which did not occur. The bands were therefore removed and the ¼ in. clearance between the two halves was increased to ⅝ in.

by machining off the adjoining faces. All cable band bolts were tightened to not less than the specified tension of 33,000 lb., the required turning moment being determined experimentally as the force that two average men could exert on the end of a 4 ft. wrench.

The coils of suspender rope were hoisted to the tower tops, uncoiled on the catwalks, and after their two ends had been brought together they were lowered through slots cut in the planking, being slid over cross timbers to protect the galvanizing, and kept under control by a tag line, snubbed around the cable. The ropes were then carefully centred on the cable bands with the red guide lines always located on top.

Suspended Steelwork

During the preliminary office studies of the erection procedure, two alternative methods for erecting the stiffener trusses and floor steel were investigated, and a small scale model was constructed to determine the respective cable distortions. The model was built to a scale of 1:48, and the substitute for a cable was a small chain, weighing .0768 lb. per ft., from which paper cups were suspended by wires at each panel point. The cable supports were made immoveable, it being assumed that the sequence of erection in the central and side spans would be regulated so as to keep the towers plumb. It was also assumed that the individual truss sections would hang freely and would not be inter-connected until after all were erected.

The relation of the chain weight to that of the actual cable was first established and equivalent weights were then computed, in the same ratio, for the suspended structure. The loads representing successive erection stages were applied to the cable, in the form of B.B. shot, and the resultant deflections were measured by means of a surveyor's level, reading on paper scales attached to the hangers.

The first method considered was based on simultaneous erection, working in opposite directions from each tower, which would necessitate the provision of four light-weight deck travellers and erection of considerable floor steel to carry the travellers and supply tracks. The resultant deflections were considered to be so large as to seriously affect the operation of traveller derricks and make difficult the framing of the floor steel. Another objection to the method was that all material would have to be hoisted at the towers and re-handled to the point of erection.

The alternative, which was finally adopted, was to hoist the steel from directly below its permanent location, by means of tackles suspended from the cables, commencing at the middle of the main span and the shore ends of the side spans. This method permitted all truss sections to be erected in advance of the floor steel, resulted in much smaller cable distortions, and did away with the requirements for travellers, tracks, special derricks at the towers and expensive re-handling of materials. The steel was unloaded from a railway siding on shore and hauled about ½ mi. across the ice, on sleighs pulled by a small caterpillar tractor.

Four-part hoisting tackles were provided, operated from engines on the main piers, and as each truss section (the heaviest of which weighed nine tons) was raised, it was permanently connected to its suspender and connected by a pair of bolts to the adjoining section. In the initial stages, due to the cable distortions, only the top chord joints could be so connected but as the curvature in the spans gradually reversed, the bottom joints closed and were bolted; at the same time some of the top chord splices were released to prevent overstraining of the trusses.

The two deck travellers used in erecting the approach spans and cable bents were started off erecting steel in the side spans and, it had been contemplated, would continue right out to the towers. However, the more direct method proved so satisfactory in the central span that the travellers were stopped after erecting six panels and their hoisting lines were reeved to operate tackles hung from the side span cables.

Erection of the truss sections immediately altered the cable stresses and the first two sections, hung in the central span, 16 tons on each cable, caused deflections of 5½ inches in the tower tops. The saddles being still offset

Fig. 7—Erection of Stiffening Trusses.

21 inches on the tower posts, it was necessary to jack them onto centre as soon as possible before their reactions became excessive, but this could not be done until the cable reactions had been built up sufficiently to eliminate all danger of slipping on the saddles.

The saddles were first moved an amount of 9 in. after five truss sections of the central span were up and the towers were leaning 8½ in. out of plumb. The saddle bases had been coated with paraffin wax to decrease friction and when the holding bolts were removed, the saddles slid forward approximately 3 in. without being forced and were then jacked a further 6 in. with two 25 ton capacity mechanical jacks, bearing against temporary brackets attached to the tower. The saddles were jacked the final 12 in. after nine central span truss sections were in place and when the towers were again leaning inwards about 3½ in. Heavy jacking became necessary as the towers were actually sprung 6¼ in. in the opposite direction, but the saddles were centered without real difficulty and the permanent connecting bolts were installed.

Erection of the stiffener trusses (Fig. 7) with floorbeams at every sixth panel to act as struts, proceeded until all sections were in place.

The hoisting tackles were then shifted back to their first positions and the remaining floorbeams, together with laterals, stringers and floor grids were raised in a similar manner. The efficiency of this erection procedure was exemplified by the fact that the entire suspended structure, weighing 1,900 tons, was completely assembled in 19 working days.

Riveting of the floorsteel, bottom chord joints and those top chord joints that were tight, was next completed, but due to the excess camber still remaining in the spans some of the latter joints were still open and were left to be driven after the floor concrete was placed. Welders followed along behind the riveters, welding the roadway and sidewalk grids to the stringers, and the fence panels to the stiffener trusses.

One week sufficed for the roadway contractor to fill the floor grids with high strength vibrated concrete which was screeded flush with the tops of the grids. Riveting of the top chord joints was then completed, most of the joints being closed easily by means of draw-bars, and those near the ends of the spans by jacking the extreme ends of the trusses, with the final result that every splice in the bridge trusses was brought to full bearing.

Up to this stage the ends of the stiffener trusses had been left free and unsupported, so that adjustment for any slight discrepancies in their final elevations could be made by shimming under the rocker posts that supported them at the towers. It was found, however, that the ends of the spans were so close to their theoretical elevations that no re-adjustment was necessary and the connecting pins were driven as for the normal setting.

Cable Wrapping

Wrapping of the cables was commenced soon after the full dead load had been placed. The strands were first painted with a heavy red lead paste after which the cedar filler strips were wired in position, ready to receive the continuous serving of No. 9 gauge galvanized wire, which was applied under tension by a motor-driven wrapping machine. The machine (Fig. 8) was built by the contractors to drawings supplied by the patentee, Dr. H. S. Robinson, and was the more or less standard type developed for this purpose.

It comprised a cast steel ring, carrying three spools of wire, which was revolved about the cable by means of a compressed air motor, through a pinion and rack gear. The motor base was rigidly affixed to a segmental bearing that rested on the cable and supported the revolving ring, and was itself prevented from rotating by vertical guides that engaged an overhead pipe frame, clamped to the cable. As the ring rotated, the three wires were fed tangentially onto the cable, passing under three case-hardened guide shoes that were shouldered so as to bear against the sides of the wires and consequently to force the machine to travel along the cable.

All wrapping was done uphill with the result that the wires were firmly compressed downwards by the weight of the machine and formed a practically waterproof covering even before the application of any paint. The machine weighed about 1,000 lb. and was designed to wrap 18 in. of cable per minute, but in practice the actual speed rarely exceeded half of this amount. The steel ring was built up of three segments, one of which was hinged in order to pass the suspenders, and the whole machine could be raised on a screw device for moving it over the cable bands.

The first and last few inches of wrapping in each panel could not be wound by the machine and was therefore done by hand and soldered in place to prevent unravelling. All crevices where water might enter the strand were caulked with oakum topped off with lead wool. Finally, the cables were painted with one coat of red lead paste, followed by two coats of the standard field paint.

Cable wrapping, necessarily a slow job with only one wrapping machine, extended over three months but did not interfere in any way with the traffic, which was admitted to the bridge on July 15th, ten months after erection of the towers had commenced.

Final Survey

On September 26th, 1935, a final survey was made to check the accuracy of the field work and to obtain a measure of the spans stiffness. The date chosen for the observations was most opportune, weather conditions being extremely favourable and the prevailing temperature being exactly 60 deg. F., the precise normal temperature for which the bridge was designed. The results of this survey proved very gratifying to all those whose privilege it had been to be associated with the enterprise.

Conclusion

The total weight of steel in the central portion of the bridge is 3,615 tons, including 420 tons of cable strands, 25 tons of suspender ropes and 520 tons of welded floor grids.

As contractors for the superstructure, the Dominion Bridge Company Limited prestressed the cable strands and suspenders, fabricated all steelwork with the following exceptions, and did all erection.

Fabrication of the 238 ft. approach spans (463 tons) was sub-let to the MacKinnon Steel Corporation of Sherbrooke, Quebec.

The welded floor grids were fabricated by the Eastern Canada Steel and Iron Works Limited, Quebec City, under arrangement with Truscon Steel Company of Canada Limited, the sub-contractors for this item.

Fig. 8—Wrapping the Cable.

The cable strands and suspender ropes were manufactured by the Dominion Wire Rope Company Limited, from wire supplied by the American Steel and Wire Company and the Steel Company of Canada Limited., respectively.

The contractors, having had no previous experience in the construction of suspension bridges, consulted the well-known engineering firm of Robinson and Steinman, principally with regard to erection problems, and acknowledgement is made of the invaluable assistance and advice rendered by Dr. H. S. Robinson, personally, and by his engineering staff. Particularly useful was the method developed by them for computing and plotting the necessary data for setting and checking the cable strands in the field.

DISCUSSION

S. R. Banks, A.M.E.I.C.[1]

Dealing with the latter part of the paper, the writer wishes to draw attention to the way in which the main towers, which were 220 ft. in height, had been erected. On account of the necessarily eccentric loading imposed during erection by the creeper-derrick, it had been impracticable to make any check measurements on the verticality of the towers until their erection had been completed and the creeper dismantled. That appears to have been a very bold procedure since, in such tall and slender structures, any faults in the dressing of the concrete pier-tops and any discrepancies in the splices of the steel columns during fabrication or assembly in the field would have been greatly magnified when they appeared as errors in the location of the cable-saddles relative to the pedestals of the towers. The contractor had evidently placed great

[1] Assistant Engineer, Monsarrat and Pratley, Consulting Engineers, Montreal.

reliance in the accuracy of both shop and field-work, and the results have entirely vindicated his confidence.

With regard to the prestressing of the cable strands and suspender-ropes, the writer points out that the plant at Longueuil, besides being the first and only one in the country, was apparently the first such plant to have been installed and operated by a structural-steel fabricating company. The Dominion Bridge Company have been pioneers in this field, and have dealt successfully with a process that has hitherto been tacitly regarded as being beyond the scope of others than wire-rope manufacturers.

In considering the accuracy of the measuring of the strands, it is observed that the loading of the strand was controllable to within 200 lb. which was equivalent to a temperature variation of approximately 1 deg. F. The mean recorded temperature, however, could not, except under very favourable circumstances, be relied upon to be equally close to the actual mean temperature of the strand. This was due to the long length of strand exposed to the weather, the impracticability of having a large number of thermometers to be read simultaneously, and the fact that the thermometers were more susceptible to local variations of temperature than was the strand itself. The only means of obviating the possibility of errors from this source seems to be recourse to the costly expedient of enclosing the whole plant inside a building. Such errors, though, were small compared with those introduced by the assumption of the two inch correction which had been applied to offset the uncertain amount by which a strand shortened when it was reeled up after it had been prestressed.

Specifications for prestressing strands usually called for the application of the prestressing load "for at least 30 minutes or until stretching has ceased," and for a longer period in the case of suspender-ropes. Prestressing was a comparatively new branch of engineering (having been used perhaps for the first time for the strands of the Grand'Mère suspension bridge), and it appears that there was still scope for study of the behaviour of strands and ropes during the process. For instance, there might be some doubt as to the benefits to be derived from maintaining the load for very long periods such as were necessary, according to the conventional specification, for ropes of larger diameters. The writer remembers reading (in connection with some experimental work carried out on rope to be used for the tie-backs of the Sydney arch during construction) that a 40 ft. length of 2¾ in. dia. rope had been subjected to a load of 100 tons for 22 days, at the end of which period stretching had been found to be still taking place. The results of prestressing the suspender-ropes of the Island of Orleans bridge were of interest in this connection. For some reason, the two ropes that had received the longest periods of prestressing exhibited the lowest resulting moduli. These five lengths of rope had been manufactured in one continuous operation, so that the variation did not appear to be due to the manufacture; but, in any case, the results suggested that the length of the prestressing period could vary considerably without significant alteration to the final modulus of the rope.

In the writer's opinion, any time that could be given to experimental work during prestressing would be well spent, and might yield information of considerable value.

F. H. Hopkins[2]

The author's able paper has been very interesting. His full description and the illustrations leave very little to be added by the writer other than to refer to the actual manufacture of the suspender strands and suspender ropes. The writer's company was entrusted with the manufacture of 185,000 ft. of 1⅜ in. galvanized special openhearth steel bridge strand, wound on special reels in 74 lengths each 2,500 ft. These strands were composed of 37 continuous main wires with 6 fillers, making in all 43 wires in the completed construction. The inside 25 wires for half the quantity being laid from left to right with 18 covering wires laid in the reverse direction. This same process was carried out for the remaining half, only with the inside wires being laid from right to left and the covering wires from left to right. The object of this being to make as near as possible a perfectly dead strand, non-twisting.

Geo. H. Atkinson[3]

First of all reference should be made to the statement made by Mr. Banks to the effect that some British made wire ropes, which were supposed to be prestressed and which were used on the Sydney bridge, continued to stretch after they were put into service. There is no doubt that this is correct, but it should be borne in mind that the cable strands referred to were exceedingly large, some of them being in the neighbourhood of 4½ in. dia. Naturally it would take a tremendous prestressing plant to fully prestress cable strand of this diameter.

Mr. Banks took issue with the author as to how much wire rope would lengthen when the socket was turned over. The author mentioned about 3 in. after one turn of the socket, whereas Mr. Banks said he had experimented and three turns of the socket only changed the length of the rope approximately 1½ in. The author was discussing at

Fig. 9—The Completed Bridge.

[2] F. H. Hopkins, President and Managing Director, Dominion Wire Rope and Cable Company Limited, Montreal.

[3] General Manager, Anglo-Canadian Wire Rope Company Limited, Montreal.

the time suspender rope which is made six strands 19 wires over independent wire rope core, whereas Mr. Banks had in mind cable strand. These are two very different types of rope and therefore both the author and Mr. Banks were correct.

There is another thing the author might have explained to the meeting which might have proved interesting and that is as to why they laid these cable strands into a hexagon rather than into a round strand. It is of course quite plain to most as to why it is laid hexagon but the writer has in mind a recent suspension main cable put up by the John A. Roebling's Sons Company at Maysville, Kentucky, in which the main cable was laid perfectly circular. This was done by using smaller strands in the corner of the hexagon laid strand and owing to the filler being less they could use aluminum as against wood without going to any extra high cost. In the case now referred to, the cable strand was only 12⅞ in. dia. whereas laid up into a hexagon it would have been at least 13¼ in.

Fred Newell, m.e.i.c.[4]

On account of the comprehensive description of this work by the author, it is rather difficult to discuss the subject without following the path which he has already taken. The writer would, however, like to stress some phases from the point of view of accuracy of the work.

During preliminary considerations of the work it was decided that absolute accuracy was necessary to get correct results with a minimum of cost and time, and with this idea in mind it might be well to run over some of the points on which great care was taken to obtain these results, even though in doing so the writer will probably mention a number of features which have already been referred to by the author in his paper.

This method of obtaining measurements between piers has been fully described and the writer will proceed to the next consideration, which is that of measuring the prestressing and marking loads. It was first of all decided that the ram pressure of the pulling machine could be used as an indication of load on the rope. On experimenting however, it was found that the pressure could be varied at least plus or minus 8,000 lb. without changing the length of rope. This was thought, first of all, to be due to friction between the wood trough and the strand. However, it was finally determined that a great deal of friction was in the ram itself, and that some other means would have to be obtained to accurately measure the load applied to the strand. It was also decided at the same time that as much of the friction as possible between the trough and strand should be eliminated. These considerations resulted in the idea of using an extensometer for measuring the load on the rope, and that if two extensometers were used—one at each end—it would be known definitely the amount of friction between the rope and the trough and that the average reading of these extensometers would give the average load on the strand. It was, however, decided that, in order to guard against eccentricity of pull on the extensometers, two micrometer clocks should be used on each extensometer, and the average reading on these clocks would be taken as the exact pull. Micrometer clocks were obtained reading to 1/1000 in. which equalled 200 lb. pull on the rope and interpolations could easily be made for reading to about one-quarter of this amount.

The ropes were also striped intermittently along their entire length so as to detect twisting during reeling and unreeling, and the engineers are confident that as a result of these precautions correct lengths are obtained within plus or minus 1 in., which, as stated in the author's paper, is equal to plus or minus 1/30000.

In the design of the anchorage arrangements considerable thought was also given to the question of accuracy, and partly with this end in view it was decided to terminate the ropes in a spherical anchorage whose radius is equal to the distance from the splay point to the anchorage. This meant that all strands could be made exactly the same length, so that one set of measurements, only, was necessary at the prestressing plant and apart from the lay of the strand any strand could be placed into any position in the cable.

Great care was also taken with the tower fabrication and while each section of the tower was assembled to the mating section in the shop the tower was never assembled complete until it was erected in place. All work in the shop was done to centrelines placed on the tower plates at the beginning of the layout work and this centreline was worked to for all operations. Squaring lines were placed at right angles to these centrelines as checking lines for end facing. The rotary planer was very carefully checked for accuracy and for its ability to machine a true plane surface.

The setting of the tower base members at the site was made to an absolute level by a spirit level. The result of this work was very gratifying as when the tops of the tower were checked by instruments it was found that they were only out by between ¾ in. and 1¼ in. from their true position in a height of 220 ft.

In conclusion it is perhaps well to realize that the final location of the centre of the span was plus ½ in. on one side and 1⅛ in. on the other side above the theoretical position, which the writer feels is a good indication of the accuracy of the work throughout the job.

J. B. D'Aeth, m.e.i.c.[5]

This paper has been of great interest but the bridge was not the first of its kind to have been constructed in Canada. In 1929 the first long span suspension bridge ever constructed with steel cable rope strands was built across the St. Maurice river at Grand'Mère. The bridge which has been described is a somewhat larger edition of the Grand'Mère one. They compare about as follows:

	Grand'Mère	Ile d'Orleans
Central span	948 ft. 10 in.	1,059 ft.
Height of steel tower piers to cable	128 ft.	220 ft.
Width c. to c. stiffening trusses	26 ft. 0 in.	31 ft. 8 in.
Total length cables—anchorage to anchorage	1,681 ft.	2,468 ft.
Clearance above high water	19 ft. 0 in.	106 ft.

Most of the steel erection on the Grand'Mère bridge was carried out during the winter months, December to March. The cables strands were pulled across the frozen river by horses. The rope strands were then lifted onto a set of trestle horses to get them up out of the snow and ice, and from there they were hoisted into position on main towers.

The stiffening trusses were also hoisted into position off the ice. By using the ice as a working platform the necessity of building a cat walk was eliminated.

The rope strands were supplied by John A. Roebling's Sons Company and were prestressed, marked and socketed at their plant before shipment to the site. The strands were stressed to about 60,000 lb. per sq. in. and then slackened to 20,000 lb. for marking and measuring.

The main cables were made up of 37 strands of acid open-hearth cold-drawn bridge wire rope, each strand containing 35 wires of various selected diameters, built up to a 1¼ in. dia. with a metal area of 0.956 sq. in. The minimum ultimate strength of each strand was specified at 180,000 lb. and showed 199,000 lb. in tests. The minimum guaranteed modulus of elasticity was specified at 21,000,000 lb. per sq. in.; tests yielded values exceeding 25,000,000 and the design was based on a modulus of 24,000,000.

The Use of Hydrogenation in the Production of Aviation Fuels*

T. E. Warren, D.Sc.,
Research Engineer, Division of Fuels, Bureau of Mines, Mines and Geology Branch, Department of Mines and Resources, Ottawa.

Presented before the Ottawa Branch of the Royal Aeronautical Society, and the Aeronautical Section of the Engineering Institute of Canada, March 3rd, 1938.

SUMMARY—Because of the nature of the meeting at which it was delivered, this paper makes specific mention of hydrogenation in relation to aviation fuels, but the developments which it describes are equally related to the whole field of fuels for internal combustion engines. It deals with the processes for making motor fuel from coal and describes the suitability of the various fuels for the different types of engines.

Two of the many uses to which hydrogenation has been put are especially worthy of the attention of aeronautical engineers. One of these is the liquefaction of coal. Already a considerable quantity of motor fuel is being made from coal and it is probable that ultimately the greater part of the world's supply will come from this source. For this reason the methods of manufacture and the limitations inherent in them are of interest to those concerned with the trend of development of internal combustion engines. The second important use of hydrogenation from the point of view of aeronautical engineers is the production of motor fuels having a very high anti-knock rating. These fuels have had an important influence on aviation in recent years and the processes employed in their production as well as the reserve and distribution of the required raw materials are matters of immediate interest.

PRODUCTION OF MOTOR FUEL FROM COAL

There are three general methods for producing motor fuel from coal, all of which are in use at present and will probably continue to be used in the future. The most important of these is the addition of hydrogen directly to coal under such conditions of temperature and pressure that the coal is largely converted to liquid. In a subsequent similar step the primary liquid is converted to motor fuel. This process is called direct hydrogenation. The second method comprises the production of carbon monoxide and hydrogen from coal and the synthesis from these gases of an oil containing a large proportion of motor fuel. This is called indirect hydrogenation. The third method is to heat coal so that a fraction distils off as tar. This tar may then be redistilled to give a small yield of motor fuel or it may be cracked or hydrogenated to give higher yields. Distillation is the basis of the various carbonization processes. However coke is the principal product of carbonization and motor fuel is only a relatively unimportant by-product. Accordingly the scope of the descriptions which follow is confined to direct and indirect hydrogenation.

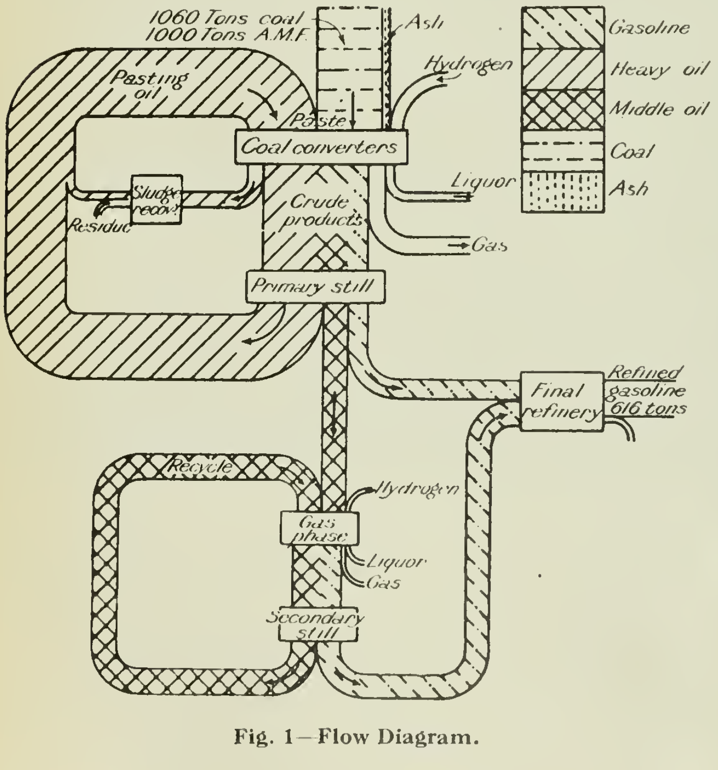

Fig. 1—Flow Diagram.

Direct Hydrogenation

Both gasoline and coal are composed to a large extent of carbon in chemical combination with hydrogen but they differ in three respects: gasoline has about 14 per cent of hydrogen and coal about 5 per cent; the average molecular weight of gasoline is about 100 while that of coal is much greater; gasoline is composed almost entirely of compounds of carbon and hydrogen whereas coal contains substantial quantities of chemically combined nitrogen, oxygen and sulphur.

It is evident, therefore, that to convert coal to gasoline three changes must be made: hydrogen must be added, the molecular size reduced and nitrogen oxygen and sulphur removed.

The hydrogenation process employs only one kind of treatment to accomplish all three changes. This treatment is to dissolve the coal in oil and heat it with hydrogen at high pressure. Under these conditions the large coal molecules break into smaller ones. Hydrogen unites with these to form a series of stable hydrocarbons including gasoline. It also reacts with the nitrogen, oxygen and sulphur in the coal to form ammonia, water and hydrogen sulphide.

As shown in Fig. 1† the process does not accomplish the entire change from coal to gasoline in one operation. It is necessary to remove the gasoline formed in the first cycle and to treat the higher boiling oils again. The heavy oil fraction is mixed with a fresh charge of coal. Enough is available for this purpose so that it is not necessary to introduce oil from an outside source. The oil of intermediate boiling range is hydrogenated further in the vapour phase.

Figure 2 is a simplified diagram illustrating the plant and flow of materials.‡ The coal is ground with heavy oil and catalyst to a fluid paste which is injected through a heating system into the converter. Compressed hydrogen is also heated and passed into the converter where the temperature is about 842 deg. F. (450 deg. C.) and the pressure is 3,000 lb. per sq. in. or more. Liquid is withdrawn from the system in order to remove the accumulation of solids consisting of ash, catalyst and combustible material. The oil is extracted from this suspension and used for pasting. The vaporized product is cooled and condensed from the excess of hydrogen. It is then separated into three fractions by distillation. The heavy oil fraction is

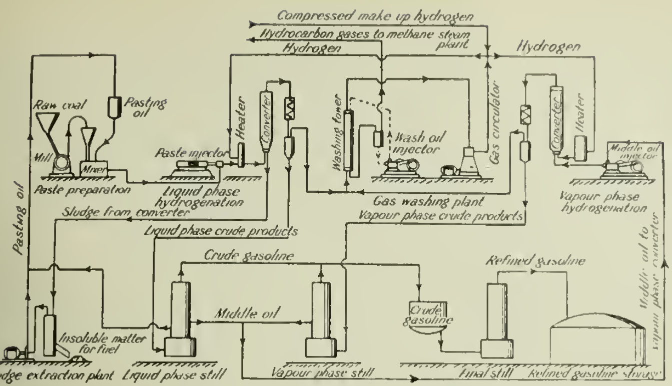

Fig. 2—Hydrogenation Plant.

used for pasting. The gasoline is sent to the refinery. The middle oil passes through the vapour phase converter. The temperature in the vapour phase converter is about 932 deg. F. (500 deg. C.) and the pressure is again 3,000 lb. per sq. in. or more. The catalyst used in the vapour phase is in the form of solid lumps and remains in the converter. The product from the vapour phase converter is separated from excess hydrogen as before and is divided into two fractions by distillation. The gasoline is sent to the refinery and the middle oil is re-cycled through the vapour phase converter. The excess of hydrogen from both phases is scrubbed with oil to remove hydrocarbon gases and is then circulated back into the system. The hydrocarbon gases are sent to the hydrogen producing plant.

Figure 3 is a diagram of the hydrogen producing plant. The hydrocarbon gases are heated with steam to yield a mixture of carbon monoxide and hydrogen. This mixture is heated with more steam at a lower temperature to convert the carbon monoxide to carbon dioxide and at the same time give a further yield of hydrogen. The carbon dioxide is scrubbed from the mixture with water under pressure and the remaining gas, which is nearly pure hydrogen, is compressed and used in the plant as shown in Fig. 2. If a sufficient quantity of hydrocarbon gas is not available, as is the case when operation is being started, the mixture of carbon monoxide and hydrogen can be made from coke and steam.

Considering the hydrogen producing plant and the hydrogenation plant as a single unit it is to be noticed that coal is the only raw material of value which is required. With minor exceptions it may be said that only coal and water are consumed and only gasoline and carbon dioxide are produced.

The efficiency of the process is illustrated in Figs. 4 and 5. The distribution of the reacting coal and hydrogen among the various products is shown in Fig. 4. One hundred tons of ash free coal plus 11 tons of hydrogen yield 62 tons of gasoline. It has been reported that even higher yields are now obtained at the Billingham plant of Imperial Chemical Industries. However the coal actually treated is only about half the total requirement because an equal quantity is used for generation of the steam and producer gas needed in the process. The thermal efficiency of the process is demonstrated in Fig. 5. The overall efficiency is about 43 per cent; that is 43 per cent of the heating value of the total coal required, including that used for steam raising, is recovered in the gasoline.

The quality of the finished gasoline can be varied considerably by changes in the operating conditions which involve no alteration of the equipment. The distillation characteristics and vapour pressure can be adjusted by the final distillation. The anti-knock rating is largely a function of the proportion of aromatics in the fuel. This proportion can be increased by raising the temperature of the vapour phase reaction. However high temperature favours gas formation and consequently a low yield of gasoline. It is therefore necessary to make an economic balance with regard to knock rating.

The properties of the gasoline produced from coal at Billingham are shown in the following table*: I is gasoline obtained directly from coal, II is a vapour phase gasoline containing lead and III is an aviation gasoline made up to 87 octane number presumably with lead.

One important limitation of the direct hydrogenation process is that it is not applicable to all coals. Anthracitic coals invariably give very small yields of oil. In the bituminous class the low and medium volatile groups also usually give unsatisfactory yields. The best coals for commercial use are found in the high volatile bituminous group. The lower ranks of coal are also to be considered for commercial use whenever they have especial advantages in price or location. There is, however, a considerable variation in the oil yields from coals classified in the same group by chemical analysis so that it is necessary to test each coal under conditions closely parallel to those of commercial hydrogenation before deciding on its merits.

Another limitation is that the final product is not entirely independent of the chemical characteristics of the original coal. While the properties of the product can be widely varied it is not possible to produce high yields of paraffinic oils. For this reason it has not yet been found possible to produce a first rate Diesel fuel by direct hydrogenation of coal.

Indirect Hydrogenation

The principal reaction of indirect hydrogenation can be expressed by the following equation.

$$CO + 2H_2 = —CH_2— + H_2O$$

The $—CH_2—$ radicals probably have a separate existence only for a very short time on the surface of the catalyst and then unite to form hydrocarbon chains of various lengths. The product has a smooth distillation curve and contains hydrocarbons varying from methane to paraffin wax and including about 60 per cent which boils within the gasoline range.

The first technical problem in the process is that of producing a mixture of carbon monoxide and hydrogen in the proportion of 1 to 2 as indicated by the equation. Ordinary water gas produced from coke and steam is largely composed of these gases in equal amounts and, after the addition of the required amount of hydrogen,

*K. Gordon, *loc. cit.*

is commonly used for the synthesis. One means of doubling the proportion of hydrogen is to divert about one third of the water gas and treat it with steam to yield hydrogen and carbon dioxide. The carbon dioxide is removed and the hydrogen is added to the remaining two thirds of the water gas to give a synthesis gas of the correct composition. The equipment used for the production of hydrogen is identical with that used for the same operation in the direct hydrogenation process.

The synthesis gas requires careful purification. Sulphur must be reduced to a value less than 0.087 grains per 100 cu. ft. (0.2 grams per 100 cu. metres). This is necessary to prevent poisoning the sensitive catalyst which, unlike those used for direct hydrogenation, quickly deteriorates in the presence of sulphur. The purification is carried out in two steps, the first to remove hydrogen sulphide and the second to remove organic sulphur.

After purification the gas is passed to the chamber containing the catalyst. The catalysts which can be used for the synthesis are basically iron, cobalt or nickel. These are usually mixed with a second metal which may be copper, manganese or thorium and are supported on a non-metallic carrier. A catalyst of cobalt and thorium supported on kieselguhr and formed by the precipitation of the nitrates with soda is stated to be the best for the commercial process, particularly with regard to its period of activity which is about 60 days.*

The temperature in the reaction chamber must be maintained at an optimum corresponding to the catalyst used. This temperature is usually between 356 deg. F. (180 deg. C.) and 392 deg. F. (200 deg. C.). Since the reaction is strongly exothermic considerable ingenuity is required in the construction of the catalyst chamber to prevent local overheating and to maintain a constant temperature. One means is to circulate hot water through tubes in the catalyst bed and to control the pressure on the circulating water so that the correct temperature is maintained. The pressure of the reacting gases in the catalyst chamber is of the order of one atmosphere.

The products are in part condensed and in part absorbed on charcoal. One product, paraffin wax, has so high a boiling point that it remains on the catalyst and has to be removed periodically. A sample of the liquid product examined by the Universal Oil Products, Company had the following properties†:

Gravity, deg. A.P.I.	63.0
Specific gravity at 60 deg. F.	0.7275

The gasoline distilled from the total product has an octane number of only 40. The total oil can be fractionated and subjected to selective cracking conditions and the olefines in the cracked gas polymerized to give a yield of 84 per cent of gasoline having an octane number of 66. An aviation gasoline can be produced by blending a low boiling straight-run fraction with the polymer gasoline produced from the gases formed in cracking the higher fractions. However, the yield of aviation gasoline obtained in this way is only 27.4 per cent by volume of the original total product. It has the following properties:

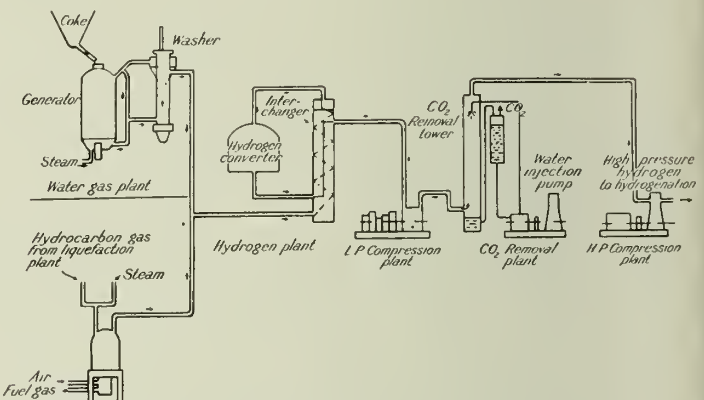

Fig. 3—Hydrogen Producing Plant.

The low knock rating of the product is the principal limitation of indirect hydrogenation. It is due to the fact that the product is largely composed of straight chain paraffin hydrocarbons.

On the other hand the ignition properties required of a Diesel fuel are the opposite of those required of a spark ignition fuel and accordingly the straight chain paraffinic product of indirect hydrogenation is an excellent Diesel fuel. In this respect direct and indirect hydrogenation are supplementary rather than competitive.

A valuable feature of indirect hydrogenation is that it can be applied to any material from which water gas can be made. The range from which the raw materials can be selected is therefore much greater than that for direct hydrogenation and includes all ranks of coal. Further the products from different raw materials are identical and the process varies only in the means adopted for the production and purification of water gas.

PRODUCTION OF ANTI-KNOCK FUELS

Two series of hydrocarbons have outstanding anti-knock values; these are the aromatics and the branched-chain paraffins. Of the latter, iso-octane is the most

*Koppers Review, Vol. 2 No. 3, 1937, p. 106. The Koppers Coke Oven Co. Ltd., Sheffield.

†Egloff, Nelson and Morrell, Ind. Eng. Chem., Vol. 29 No. 5, May 1937.

important individual and it is now being prepared commercially as a blending agent for the manufacture of 100-octane fuels. Hydrogenation is used in the production of both aromatics and iso-octane.

Aromatization

Liquid hydrocarbons are largely composed of four series of compounds namely paraffins, olefins, naphthenes and aromatics. The most resistant to heat of these are the aromatics and to increase their proportion in a mixture it is sufficient to heat it strongly, in which case the less refractory molecules are broken down to gas and coke and the aromatics remain. There is, moreover, a tendency for the other groups to be converted into aromatics under the influence of heat. An example is the conversion of cyclohexane to benzene. The reaction is expressed by the following equation

$$C_6H_{12} = C_6H_6 + 3H_2$$

This reaction is obviously the opposite of hydrogenation and by applying hydrogen under pressure can be made to go in the reverse direction. By selecting conditions of temperature and pressure it is possible to control this reaction at will.

However another reaction involving loss of hydrogen produces an undesirable result. This is the conversion of paraffins to olefins. When strongly heated olefins tend to polymerize and crack repeatedly, forming at each step more complex compounds which are more deficient in hydrogen, until the final product is tar or coke. It is important therefore to reduce the concentration of olefins in the reacting oil to a minimum. A typical example of olefin formation is the dehydrogenation of octane to octene which is shown in the following equation

$$C_8H_{18} = C_8H_{16} + H_2$$

This reaction is also reversible and can be made to go in either direction by adjusting the pressure of hydrogen.

A very important fact is that the pressure of hydrogen required to reverse the paraffin-olefin reaction is less than that required to reverse the naphthene-aromatic reaction. This is the basis of the process of aromatization which is to apply to a hydrocarbon mixture a temperature and pressure of hydrogen such that aromatics are formed while at the same time the production of olefins is prevented. The equipment in which this process is carried out is similar to that used for the vapour phase stage of coal hydrogenation.

This means of producing aromatic hydrocarbons is especially applicable to the primary product of coal liquifaction which is already rich in aromatics. For example the neutral oil fraction boiling up to 572 deg. F. (300 deg. C.) from a primary oil made from Nova Scotia coal contained 74 per cent of aromatics. Although experimental data are lacking it is probable that a 100-octane fuel could be made from such a stock.

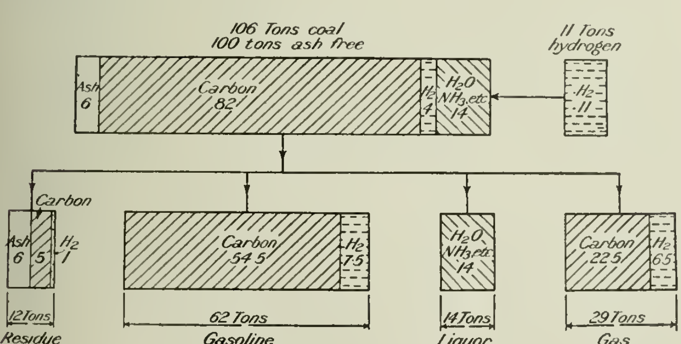

Fig. 4—Material Balance.

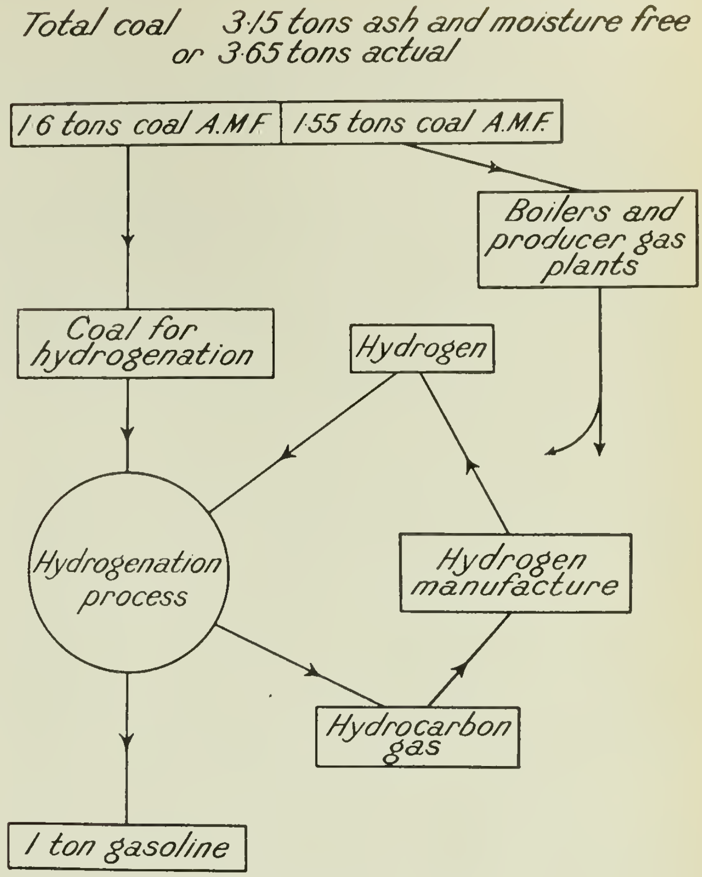

Fig. 5—Thermal Balance.

The aromatizing process is also applicable to petroleum stocks.* Ordinarily, aviation gasoline is made by distilling crudes which have been carefully selected for their high anti-knock properties. Tetra ethyl lead is added to bring the octane rating up from about 75 to the desired value. However it is rarely possible to reach an octane rating of 90 by the addition of 3 c.c. of lead per gal. Moreover the supply of suitable base stocks is not great. However by hydrogenating aromatic stocks it is possible to produce a fuel with satisfactory volatility and having an octane number of 75 to 78 which can be raised to above 90 by the addition of 3 c.c. of lead per gal.

Another use of aromatization is the production of aviation safety fuel.† This is a hydrocarbon fraction boiling between 310 deg. F. and 410 deg. F. Because of its high initial boiling point it has a high flash point and is less apt to ignite accidentally than gasoline. A fraction of untreated petroleum boiling within the required range could not be used for this purpose because of its low anti-knock value. However by aromatizing a suitable petroleum stock a safety fuel having an octane number above 100 can be made without the addition of any lead. Such a fuel obviously lacks the low-boiling fraction necessary for use with an ordinary carburettor. One of the best means of introducing the fuel into the cylinders appears to be direct injection although this problem at present has not been satisfactorily solved.

Synthesis of Iso-octane

Hydrogenation is also used in the commercial preparation of iso-octane. This process takes place in two steps as shown by the following equations:

---

*Brown and Gohr, World Petroleum, Vol. VIII No. 11, Page 49, October 1937.

† Howard, Oil Gas J., 30, No. 46, 90 (1932).

(1) $$\underset{\text{isobutylene}}{2C_4H_8} = \underset{\text{di-isobutylene}}{C_8H_{16}}$$

(2) $$C_8H_{16} + H_2 = C_8H_{18}$$

In the first step isobutylene is polymerized to di-isobutylene. In the second the di-isobutylene so formed is hydrogenated to iso-octane.

The present source of isobutylene is the gas produced in the cracking of petroleum. Isobutylene can also be made from isobutane which occurs in natural gas. The supply of isobutylene is adequate for any demand which is likely to arise in the near future. Estimates of the potential supply of iso-octane from this source in the United States vary between one billion gallons and 155 million gallons per year.* The higher figure is more than 15 times the total consumption of aircraft fuel in the United States in 1934.

The process of production of iso-octane begins with the removal of the butane-butylene fraction from the gas by distillation. This fraction comprises four hydrocarbons, namely butane, butylene, isobutane and isobutylene. Of these, isobutylene, which has the desired branched chain structure, polymerizes most readily.

Advantage is taken of the activity of isobutylene in the three major processes of catalytic polymerization.† All three use a strong acid to catalyse the reaction shown in equation (1). The so-called cold acid process uses 60 to 70 per cent sulphuric acid at 68 to 95 deg. F. to selectively absorb isobutylene from the butane-butylene mixture. The acid containing the isobutylene is then heated to 212 deg. F. which causes the absorbed isobutylene to polymerize to di-isobutylene. The other two processes employ hot sulphuric acid and hot solid phosphoric acid respectively as catalytic agents. Selective absorption and polymerization proceed simultaneously in the presence of the hot acids. The hot acid processes have the advantage of a higher yield but the disadvantage of an impure product. This is because their selectivity is not so exact and some of the butylene reacts along with the isobutylene.

The di-isobutylene produced by any of these processes is not suitable as an aviation blending fuel because its anti-knock rating is only about 84. However on combining hydrogen with it, iso-octane is formed, which of course has an octane number of 100. Hydrogenation of di-isobutylene can be carried out in equipment similar to that used for the vapour phase step of coal hydrogenation.‡ Either high or low pressure can be employed. High pressure has the advantage that a less active but more durable catalyst can be used.

†McAllister, Paper to American Pet. Inst., Nov. 12, 1937.

CONCLUSIONS

In the foregoing outlines it has been shown that where coal only is available as the raw material, it is possible to make a highly aromatic gasoline by direct hydrogenation or a good Diesel fuel by indirect hydrogenation. It is also conceivably possible to utilize the isobutane in the gas produced by direct hydrogenation to make iso-octane. This however will not be commercially feasible until a hydrogenation industry of very large proportions has been built up. At present, therefore, there is no satisfactory method of producing iso-octane from coal.

On the other hand, where a variety of petroleum stocks is available and there is a large supply of cracked or natural gas, it is possible to make not only aromatic gasoline and Diesel fuel but also iso-octane and similar branched-chain paraffins.

Comparing branched-chain paraffins with aromatics it is to be noticed that the latter have certain disadvantages. One of these is that some of the aromatics, notably benzene and para-xylene have high freezing points and therefore cannot be used in high concentration in aviation fuels. Another disadvantage of the aromatics is that they have lower calorific values than the paraffins. For example the gross heat of combustion of toluene is about 11 per cent less than that of octane.§ High calorific values are of course essential to long distance non-stop flying. The relative anti-knock ratings of aromatic and branched chain paraffins depend to a great extent on the type of engine employed. Water cooled engines favour aromatics and air cooled engines favour paraffins.

It would appear, therefore, that where coal is to be used as the source of motor fuel the trend of development will be towards water-cooled spark ignition engines for short distances and Diesel engines for longer distances. Where iso-octane is available it should be possible to combine the advantages of both to a large extent in a single engine.

Welded Steel Pipe for the City of Toronto Water Works Extension

Carl R. Whittemore, A.M.E.I.C.,
Metallurgist, Dominion Bridge Company Limited, Montreal.

Paper presented before the Toronto Branch of The Engineering Institute of Canada on November 4th, 1937, and before the Montreal Branch on February 10th, 1938.

SUMMARY. This paper describes a pipe making process which never before has been done in Canada. It deals with design, manufacture and installation of 48 in. internal diameter concrete lined, welded steel pipe for the city of Toronto, and outlines the methods and equipment for the automatic welding process, the centrifugally placed concrete lining, the hydrostatic tests and the field assembly.

A vital factor in the life of mankind is an abundant supply of pure and fresh water which must be conveyed by some means to the points of consumption. The term "aqueduct" embraces all types of artificial works designed for the purpose of conveying water from one place to another. Generally the term is applied only to works of considerable magnitude.

In ancient times, wells were dug to underground waters. In the cities the populations were dependent on the water carrier, who filled his bags of skin from the wells and springs. These conditions exposed the inhabitants to the danger of an insufficient water supply during a long drought or a siege, so, with the advance of civilization, measures were taken to provide an adequate supply at all times.

The oldest inscription known—that upon the Moabite Stone in the tenth century, B.C.—records an aqueduct for carrying water to supply the cisterns of Kancha. Early forms of conduit found at Jerusalem and dating from the time of the Judean kings were pierced stones and tunnels. One of these consists of limestone blocks, each pierced by a hole, fifteen inches in diameter, chiseled out by hand. The blocks were covered by masonry. The other is the 1,700 ft. tunnel connecting the Virgino Pool with the upper Pool of Saloam. Other forms of early conduit are pipe made of wood, lead and potters clay.

In Egypt, Babylonia and Assyria water was supplied by means of open canals and large basins. In relation to the achievements of Greece and Rome, the Phoenicians were the most important among the engineers of their day. Their most noted water works was the well of Ras-el Ain near Tyre, comprising four octagonal towers in which water rises to a height of 18 to 20 ft. from four deep artesian wells. The accumulated water was carried off in conduits.

The earliest attempts in Europe to solve the problem of water supply were made by the Greeks. Examples of Greek work are the tunnels draining Lake Copais in Boeotia.

The Romans built aqueducts across valleys as a matter of economy, in preference to carrying pipes underground. Pipes had to be made of lead which was weak, or of bronze, which was expensive; and the Romans were not sufficiently expert in the casting of large pipes of these materials which would stand a moderate pressure.

The first known superintendent of water works was Frontinus, appointed curator aquaruum for the city of Rome by the Emperor Nerva, in 97 A.D. In his treatise on the aqueducts of the City of Rome he mentions nine aqueducts the substructures of which were in masonry while the water channels were brick-lined and faced with concrete.

During the Mediaeval Ages small lead pipes were used for water distribution in such cities as London and Paris. In England, water was conveyed across valleys in wooden troughs. These were lined with lead and supported on wooden arches. One of England's oldest water works, where the supply was taken from a river, was installed in London in 1582. Later two types of aqueduct were used, the one being built of brick, concrete, stone, etc., the other of cast iron.

The first experiments in the manufacture and use of cast iron pipe were made at Versailles in 1664 but it was not until 1738 that economical production was attained. The joints of all the earlier lines were of the bolted types, with lead gaskets, and gave trouble through the rusting of the bolts. This difficulty was overcome by Thomas Simpson, of London, who, in 1785, invented the bell and spigot joint that has been used so extensively ever since.

In 1775, at Bethlehem, Pennsylvania, there was installed one of the first public water supplies in the United States. It consisted of a pipe system of bored logs which carried the water to points of consumption. In 1800, in New York city, a company was granted permission to dig wells at various points and to lay to a number of houses wooden water mains, bored from pine logs. In 1830 the first cast iron water mains were installed.

Cast iron water mains have been and continue to be widely used throughout the world with varying degrees of success, depending upon the nature of the soil and the character of the water conveyed. In recent years the following economical limitations have been placed upon cast iron pipe:

(1) A maximum diameter of 36 in.
(2) Pressures not in excess of 180 lb. per sq. in.
(3) Uncertain resistance to pulsations caused by water-hammer and stress of "street conditions."
(4) Decrease of carrying capacity with age due to tuberculation and incrustation.

At Hartford, Conn., a flow test on a 30 in. main showed a coefficient of 61 by the Hazen and Williams formula. The age of the pipe was 30 years but its condition gave an equivalent age of 70 years, indicating a reduction of 28 per cent in carrying capacity in 15 years. The coefficient required in the call for tenders was $C = 80$.

To prevent tuberculation in cast iron pipe and the pitting and corrosion of steel pipe it was found over a hundred years ago that a cement lining was most effective. An investigation of pipe corrosion by the French Academy of Science in 1836 states that "hydraulic cement, applied 1/10 in. thick, is of all compositions, combining facility of application and cheapness, the most indestructible, and prevents most effectively all oxidation and consequent formation of tuberculation or incrustation of the pipe."

In America, experience with cement lined pipe covers a period of about ninety years. An early type of cement lined pipe was the Phipps Patent Pipe. It consisted of a thin sheet of iron (about 1/16 in. thick) riveted into pipe form and then lined inside and covered outside with one-half to three-quarters of an inch of cement. The exterior cement was held in place by an outer sheet iron shell, which in corrosive soils, rusted away. This type of pipe removed after forty to sixty years service has always shown the lining to be in good condition and free from tuberculation and incrustation.

Following the cement lined pipe, reinforced concrete pipe was first developed in France between 1895 and

1900 and introduced into America in 1905. It was developed to meet the main requirements of pressure pipe lines, namely, ability to withstand internal and external pressures, a sustained minimum coefficient of friction, minimum leakage, minimum maintenance, permanency of construction and low construction costs without sacrificing these requirements.

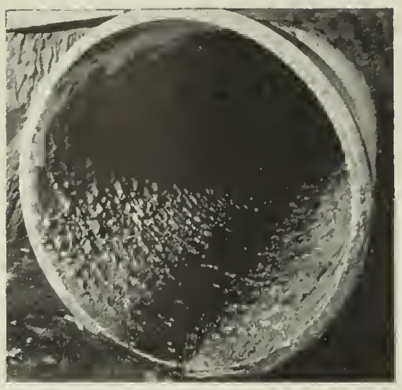

Fig. 1—Tuberculation and Incrustation of Cast Iron Pipe.

Reinforced concrete pipe, correctly designed, will resist internal and external pressures and will work within safe limits up to a water pressure of 150 ft. head. Pipes for higher pressures with the attendant benefits of efficiency and durability comprise a steel shell, lined centrifugally with concrete and protected on the outside with a covering of concrete, a fabric, wrapped and impregnated with a bitumastic composition, or coated with a bitumastic composition.

This type of pipe, for main water supply lines, has been in successful use in the United States and Canada since 1919. Its widest use has been in Europe, Africa, Australia, the Malay States and parts of India. All installations show a uniformly successful record as to carrying capacity, water-tightness and permanence, with negligible cost of maintenance.

In recent years, particularly in active water areas, the use of cement or concrete lined pipe has increased due to the appreciation of the fact that what is really being purchased is water carrying capacity. The composite steel concrete lined pipe permits more economical laying than either the reinforced concrete or cast iron pipe since lengths up to 36 ft. are readily fabricated.

Fabrication of 48-inch Internal Diameter Pipe

The design, fabrication and installation of approximately 38,380 lin. ft. of 48 in. internal diameter steel-cylinder reinforced concrete pipe comprises part of the Toronto water works system as originally decided upon in general principle in 1926 under the direction of R. C. Harris, Commissioner of Works. This scheme selected Victoria Park as the proper location for a raw water intake and the above pipe line comprises the distribution main from this point to the existing system at Dupont Street and Davenport Road, which supplies the St. Clair Avenue-Spadina Road reservoir.

In December, 1936, the Corporation of the City of Toronto called for tenders for riveted steel pipe, or alternatively electrically-welded steel pipe, concrete lined and when laid, encased in concrete. The general contract for supplying and laying the pipe was awarded to the Atlas Construction Company who called for tenders for fabrication of the pipe and joining of the pipe lengths in the field. This portion of the work was awarded to the Dominion Bridge Company, Toronto, in March, 1937, who tendered on a shop welded steel pipe centrifugally concrete lined and welded field joints. All welding was to be in accordance with the American Society of Mechanical Engineer's Welding Code for Unfired Pressure Vessels, paragraph U-69 (formerly Class 2).

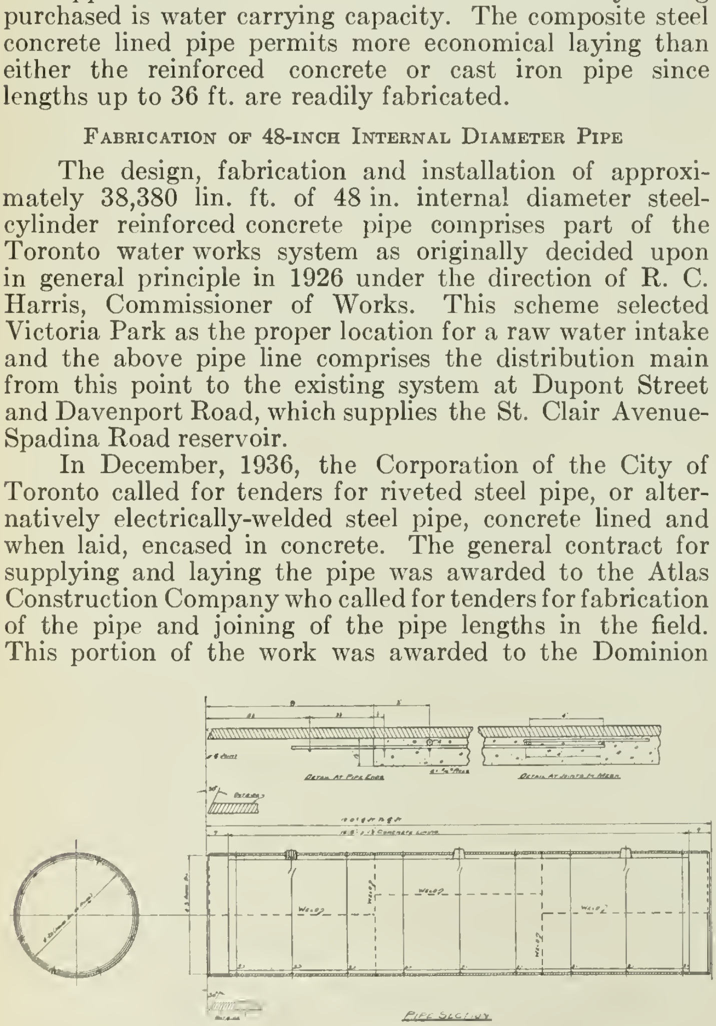

Fig. 2—An 18 ft. Pipe Length Illustrative of the Design.

In manufacture and installation three general types of pipe are recognized: standards, specials and bends. Standards are made in 12, 18 and 30 ft. lengths. The 12 and 18 ft. lengths for the tunnels and shafts are made of 9/16 in. plate, six feet wide, thereby requiring one and two circumferential joints, respectively. The 30 ft. lengths for open trench work comprise the majority of the pipe lengths and are made of ½ in. plate, 6 ft. wide, thus requiring four circumferential joints. Specials comprise closing sections, tees, straight sections jointed at an angle, reducing sections, etc.

All standard pipe lengths are automatically metallic arc welded. Straight pipe sections are centrifugally concrete lined whilst all others and the field joints are lined with gunite.

Training and Qualifying Welding Operators

Upon the decision to electric arc weld the field joints it was fully appreciated that competent welding operators would not be available and that training would be necessary. It was therefore decided to form a welding school to specifically train men for hand welding the specials, bends and field joints.

The company advertised first for experienced welders and received many applications, none of which were considered acceptable without further training in vertical welding. Many could not pass the necessary test on the flat. In answer to the advertisement that a welding school was to be started some 400 applications were received and from these 25 men were selected.

Each man was accepted on the understanding that he would serve a probational period of about two weeks, for the purpose of ascertaining his adaptability to and interest in welding. This avoided undue waste of the individual's time and unremunerative outlay of equipment and time by the company.

The proper training of welders usually presents many difficulties on account of the varied classes of work to be done but in this case the ultimate aim was that the student or "improver" should be capable of passing specific tests in accordance with the A.S.M.E. Welding Code for Unfired Pressure Vessels, paragraph U-69. In order to fulfil the specifications of the Code the "improver" was required to undergo a practical shop training period, approximately 400 hours, covering general welding as set forth in the Dominion Bridge Company Welding Manual. Upon the completion of these lessons, instruction was concentrated on the welding of ½ in. plate in the flat and vertical positions.

Instruction

Instruction consisted of twenty-five lessons. The first nineteen lessons were on bare wire welding and the remainder on covered electrode welding. It is advisable to start with bare wire welding because a higher degree of skill is required in its manipulation than with covered wire and the fundamentals of good fusion, penetration, arc length, etc., are more readily emphasized. A number of suitable lectures on welding hazards, the theory of welding, and the care and operation of welding machines were also included in the course.

The "improvers" were divided into two classes, each being continually supervised by a practical instructor who in turn was responsible to the engineer in charge of welding. The work week was forty-two hours and to assist the individual financially he was paid a small hourly rate for the training period. Towards the end of the training period the "improver" was given a certain amount of simple welding, such as tacking, and was paid the wage that such work commanded.

The qualifying of welders and poor quality welding in production work are naturally costly operations. To ensure satisfactory welding, each welder was thorughly instructed in the so-called "trifling defects" which result in failure of the test plate and increase the cost of testing. In production they result in inferior work. As illustrative of the factors which contribute to inferior welding, consider the causes of failure of a test plate made to fulfil the A.S.M.E. Code requirements, paragraph U-69.

Failure in most cases is due to porosity or poor fusion, causing rejection of the nick-break and free-bend specimens. These defects are usually attributable to one of the following:—

(*a*) Nervousness of the welder.
(*b*) Improper current and arc voltage.
(*c*) Improper rate of travel.
(*d*) Joint design.

(*a*) Although the welder must realize the difficulties in making a weld conforming to Code requirements this realization sometimes causes the welder to experience something like "stage fright" from trying too hard. This condition is best overcome by welding sufficient preliminary test plates to give him confidence.

(*b*) For a given size of electrode a wide current range is recommended by the manufacturer but for best results on a given plate thickness the range of adjustment is fairly narrow. Too high a current produces undercutting at the surface of each layer and if not chipped out, slag inclusions will result when the next layer is deposited. It also causes excessive boiling of the deposited metal and the formation of gas pockets. Too low a current results in poor fusion, entrapped slag and gas pockets, and is the most frequent cause of failure. Too long an arc or a high arc voltage also causes undercutting and too short an arc will cause porosity.

All noticeable gas pockets and slag inclusions in any deposited layer must be removed as they will cause defects in subsequent layers. The arc craters must be clean, shallow and free from porosity.

(*c*) The rate of travel of the electrode if too slow will give a heavy deposit of metal which tends to porosity due to entrapment of the gas by rapid solidification. Subsequent layers will not completely re-crystallize and alternate coarse and fine structures will result. Deposited layers should not be over one-eighth inch in thickness.

(*d*) The joint design must be such that all points of fusion are nearly equi-distant from the electrode tip so as to remove an equal amount of heat to give uniform fusion. The electrode size selected must be suitable for the type of groove.

The above mentioned factors which affect weld quality and joint efficiency must be thoroughly understood by the welding supervisor and frequently impressed upon the welder.

From the class twenty-two men were qualified, in accordance with the Code, in the flat position and ten of these in the vertical position. In no case was there a failure of an individual test in the flat position and no complete failure in the vertical position.

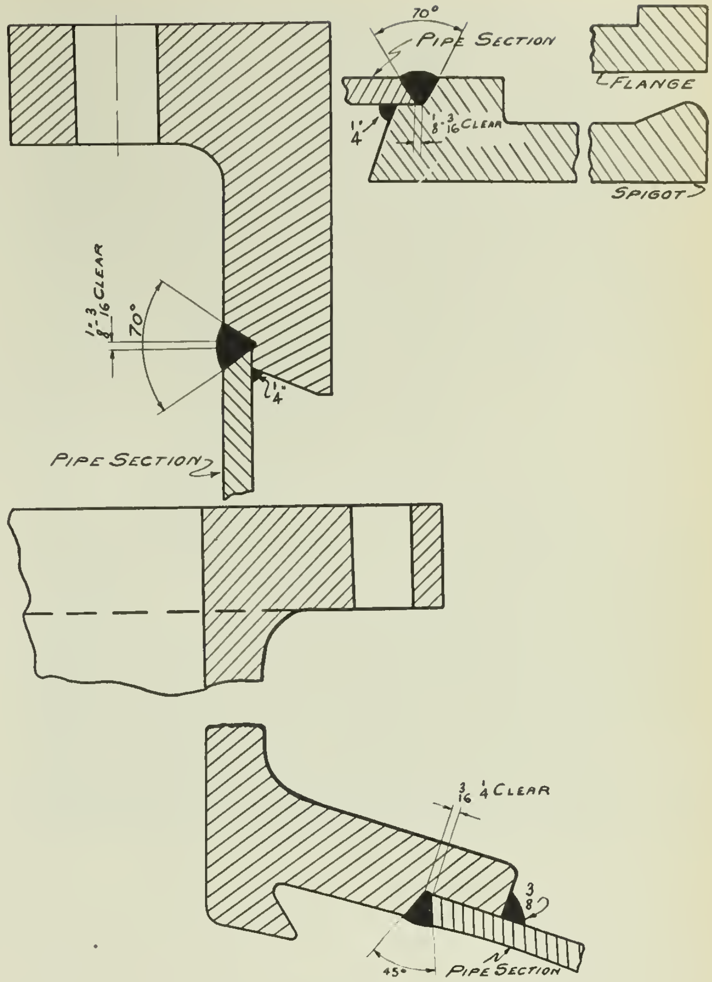

Fig. 3—Joint Details for Fittings.

With the careful selection of the welding personnel, thorough training and qualified supervision at all times, the "human factor" element was reduced to a minimum.

At no time should a welder be employed merely upon his claim of years of experience in arc welding. While the welder's claim may be quite correct for one class of work he might be unable to perform the work required. Each man should be given a suitable preliminary test to ascertain his ability to weld on the flat and in the vertical position.

Fabrication of Steel Shell

Material

Steel plate

Steel plates ½ in. and 9/16 in. in thickness were purchased to specification A.S.T.M. A78-33, grade B, covering plates of structural quality for forge welding, except that a tensile strength of 55,000 lb. per sq. in. minimum was required. The average chemical composition was—carbon 0.20 per cent, manganese 0.43 per cent, phosphorus 0.014 per cent, sulphur 0.043 per cent. Physical properties averaged 36,690 lb. per sq. in. yield point, 60,750 lb. per sq. in. tensile strength, 29.0 per cent elongation in 8 in.

Wire Mesh Reinforcing

A galvanized and welded wire mesh 4 by 4 in. square, 10 gauge was purchased in sheets 82 in. long by 13 ft. 10 in. to C.E.S.A. Specification A-9-C, 1923, for cold drawn wire for concrete reinforcement.

Spacing Wire

Steel wire, 5/16 in. dia., was used for spacing the wire mesh away from the shell of the pipe. The wire was purchased in coils, rolled to the required diameter and cut to length.

Piezometers and Pitot Tube Nozzles

Round bar material for the piezometers and pitot tube nozzles was of chrome-nickel-iron containing 18 per cent chromium, 8 per cent nickel, 0.15 per cent carbon, 0.50 per cent of manganese and 3.0 per cent molybdenum.

Bolts and Nuts

The eye bolts for the 36 in. dia. pressure manhole covers, the bolts and eye bolts for the ladders and gratings were chrome-nickel-iron containing 18.0 per cent chromium, 2.0 per cent nickel, 0.10 per cent carbon and 0.50 per cent manganese. All other bolts and nuts conform to A.S.T.M. Specification A-50-33 for Quenched Carbon Steel Track Bolts. The minimum physical requirements were 70,000 lb. per sq. in. yield point, 100,000 lb. per sq. in. tensile strength and 12 per cent in 2 in. elongation.

Steel Castings

Steel castings conform to A.S.T.M. Specification A27-24, Class B, Medium Grade. The minimum physical requirements were 31,500 lb. per sq. in. yield point, 70,000 lb. per sq. in. tensile strength, 20 per cent elongation in 2 in. and 30 per cent reduction of area.

Design

The steel cylinder, 51 in. internal dia. is designed and fabricated to withstand all stresses due to internal pressure whilst the concrete lining with wire mesh reinforcing provides permanent protection and maintenance of high water carrying capacity. Figure 2 shows an 18 ft. pipe length which is illustrative of the design.

The pipe lengths in the open trench are fabricated of ½ in. steel plate which at 195 lb. per sq. in. test pressure produce a unit stress of 10,000 lb. per sq. in.

The pipe lengths for the tunnel and shaft sections, specials and bends are fabricated of 9/16 in. steel plate which at 255 lb. per sq. in. test pressure produce a unit stress of 12,500 lb. per sq. in.

Air valve connections, drain nozzles, the ends of the steel pipe and pipe specials requiring connections by Victaulic couplings, manholes and flanges are of cast steel and designed for butt welding to the steel shell as illustrated in Fig. 3.

The use of steel plate insures convenience and adaptability in meeting almost any condition of construction required in the field. Therefore, all bends, both horizontal and vertical, are of the welded segmental type, and fabricated in the shop for all angles over one degree. They are made symmetrical, with each deflection an even degree, to simplify manufacture; that is, a 90 deg. bend would be made up of deflections as follows:—8 at 5 deg., 1 at 4 deg., 1 at 2 deg., 1 at 4 deg., and 8 at 5 deg.

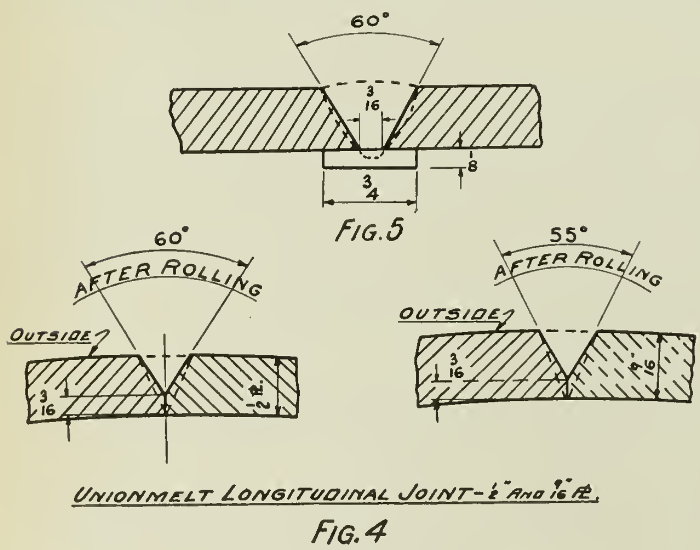

Fig. 5—Joint Design.

Joints

The edges of plates ½ in. and 9/16 in. in thickness, which are to be automatically welded by the Unionmelt Process, are bevelled to form a 60 and 55 deg. vee respectively with a 3/16 in. lip as illustrated in Fig. 4.

The plate edges forming the field joints of all horizontal pipe are fully bevelled, inside for the lower half and outside for the upper half of the circumference, at an angle of 30 deg. Figures 2 and 5 show the joint design.

The pipe lengths for the shafts require that the field joint be fully welded from the inside. One end of each pipe length is 90 deg. to the vertical axis whilst the opposite end is fully bevelled to an angle of 45 deg. with the vertical axis. Two pipe lengths are assembled to form a joint as illustrated in Fig. 6.

All specials and bends are made up of segmental sections, manually metallic arc welded. The edges of the adjoining sections are fully bevelled to form a 60 deg. vee, as shown in Fig. 7, for both circumferential and horizontal joints.

Plate Edge Preparation

The edges of the plate are prepared for automatic or hand welding by planing and by machine gas cutting. The plate as received from the mill is squared from one long side and end, then marked to length. The sides of the plate are next prepared by two Niles Bement Pond plate planers. The plate is not planed to a given width since closing pieces are used in the pipe line wherever required.

After the sides are prepared the plate is set up to stops on a table and one end cut and bevelled in the same operation using a special gas cutting machine (Fig. 8). The plate is then turned around, cut to length and bevelled, also, in one operation.

The machine is essentially a standard cutting machine with plate edge bevelling attachments which permit a uniform bevel cut since the guide wheel follows the contour of the plate. The commercial success of simultaneous cutting and bevelling depends primarily on the condition of the slag formed and its ease of removal. The control of the slag is governed by the velocity of the cutting oxygen stream and the bevel cutting reaction temperature. The smoothness of the gas cut edge is influenced by the preheat flames of both blowpipe nozzles.

The edges of the plate are next ground by an electric hand grinding wheel for a distance of about one inch from the edge for the purpose of removing mill scale which would contaminate the weld metal.

Rolling

The plates are rolled on a ten foot Bertsch Roll, equipped with a hydraulic drop housing which permits quick removal of the rolled plate. As the plate must be formed accurately, no flat spots at the joint being permitted, the first operation is to break one plate edge for a distance of six to seven inches by entering the plate at the rear of the rolls. The plate is then removed by reversing the rolls, the formed edge entered from the front of the machine and the plate rolled to the required diameter in two or three passes. This gives a true circular pipe.

Assembly for Longitudinal Welding

The plate edges of a six foot can section are placed in alignment and tacked together at 12 to 18 in. intervals. At either end of the section a steel tab, 8 in. wide by 4 in. long by the thickness of the shell and curved to its radius, is solidly welded for the starting and finishing of the electrode and to prevent the weld from cracking longitudinally at the finish.

Figure 9 shows the clamps for lining up the plate edges and taking out any twist due to rolling. The plate edges are made flush on the underside by jacking the edges into position and tacking on the groove side. The assembled can section is now ready for automatic welding.

Trueing

The operations of trueing and assembly for circumferential welding which follow the longitudinal welding are now considered in order to maintain continuity in describing the automatic welding process.

The longitudinal welding tends to peak the can section along the welded joint. In order to obtain proper joints for circumferential welding it is necessary to make the can section truely circular by passing the welded seam between top and bottom dies radiused to the outside and inside diameters, respectively, of the pipe.

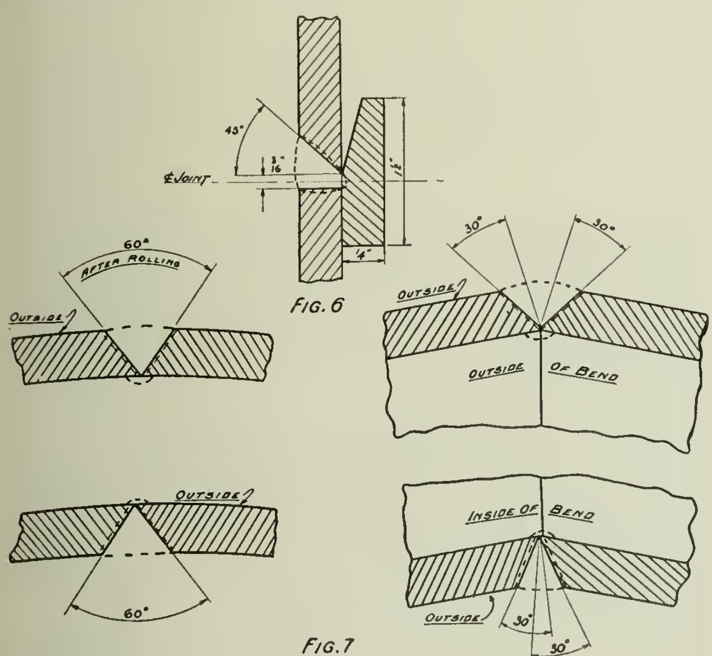
Assembly for Circumferential Welding.

The six-foot can sections are assembled end to end on a roller bed to form 12, 18 and 30 ft. pipe lengths as required.

Assembly rings are placed in one section of the pipe, the next section of pipe is slipped over the ring with the longitudinal seam offset six inches from that of the previous section. The next ring is similarly placed on and the longitudinal weld placed in line with the first pipe section. When the required number of sections are placed together they are drawn tight by means of clamps and the joints tack welded at intervals of about 18 in. The pipe is now ready for the circumferential welder.

Automatic Welding

Before describing in detail the automatic process used in welding the steel pipe shell, it will be instructive to consider automatic welding generally.



Horizontal Joint **Circumferential Joint**

Fig. 6—Two Pipe Lengths forming Joint.

Automatic welding is of great value in fabrication when the work involves large numbers of similar articles. It has the advantage of showing a saving in time and labour charges in conjunction with a greater degree of reliability in the finished product.

To obtain the full advantage of automatic welding it is essential that the following operations be properly balanced.

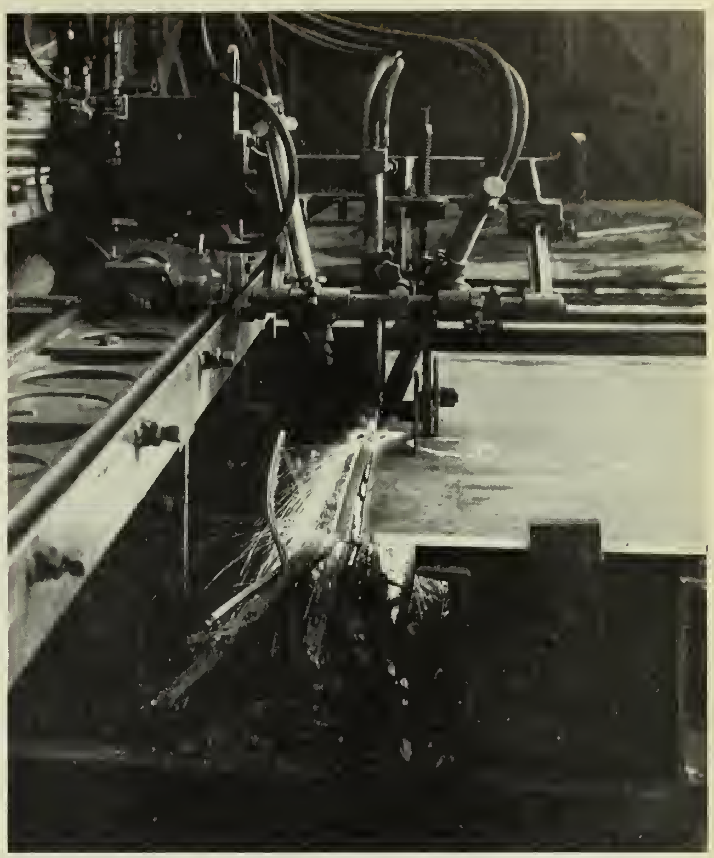


Fig. 8—Special Gas Cutting Machine which Cuts and Bevels at the Same Time.

(1) That care in preparation be no more than that necessary for hand welding.
(2) That the loading and unloading of the machine be in proportion to the welding time which necessitates that the former be less than the latter.
(3) That the output of the welding machine is not in excess of the capacity of the equipment following, so that the machine is not idle part of the time.

In hand welding with an experienced welder the arc length is controlled by eye and ear, and skill is required in the control and movement of the electrode. These factors, therefore, are not the same from day to day and the quality of work cannot be consistently uniform.

Automatic welding enables the maintenance of constant arc conditions and uniform speed. Thermal conditions are therefore constant with the result that uniform penetration, appearance and quality of weld are obtained. Higher welding speeds are obtainable as the current input to the electrode is only a few inches from the point of consumption which enables the current to be three to four times as great, for a given size of electrode, as used in hand welding. Also there is no loss of time due to changing electrodes and practically no wire wastage as compared to approximately 15 per cent from stub ends of hand welding wire.

From the foregoing one would consider that automatic welding was the solution to the welding engineers' problems and wonder why automatic welding has not been used more extensively. Unfortunately, it is beyond the scope of this paper to discuss the various types of automatic equipment developed to date, but two of the chief difficulties have been their complicated mechanical and electrical designs and the feeding of covered electrode. This latter requirement has been the major cause of complicated design as the units for feeding bare wire are now quite simple. Un-

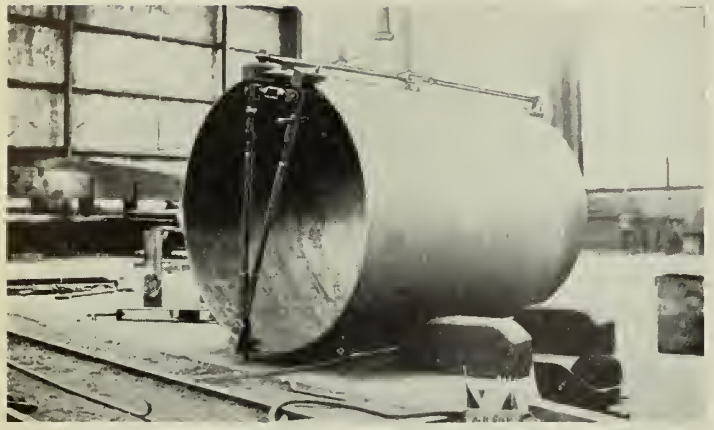

Fig. 9—Clamps for Lining up Plate Edges.

fortunately, the metallurgical and physical properties of bare wire weld metal, as is well known, are no longer satisfactory for the majority of applications.

Another means of providing protection to the metal being deposited is to cover the seam to be welded with finely divided flux material and to feed by conventional means a bare wire electrode, striking the arc under the powdered flux. Although this method has been known for several years it has not, until recently, met with much success owing to the variable porosity resulting from the type of flux and comparatively low currents used.

Realizing that the principle of such a method would be of great economic importance if welded joints conforming to the A.S.M.E. Code for power boilers and unfired pressure vessels could be made, the Union Carbide and Carbon Corporation investigated the method and over a development period of four to five years succeeded in meeting Code requirements and in welding greater plate thicknesses in a single pass than formerly, viz. above ½ in. This process will hereinafter be referred to as the Unionmelt Process.

The Unionmelt Process is undoubtedly the most unique and fundamentally sound automatic welding process evolved to date. It provides a process by which plates up to and including two inches can be welded in a single pass at speeds greater than any other automatic process. Plates over two inches are welded in a plurality of passes. The welds thus produced are equal in density and physical properties to the parent material. The process also eliminates arc blow and avoids the necessity for flux covering the electrode.

The above results are accomplished by the use of high currents and a flux or welding composition which forms a high resistance melt providing heating means, controlling the welding speed, the penetration, the quality of weld and protecting the molten metal.

The properties of a welding composition capable of producing quality welds must fulfil the following requirements:

(*a*) Complete the chemical reactions between the components of the melt, otherwise porosity will result.
(*b*) Must be capable of controlling the penetration and width of weld.
(*c*) Fluidity at welding temperatures must be such that it will not be entrapped in the molten metal.
(*d*) Chemical elements must not be detrimental to the weld metal.
(*e*) Resulting slag must be readily removable from the finished weld.

The above requirements are fully embodied in the Unionmelt welding composition. A process so different to other automatic processes naturally requires innovations in the design of equipment, joints and operating technique.

Equipment and Materials

Welding Head

The source of welding current may be either direct current or alternating current. The former is used by Dominion Bridge Company Limited and is supplied by two standard 600 ampere Lincoln welding machines connected in parallel.

The welding head is designed to feed the electrode automatically, and to conduct current to the "bare" wire electrode. The welding head and flux hopper are mounted on a travelling carriage.

Welding Flux

The flux, which at all times covers and surrounds the electrode, is fed down through a tube from the hopper. The amount fed is regulated by a small adjustable valve at the end of the tube and distributed to an even height and width during welding. Immediately behind the completed weld a suction tube picks up the unused flux and returns it to the top of the hopper in which a screen is inserted for the removal of partially fused particles. Ahead of the completed weld and running in the joint are two guide rollers which keep the electrode in the proper relative location to the seam being welded. These rollers operate integrally with the welding head.

Electrode

The electrode is a "bare" metal electrode, ¼ in. in dia., with a copper finish for protection from rusting. The chemical composition is carbon 0.12 per cent, manganese 0.97 per cent, silicon 0.30 per cent, sulphur 0.0266 per cent. The electrode is furnished in coils of 150-170 lb.

Fixture for Longitudinal Seam

The welding fixture for the longitudinal seam comprises a welding head and flux hopper suitably mounted on a track over an air operated clamping fixture designed to accommodate a six foot pipe section (Fig. 10).

The joint to be welded is backed up by a water-cooled copper backing bar which is attached by means of an arm to the travelling welding head and centred directly under the electrode.

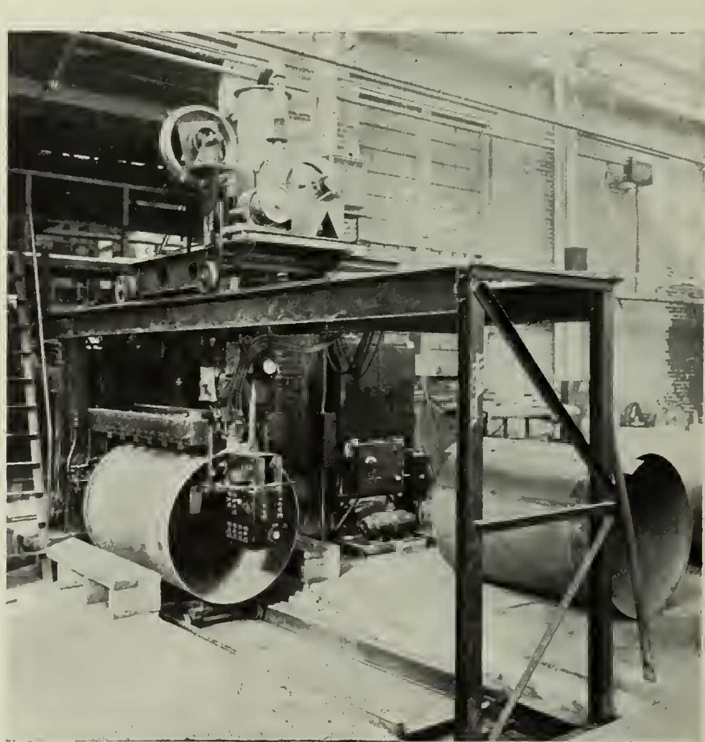

Fig. 10—Welding Fixture for Longitudinal Seam.

In the welding of the longitudinal seam the pipe section remains stationary and the welding mechanism automatically traverses at a predetermined speed along the seam.

Welding Fixture for Circumferential Seams

The fixture for welding the circumferential seams accommodates a 30 ft. pipe length and comprises a rotating mechanism over which is mounted a steel framework carrying the welding head and flux hopper (Fig. 11). In this welding operation the head, having been previously set in the proper position over the seam to be welded, remains stationary, whilst the pipe revolves at the predetermined welding speed. When the electrode feed is started, power is simultaneously applied to the rotating mechanism and the pipe revolves.

Welding Technique

It is essential that the plate edges, prepared as shown in Fig. 4, be tight throughout their entire length and flush on the underside, this being obtained as described under Assembly for Longitudinal Welding.

The flux composition when cold is non-conductive and to provide a conductive path for the current the gap between the electrode and the work is bridged by a ball of steel wool about ½ in. in dia. Flux is then fed around the electrode and the power applied. The flux is locally heated until it fuses and becomes conductive, forming a subsurface pool and immediately thereafter the end of the electrode fuses and the molten metal begins to deposit in the groove, displacing the subsurface pool of fused flux. At the same time the plate edges fuse and coalesce with the metal deposited as the electrode continues to feed under a protective layer of flux. About one minute after completion of the weld the fused slag covering lifts away from the weld exposing a clean and uniform surface.

The weld quality is influenced by the voltage difference between the electrode and the work, by the current, the size of electrode, the rate of feeding the electrode and the speed of travel along the seam. Keeping the welding speed constant, the arc voltage and current vary with the plate thickness, each being a function thereof. The proper welding current for a given plate thickness is a function of the diameter of the electrode, the degree of penetration, rate of deposition of metal, welding speed and the composition of the flux.

Welding conditions for ½ in. and $\frac{9}{16}$ in. plate are as follows:—

Plate Thickness—inches	Current Amperes	Arc Voltage	Speed in. per min.
½	900	32	14
$\frac{9}{16}$	920	32	13
	900	32	12

These conditions in conjunction with the proper design of backing-up bar produce full penetration with a slight reinforcement on the underside. If at any point in the weld length penetration is lacking the unfused portion is chipped out and rewelded by hand.

With sufficient welding generator capacity the welding currents and speeds may be increased to 1,075 to 1,175 amperes and 20 to 23 in. per min. for ½ in. plate, and 1,150 to 1,200 amperes and 16 to 19 in. per min. for $\frac{9}{16}$ in. plate without affecting weld quality.

Metallurgical Examination of Unionmelt Welded Joint

The chemical and physical properties of the plate material conforming to A.S.T.M. Specification A78-33, the weld metal and the welded joint are as follows:—

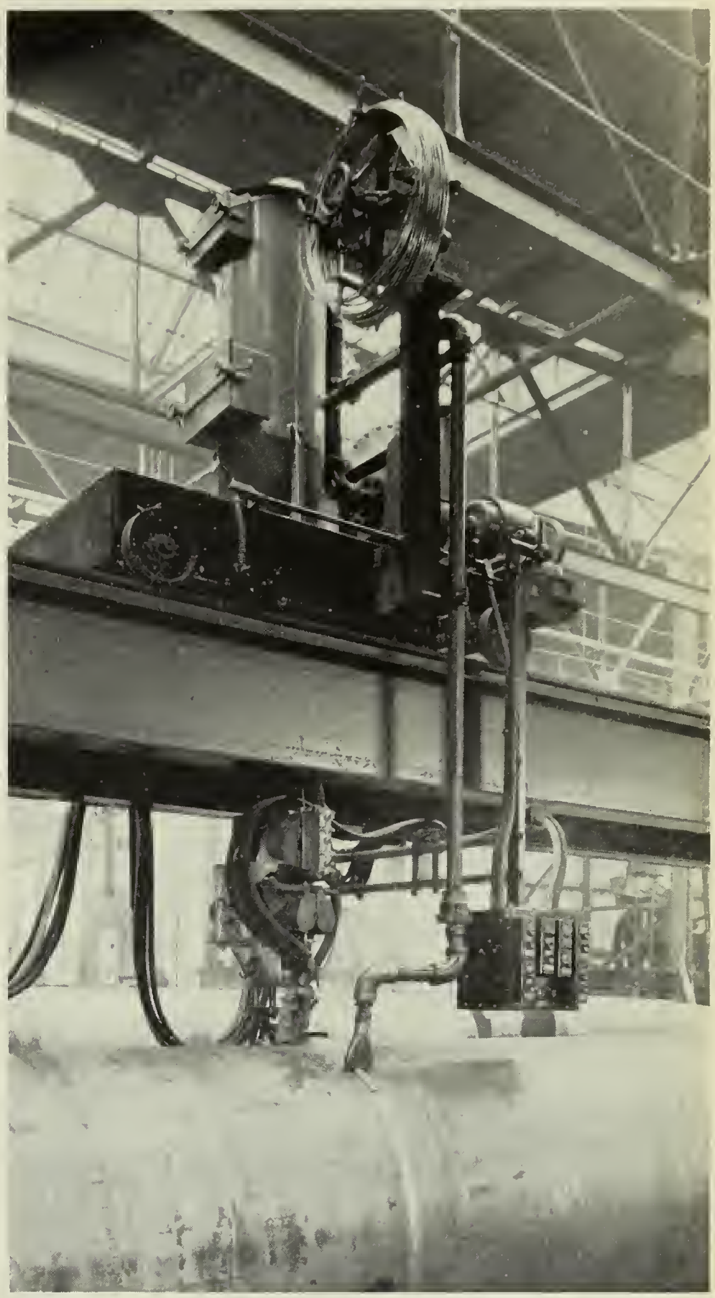

Fig. 11—Welding Fixture for Circumferential Seams.

One-half inch Welded Plate

Plate Material

Chemical Composition		Physical Properties	
Carbon	0.18%	Yield point	37,140 lb. per sq. in.
Manganese	0.44%	Ultimate strength	60,920 lb. per sq. in.
Phosphorus	0.016%	Per cent elong. in 8 in.	29.0
Sulphur	0.04%		

Weld Metal

Chemical Composition		Physical Properties—as welded	
Carbon	0.15%	Yield point	42,600 lb. per sq. in.
Manganese	0.37%	Ultimate strength	70,600 lb. per sq. in.
Silicon	0.14%	Per cent elong. in 1½ in.	22.0
Sulphur	0.033%	Per cent reduction of area	29.4
		Impact — Charpy	
		Transverse	29 and 33 ft. lb.
		Longitudinal	17 and 22 ft. lb.

Welded Joint

The following physical tests, non stress-relieved, in accordance with paragraph U-69 A.S.M.E. Code requirements are representative of those made during progress of fabrication:—

Reduced Tensile

No.	Ultimate Strength lb. per sq. in.	Remarks
1	62,389	Fracture in plate 1¼ in. from weld
2	60,824	" " " 1¼ " " "
3	59,452	" " " 1⅜ " " "
4	59,685	" " " 1¼ " " "

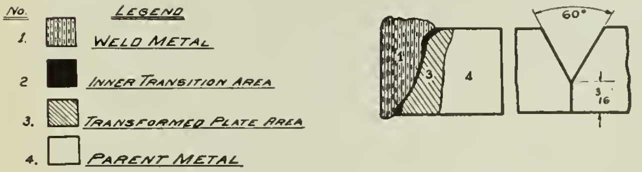

Fig. 12—Transformation Zones on $\frac{9}{16}$ in. Pipe.

Free Bend

No.	Per cent elongation of outside fibres	Remarks
1	60.5	No failure, no fracture, 180 deg. bend
2	62.5	No failure, no fracture, 180 deg. bend
3	51.2	No failure, no fracture
4	43.9	No failure, no fracture

$\frac{9}{16}$ in. Welded Plate

Plate Material

Chemical composition – Per cent		Physical properties
Carbon	0.20	Yield point—39,220 lb. per sq. in.
Manganese	0.54	Ultimate strength—63,150 lb. per sq. in.
Phosphorus	0.03	Per cent elongation in 8 in.—27.5
Sulphur	0.04	
Silicon	0.02	

Weld Metal

Chemical composition—Per cent		Physical properties—as welded
Carbon	0.17	Yield point—62,000 lb. per sq. in.
Manganese	0.70	Ultimate strength—78,000 lb. per sq. in.
Silicon	0.34	Per cent elongation in 2 in.—21.0

Welded Joint

Forward bend	48.5 per cent elongation of the outside fibres, no failure, no fracture, no porosity.
Back bend	180 deg. without evidence of fracture, porosity, or slag inclusion.
Nick break	Uniform crystalline structure—no slag—no porosity.
Exograph	The exographs show no porosity, no slag and no lack of fusion.

Hardness

Seleroscope hardness readings taken across the welded joint indicate only 1 to 2.5 points of hardness increase in the weld above that of the plate.

Microstructure of Welded Joint in $\frac{9}{16}$ in. Plate

The Unionmelt weld being a single pass weld for plate thicknesses up to and including two inches has certain distinguishing characteristics.

Microscopic examination of a cross-section of the welds of different plate thicknesses shows that the planes defining the zone of fusion at the sides of the weld and the zone boundary of the transformed plate are approximately parallel. The microstructure of these zones throughout the cross-sectional area are very uniform, indicating that the heat conditions from the top to the bottom of the weld do not differ greatly. Such a condition materially decreases the unequal stresses and lessens the distortion of the plate.

The following microstructures are typical of welds made by the Unionmelt Process on $\frac{9}{16}$ in. and ½ in. plate.

Figure 12 shows diagrammatically, to twice full size, the extent of the transformation zones on $\frac{9}{16}$ in. plate.

Figure 13 shows the microstructure at a magnification of 100 times of the weld metal. It is a fine cast structure composed of pearlite and ferrite uniformly distributed.

Figure 14 represents the microstructure at a magnification of 100 times of the transition zone adjacent to the weld metal.

Figure 15 represents the microstructure at a magnification of 100 times of the transition zone adjacent to the plate. The structure has been refined at a temperature of 1,500 deg.-1,550 deg. F. within the thermocritical range.

Figure 16 shows the microstructure at a magnification of 100 times of the parent plate. The structure is typical of low carbon plate comprising ferrite and pearlite (dark).

Pipe Testing

The welded pipe length from the circumferential welding machine is inspected for visible defects inside and out, and the necessary repairs made. Small outlets, if required, are then welded in and the pipe made ready for the insertion of gaskets at either end for the hydraulic test.

The pipe is rolled into the press and the moveable head set up to with $\frac{1}{16}$ in. of the pipe. The low pressure filling pump is started and the air release valve opened permitting the air to be displaced by the filling water. When the pipe is full of water as shown by the escape of water from the air valve, the filler pump is stopped, the valve closed and the triplex pressure pump started. The pump is set to by-pass

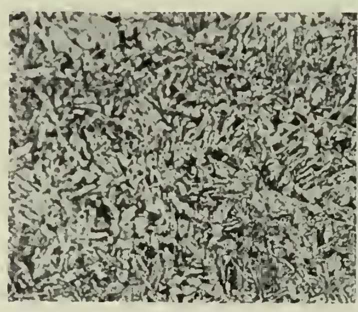

Fig. 13

Fig. 14

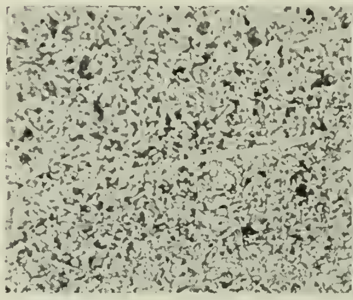

Fig. 15

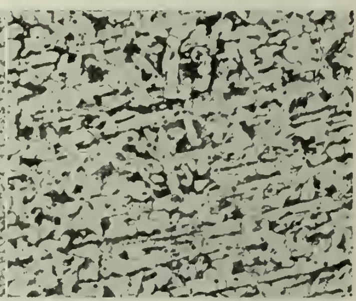

Fig. 16

Figs. 13, 14, 15 and 16—Microstructure of Weld Metal Transition Zone and Parent Plate.

at the test pressure so that it can operate whilst the pipe under test is inspected for leaks. Pipes having a ½ in. wall thickness are tested at 195 lb. per sq. in. pressure and those having a $\frac{9}{16}$ in. wall thickness at 225 lb. per sq. in.

The hydrostatic testing of the specials and bends presented a problem as regards evolving a quick and economical method. This was satisfactorily solved by clamping a wide band onto either end of the special or bend. The band is notched out at eight points equally spaced around the circumference and sixteen one and one quarter inch bolts welded to the band for attachment of a two-inch steel plate head with gasket. The clamp is firmly held by tabs welded onto the steel shell into which the notches fit. Upon completion of the test the head and clamp are unbolted and lifted off. The tabs are left on the pipe.

Placing of Wire Mesh for Concrete

The sheets of wire mesh are rolled to a diameter of 49⅞ in. and the $\frac{5}{16}$ in. dia. spacing wire rolled to 50⅛ in. dia. The wire hoop spacers, starting one foot from each end, are tack welded at intervals of two feet leaving about 1/10 in. gap between the spacer and the shell. The wire mesh is placed on top of the spacers to within 9 in. from either end of the pipe. The mesh is fastened to the spacers by means of spring steel clips.

Centrifugal Placing of Concrete Lining

The outstanding properties of centrifugally spun concrete are its smooth finish, high compressive strength, and high density which give excellent resistance to wear and erosion. It has been shown that wear is inversely proportional to the strength of the concrete; the wear for 6,000 lb. concrete being one half of that for 3,000 lb., one third that for 2,000 lb., and one fifth that for 1,200 lb. concrete.

Apart from the compacting by centrifugal force, the factors which produce concrete of high strength are:—

1—High cement content.
2—Minimum quantity of mixing water.
3—Correct grading of aggregate.
4—Proper curing of the concrete.
5—Control of mixing time.
6—Age: the older the concrete, the greater its strength.

Details of the equipment and the procedure followed in centrifugally placing a 1½ in. concrete lining in the steel pipe follow:—

Equipment

(a) *Retainer Rings*

The retainer rings determine the thickness of lining and are placed nine inches from each end of the pipe.

(b) *Spinning Cage*

The spinning cage is a reinforced steel shell made in two halves which are clamped around the pipe and bolted together. Steel tires are then placed at either end and the whole unit placed on the spinning machine.

(c) *Spinning Equipment*

The spinner is a four trunnion machine driven by a direct current motor with rheostat control for obtaining any required speed.

The concrete loading is accomplished by means of a filling trough travelling on a track and operated for dumping by an electric motor.

Figure 17 shows the concrete mixing, loading and spinning equipment.

Materials

Cement

Portland cement was purchased to Canadian Engineering Standards Association Specification A5-1927.

Stone

Stone was obtained to fulfil the following specification:

The crushed stone shall be clean and free from shale, slate or other soft friable material.

The crushed stone shall range in size from fine to coarse within the following limits:—

Size	Percentage retained
⅜	3.0
4	40.5
8	93.5
14	97.0
28	99.5
48	100.0
100	100.0
	F.M. 5.38

The fineness modulus shall be kept within the range 5.2 to 6.0 in. In other respects the material shall conform to the C.E.S.A. A23-1929 Specification.

Sand

Sand was purchased to the following specifications:—

The sand shall consist of clean, uncoated grains of strong durable minerals.

The sand shall be free from organic matter especially tannic acid and shall not contain soft friable laminated particles totalling more than 2.5 per cent or fines passing a 100 mesh sieve in excess of 3.0 per cent.

Fig. 17—Concrete Mixing, Loading and Spinning Equipment.

The sand shall range in size, closely to the following screen analysis:

Sieve No.	Percentage retained
⅜	....
4	1.00
8	9.00
14	28.00
28	70.00
48	93.00
100	99.00
	F.M. 3.0

The fineness modulus of the sand may vary from 2.8 to 3.2. In other respects the material must conform to the C.E.S.A. Specification A23-1929 for fine aggregate.

Concrete Mix

The concrete mix consisted of 1 part of Portland cement, 1.93 of sand and 1.36 of stone, measured by volume, loose and uncompacted. The amount of water per bag of cement is about 4.0 gal. per bag of cement being regulated to give approximately a 3.5 in. slump.

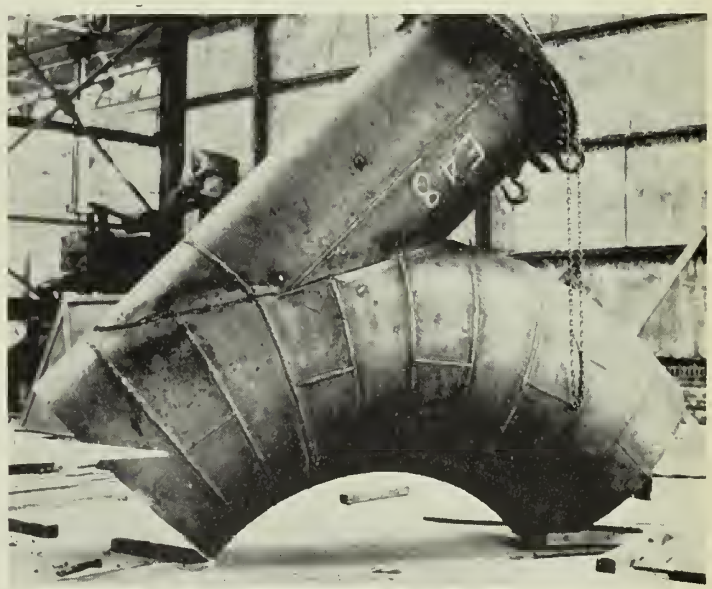

Fig. 18—A typical Bend.

The total mix for the pipe is made in two batches, the first being sufficient to completely cover the wire mesh and the second to give the proper thickness of lining. Each batch is mixed for a period of three minutes then discharged into the loading trough.

Representative tests of the concrete mix previous to spinning are shown in Table I. The centrifugal compacting was observed by spinning concrete cylinders 2 in. dia. by 4 in. high simultaneously with the pipe. The test results at the end of 28 days are as follows:

Date	Compression strength lb. per sq. in.
Oct. 7	6,462
8	6,541
13	6,334
27	6,048
28	7,735

Table I

Concrete Compression Tests

Mix for 1½ inch Centrifugally Spun Lining—1.0 Cement, 1.93 Sand, 136 Stone

Date	Serial No.	Lb. per sq. in.		Slump in.

" 28	403	3,650	4,740	3.00
Nov. 1	421	4,280	5,480	3.50

Spinning Lining

The spinning operation consists of rotating the pipe at a relatively low speed while introducing the concrete mix and then rotating the pipe at a relatively high speed to compact the lining and remove excess water. In general, the placing speed must be a little greater than that necessary to overcome gravity, and the length of time at this speed being sufficient to permit uniform distribution. The final spinning speed is high enough to throw out all excess water and of sufficient duration to give the concrete an initial set. For the 52 in. outside diameter pipe the filling speed is 800 ft. per min. and the final speed 2,400 ft. per min.

When the lining is placed in two stages it is necessary that the first stage be spun till initial set occurs and the spinning stopped for draining off the expelled water.

Curing

Upon completion of the lining the pipe is placed on the curing bed and the ends of the pipe covered. Six hours later moist steam is introduced, and the lining cured at a temperature ranging between 80-90 deg. for a period of six hours. Twelve hours later the lining is moistened by sprinkling with clean water after which the pipes are kept continuously moist for a period of ten days.

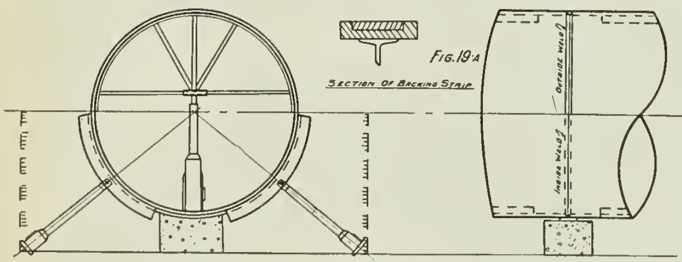

Fig. 19 and 19a—Backing Base for Field Welding.

Pipe Bends

The segments forming the bend are laid out to template on flat plate, cut to shape and bevelled by machine gas cutting. The segments are rolled to the proper diameter and assembled in units which are easily turned by hand. These units are welded and then assembled to form the completed piece which is turned by crane so that welding may be done in a downhand position. The ends of the pipe bend are held circular by welding struts two inches from either end. The bracing is left in until the bend is assembled in the field, then removed by gas cutting.

The design of the joint is shown in Fig. 7. The horizontal welds are first made, then the circumferential welds. A 5/32 in. dia. covered electrode is used for the first pass and a $\frac{3}{16}$ in. dia. covered electrode for the subsequent three passes. Each deposited layer of weld metal is thoroughly cleaned by a Pneumatic Weld-Flux Chipper and wire brushed. The back of the weld is chipped out and a single pass weld made with $\frac{3}{16}$ in. dia. electrode.

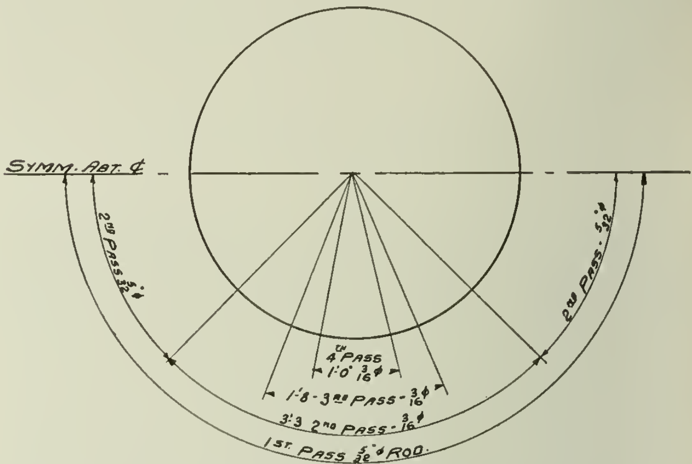

Fig. 20—Weld Metal Deposition Diagram for Circumferential Weld, Specials and Field Welding.

Nozzle outlets or branches are then welded in place and the bend subjected to a hydrostatic test pressure of 255 lb. per sq. in. A typical bend is illustrated in Fig. 18.

After testing, wire mesh reinforcing is placed inside of the bend to within four or five inches of the ends and then lined with gunite to within nine inches of the ends. The mix used is 1 part of cement to 3.26 parts of sand by volume. This gives in place a mix of approximately 1 to 2.75. The compressive strength at the end of 28 days is approximately 5,500 lb. per sq. in.

Hauling and Laying Pipe

After curing, and as required, the pipe is loaded on a truck equipped with cushioned bunks so as to minimize any shock occurring in transit, and hauled to the trench side. One pipe is carried at a time and upon delivery at the site the pipe is carefully unloaded from the truck by a caterpillar tractor crane. The unloading of the pipe at the site, the placing for jointing by welding, the encasing in concrete and backfilling was carried out by the general contractor.

The horizontal pipe lengths are placed on concrete blocks set to grade. At each field joint a steel plate 3 in. by $\frac{3}{16}$ in. by 14 in. formed to the contour of the pipe, is placed between the pipe and concrete block, central with the joint. The ends of the pipe are placed to within about $\frac{3}{16}$ of an in. and then jacked in or out as required to give a uniform gap of $\frac{3}{16}$ in. throughout the circumference. The joint is next backed up by inside and outside steel backing bars tightly jacked against the shell (Fig. 19). A steel strip three quarter inch by one eighth inch is inserted in the backing-up bars (Fig. 19A) and is welded to the joint, thus providing complete fusion throughout the entire plate thickness. The joint is welded on the outside of the top half and on the inside of the bottom half simultaneously using $\frac{5}{32}$ and $\frac{3}{16}$ in. dia. covered electrodes. The sequence of deposition of weld metal is shown in Fig. 20. Upon completion of the welds the backing bars are removed and the junctions of the inside and outside welds gouged out. The joint is rewelded to ensure good weld metal.

It is of interest to note that the field welding was satisfactorily carried out during the winter months by enclosing each joint with a canvas canopy, pre-heating the joint and allowing it to cool slowly after welding.

Welding current is supplied by 300 ampere gasoline driven welding units. The fumes from welding are exhausted by a fan electrically driven by power supplied from the welding unit. The fan is located a few inches from the joint being welded.

The welded joint is next prepared for concrete covering with gunite. As previously noted the concrete lining stops within nine inches of the end of the pipe (Fig. 2) thus leaving a width of eighteen inches to be covered. Wire mesh reinforcing is placed so as to overlap the edges of the reinforcing wire protruding from the lined section. Gunite is then applied. The gunite coating was applied by Gunite and Waterproofing Limited of Toronto.

The pipe line is next encased in concrete, the minimum thickness being four inches, and after setting the trench is backfilled. The pipe line is then subjected to a hydrostatic test between valves.

Acknowledgment

The writer wishes to acknowledge gratefully the valuable assistance of C. H. Timm, A.M.E.I.C., and Mr. G. J. Price, of the Dominion Bridge Company Limited, in the preparation of this paper.

Self Preservation in the Northern Wilds

Inspector C. E. Rivett-Carnac,
Royal Canadian Mounted Police.

Presented before the Aeronautical Section of the Ottawa Branch of The Engineering Institute of Canada, March 17th, 1938.

SUMMARY.—This paper outlines ingenious but practical methods of meeting the challenges of the northern wilds. It lists and describes supplies and equipment that are necessary, such as food, heat, utensils, tools, firing arms, nets (fish and mosquito), clothing, bedding, and tells what to do with frost bite, wet clothing, snow blindness—how to make a camp, catch fish and game—in short, how to live off the land in winter and summer, in storm or fair weather. It is a short text book on a subject of importance to many engineers, and of interest to all.

In that part of Canada lying between the northerly boundaries of the organized Provinces and the Arctic sea is a vast stretch of country known as the North West Territories, sparsely settled by Indians, Esquimaux, white trappers, fur traders, prospectors and mining men, missionaries, government employees and Mounted Police. The total population is around 10,000; the total area more than a million square miles; so it can readily be seen that it can truthfully be described as 'The Wilds.' It is a country of extremes; of forbidding cold and deep snow during the long winter months; of heat and maddening flies during the summer; of thick bush and barren wastes; of no roads except such as are afforded in summer by the waterways, or in winter by the snow. The only means of transportation are dog sleighs, boats or aeroplanes. It is proposed to deal in this paper with the problems that arise in this country, if one is cast on his own resources.

Perhaps the most important thing before setting out on a journey in the wilds is to obtain maps of the country to be traversed. Fairly accurate topographical maps can now be obtained. These should be carefully studied, especially as regards the water routes, settlements, radio stations and trappers' cabins. One can also nearly always get reliable information from men knowing the country. The best safeguard of all is to obtain the services of a local native Indian or Esquimau, in fact if one does this one's problems are practically solved. A long winter journey should never be attempted, especially in the farthest north, without a native guide, except perhaps by aeroplane.

Very careful consideration should be given to planning an emergency supply of food, clothing and equipment. Conditions across the whole of the northern parts of Canada are very different after passing the northern timber limit. Lakes are much more numerous within the timber belt and along the northern boundaries of the provinces than in the barren lands. There is a great difference in the texture of the barren lands snow, which is fine and drifted hard by the prevailing winds, as compared with the deep, soft snow of the timber country. Hunting and travelling in the timber country in the winter is practically impossible without snowshoes, while many Esquimaux further north have never even seen snowshoes. The hard drifted snow makes excellent material for constructing snow shelters. Even an inexperienced man may easily cut snow blocks and build a shelter, over which a tarpaulin may be placed and weighed down with snow blocks, which provides much more warmth and security than a tent against the Arctic winds.

Below is an outline of the emergency supplies which should be carried on any extended patrols in the Arctic, where food values and the conservation of weight and space mean so much.

Fig. 1—Pangnirtung Fiord, N.W.T.

Provisions

Pemmican

Pemmican is a preparation which contains no ingredients other than meat and tallow. The water content of the meat is removed by a drying process. The meat is then ground or pounded and mixed with rendered tallow. It provides a very high food value for its weight, will keep indefinitely and can be eaten without cooking in extremely cold weather. It is approximately 60 per cent meat, 40 per cent tallow, and sometimes contains raisins. The best substitute for pemmican is dried or pounded moose or caribou meat. This may be obtained at some of the northern trading posts or from northern natives.

Bacon

The high percentage of fat in bacon makes it a very useful northern food, as it is generally used in conjunction with the cooking and eating of bannock. Many northern men prefer their bacon raw on the trail. It is not unpalatable when frozen.

Corned Beef or other Canned Meats

If neither pemmican or dried meats are obtainable one would have to fall back on canned meats. Of these, 'bully beef' (in 12 oz. tins) is undoubtedly the best. Many canned meats have a large water content, which only adds to the weight and forms ice in the winter.

Concentrated Soups

Soup powders, such as pea flour, are light in weight and nourishing.

Evaporated Vegetables

Riced or flaked evaporated potatoes are perhaps the most important under this heading. Almost any vetegable can be obtained in evaporated form. Onions are put up in compressed blocks, which have the appearance of plug tobacco.

Biscuits, Flour, Bannock, Salt

Hardtack as used with bully beef for army 'iron rations' is recommended. Flour saves excessive bulk. Bannock is a food known all over the north, and can be made over open fires in the timber, or over a primus lamp in the barren lands.

Doughnuts

This form of food has been used with much success by winter sledging parties in the far north. They are not a very compact form of food, but if made with a generous proportion of milk powder and sugar, mixed with the flour, baking powder and shortening, they are a very nourishing ration. Doughnuts should be fried in deep fat, which helps to give them a good fat content, and makes it easy to thaw them so that they can be eaten in extremely cold weather.

Beans

Another very nourishing food, and one which is used as a staple ration throughout the north. Beans are boiled before starting and frozen separately on a board.

Chocolate

This has an excellent food value, and provides energy more quickly than any other food. As very sweet chocolate induces thirst, bitter-sweet or milk chocolate, in quarter pound sizes to facilitate rationing, should be used.

Rice and Raisins

These are both good foods. For its food value, rice takes up very little space, and requires considerable water to cook.

Beverages, Tea, Coffee, Milk

This is a matter of personal choice, but it should be remembered that cocoa is the most nourishing, and that tea will go much further than coffee. Spirituous liquors are not generally considered as emergency rations. In cases of extreme urgency, liquor may provide the necessary stimulant, but it is not recommended for a person who is undernourished or suffering from the cold.

Fig. 2—Esquimau Camp—Baffin Island, N.W.T.

Sugar

This is an essential part of any emergency ration.

Milk

Milk would best be carried in powder form, such as whole "Klim," and mixed with water as needed. It may also be mixed dry with granulated sugar and carried in this way ready to be put into hot beverages.

Tobacco

While this is not an indispensable item, it is a thing that depends upon the individual. Those who are accustomed to smoking would find it a great comfort—and to a certain extent it helps to tide the accustomed smoker over the bad times when one is inclined to worry. Fine cut tobacco and cigarette papers and plug tobacco will go further than cigarettes and cut tobacco.

Emergency Equipment

Tent

An A-shaped tent, with or without wall, 8 ft. by 10 ft. with 3 light poles will accommodate 3 or 4 men. On the barren lands, it may be pitched with rocks or by making loop-holes in the sea-ice to anchor it.

Primus Lamps

Primus lamps are used in the barren lands, where no fuel is available. These are pressure lamps (sometimes known as "Optimus" primus stoves). They are generally adapted to burn coal-oil, but gasoline may be used. A spare burner and cleaning needles should be carried, also a small quantity of solidified alcohol for starting.

Cooking Utensils

A frying pan for bacon and bannock, and some aluminum pots for hot beverages, meat and soups. This supply depends upon the size of the party.

Butcher Knife

A knife 10 or 12 in. in length, with a pointed blade, for general purposes, and for cutting loop-holes in the ice.

Sleeping Bags

Eiderdown sleeping robes are recommended.

Rifles and Ammunition

For hunting big game, a .303, or similar gauge rifle, with 200 rounds of ammunition, should be taken. For small game (including seal) two or three .22 repeating rifles (depending on the size of the party) should be included, with 2,000 rounds of ammunition (longs).

Fish Nets

One net (1½ in. mesh), 30 meshes deep and 25 to 30 ft. long, for small trout, grayling and other small fish found in freshwater lakes and rivers. One net (2½ in. mesh) 30 meshes deep and about 60 ft. long, for larger fish, such as white fish, salmon trout, and lake trout, found in lakes, rivers and salt water bays of the Arctic. Fish nets should be hung on backing twine and string arranged to tie on wood for floats, and small rocks for sinkers. A spare hank of No. 9 backing twine should also be taken.

Ice-tester

This is a useful tool. A six foot length of cold rolled steel, ½ in. in diameter, with a blunt point, it is very useful for testing the thickness of ice, or the texture of snow-drifts, for shelter blocks. It will be found very useful on many other occasions.

Fish-hooks and Lines

A small quantity of assorted common fish-hooks for bait fishing and a few swivel spoon baits with the necessary line might prove useful.

Hand-saw and Axe

A hand rip-saw is recommended for cutting snow-blocks for building a shelter.

Tarpaulin

A small tarpaulin, 8 ft. by 10 ft., can be used as a ground sheet, as a roof for a snow shelter, and for many other purposes.

Carborundum Stone

A small stone for sharpening knives and axes is indispensable.

Sleigh Material

Two common boards about 5 ft. in length and 7 or 8 in. wide, and about 1¼ in. thick, for runners. If designed to run *with the grain*, shoeing would not be essential. Quarter inch holes should be bored in the runners to lash on the cross-pieces (of cedar, which would save weight). These pieces should be approximately 2 ft. 6 in. in length, 4 in. wide, and one inch thick. About 6 or 7 pieces are required for this purpose. These might, if necessary, be utilized as floats for the fish nets, and the runners for other purposes, if it is found to be impracticable to build a sledge for any purpose. In many sections of the north it is not possible to find even a small stick of wood.

Mosquitoes

In many districts of the north, the mosquito pest and other types of annoying insects, such as sand flies, bull-dogs, etc., are a great drawback in the summer months, and would add greatly to the discomfort of a party in distress. A net large enough for each person to sleep under is recommended, as well as single veils to cover the head and neck. A light weight mosquito-proof tent would take the place of individual nets for sleeping. In the timbered area, camp fire smoke and certain lotions, most of which contain citronella, are used. In choosing a camp site in the summer, it is always advisable to select a place in the open where there are air currents. Generally speaking, sites along the coast line in the Arctic, particularly when a breeze is coming from the sea, will be free from mosquitoes.

Clothing

The following clothing is suggested for each member of a party journeying in the north. It should be remembered that proper clothing will go a long way towards preservation of life in the fall and winter, because without warm clothing, and particularly good warm foot-wear, one cannot travel or hunt or sleep comfortably.

Parka

A parka is a windproof pullover with headpiece (hood) attached. Under this is worn an inner parka made of Hudson's Bay duffle or blanket material, also with attached hood. This is the best combination for warmth in timber country.

Sweater

Under the parka wear a heavy, wool pullover.

Footwear

Good footwear is most important of all. For the timbered areas, take two pairs of Indian tanned moccasins and at least two pairs of snowshoes for any party. For the barren lands, wear shoe-packs, knee or three-quarter length, or three-quarter length gum rubber boots. *All footwear for the north should be a size larger than is usually worn* to allow room for extra socks and also because of the fact that all footwear, whether imported or native made, will contract with the frost after being damp, however slight.

Winter Clothing

If it is possible to obtain it, clothing of native manufacture is preferable for winter. An artiki, or capote, of deer or seal skin will keep out the wind better than anything. These garments are made of the tanned caribou hides, or seal, with the hair left on, and with hoods attached. They are trimmed around the edge of the hood with wol-

Fig. 3—Dog Team—Western Arctic.

verine, if it can be obtained, as the moisture of the breath does not freeze and form ice on this wolverine fur. The capote is a long garment which opens in front like an overcoat, and is an Indian style worn in the wooded country. The artiki is a pull-over garment, and the natives wear two in very cold weather; the inner one with the hair next to the body, and the outer one with the hair out. There are two kinds of hoods on artikis, the Western Esquimaux fashion, which fits closely to the head and does not come far forward, or the Eastern Esquimaux style, which is pointed and comes far in front of the face so as to give it shelter from the wind. The latter type is better for white people.

Indian moccasins made of wood caribou or moose skins are the best footwear for winter time; the Esquimaux seal skin waterproof boot is excellent for summer wear when one is travelling near water or near the coast. Duffle should be worn inside this footwear. Duffles are usually now made like bed-room slippers, and of Hudson's Bay blanket, or duffle cloth; untanned rabbit skin with the hair next to the foot is also sometimes used; these latter are very warm. Indian moccasins are of several patterns, but for white men the pattern known as a 'mitt' moccasin is the best; this moccasin is wider than the usual Indian type. All moccasins should be made so as to fit loosely when the duffle and two pairs of socks are worn. As many pairs of socks should be taken as can be carried, also several pairs of duffles. It will be found that after a days travel in most cases the footwear is wet, and it will have to be dried out each night.

Socks

Each member should be equipped with at least three pairs of heavy wool socks.

Insoles

These add warmth and protect the soles of the feet when walking over rough ice, etc. Felt or duffle insoles are recommended. Like socks, they should be kept as dry as possible.

Mitts

One pair of outer skin mitts and two pairs of inner wool mitts. Fur mitts are not recommended. They are apt to gather snow and are usually clumsy.

Underwear

One change of heavy woollen underwear with long sleeves and legs.

Winter Cap

A winter cap with ear flaps or a fur cap should be carried.

Extras

Each member would be well advised to carry a small waterproof matchbox, and one member should have a compass and a pair of binoculars.

Frost Bites

One of the chief reasons for frost bites is moisture. Wet feet or hands are usually the result of perspiration, which should be avoided as far as possible. Inner mitts and footwear should never be allowed to come into contact with snow. Northern Indians and Esquimaux are most particular in this respect. When there is no available heat to dry socks and mitts overnight, a good plan is to lie on them in the sleeping bag. In cases of severe frost bites, the affected part should not be exposed to the heat of a fire. A badly frozen hand, foot or even an ear is much better when placed in cold coal oil or cold water, not below freezing point, which will aid in drawing the frost out, whereas excessive heat will tend to drive the frost inward.

Game and Fish North of the Timber Limits

One does not find a great variety of game north of the timber, and it should be remembered that weather conditions often prevent hunting. Blizzards blow up very quickly in the barren lands and the Arctic islands, which makes hunting conditions more difficult there. During the fall of the year there is the ever shortening period of daylight as a further hindrance. Individual members of small parties should not hunt alone for more than a few miles from their camp.

Importance of Reaching Coastline in Barren Lands

If a party should be stranded in the Arctic anywhere near the coastline, when there is no indication of game near, they move towards the coast. This is even more important in the fall and winter, unless caribou or fish are easily obtainable. One would be much more likely to find small game along the shores in the Arctic, especially sea birds, eider duck, seal, and Arctic hare. This would also be the best method of trying to get into touch with Esquimaux, as they are usually to be found on the coast; also, by hunting along the shoreline there would be much less chance of becoming lost. A small party following the shoreline would stand a good chance of obtaining small game on which they could at least exist, or they might meet a party of Esquimaux hunters, providing that there were any Esquimaux living in that district. A glance at the map of the North West Territories will show that all trading and police posts are located on waterways, and in the Arctic proper they are all on the coastline.

Esquimaux

If a party in these circumstances should be so fortunate as to come across an Esquimau, they would find him most friendly, and willing to help at hunting or as a guide, but there would be the language difficulty in trying to make known one's situation. The average Esquimau is quite intelligent, but would probably be very bashful at first. The best way for a party to make known their wants would be for one member to converse with him through the use of sign language. If the party did not know its location, the average Esquimau man could, with a pencil and paper, make a rough sketch of the surrounding district. In any case, he would be sure to know the nearest trading post, or perhaps a white trapper, which he could indicate. The Esquimau term for 'white man's house' is '*kod-loo-nah igloo*.' These words would be readily understood by the Esquimaux in any part of the far north. A more or less intelligent conversation would be carried on in regard to hunting, etc., by making sketches of fish, birds and animals. In speaking of distances, an Esquimau uses the term 'so many *sleeps*'; the Indian '*nights*.' If an Esquimau says that '*kod-loo-nah igloo*' is 'one sleep away,' it can be taken for granted that it is two days travel.

Mooring an Aircraft on Ice

The following Esquimau system of fixing anchors in flat ice would be suitable for mooring an aircraft, pitching a tent, or for any purpose where a snubbing post is necessary. The method is to make a 'loop hole' or bridge in the ice. First, carefully chip two parallel lines in the ice, not less than six inches apart. Then gouge holes downwards from these lines at an angle of 45 deg., towards each other, until they meet about six inches under the surface of the ice, thus forming a bridge under which a rope may be passed. Special care should be taken to ensure that there are no cracks in the 'bridge.' This type of anchor will withstand a tremendous horizontal pull, and can be made with a pointed knife with a 10 or 12 in. blade. Three such loops should safely hold an aircraft on the sea ice, or on a barren land lake, against a very high wind. This system is used by the North Greenland Esquimaux in handling heavily loaded sledges on steep glaciers, and in hauling heavy walrus up to the shore ice from the sea. Making a loop hole in sea ice is not a difficult matter, but in fresh water ice, which is more brittle, greater patience is required.

Barren Land Lakes

An interesting observation which has been made in flying over the barren lands in winter, is that it is extremely difficult in some cases to tell a lake from the land. Sometimes the lake ice may be seen in bare patches, where the snow has been blown away, but there is often nothing whatever to indicate the flat shores of lakes where snow or ice covered boulders might be encountered in landing.

Open Patches of Water in Sea Ice

Another point which will be of interest to northern flyers, particularly in the Eastern Arctic, is open patches of water in the sea ice. These open patches, sometimes a mile or more in length, which appear as placid lakes from the air, would make dangerous landing places. Aircraft should not be landed on or near such places. These open patches are caused at intervals during the winter by the fast tidal currents, particularly during high tides, wearing the ice away from beneath. It therefore stands to reason that these open places would not occur were it not for the very fast currents, usually in the vicinity of narrow channels, or near prominent capes. Large pans of ice weighing hundreds of tons will break from one end of an open patch of water to be carried by the tide to the opposite end where the terrific pressure either pushes it up on the main pack or forces it to turn on end and go under the pack. One wonders how long an aeroplane would last under such conditions.

Seasonal Conditions in the Arctic Archipelago

The weather averages fine and warm in May, June and July, all over the Arctic Archipelago. As evidence of this, many species of wild flowers grow in June and July in North Greenland and Ellesmere Island, which is approximately five hundred miles from the North Pole. Lake Hazen, on Ellesmere Island, the most northerly lake in Canada, is surrounded by ice-capped mountains, but it thaws during the short summer months, and is a well-known breeding ground for geese.

Care of the Eyes

Be very careful with your eyes, as without sight one is indeed in a serious plight in the wilds. Snow-blindness is brought on by strain and glare. A person is more likely to go snow-blind on what is termed a 'white day,' than on a bright clear day. A 'white day' is one which is inclined to be foggy or misty, with the sun not visible, but casting a glare through the mist which fails to throw shadows. On a day such as described it is very hard to tell the difference between a snow-bank and a depression, and, if travelling, there is a continuous strain on the eyes. Snow-glasses are very useful on a day such as this, as they act as a filter on a camera bringing out objects such as snow-drifts, depressions and such like, and relieving the eyes of much strain. If, for some reason one's glasses become broken, an improvised pair could be made, such as used by the more primitive Esquimaux. You cut out a piece of wood in the shape of an arc, hollow out part fitting over the bridge of the nose, for it to fit up close to the cheek bones. Next hollow out the part in front of each eye, but not all the way through, leave a thin film of wood on the outside surface into which a very narrow horizontal slit is made in front of each eye.

A good treatment to ease the pain should your eyes become affected, is to insert a little murine or boracic acid solution, and apply cold moist tea-leaves.

How to Make a Camp

In the timber country pick out a location for the camp near a stand of dry timber if possible, also keeping in view sufficient evergreen trees to obtain boughs. As the snow is usually two feet or more in depth, scoop it away down close to the ground for an area of about 6 by 8 ft., this of course will depend on the number of persons camping. Leave the walls formed by cutting away the snow intact, and arrange to have the back wall to the wind. A snowshoe will be found very useful to use as a shovel. Fill in with boughs the area cleared of snow, placing them well up about the sides and walls to prevent bedding from coming in contact with the snow. The sticks from which the boughs have been trimmed, may be placed about the walls and back of camp to help as a wind-breaker. If the weather is inclined to be stormy, cut extra, small evergreen trees and place the butts in the snow at the back so as the tops overhang the camp. This may be done about the sides also, but is not necessary in good weather. Cut fire-wood in long lengths, placing them end to end in such a manner so that they overlap where the fire is to be built in front of the camp. In this way fire-wood may be pulled in together as it burns off without leaving the camp, and this also saves much work in cutting up the wood. A camp built in this manner will take but very little time, and will be found quite comfortable, if no tent is available.

Making a camp in the Arctic you have to resort to snow, and the best camp in cold weather is the snow-igloo, but the art of building an igloo can only come by experience and much practice. However, a good camp can be made by means of snow-blocks, cut about 26 by 18 in. and about 6 in. thick. Place in a circle or oval shape having a diameter about 7 or 8 ft. at bottom, blocks to be placed so that they slant slightly inwards at top. Build the walls about three blocks high, having each row slanting a little more inwards, and build in the form of a spiral if possible, as one block will help to hold the next. Cover the top with a canvas or sled wrapper and chink up the holes.

If this type of shelter is built on a good deep snow-bank, the diameter of the first row of blocks need not be so great, and possibly two blocks high would be sufficient. Then cut out the snow in blocks from the inside and work down, making the inside larger as you work down until you have sufficient room inside. Cut out the door at the bottom making it just large enough to crawl in through, a snow-block will be used as a door. Two large caribou skins to sleep on will be enough for each person. Place the hair of one skin next to the snow, and the other skin on top of this with the hair upwards; the eiderdown or sleeping-bag is then placed on top. Be sure to brush off all snow and frost from bedding and clothing, as this will prevent dampness when the primus stove is lighted. Leave an air hole near the top above where the primus is to be placed, and a small hole near the bottom of the door for air, for if your camp is tight the primus stove will soon use up all the oxygen, and this will be noticed by the candle going low. As holes form about the top of the camp due to heat, cut off small lumps of snow and place in the holes, and when the snow becomes soft enough press gently into place. Do not leave the primus burning any longer than necessary after cooking meal, get into your eiderdown and take your mitts and socks with you to dry them out.

Living Off the Country

If called upon to live entirely off the country, remember that it has been accomplished, and a little knowledge along these lines will be of great assistance to one in case of emergency. Practically all our larger lakes, and many of the smaller ones, in the north country contain fish, which may be caught by means of a net, and some by hook and line. The former is more dependable. The best place to make a set as a rule, if in rivers, is in a small eddy or backwater, where the current will not affect the net to any great extent, and where the fish are most likely to be found. If making a set in a lake, do not get in too deep water. At or near the mouth of a small river or stream is an ideal location.

Nets may also be set in the winter under the ice. This is accomplished by making a series of small holes where the net is to be placed. The distance the holes will be apart, will depend on the length of the pole used to pass the rope under the ice. The rope or line is attached to the pole, and the pole pushed under the ice towards the next hole. It is guided along to the end hole by means of a stick with a fork in the end. After the rope has been passed under the ice, you are ready to attach the net which is pulled under. After the set has been made bank up the end holes well with snow, as this will prevent the ice forming to any great extent over the holes which will be required to pull out the net. When pulling out the net, if it is to be reset, keep it as straight as possible, as it will freeze very quickly in the open.

In cases of starvation, the Esquimaux along the Arctic coast will invariably resort to jigging tom-cod as a means of existence. In many of the bays and inlets along the coast tom-cod are quite plentiful, and as there are many pressure ridges and cracks in these bays it eliminates the necessity of cutting holes. The type of hook used for this purpose is made of ivory, cut in the shape of a small fish with a hook protruding from the end. An empty cartridge shell can be used with good results, by attaching a hook to the end and filling the shell with lead to make it sink easily. The hook is lowered to the bottom and then pulled up about four feet, when the jigging operations will commence. No bait is used, but a small white ribbon or other white object should be attached to the line near the hook. A place should be picked out where the water is not too deep, to obtain the best results.

Snares for Rabbits

In many places in the bush country rabbits are plentiful, and as practically everyone knows how to set a snare in a rabbit's runway, snare line, or wire, should always be included in emergency equipment.

Game

There are many kinds of game in the north, both big and small, which may be procured by means of a rifle, shotgun, or other small arms such as a .22 calibre. Big game is plentiful in many parts, but it is possible to travel, or hunt, for days without seeing any. In practically all parts smaller game may be secured, and it is for this reason that it is recommended that a shotgun or .22 rifle should be included in equipment. However, should a party be travelling together and it is necessary to eliminate extra weight, at least one of the party could carry a shotgun or .22 in place of a heavier rifle. Never lose sight of the fact that practically every kind of animal, such as Arctic lemming, muskrat, fox, beaver, seal, squirrel, and every kind of fowl, may be used for food in cases of emergency. It would require far too much detail to begin to explain the methods used in hunting the different kinds of game. However, one should know at least one method of hunting seal; that is if Arctic travel is contemplated, as seals are very plentiful in all the Arctic waters.

In the spring and early summer when the seals come up on the ice, they may be obtained without much difficulty. It is possible to crawl up very near to a seal lying on the ice, providing one does the crawling during the time the seal has its head down sleeping. Lie flat on the ice with your head down during the time the seal's head is up and looking about, for even if it does see you it will probably take you for another seal and not become suspicious. Crawl up near enough to see the head distinctly before taking a shot, and remember to shoot for the head. The seal has to be knocked outright, as they sleep very near the hole and with but a wiggle they are gone. The best method of approach is to have the seal's head towards you, for when you shoot, should you miss the head, the bullet may penetrate the neck or chest. But this cannot always be accomplished, for you have to approach up wind, as the seal has a keen sense of smell. You can walk towards the seal until you are near enough to distinguish its head, when you will begin to crawl. After shooting, should you hit the seal, run and pull it away from the hole or crack, as it may only be temporarily paralyzed.

Seals may also be obtained near the floe-edge during the winter months, during which time they will float after being shot. Should you be without a boat, wait for the seal to approach near the floe-edge before shooting. It may be retrieved by means of a bobbin (i.e. a round piece of wood with hooks, attached to one end, and a long line to the other), which may be whirled and then cast out over the seal. They may be thrown for a remarkable distance, and if successful in casting directly over it, pull in gently until it is hooked.

Seals are very curious animals, and if seen in the water far out from the floe-edge they may be enticed in by making certain noises, such as knocking two pieces of wood together, whistling, and similar other noises. Remain out of sight behind a piece of ice or snow, or sit near the edge without making any movement. Keep a continual watch, as they will sometimes break water very quietly, and one has to take aim without making much movement.

A seal may be pulled to camp very easily by attaching a line to its nose. When cutting it up, strip off the fat with the skin; this will leave the flesh part of the seal exposed which will not be found greasy.

The common 'Hair Seal' is to be found almost anywhere in the Arctic in salt water, and often near the shores. It should be remembered that seals do not always float. That depends on the amount of blubber they have under the hide, and to a certain extent, whether there is any air in the lungs when killed. In the cold months a seal has a thicker layer of blubber and will float, but in July, August, and September, they are more likely to sink. It is very disappointing when one is desperate for meat to lose a seal in this way. There would not be much object in killing a seal when the tide is going out, without some means of going after it, whereas, on an incoming tide, a seal might float long enough to reach the shore, or the shore ice, when it could be lifted from the water. The common seal weight is from 50 to 200 lb. All the red meat is edible. Contrary to general belief, Esquimaux do not eat seal blubber (the two or more inches of fat which lies between the skin and the red meat) unless they are starving. It is then eaten with some roughage, such as caribou hair. When blubber is consumed it immediately turns to oil and if a newcomer tried to make a meal of blubber it would, in all probability, act as a severe purgative. The meat, ribs and flippers are very nourishing and are usually eaten in a stew, or just boiled in chunks. Most experienced northern men consider fried seal liver with bacon a very good dish.

General

If travelling in the winter, when the weather is very cold, take every precaution against getting over-heated, as this will cause moisture to form on the inside of skin clothing, which will freeze and turn into ice. If likely to perspire, remove skin clothing and put on a canvas parka, or similar garment.

Never travel or try to make a certain point with wet feet, as one's feet will freeze very quickly if in a wet condition, and with frozen feet one cannot hope to travel very far. If in the Arctic, where extra footwear and mitts should always be carried, stop immediately and change. If in the bush country in winter and clothing becomes wet, stop, build a fire and dry out, even though extra clothing is carried; for as it sometimes happens one will get into over-flow soon after changing.

Avoid over-flow, which is usually found near the shores of lakes and rivers, and is sometimes hard to see owing to deep snow.

There have been many cases in the north where men have gone into over-flow, perhaps only a few miles from their cabins and have not bothered to stop and change or dry out, thinking that they could reach their shelters before freezing; the result in many instances has been frozen feet.

Bear in mind that snow is a good absorber of moisture, and if one can get into snow soon enough after breaking through into water, you will find that the snow will take up a great deal of the moisture which otherwise would penetrate into your clothing.

Do not venture on black or dark looking ice without first testing, as new ice appears dark in colour. If on the sea-ice near the vicinity of open water, be careful in crossing cracks, stop and watch the crack for awhile to see if it is widening, as sometimes, especially in the eastern Arctic, near large bays or sounds, fields of ice will break off from the main pack and be carried very rapidly out to sea by wind or current.

Never try to travel in a blizzard, as you will only use up your energy and accomplish very little; this applies more or less to Arctic travel where there is little or no shelter. If overtaken by a storm prepare to make a shelter at once. A few blocks of snow arranged in the proper order will afford an effective windbreak.

If travelling by dog sled or hand-sled, arrange loads so that each sled will have a supply of necessary articles to maintain existence of the persons travelling with that sled, such as axe, rifle, matches, food, bedding and cooking utensils, in the bush country; in the Arctic, snow-knife, rifle, primus stove, coal-oil, matches, food, bedding and cooking utensils. This precaution should be taken in event of parties becoming separated, or outfits getting wet. This also would apply if travelling by canoe during the summer months.

As to firearms, if intended for use during the winter months, you should be very careful to clean off all particles of grease from the working parts. It may be necessary to boil the bolt to accomplish this, as in very cold weather the grease will harden and possibly prevent the rifle from firing. If in constant use, leave firearms in a cold place, for if brought into a heated camp they will sweat, and every part will have to be thoroughly dried out. There is very little need to clean the barrel even though it has been fired a few times, for during very cold weather corrosion will not take place to any extent.

The above has been a necessarily brief summary of suggestions for self preservation in the wilds. It has been impossible to deal fully with this matter as the subject would fill a book. But the most important matters have been dealt with, and this paper may serve a useful purpose to those who find themselves thrown on their own resources in the Arctic.

Council Meets in Ottawa

Local Branch Has Veritable Field Day in Honour of Occasion

Friday, June 24th, was a busy day in Ottawa. In the morning there were group meetings of councillors in the President's suite. At noon there was the luncheon meeting of the Ottawa Branch. All afternoon there was a meeting of Council. At 6.30 p.m. we had the special E.I.C. concert from the Peace Tower by the Carillonneur, and at seven o'clock there was the President's dinner at the Rideau Club. We repeat—it was a busy day.

The Ottawa Branch has built up a reputation for doing things well, and on this occasion they certainly added to their laurels. The noon meeting of the branch at the Chateau Laurier had an attendance of a hundred, with all the out of town councillors as guests of the branch. Chairman W. F. M. Bryce presided, with President Challies on his right and Dr. T. H. Hogg on his left. Other head table guests were Past-Presidents Dr. Charles Camsell, C.M.G., Dr. F. A. Gaby, and G. J. Desbarats, C.M.G.; Vice-President J. A. McCrory, and the following members of Council: W. E. Bonn, Dr. R. W. Boyle, J. L. Busfield, R. H. Findlay, A. B. Gates, Lieut.-Col. L. F. Grant, F. S. B. Heward, H. A. Lumsden, W. R. Manock, F. Newell, J. A. Vance, E. Viens; Treasurer deGaspe Beaubien, and General Secretary L. Austin Wright.

The President traced the development of the status of the engineer from the time of Confederation (when there wasn't any) up to the present when a standing at least the equal of the other professions, is enjoyed. He complimented the Canadian universities on their excellent engineering equipment, and competent staffs, and expressed the opinion that they were second to none in the world. He touched on the Provincial Professional Associations and the splendid work they were doing in protecting the engineer and the public.

The General Secretary, Austin Wright, thanked the officers of the Ottawa Branch for the opportunity of making his first appearance before the branch, under such favourable circumstances, and spoke briefly on changes that were proposed for The Journal.

Immediately after the luncheon meeting, Council convened at 2.15 p.m. for one of the best attended regular meetings of its history. Thirty-five councillors and guests sat down for an interesting and important session that lasted until six o'clock. All past councillors resident in Ottawa, and the officers of the local branch, were especially invited to attend, so that they might have a more intimate knowledge of the problems and developments of The Institute, and give Council the benefit of their opinions and advice.

Many important matters were discussed, all of which will be described in the next issue of The Journal. The proposed agreement with the Association of Professional Engineers of Saskatchewan, which has had the approval of the executives of both organizations in Saskatchewan, was examined very carefully, and was finally approved by every councillor at the meeting. The full context of this important document will be disclosed in the next number of The Journal, and every member will be able to see for himself the simple but solid basis upon which this desirable co-operation can be achieved.

A very enthusiastic outburst of applause greeted Past-President Gaby's announcement that a Doctorate of Engineering would be conferred on President Challies by the University of Toronto at the October Convocation.

The carillon concert was arranged specially for the occasion through the kind offices of Mr. J. B. Hunter, the Senior Deputy Minister of the Federal Public Works. It was a very pleasant experience to be able to stand out on the upper balcony of the Rideau Club in the cooling air of the evening with the beautiful buildings and grounds of the House of Parliament right in the foreground, and listen to the lovely music of the bells.

The President's dinner was a great success. Almost fifty guests joined him in the lounge and on the balcony, and with him shared the comfort and hospitality of this grand old institution. The special guests of the evening were the Hon. C. D. Howe, Minister of Transport, and the Hon. Grote Stirling, both Honorary Members of The Institute, Mr. J. B. Hunter, the Deputy Minister of Public Works, and Mr. J. C. Beauchamp, the President of the Dominion Institute of Professional Civil Servants.

Mr. Challies is very much at home in Ottawa, and it is doubtful if he could be happier than he appeared on this occasion as chairman of his own dinner, surrounded by old Ottawa friends and councillors of The Institute. The head table, arranged from right to left, was deGaspe Beaubien, J. A. McCrory, J. B. Hunter, Dr. F. A. Gaby, Hon. C. D. Howe, Hon. Grote Stirling, J. B. Challies, G. J. Desbarats, J. Clement Beauchamp, Dr. Charles Camsell, L. Austin Wright. Four smaller tables, each under the sub-chairmanship of a councillor selected by the President as his representative, provided for the balance of the party. These sub-chairmen were—F. Newell, J. L. Busfield, J. A. Vance and Dr. R. W. Boyle, and the guests were—W. E. Bonn, W. F. M. Bryce, K. M. Cameron, E. V. Caton, Hon. George H. Challies, T. H. Dunn, Lieut.-Commdr. C. P. Edwards, O.B.E., R. H. Findlay, O. S. Finnie, G. A. Gaherty, A. B. Gates, F. G. Goodspeed, Lieut.-Col. L. F. Grant, A. K. Hay, F. S. B. Heward, Dr. T. H. Hogg, J. T. Johnston, H. A. Lumsden, F. C. C. Lynch, J. G. Macphail, W. R. Manock, W. H. Munro, John Murphy, John McLeish, Major-General A. G. L. McNaughton, C.M.G., F. H. Peters, J. L. Rannie, Group-Capt. E. W. Stedman, O.B.E., and E. Viens.

Hon. Mr. Howe spoke in a very pleasant vein. He referred to the pleasure that it had given him last year to be awarded an Honorary Membership. He said he had never received any honour that he prized so highly as he did this. He humorously referred to parliamentary life for an engineer, and indicated that the usual hard work and long hours that were the experience of all engineers were nothing compared to the task of being a Minister of the Crown. In conclusion he offered his services to The Institute if at any time there should be need of them.

Hon. Mr. Stirling followed, and gave an excellent exposition of one of those talents for which he is famous—after dinner speaking. He, too, referred to the life of an engineer in Parliament, and in a very amusing manner described his experiences as an engineer, both in and out of the House. It is a great treat to hear such a charming speaker in such an informal mood.

The President is such a leader in demonstration of appreciation for other people, that it was rather amusing to see his discomfiture when the entire gathering stood up and sang with an enthusiasm that made up for their lack of musical ability "For He's a Jolly Good Fellow." It was on this note that the party adjourned to the balcony for the balance of the evening.

THE ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

Editor L. AUSTIN WRIGHT

Advertising Manager N. E. D. SHEPPARD

VOLUME XXI JULY, 1938 No. 7

Saskatchewan Takes the Lead

Such progress is being made in the negotiations for a co-operative agreement between the Association of Professional Engineers of Saskatchewan and The Institute, that it now appears that such an agreement will be consummated early this Fall. An account of a recent joint meeting between the two bodies appearing in this issue in the branch news for Regina, gives some indication of how these negotiations have been conducted.

Books—A New Service

Attention is called to a new feature of The Journal. It has always been acknowledged that news of technical books is of real value to the engineer, but many difficulties have made it impossible for The Journal to give its readers a comprehensive picture of the field of new technical literature. It is, therefore, with a great deal of pleasure and satisfaction that we are able to announce that arrangements have been completed with the Director of The Engineering Societies Library of New York, Dr. Harrison W. Craver, to permit us to use the same list of books, and his notes on them, that he prepares for the publications of the four Founder Societies—Civil Engineering, Mechanical Engineering, Electrical Engineering, and Mining and Metallurgy. This list is probably the most complete of its type that is published anywhere, and it is very gratifying to The Journal to know that it is the intermediary that makes it possible for members of The Institute to have such complete information at their disposal.

Please bear in mind that these books are not necessarily in The Institute library. If readers are interested in securing copies for study or for their library, inquiries will be welcomed at Headquarters, or communications may be sent direct to the publisher whose identity is given with each book listed. It will enhance our position with the publishers if The Journal is mentioned in such inquiries.

It is an exceedingly helpful and friendly gesture on the part of the Founder Societies to permit us this privilege. It is another indication of the splendid relationships that exist between The Institute and the four great sister societies to the south. We are very grateful to Dr. Craver and to his societies.

Engineer versus Politician

Engineers throughout Canada will have been interested in following the accounts of a recent governmental power inquiry. Usually in such inquiries the main issues are obscured by a flood of irrelevant questions, charges, accusations and recriminations, and this one seems to be no exception to the custom. To have in mind the purpose of the inquiry, and to attempt to tie into it the evidence as it appears at this distance, is to put a great strain on one's mental equipment. Perhaps if one's training is political rather than logical, the relationship can be more easily discovered.

The one simple, clear and conclusive lesson that can be learned from all this discussion, debate, and disclosure over the power problems of central Canada, is that there is an imperative need of sound engineering leadership in such matters and less political meddling with any industry so technically complicated and so basically important to every citizen, as the electrical services of a great province.

Work to Do

Opportunities for service are always present, but it is doubtful if The Institute has ever been in a position where it can do more for the profession than that in which it now finds itself. There are so many things presenting themselves for attention, some new, some old, but all important and all strictly of real concern to The Institute and to the membership. None of the problems is impossible of solution, yet none of them will be answered without great effort—not the effort of one or two, but the effort of many. Wisdom will be required, patience, perseverance, and we repeat—effort.

Such a situation should not frighten us. Look back at what has been accomplished—the mountains which have been crossed—and we should find encouragement for the future. The presence of problems is a natural condition. In a recent number of Engineering News-Record, Colonel William Chevalier refers to the visitor to New York who said "New York will be a great city if they ever get it finished." But they never will, because there is no finish to the problems of living things. The ability to see these problems as opportunities to accomplish something worth while is one of the things which make a person or a nation great.

* * *

What are these problems that afford us these opportunities? At the moment space does not permit of a sufficient description or discussion, but we can attempt a sketchy outline that may serve to recall them to mind. In later issues, we plan to deal with each one separately in the hope that such a discussion will concentrate the attention of the membership on it, which is the first step towards finding the solution.

MEMBERSHIP is always of paramount importance. The situation to-day, in the light of past records, is excellent, but the desire for more members is based on an appreciation of two things. First, such an increase means increased opportunities for service. Second, increased membership means increased revenue, which in turn makes possible an improvement in existing services and the establishment of additional ones.

EMPLOYMENT for members who from time to time find themselves out of work is one of The Institute's real concerns. Great things have been done in the past, but with the recent increased call for positions greater demands have been placed on this department. Certain handicaps, principally of finance, make it difficult to enlarge the activities sufficiently to be equal to the new opportunities. The field of usefulness for this phase of our activities is very broad, and of itself is almost sufficient to justify the existence of The Institute.

CO-OPERATION with other engineering societies has been a long-time ambition of The Institute. All these bodies have similar objectives. It is therefore reasonable that they should work together to accomplish them. Great progress to this end has been made, but the big work is still ahead. Beyond a doubt, co-operation is "just around the corner," but the remaining distance cannot be covered by coasting.

THE ENGINEERING STUDENT and the recent graduate seemed to present a great opportunity to render a real service that cannot come from any other source. How just to go about this is a large and complicated problem, but the desire of senior practising engineers to pass on to these embryos the benefits of their experience, is genuine. The problem for The Institute is to make this possible. Much thought has already been given to it by senior officers and it is expected that some genuine progress will be indicated before long.

* * *

These are all activities with an "outward look"—things which The Institute can do for others. Surely for a time we have had enough of introspection. Many changes in by-laws have been suggested and voted upon. Some have been approved—others rejected, but the great needs of our membership, the great opportunities of The Institute are not going to be met by tinkering with the constitution. At the moment there are no controversial issues, no outcries for legislative reform. Is this not an excellent time to concern ourselves more deeply with the welfare of our profession and the usefulness of The Institute in promoting such development?

Honours for the President

At the last minute before going to press word has been received from the Registrar of the University of Toronto that at a special convocation to be called on October 14th, the degree of Doctor of Engineering will be conferred on J. B. Challies, C.E., M.E.I.C. Time does not permit now of making proper acknowledgment of this well deserved honour, but the news will be welcomed by our entire membership and by members of the profession everywhere. Subsequently more time and space will be given to this very important announcement.

A Registrar is Appointed

Dr. A. R. Decary, M.E.I.C., President of the Corporation of Professional Engineers of Quebec, announces the appointment of C. Leroux Dufort as registrar of that body, the appointment having been made necessary by the much regretted death of Dr. Adhemar Mailhiot, the former incumbent of that office.

Mr. Dufort was born and educated in Montreal, obtaining his B.A.Sc. and C.E. from the Ecole Polytechnique. From 1905 to 1919 he was engaged in private practice in structural, municipal and general engineering and land surveying. To April 1938 he was with the Department of Colonization of the Province of Quebec as engineer, and for the latter six years as chief engineer. At the time of his appointment he was city engineer of Drummondville, Que.

The Institute congratulates Mr. Dufort on his appointment, and wishes him success and happiness in his new work. At the same time we wish to offer to him, and through him to the Corporation, any assistance that we may be able to give that will help him in his endeavours to promote the welfare of the profession in the Province of Quebec.

A Romance in Engineering

The recent election of W. D. Black, M.E.I.C., to the Presidency of the Canadian Manufacturers Association, brings to light other features of his interesting career. Here is a story that breathes of inspiration to the young engineer and brings satisfaction to the older members of the calling—the story of a man who was determined to complete his education, even to post graduate studies, in spite of severe difficulties; who all his life accepted responsibility both in and out of his professional field—who steadily year by year mastered the industry in which he was interested, and correspondingly year by year stepped in steady measure from labourer to President in the same company.

It is a saga such as novelists invent to entertain their public, and yet it is given to our readers herewith just as a chronological series of actual events. The steady climb from obscurity to national reputation and national service is plainly told. The strength of the story is not reduced by the simplicity of the telling.

William Duncan Black (better known as "Dolly"), born in Toronto, was educated at Dufferin School, Technical High School and the University of Toronto. Attended night classes at technical school four years, working day time as street car conductor; labourer and later foreman, on elevator installation for Fensom Elevator Works. He entered S.P.S. University of Toronto 1906, graduated B.A.Sc. 1910; President, Engineering Society 1909; joined Otis-Fensom Elevator Company 1910 as Superintendent, Montreal and Eastern district; 1913, Manager, same district; 1918, in charge of munitions manufacture for company at Hamilton; General Construction Manager 1919, Works Manager 1921, General Manager 1925, Vice-President 1927, President 1935; Commissioner, Hamilton Hydro-Electric Commission 1933, chairman 1934 to 1936; President, Engineering Alumni Association, University of Toronto, 1936; Canadian Employers representative, Geneva Labour Conference 1934; Director, Bank of Canada, 1936 to date; member, Advisory Board, Canadian Construction Association, and now President Canadian Manufacturers Association 1938.

He has four children, three girls and one boy; owns a three hundred acre farm near Hamilton on which he has one hundred pure bred Ayrshires; belongs to many clubs and has many recreations.

He has been a member of The Engineering Institute of Canada since 1908 when he joined as a Student.

An Appreciation

The following article appeared in the May number of Mechanical Engineering under the heading "Durley." It is reprinted here as it is thought that members will be interested in knowing that Secretary Emeritus R. J. Durley is held in the same high regard in the United States as he is in Canada.

"On March 18 the President and Council of The Engineering Institute of Canada announced the retirement as secretary of the Institute of Richard John Durley, member since 1899 of The American Society of Mechanical Engineers. Captain Durley becomes secretary-emeritus. The duties of the secretaryship were taken over on April 1 by Leslie Austin Wright.

"Captain Durley became secretary of The Institute in April 1925, and in June of that year assumed editorship of The Engineering Journal, official publication of the Institute. Educated in England at the University College, London, he acquired by apprenticeship and engineering practice a background of experience that lent authority to a teaching career begun at Hull, England, in 1894 and continued at McGill University, Montreal, when he went to Canada in 1897. Through his teaching, his consulting practice, his service during the war as officer in charge of the Division of Gauges and Standards, Imperial Ministry of Munitions, Inspection Department (Canada), and his work as secretary of the Canadian Engineering Standards Association he became favorably known to Canadian engineers and added to his professional qualifications those personal characteristics that made his selection, in 1925, as secretary of The Engineering Institute of Canada a fortunate choice.

"Spread out over a narrow strip of territory extending from ocean to ocean in a country where great pioneering works of engineering construction and development are going on simultaneously with highly progressive manufacturing establishments of the most modern type, a country rich in agricultural, mineral, and natural power resources, members of the Institute represent every phase of engineering practice. It has been Captain Durley's task to co-ordinate these diverse professional interests during a period of economic stress and in the face of difficulties inherent in the wide separation of industrial centers and the even more extensive scattering of the districts that make up the engineering frontier. As editor of the Journal of the Institute he produced an engineering magazine of high quality, recording the best developments in technology in Canada. Fortunately his services are not lost to the Institute and the Journal for, as his health permits, he will continue to be active in both."

Presidential Activities

The President and the General Secretary were the guests of the Grand Valley Group of Professional Engineers at the Group's Annual Banquet, at Brantford, Ontario, on Friday, May 27th. Nearly one hundred engineers participated in this extremely enthusiastic engineering function. Other guests included the President of the Ontario Association of Professional Engineers, two members of the Ontario Government, the Speaker of the Ontario Legislature, local members of Parliament, and the Mayor of Brantford. The President was accompanied by Vice-President Buchanan, Councillors Vance and Manock, the chairmen of the London, Toronto, Hamilton and the Niagara Peninsula branches, Fraser S. Keith M.E.I.C., of Montreal, W. J. Johnston, A.M.E.I.C., of Winnipeg, Dr. Charles A. Robb, M.E.I.C., of Edmonton, and the General Secretary.

As the principal speaker of the evening, the President took as his theme "The Engineer in Public Service," and congratulated the Grand Valley Group on their unique service to the public through a "better light better sight" campaign in the schools, for their promotion of a reforestry programme in the surrounding district, and for the advocacy of the conservation of the Grand River waters. He recounted similar notable services by such early leaders of the profession who left their imprint on that part of the Dominion, as Sir Casimir Gzowski, Sir Sandford Fleming, Sir John Kennedy, the two Keefers, and Dr. John Galbraith, all prominent pioneer members of The Institute. He called attention to the progress of the profession as evidenced by the growth of engineering education in all the provinces, by the progress of The Engineering Institute, and the widespread acceptance of provincial registration and licensing, and by the key positions now held by engineers in political life, in the public service, and in big business throughout the Dominion.

The annual banquet of the Grand Valley Group of Professional Engineers is a unique event among engineers in Western Ontario. This year The Institute was privileged to take a leading part in it.

The President, the Ontario Vice-President, and the General Secretary, spent the afternoon and evening of Saturday, May 28th, with members of the Border Cities Branch. Most of the afternoon was devoted to discussions of Institute affairs with Councillor Chambers, Branch Chairman Krebser, and the local executive committee. In the evening, following a well attended supper in the Prince Edward hotel, the President informally discussed the status of the profession, spoke of the co-operative movement which is now progressing satisfactorily in the form of active negotiations for closer relationships between The Institute and the Provincial Professional Associations pursuant to the new enabling By-law No. 76. There followed an hour and a half of spirited and helpful round-the-table debate on engineering matters, which indicates a very active and informed professional personnel in the Border Cities Branch. An interesting feature of the evening meeting was the presentation by the President, on behalf of the Branch, of a suitably engraved gift to W. H. Baltzell, M.E.I.C., one of the oldest members in The Institute, who is retiring from active professional work.

As part of the symposium on "Natural Resources of Canada, and Their Development through Chemical Research," the President delivered a paper on "Water Power and the Electrochemical Industry" at the Fifty-Seventh Annual Meeting of the Society of Chemical Industry in Ottawa on June 21st.

Vice-President E. V. Buchanan arrived in Montreal on the morning of June 10th on his way to the Old Country on vacation. The President, accompanied by Mrs. Challies, Past-President J. M. R. Fairbairn, the General Secretary and Mrs. Wright, was at the station to greet him. The entire party breakfasted with Mr. Challies, after which the visitors enjoyed a short sightseeing trip with the President before embarking on the *Duchess of Richmond.*

The Engineering Institute of Canada Prize Awards 1938

Eleven prizes known as "The Engineering Institute of Canada Prizes" are offered annually for competition among the registered students in the year prior to the graduating year in the engineering schools and applied science faculties of universities giving a degree course throughout Canada.

Each prize consists of twenty-five dollars in cash, and having in view that one of the objects of The Institute is to facilitate the acquirement and interchange of professional knowledge among its members, it has been the desire of The Institute that the method of award should be determined by the appropriate authority in each school or university so that the prize may be given to the student who, in the year prior to his graduating year, in any department of engineering has proved himself most deserving as disclosed by the examination results of the year in combination with his activities in the students' engineering organization, or in the local branch of a recognized engineering society.

The following are the prize awards for 1938:—

University of Alberta	LeRoy Allan Thorssen, S.E.I.C.
University of British Columbia	Arthur Leslie Sutton
University of Manitoba	Aaron Gusen
McGill University	William Hartley MacGowan
Ecole Polytechnique	André Dufresne
University of New Brunswick	Cyril J. Gray
Queen's University	Norman Salisbury Edgar
Royal Military College	Lindsay Hugh Brown, S.E.I.C.
University of Toronto	Paul C. Anderson
University of Saskatchewan	Joseph Louis de Stein
Nova Scotia Technical College	James Philip Dumaresq

PERSONALS

Dr. William Lindsay Malcolm, M.E.I.C., professor of municipal engineering in Queens University, Kingston, Ont., has been appointed director of the School of Civil Engineering, Cornell University, it was announced recently by President Edmund E. Day. The appointment was recommended by Dean S. C. Hollister of the College of Engineering and approved by the Board of Trustees at the June meeting.

Charles G. Williams, B.A.Sc., has been appointed Professor of Mining Engineering at the University of Toronto in succession to Professor H. E. T. Haultain, C.E., M.E.I.C., who has resigned. Professor Williams is a graduate of S.P.S. in 1903 and has spent all the intervening years in practical mining work in Northern Ontario. For fifteen years he was with Hollinger Consolidated Gold Mines, and most of that time as General Superintendent. Latterly he has been in private practice in Toronto.

E. V. Buchanan, M.E.I.C., Vice-President for Ontario, passed through Montreal on June 10th on his way to the Old Country, where he will represent The Institute at the International Engineering Congress to be held in Glasgow on June 21st to 24th. Mr. Buchanan was accompanied by Mrs. Buchanan and his son William and daughter Mary. He will also attend the meeting of the International Electrotechnical Commission in London on June 22nd to July 1st. He returns to Canada at the end of July.

R. J. Durley, Secretary Emeritus, at the time of going to press, is still in hospital, but his condition is so greatly improved that it is expected he will be home in ten days' time. A second operation has been performed and with very successful results.

Charles A. Robb, M.E.I.C., Professor of Mechanical Engineering at the University of Alberta, has received the degree of Doctor of Engineering from the Johns Hopkins University, Baltimore. His investigations and report on "Recompression Phenomena in Steam Nozzles" was the basis of the award.

Dr. Robb is a graduate of McGill University in mechanical engineering, and a Master of Science of the Massachusetts Institute of Technology. In 1931-2 he was in residence at Johns Hopkins University doing graduate study under Professor A. G. Christie and Professor D. H. Andrews, leading to the doctorate degree. In May of the year he returned to Baltimore and completed the requirements. He is active in Institute affairs, and has delivered excellent papers at important meetings such as the Semi-centennial meeting of June 1937 and the Annual Meeting in February last, in London, Ont.

Julian C. Smith, LL.D., M.E.I.C., President of the Shawinigan Water and Power Company, has been elected for a second year of office a Member of Council, resident in Canada, of the Institution of Civil Engineers.

Robert F. Legget, A.M.E.I.C., who for the past two sessions has been a lecturer in the Department of Civil Engineering at Queen's University, Kingston, has been appointed assistant professor of civil engineering at the University of Toronto. Mr. Legget received the degree of M.Eng. from the University of Liverpool, England, in 1927 and has been engaged in professional work in Canada since 1929. He has always taken an active interest in Institute affairs.

Fraser S. Keith, M.E.I.C., was elected chairman of the Board of Management of the Presbyterian College of Montreal at the annual meeting of that body. Mr. Keith was re-elected chairman for the fourth consecutive year.

OBITUARY

Alexander Ritchie Dufresne, M.E.I.C.

Members of The Institute will learn with regret of the death of Alexander Ritchie Dufresne, M.E.I.C., which occurred in Montreal, on June 2nd, 1938.

Mr. Dufresne was born in Ottawa, Ont., on December 18th, 1872. He graduated at McGill University with the degree of B.Sc. in 1896 and was placed in charge of work dredging a channel in Lake St. Louis. The following year he became assistant engineer on construction of the Soulanges Canal. From 1900 to 1902 he was assistant engineer of the Hydrographic Survey of the St. Lawrence river from Kingston to Prescott. In 1902 he went to Red River, Man., in charge of construction of the St. Andrews lock and dam. In 1905 he joined the staff of the Dominion Public Works Department for Manitoba. In 1910 he was appointed assistant chief engineer of the Department. He remained in this position until 1918 when he resigned to become manager of the Saint John Dry Dock and Shipbuilding Company, Saint John, N.B. From 1931 until December last, Mr. Dufresne was chief engineer and director of the Canadian Dredge and Dock Company, Montreal.

He joined The Institute in 1894 as a Student, becoming an Associate Member in 1902 and a full Member in 1911.

Gerald N. Martin, Jr.E.I.C., who for the past four years has been with the Dominion Bridge Company Limited as designer in their Structural and Boiler Departments, is being granted two years leave of absence to obtain added experience and to study modern combustion engineering under the Central Electricity Board in London, England, and also with some of the large combustion firms in that country. Mr. Martin is a graduate of Mont Saint-Louis and Ecole Polytechnique. At the latter institution he obtained a Diploma in Civil Engineering, the Degree of Bachelor of Applied Science (U. of M.) and Gold Medal 1934.

Mr. Martin is a member of the executive of the Junior Section of the Montreal Branch of the E.I.C., and in 1937 was awarded the Phelps Johnston prize for his paper on "The Elements of Modern Combustion Engineering." He will again take up his work in the Combustion Engineering Department of the Dominion Bridge Company Limited on his return to Canada.

C. R. Whittemore, A.M.E.I.C., has been made vice-chairman of the Montreal Chapter of the American Society of Metals. He is metallurgist with the Dominion Bridge Company, and is the author of a paper appearing elsewhere in this number of The Journal.

F. R. Park, S.E.I.C., who has been with the Northern Electric Company, Montreal, has now been transferred by that company to Calgary.

R. H. Findlater, F.I.C., M.E.I.C., has recently taken charge of the Montreal and Eastern Canada business of Bruce Ross Limited, Montreal, importers and exporters of chemical supplies. Mr. Findlater began his professional career with the Broxburn Oil Company, Broxburn, Scotland, but in 1911 went to Newcastle, N.S.W., as chief chemist and refinery manager, British Australian Oil Company Limited. In 1916 he returned to Scotland to the Broxburn Oil Company, remaining with them until 1921 when he accepted the position of refinery manager of the Egyptian Government Refinery, Suez, Egypt. This latter position he held until 1925, when he came to Moncton, N.B., as petroleum chemist and assistant manager, New Brunswick Gas Oil Fields Limited.

W. A. Logie, S.E.I.C., has recently come to Montreal, having accepted a position with the Montreal Light, Heat and Power Consolidated.

W. W. H. Dean, S.E.I.C., has accepted a position with the Trans-Canada Airlines, and is now located at the Stevenson Airport, Winnipeg, Manitoba. Mr. Dean graduated at McGill University in 1937 with the degree of B.Eng. in electrical.

Clifford G. Wallman, S.E.I.C., is now with the Canada Starch Company at their plant in Cardinal, Ont. Mr. Wallman graduated at McGill University with the degree of B.Eng. in mechanical engineering, this spring.

J. W. Stafford, S.E.I.C., who has been located at Arvida, Quebec, with the Saguenay Power Company Limited as junior engineer has been transferred to the company's Isle Maligne Station as plant engineer. Mr. Stafford was graduated from the University of Alberta in 1937 with the degree of B.Sc. in electrical engineering.

E. L. Cousins, M.E.I.C., Manager of the Toronto Harbour Commission, was recently bereaved by the loss of his father, E. J. Cousins, who died in his 84th year, after a short illness. He was President of Wilson and Cousins Limited, manufacturers of machinery and supplies in Toronto.

Alex T. Cairncross, B.Sc., A.M.E.I.C., sends us interesting letters from China. The latest word is that he is on his way home to Canada from Shanghai on vacation. He is employed by the Shanghai Municipal Council. During the general melee he has lost all his personal belongings, but is glad he still has his life. He regrets that the lack of "freedom of speech" prevents him expressing himself properly in his letters. We are looking forward to seeing him at Headquarters in August, and getting the whole story.

Frederick G. Goodspeed, M.A., B.Sc., M.E.I.C., District Engineer of the Department of Public Works at Winnipeg, has been moved by the department to Ottawa as Supervising Engineer. Mr. Goodspeed has always taken an active interest in the affairs in The Institute and his move will be good news to the Ottawa Branch. He was a member of Council in 1934 and 1935.

John Murphy, M.E.I.C., senior electrical engineer with the Department of Transport and Board of Railway Commissioners at Ottawa, is now on six months leave of absence, and retires on his seventieth birthday, December 17th, 1938. An account of Mr. Murphy's career will be given in the August issue.

W. Chase Thomson, M.E.I.C., has accepted a position on the engineering staff of the Department of Public Works of the Province of Quebec. Mr. Thomson has now moved to Quebec City from Montreal, where he has been resident for some time.

Guy Beaudet, S.E.I.C., a graduate in engineering from the Ecole Polytechnique in 1938, has been appointed city engineer of Thetford Mines, Que. Mr. Beaudet was awarded the Médaille de Bronze de l'Association des anciens Elèves at his graduation.

W. E. Sprague and H. A. Cooch have been elected to the vice-presidency of the Canadian Westinghouse Company Limited. Mr. Sprague started with the company in Pittsburgh in 1899 and Mr. Couch who is a graduate in engineering of the University of Toronto joined the organization in 1910.

Miss Ellen L. Boyden, accountant of Headquarters Staff, celebrated the twentieth anniversary of her employment with The Institute, on June 15th. She was the recipient of many congratulations and good wishes for the future.

Recent Graduates in Engineering

Congratulations are in order to the following Associate Members, Juniors and Students of The Institute who have completed their course at the various universities:—

Nova Scotia Technical College

Degree of Bachelor of Engineering

Forster, Alfred Manning, Halifax, N.S.—B.E. (Elec.).
MacDonald, Arthur Lamond, Glace Bay, N.S.—B.E. (Elec.).
Martin, Clifford Davison, Amherst, N.S.—B.E. (Elec.).
Rees, Frederick, Bell Island, Nfld.—B.E. (Mi.).

The University of New Brunswick

Medal Awards

Dunphy, Kenneth Rae, Fort William, Ont.—B.Sc. (Elec.); City of Fredericton Gold Medal for Highest Standing in Fourth Year Hydraulics; Brydone-Jack Memorial Scholarship for Highest Standing in Electrical Engineering of the Fourth Year.

Degree of Bachelor of Science

Campbell, Gerald Arthur, Fredericton, N.B.—B.Sc. (Ci.).
Connell, Edwin Allison, Woodstock, N.B.—B.Sc. (Elec.).

Swain, Douglas Smith, Winnipeg, Man.—B.Sc. (Elec.).
Taylor, William Irwin, Winnipeg, Man.—B.Sc. (Ci.).
White, Clifford Hubert, Winnipeg, Man.—B.Sc. (Elec.).

University of Saskatchewan

Degree of Bachelor of Science

McCallum, Francis, Saskatoon, Sask.—B.Sc. (Ci.).
Snyder, Robert Bertrum, Lashburn, Sask.—B.Sc. (Ci.).

J. S. Cooper, Jr.E.I.C., of the engineering staff of the Wabi Iron Works Limited, New Liskeard, Ont., has recently been appointed chief draughtsman of that company. Mr. Cooper graduated at the University of Toronto in 1934 with the degree of B.A.Sc. in civil engineering.

E. P. Fetherstonhaugh, M.E.I.C., Dean of the Faculty of Engineering and Architecture at the University of Manitoba, was a visitor to Headquarters on May 28th.

C. H. Davis, Jr.E.I.C., chief engineer of the Robb Wave Organ Company, Belleville, Ont., was a visitor to Headquarters on June 6th. Prior to accepting his present position in October 1937, he had been connected with the Northern Electric Company for three years.

Paul MacNeil, Jr.E.I.C., who is with the Dominion Coal Company, at Glace Bay, Nova Scotia, was a visitor to Montreal recently while on his vacation.

S. J. Hayes, A.M.E.I.C., Assistant Professor of Engineering at the Memorial University College, St. John's, Newfoundland, visited Headquarters on June 16th.

K. L. Dawson, M.E.I.C., superintendent of the Nova Scotia Light, Heat and Power Company Limited, Halifax, was a recent visitor to Headquarters.

Queen's University

Honours and Medal Awards

McGinnis, Arthur David, Kingston, Ont.—B.Sc. (Ci.); Honours in Civil Engineering; Departmental Medal.
McKibbin, Kenneth Holdsworth, Kingston, Ont.—B.Sc. (Mech.); Honours in Mechanical Engineering; Departmental Medal.

Degree of Master of Science

Katz, Leon, Toronto, Ont., B.Sc. (Queen's '34); M.Sc. (Physics).

Degree of Bachelor of Science

Allan, Robert Gage, Toronto, Ont.—B.Sc. (Ci.).
Brown, Donald Whidden, Ottawa, Ont.—B.Sc. (Mech.).
Callum, John Park, Sarnia, Ont.—B.Sc. (Mech.).
Campbell, Albert Murray, St. Thomas, Ont.—B.Sc. (Mech.).
Campbell, Kenneth William, St. Thomas, Ont.—B.Sc. (Mech.).
Craig, Clarence Edward, Kirkland Lake, Ont.—B.Sc. (Mech.).
Morazain, Jules Fernand, Quebec, Que.—B.Sc. (Ci.).
Neal, Eugene Laurence, Quebec, Que.—B.Sc. (Mech.).
Ramsay, Robert Drummond, Sarnia, Ont.—B.Sc. (Mech.).

Results of May Examinations of The Institute

The report of the Board of Examiners, presented at the meeting of Council held on May 20th, 1938, certified that the following candidates, having passed the examinations of The Institute, have satisfied the examiners as regards their educational qualifications for the class of membership named:

Schedule "B"—For admission as Junior:
Harry G. Stead, London, Ont.

Schedule "C"—For admission as Associate Member:
Eric Grant, Jr.E.I.C., Montreal, Que.
A. R. Moffat, Jr.E.I.C., Bourlamaque, Que.

Leonard Medal Presentation

On June 21st, at Sydney, N.S., Vice-President R. L. Dunsmore, on behalf of The Institute, presented the Leonard Gold Medal to T. L. McCall, M.E.I.C. Mr. McCall was awarded this prize for his paper on "Coal Mining Practices of the Dominion Steel and Coal Corporation Limited," of which corporation he is Chief Engineer.

The Leonard Medal was established by the late Lt.-Col. R. W. Leonard, and is an annual award for an outstanding paper on a mining subject by one who is a member of The Engineering Institute of Canada or the Canadian Institute of Mining and Metallurgy. This year the winner is a member of both organizations.

Technical Books, etc.

Airplane Structures. By Alfred S. Niles and Joseph S. Newell. 2nd ed. N.Y., Wiley, 1938. 2 vols., figs., tables, charts, 9¼ by 6 in., cloth, $7.75.

A Practical Treatise on **Chimney Design.** By D. A. Molitor. Detroit, Mich., Peters Co., 243 W. Congress St., 1938. 123 pp., diagrs., tab., charts, 9 by 7 in., paper, mimeographed, $2.50.

A comprehensive treatise on the structural stability and practical design of chimneys. General factors relating to selection of types and materials, theoretical stress analysis, and chimney foundations are covered in the first few chapters. Then follow three chapters treating respectively of brick, reinforced concrete, and steel types. Comparative design data and costs are given for corresponding chimneys in the three materials. Chimney builders are listed.

Elements of Structural Engineering. By Edward S. Sheiry. Scranton, International Textbook Co., 1938. 326 pp., illus., diagrs., tab., charts, 5½ by 8½ in., lea., $4.00.

Fundamentals of Electrical Engineering. By M. B. Reed. Scranton, International Textbook Co., 1938. 326 pp., illus., diagrs., charts, tab., 9 by 5 in., lea., $3.00.

An elementary textbook covering the customary electrical quantities and phenomena, including chapters on transients and conduction through gases. In the treatment of electric circuits the double-subscript method now in use for a.c. circuits is applied to d.c. Explanatory problems are given.

Simplified Engineering for Architects and Builders. By Harry Parker. N.Y., Wiley, 1938. 214 pp., $2.75.

BOOK REVIEWS

Boulder Canyon Project Final Reports Part VI: Hydraulic Investigations

Bulletin 1. Model Studies of Spillways. U.S. Bureau of Reclamation, Denver and Washington. 190 pp., 9¼ by 6¼ inches; Cloth $1.50, paper $1.00, post free.

Bulletin 2. Model Studies of Penstocks and Outlet Works. U.S. Bureau of Reclamation, Denver and Washington. 165 pp., 9¼ by 6¼ inches; Cloth $1.50, paper $1.00, post free.

Reviewed by J. B. Macphail, A.M.E.I.C.*

The United States Bureau of Reclamation is preparing for publication a series of bulletins on the Boulder Canyon Project, to record the history of the development, the results of technical studies and experimental investigations and the more unusual features of design and construction. There will be some forty in all, and these two are the first to appear.

In designing the spillways, a flood of 400,000 cu. ft. per sec. had to be taken past a dam 500 ft. high. The bulletin first mentioned describes various methods which were found to be unsatisfactory, and the various steps leading to the final design of two spillways, each discharging into a deep trapezoidal side channel only 40 ft. wide at the bottom, and then into tunnels. The present theory of design was found to be satisfactory, except for flows near critical depth, and little was added to it, but the great use of the models was in developing refinements in details, to eliminate undesirable eddies and turbulence. Without these experiments, according to the authors, the same degree of security could have been attained only by the expenditure of several million dollars more. Much of the space in the bulletin is devoted to a description of the effects of the various changes in details, and it appears likely to be of use to those who have similar problems to face.

Model tests at different scale ratios of 1/100, 1/60 and 1/20 gave satisfactorily consistent results even in wave forms, and their extension up to full size is therefore partly justified. The final proof, a comparison of photographs of model and prototype for similar flows, is difficult to get because of the infrequency of high flows, but it is to be hoped that something will be done in this direction. There is a reference to some comparisons of this kind wherein the prototype flow was rougher than the model flow, with more foam and mist, a thing which, incidentally, has been found elsewhere in other circumstances. There is a good discussion of the effects of entrained air, leading to the conclusion that allowance for it is most needed only at low and unimportant flows.

Some experiments on a Stoney gate 60 ft. wide by 80 ft. high were made in one scheme, and the discharge was found to agree well with theory but the water surfaces did not. Lack of time prevented further enquiry. Some observations of flow in the model tunnels are reported; and some experiments with jets show that velocities of 175 ft. per sec. may safely be used on the concrete lining.

The second of the bulletins describes some model tests of other elements. The loss of head at pipe junctions was very thoroughly investigated, with the conclusion that a short conical section in the branch at the junction with the main reduces the junction loss by two-thirds, and that full scale losses are probably less than model losses.

Tests were also made on models of the intake towers and penstocks, on the use of needle valves for discharging surplus water and the effect of the outlet works on the topography of the tailrace. Many results, useful both in construction and operation were obtained.

Both bulletins accomplish very successfully their purpose of describing the experimental methods used in investigating specific problems, and in giving sufficient extracts from a large mass of test data to support the conclusions which were reached. References to theory, and to other experimental work, are intentionally confined to separate bibliographies for the various subjects.

**Shawinigan Engineering Company, Montreal, Que.*

Transactions and Year Book

The Engineering Society of the University of Toronto, 1938

An interesting publication in the form of Transactions and Year Book has recently been issued by the Engineering Society of the University of Toronto. There are in all one hundred and eight pages containing messages from University officials, transactions of the Society, and the year's record of general activities. It is beautifully printed and bound, and is a great credit to this undergraduate society.

The balance sheet accompanies the book as supplement, and is perhaps the most interesting feature of it all. It shows assets of almost $10,000 with a portfolio of investments that is steadily growing from year to year. Sales of supplies to students amounted to almost $13,000, from an inventoried stock of nearly $2,000. Any organization that can turn over its merchandise six and a half times in an operating year of only six months has something to show to business in general. Our congratulations to the Engineering Society.

Thermal Conductivity of Building Materials

By Frank B. Rowley and Axel B. Algren, Engineering Experiment Station Bulletin No. 12, University of Minnesota, Minneapolis, 1937. 134 pp., 9 by 12 inches. $1.00 (cloth $1.50).

Reviewed by Professor E. A. Allcut, m.e.i.c.*

This bulletin is a summary of the work done by Professor Rowley and his associates at the University of Minnesota on the transmission of heat through building materials and walls. Most of it has been published in the Transactions of the American Society of Heating and Ventilating Engineers, and a list of the papers is given in the bulletin, but it is very convenient to have the material collected together in this form.

The first part consists of descriptions and illustrations of the apparatus used in making the tests. The materials were tested in a guarded hot plate apparatus 12 in. sq. This indicates that the experiments were confined to thicknesses not greatly exceeding one inch. Thicker specimens and wall sections were tested in the guarded hot box which is approximately 5 ft. cube and has a test surface 3 ft. sq.

An interesting piece of test apparatus is that used for measuring surface coefficients or the effect of wind direction and velocity on heat losses. The curves indicate that the relationships between the surface conductance and the mean temperature and air velocity, respectively, are practically represented by straight lines, so that simple formulae may be derived for them. The influence of the character of the surface and that of different angles of incidence are also indicated, so that corrections may be made for winds of different speeds and blowing from different directions.

A large number of test results and curves are given for air spaces, and these indicate that no increased thermal resistance is obtained by increasing the thickness of an air space beyond ⅞ in. Test results, obtained by the reviewer, do not agree with this general conclusion. The influence of bright surfaces such as aluminum foil, on the heat transmission across an air space is also discussed in some detail.

Considerable space is given to test results on timber in the dry and moist states, but there does not appear to be any indication of the thickness of the samples tested. This will probably have some influence on the results, particularly as the moisture tends to migrate from the hot to the cold side of the specimen. The general impression that the heat transmission increases in direct proportion to the moisture content, is confirmed by these tests.

The bulletin ends with a large number of test results on walls of frame, brick, hollow tile and monolithic construction, and these tables are very useful for reference purposes. While the whole of this work is very valuable, test apparatus and procedure are still insufficiently standardized and therefore the figures given should be regarded as relative only and should be applied with discrimination.

*Professor of Mechanical Engineering, University of Toronto, Toronto, Ont.

Trade Literature*

Floodlighting.—The Northern Electric Company Limited, Montreal, have published an 8-page bulletin on this subject, illustrating their different types of floodlights and the uses to which they may be put.

Refrigeration.—A 36-page catalogue has been received from Canadian Ingersoll-Rand Company Limited, New Birks Bldg., Montreal, Que., reviewing the development, perfection and advantages of their centrifugal water-vapour refrigeration system.

Roofing and Siding.—The Canadian Johns-Manville Company Limited, Laird Drive (Leaside), Toronto, have issued a 12-page booklet on industrial roofing and siding. Typical installations of their corrugated transite are illustrated.

Motors.—A 4-page leaflet, which has been received from the General Electric Company Limited, Montreal, Que., describes motors for every running-speed condition.

Motor Testing.—A 4-page booklet has been received from the Canadian General Electric Company Limited, Montreal, Que., on the selecting of portable electric instruments for motor testing.

Prospecting.—The Geophysical Instrument Company, Washington, D.C., have issued a 4-page bulletin on their seismic prospecting apparatus, refraction type, for mineral and oil prospecting, engineering and geological sub-surface investigation, solution of foundation problems and study of vibration problems.

Friction Materials.—An 8-page brochure recently received from the Canadian Johns-Manville Company Limited, Laird Drive (Leaside), Toronto, presents data on the lines of industrial brake linings and blocks and clutch facings for all types of industrial equipment. Illustrations and tables accompany the next.

British Manufactures.—The British Engineers' Association, 32 Victoria Street, Westminster, London S.W.1, England, have issued the 1938 edition of their Classified Handbook of Members and their Manufactures.

*Copies of the above publications may be obtained by writing to the companies mentioned.

BOOK NOTES

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet, the books are not in The Institute library, but inquiries will be welcomed at Headquarters, or may be sent direct to the publishers:

Analytical Chemistry of Tantalum and Niobium. By W. R. Schoeller. London, Chapman & Hall; New York, Nordemann Publishing Co., 1937. 198 pp., tables, 9 x 6 in., cloth, $5.50.

A practical manual for the quantitative analysis of their pentoxides and the separation of tantalum and niobium from each other and from the rare metals and the earth oxides. Brief historical material is included and special attention is given to the application of tannin in gravimetric analysis of the various rare metals and earths.

Army Engineering. By W. A. Mitchell. 5 ed. Washington, D.C., Society of American Military Engineers, 1938. 329 pp., illus., diagrs., charts, tables, 7 x 4 in., lea., $3.00.

"Army engineering" designates that portion of military engineering not included in fortification. As a consequence this United States Military Academy textbook covers mapping, roads, railways, bridges, camouflage, explosives, gasoline engines, power plants, chemicals, and river and harbour engineering from the point of view of military operations. There is also brief information on fortification, although there is a separate text on that subject.

British Non-Ferrous Metals Research Association Series No. 473. **Elastic Properties of Non-Ferrous Metals and Alloys: Collected Data.** By J. McKeown and E. D. Ward. London, British Non-Ferrous Metals Research Association, Regnart Bldgs., Euston St., 1938. 35 pp., charts, tables, 12 x 10 in., linen, 6s.

The data presented in this report have been selected after a critical survey of a large mass of published information. Copper, nickel, aluminum, magnesium, gold, silver, the platinum group metals, and their alloys are included. The elastic properties are presented in tables or graphically, with information on the ultimate tensile strength and elongation of the materials in many cases. A list of sources of the data is included.

Chinese Bridges. By H. Fugl-Meyer. Shanghai, Hong Kong, Singapore, Kelly and Walsh, Ltd., 1937. 138 pp., illus., diagrs., 9 x 6 in., cloth, $5.00. (Also K. Paul, London, 9s.)

Descriptive information concerning old Chinese bridges, including stone and wooden trusses, stone and brick arches, wooden cantilevers, and rope and chain suspension bridges. Historical notes, superstitions, and the results of some bending tests on stone beams are also included.

Einführung in die Technische Schwingungslehre, Bd. 1, Einfache Schwinger. By K. Klotter. Berlin, Julius Springer, 1938. 206 pp., diagrs., charts, tables, 10 x 7 in., cloth, 19.80 rm.; paper, 18 rm.

This is the first part of a three-volume introduction to vibration in engineering. In the present work the characteristics of simple oscillating bodies and mechanisms are considered theoretically. An introductory section on the general theory of vibration is followed by a discussion of the kinetics of simple oscillators under varying conditions of free or forced, damped or undamped vibration, including material on starting effects and maintained vibrations.

Elasticity Structure and Strength, Philosophy Natural versus Sophistical for Problems of Astronomy and Physics, Promotion of Progress in Engineering and Chemical Mechanics and Analysis of the Structure of Matter: Electronics and Organic Functions, Part 2. By C. A. P. Turner. Columbus, Ohio, 964 North High St., the author, 1938. 82 pp., charts, 12 x 9 in., paper, manifold copy, apply.

Chemical mechanics is conceived as a science through which the physical properties of matter may be determined quantitatively from chemical structure. The postulation of this structure as triunal, consisting of a group of atoms enclosing an atmosphere of pulsation and enclosed by an atmosphere of vibration of a fundamental aether, and of an inherent relation between atomic weights and various chemical, electrical and mechanical properties, permits the calculations produced.

Electric Welding. By M. H. Potter. Chicago, American Technical Society, 1938. 77 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $1.25.

A practical book for the inexperienced welder, describing processes and equipment, methods for various metals, shapes and types of work, the weldability of different metals, and certain special jobs. The last chapter covers power tube rectifiers and their utilization in welding equipment.

Elements of Physics. By A. W. Smith. 4 ed. New York and London, McGraw-Hill Book Co., 1938. 790 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $3.75.

A further revision of a standard textbook on physics, covering under the headings: mechanics, wave motion and sound, heat, magnetism and electricity, electronics, physical and geometrical optics, radiation and atomic structure, the manifold phases of the modern subject. Two new chapters are devoted to nuclear physics and astrophysics.

Elements of Steam and Gas Power Engineering. By A. A. Potter and J. P. Calderwood. 4 ed. New York and London, McGraw-Hill Book Co., 1938. 374 pp., illus., diagrs., charts, tables, 8 x 6 in., cloth, $2.75.

The beginning chapters cover the fundamentals of thermodynamics, fuels and combustion. Succeeding chapters cover steam power-plant machinery, auxiliaries and accessories, and internal-combustion engines, fuels and auxiliaries. The final chapter treats of the application of steam and gas power to locomotives, automobiles and airplanes. Problems are included.

Elements of Thermodynamics. By E. M. Fernald. 2 ed. New York and London, McGraw-Hill Book Co., 1938. 330 pp., diagrs., charts, tables, 9 x 6 in., cloth, $3.50.

A textbook presenting the subject with special reference to its applications in engineering. The customary topics of general phases and states, steam cycles, refrigeration cycles, gas mixtures, compressed air, flow phenomena, combustion and available energy are included. The last chapter, however, represents an endeavour to present the essential structure of thermodynamics from the viewpoint of pure energy relations.

Engineering Electronics. By D. G. Fink. New York and London, McGraw-Hill Book Co., 1938. 358 pp., illus., diagrs., charts, tables, 6 x 9 in., lea., $3.50.

A practical volume for engineers who wish to take up or review electronic principles and their application in typical engineering problems of tube use and circuit design. Covers the fundamentals of electron physics and electron tube structures, the engineering characteristics of a wide variety of tubes, and a demonstration of the application of tubes in a variety of electrical and industrial problems.

From Plan to Reality, Two, ed. by the Staff of the Regional Plan Association, April 1938. New York, Regional Plan Association, 400 Madison Ave. 95 pp., illus., diagrs., maps, charts, tables, 12 x 9 in., cloth, $2.00.

Describes the developments carried out according to the "Regional Plan of New York and Its Environs," particularly during the last four years, with a general summary of the last eight years. Highways and parkways, rail and air transportation and other public services, parks and reservations, and the organization for future planning are covered. Maps, diagrams and photographs illustrate the text.

Great Britain. Dept. of Scientific and Industrial Research. **Building Research** Technical Paper No. 20. London, His Majesty's Stationery Office, 1938. 111 pp., illus., diagrs., charts, tables, 10 x 6 in., paper, 3s. [obtainable from British Library of Information, 270 Madison Ave., New York, $0.95].

For a number of years the Department, with the co-operation of the Institution of Civil Engineers, has been studying these stresses. The outcome of these investigations has been the formulation of a theory that explains the phenomena observed and which has made it possible to construct charts for the guidance of engineers in safeguarding the pile from excessive stresses. The theory will also assist in diagnosing the cause of failure. The theory is presented in this pamphlet, together with recommendations concerning the manufacture, handling and driving of reinforced concrete piles, based upon the investigations.

Great Britain. Dept. of Scientific and Industrial Research. **Fuel Research,** Physical and Chemical Survey of the National Coal Resources No. 43. The **Leicestershire and South Derbyshire Coalfield, South Derbyshire Area,** the **Stockings Seam.** London, His Majesty's Stationery Office, 1938. 59 pp., illus., tables, 10 x 6 in., paper, 2s. [obtainable from British Library of Information, 270 Madison Ave., New York, $0.65].

Results of a comprehensive and detailed examination, from floor to roof, of eight pillar sections taken from points distributed over the area of the important coal seam in question. The results of the various analyses are given in tabular form with a summary for the whole seam.

Great Britain. Dept. of Scientific and Industrial Research. **Water Pollution Research** Technical Paper No. 7. **Estuary of the River Mersey.** London. His Majesty's Stationery Office, 1938. 337 pp., diagrs., charts, maps, tables, 13 x 8 in., cloth, £1 10s. [obtainable from British Library of Information, 270 Madison Ave., New York, $7.75].

In 1932 the Department of Scientific and Industrial Research undertook an investigation of the possible effects of the discharge of untreated sewage into the estuary of the River Mersey upon the amount and hardness of the deposit in the estuary. The investigation was completed in 1937 and the methods and conclusions are now available in this report which is of interest to students of sedimentation generally. So far as this case was concerned, the sewage discharge was found to have no appreciable effect.

Great Britain. Dept. of Scientific and Industrial Research. **Fuel Research** Technical Paper No. 44. **The Action of Hydrogen upon Coal,** Pt. 3. The Development of a Small-Scale Liquid-Phase Continuous Plant, by N. Booth, F. A. Williams and J. G. King. London, His Majesty's Stationery Office, 1938. 27 pp., illus., diagrs., charts, tables, 10 x 6 in., paper [obtainable from British Library of Information, 270 Madison Ave., New York, $0.30].

Continuing a research on the action of hydrogen upon coal, this part describes the layout and development of a small-scale plant for the continuous hydrogenation of coal in the liquid phase. There is also information concerning the influence of coal composition on the process.

Great Britain. Dept. of Scientific and Industrial Research. **Investigation of Atmospheric Pollution,** Report on Observations in the Year ended 31st March, 1937. 23rd Report. London, His Majesty's Stationery Office, 1938. 161 pp., charts, maps, tables, 11 x 9 in., paper [obtainable from British Library of Information, 270 Madison Ave., New York, $2.15].

Tabular and explanatory data regarding observations made with deposit gauges and automatic filters, measurements of sulphur pollution, daylight, and ultra-violet radiation, including the effect of the site of the station upon recorded observations.

Great Britain. Mines Dept. **Report of the Committee on the Firedamp Detector Regulations.** London, His Majesty's Stationery Office, 1938. 55 pp., charts, tables, 10 x 6 in., paper, 1s. [obtainable from British Library of Information, 270 Madison Ave., New York, $0.35].

The report includes the working of the regulations (the text of which appears in Appendix I), a comparison of flame lamps and automatic detectors, a consideration of the Ringrose alarm (tests of which appear in Appendix II), recommendations and reservations as to the use of automatic firedamp detectors in mines.

History of the Gas Industry. By L. Stotz in collaboration with A. Jamison. New York, American Gas Association, 420 Lexington Ave., 1938. 534 pp., illus., maps, tables, 9 x 6 in., cloth, $3.50 ($3.00 each for 10 or more copies).

A non-technical story of the gas business in the United States, covering the period from its introduction in Baltimore in 1816 to the present day and including developments, expansion of uses, financial and business activities, rates, etc., with a section on natural gas.

Household Electric Refrigeration. By J. F. Wostrel and J. G. Praetz. New York and London, McGraw-Hill Book Co., 1938. 406 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.00.

A practical manual for refrigeration service men, electricians, salesmen and others interested in the operation, construction, adjustment and servicing of household refrigerators and their control devices. In non-technical language it covers refrigeration fundamentals and the various types of household machines and systems, and gives facts and instructions for trouble-shooting, service shop equipment, etc.

Introduction to College Physics. By C. M. Kilby. 2 ed. New York, D. Van Nostrand Co., 1938. 398 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $3.25.

This text book is intended to present a brief course in the fundamentals of physics. The arrangement of material is orthodox, there being five main sections on mechanics, sound, heat, magnetism and electricity, and light. There are many worked-out problems in the text material and lists of review problems with each chapter.

Introduction to Yacht Design. By A. A. Symonds. London, Edward Arnold & Co.; New York, Longmans, Green & Co., 1938. 142 pp., diagrs., charts, tables, 9 x 6 in., cloth, $3.50.

This introduction is intended for the amateur, and presents the elementary theoretical and practical principles in simple language. The physical principles involved in floating and sailing are discussed in the first part, and accommodation and draft requirements and their bearing upon design are considered. The second part deals with the practice of design, following the practice, step by step.

Introductory Economic Geology. By W. A. Tarr, 2 ed. New York and London, McGraw-Hill Book Co., 1938. 645 pp., illus., diagrs., charts, maps, tables, 9 x 6 in., cloth, $5.00.

A comprehensive general survey of the earth materials used by man. Historical material and the principles of the formation of mineral deposits appear in Part I. Parts II and III cover respectively metallic and non-metallic (coal, petroleum, minerals) materials, including the occurrence, geographic distribution, mining, treatment, applications, and production statistics of the various materials of economic importance.

Isaac Newton 1642-1727. By J. W. N. Sullivan, with a memoir of the author by C. Singer. New York, Macmillan Co., 1938. 275 pp., 9 x 6 in., cloth, $2.50.

A new biography in which the purpose has been to paint a clear picture of Newton, the man, stressing the events which influenced his career and throw light on his character. His scientific achievements are discussed particularly with reference to their relation to the contemporary scene and subsequent developments.

A Manual of Porcelain Enameling. Ed. by J. E. Hansen; published for the Ferro Enamel Corporation by The Enamelist Publishing Company, Cleveland, Ohio, 1937. 513 pp., illus., diagrs., charts, tables, 9 x 6 in., lea., $5.00.

A collection of articles upon the application of wet-process enamels to sheet iron and cast iron. A diversity of subjects is covered, including design and fabrication of sheet-iron parts, equipment and methods for preparing and applying enamels, inspection and decorative effects. Short bibliographies and a glossary add to the value of the book.

National Physical Laboratory Report for the Year 1937. London, His Majesty's Stationery Office, 1938. 150 pp., tables, 10 x 6 in., paper, 2s. 6d. [obtainable from British Library of Information, 270 Madison Ave., New York, $0.80].

In addition to general information concerning the laboratory and its work, this publication presents the reports of the William Froude Naval Laboratory and the departments of physics, electricity, radio, metrology, engineering, metallurgy and aerodynamics, indicating the state of the current researches.

Newfoundland Geological Survey, Information Circular No. 4. **Mines and Mineral Resources of Newfoundland.** By A. K. Snelgrove. St. John's, Newfoundland, Geological Survey, 1938. 162 pp., illus., maps, diagrs., charts, tables, 9 x 6 in., paper, free upon application.

Aims to give an authoritative account of the past and present mining industry and to eall attention to opportunities for further development. The geology of the eountry and the conditions affecting mine development are discussed briefly. The active mines and quarries are described and about one-half the report is devoted to inactive mines and projects. A number of maps accompany the report.

On the **Edeleanu Process.** By J. C. L. Defize. Amsterdam, D. B. Centen's Uitgevers-Nastschappij N.V., 1938. 310 pp., illus., diagrs., charts, tables, 10 x 6 in., cloth, $7.50.

A full description of the process for the selective extraction of mineral oils with liquid sulphur dioxide. The plant is described with the aid of flowsheets and photographs, the purpose and nature of the process are explained and the basic theoretical considerations are stated in the early chapters. The major part of the book is devoted to experimental work on kerosenes, lubricating oils, petrols, etc. References and a patent list are given.

Radio-Frequency Electrical Measurements. By H. A. Brown. 2 ed. New York, McGraw-Hill Book Co., 1938. 384 pp., diagrs., charts, tables, 9 x 6 in., cloth, $4.00.

A guide for radio engineering laboratory instruction. Within each chapter, covering a particular group of measurements of circuit constants, frequency, electron-tube coefficients, etc., the principles are explained, the laboratory equipment and procedure are described, and the precision attainable, the necessary precautions and the merits of the methods are discussed.

Sand, Gravel and Other Aggregates. Methods of Testing. By J. Watson. New York, Chemical Publishing Co., 1938. 48 pp., illus., 9 x 6 in., cloth, $1.75.

Testing methods for sand, gravel and other aggregates for use as construction materials, in moulding practice, and as refractories. The importance, evaluation, procedure, and equipment of the tests are discussed.

A Short History of Naval and Marine Engineering. By E. C. Smith. Cambridge, England, University Press; New York, The Macmillan Co., 1938. 376 pp., illus., diagrs., charts, tables, 10 x 6 in., cloth, $6.00.

This book, it is claimed, is the first to give a consecutive account of the whole progress of marine engineering. Its author, an Engineer Captain of the British Navy, has devoted many years to collecting the material which is here presented in pleasant, readable form. A large amount of information is presented upon the development of screw propellers, marine boilers and engines, steam turbines, auxiliary machinery and internal-combustion engines, as well as about the men responsible for this development.

Then Came Oil. By C. B. Glasscock. Indianapolis and New York, Bobbs-Merrill Co., 1938. 349 pp., illus., 9 x 6 in., cloth, $3.00.

Oklahoma history from the time of the Indian Territory to the present day, written around the development of the oil industry. Indian troubles, settlement rushes, gushers, oil pools, bad men, financial and promotional personalities, fortunes made and lost, and the final solid accomplishments are presented in this picture of the wiping out of the last frontier.

Trane Air Conditioning Manual. 2 ed. La Crosse, Wisconsin, The Trane Co., 1938. 333 pp., illus., diagrs., charts, tables, 11 x 8 in., cloth, $5.00.

Primarily concerned with the application of the fundamental faets of engineering to the design of air conditioning systems, this publication touches on all phases of the field. Heat and its transmission, physical comfort, air properties and supply, psychrometry, refrigeration and ventilation processes, and the functions of water in air conditioning, all these, with numerous diagrams, tables, problems and numerical examples, comprise a comprehensive practical treatment of the subject.

Journal Cover Competition

The Publications Committee has been pleasantly surprised at the number of designs that have been submitted. The suggestions are all excellent and the task of choosing one as being more meritorious than the others is not going to be an easy one. The competition closed at the end of June, but that was too late for any announcement to be made in this number. Definite word should be available for the next issue.

BRANCH NEWS

C. E. Sisson, M.E.I.C.
Newly Elected Chairman of the Toronto Branch

Halifax Branch

R. R. Murray, M.E.I.C., Secretary-Treasurer.
A. D. Nickerson, A.M.E.I.C., Branch News Editor.

On the evening of April 30th, 1938, the Halifax Branch E.I.C. tendered a reception to a visiting party from Montreal consisting of President J. B. Challies and Mrs. Challies, General Secretary L. Austin Wright, Vice-President J. A. McCrory and Councillor F. Newell.

President Challies was the principal speaker of the evening. He referred to the high regard with which the Canadian engineers had been held at the first World Power Conference in London in 1924. Speaking of the work done by the 1924, 1930 and 1936 Power Conferences, Mr. Challies discussed the national policies of various countries in providing a network system of primary electric energy. Canada was now recognized as one of the most advanced countries in the world in respect to hydro-electric development.

Other speakers included L. Austin Wright, A.M.E.I.C., J. A. McCrory, M.E.I.C., F. Newell, M.E.I.C., and Hon. Michael Dwyer, A.M.E.I.C., Minister of Public Works and Mines for Nova Scotia.

Following the banquet the party adjourned to the hotel ball room where dancing was enjoyed.

On Sunday, May 1st, Mr. and Mrs. J. B. Challies entertained the members and wives of the Halifax Branch at afternoon tea at the Lord Nelson hotel. About 150 guests were present at this very enjoyable affair.

London Branch

D. S. Scrymgeour, A.M.E.I.C., Secretary-Treasurer.
Jno. R. Rostron, A.M.E.I.C., Branch News Editor.

A very successful joint meeting was held at Brantford on May 27th, 1938 (taking the place of the regular monthly meeting of the Branch), when the Grand Valley Group of Professional Engineers under the chairmanship of E. C. Caton, M.E.I.C., acted as host to members of Niagara Falls, Hamilton and London Branches of the E.I.C.

Approximately 100 members and guests sat down to a delightful dinner served at the Kerby House.

A large number of distinguished guests were there including President J. B. Challies and Vice-President E. V. Buchanan, E. P. Muntz, M.E.I.C., Chairman of the Association of Professional Engineers of Ontario, the Honourable M. McBride, Minister of Labour (whom we note with deep regret has passed away since this meeting was held), the Honourable Duncan Campbell, Minister of Public Works, Honourable H. E. Hipel, Speaker of the House, and J. R. McAllister, Deputy Minister of Public Works.

Among the visitors we were especially happy to see Professor C. A. Robb, M.E.I.C., of the University of Alberta, Edmonton, who, we understand, has again recently added distinction to himself and honour to the profession. We were also particularly glad to note the presence of W. J. Johnstone, A.M.E.I.C., District Engineer, Department of Public Works, Winnipeg, who with others were able to renew old friendships.

A representative number attended from the various Branches of the E.I.C. headed by W. J. Reid, M.E.I.C., chairman of the Hamilton Branch, and our own chairman, A. O. Wolff, M.E.I.C.

During the afternoon golf, skeet and trap shooting were indulged in by devotees of those sports.

Our General Secretary, L. Austin Wright, made his first appearance in these parts and left a good impression.

A civic welcome was tendered by the Mayor of Brantford after the dinner, following him the Honourable Duncan Campbell paid a warm tribute to the engineers for always having held up the standard of their profession but he stressed the need for leadership in the country's affairs today which he felt the engineering profession was so well qualified to meet if, as individuals, they would take a more active part in public affairs.

Mr. Muntz, in speaking about the Professional Associations' influence, pointed out the enabling legislation that now existed for the benefit of the profession in Ontario and in fact all over the Dominion. He expressed the opinion that the real groundwork had been provided for the engineer to make himself a little more constructively prominent in community and general public welfare.

Following him George D. Leacock, President of Moloney Electric Company, Toronto, and a brother of the exceptionally fine Canadian Stephen Leacock, gave a very humorous and entertaining address.

President Challies gave the main address of the evening paying a glowing tribute to those outstanding engineers, many of whom had been born and raised in this part of Ontario and who had in the past given so much of their personality, training and ability, not alone to engineering developments and great projects but had contributed in equal measure to the building and progress of our country. He pointed with pride to the magnificent achievements that had been made and are still being accomplished through the individual and collective efforts of members of our profession. The complexity of our problems, engineering, as well as social, contains an ever fresh challenge to us all. Their solving is one well within the confines of our training and one worthy of our attention.

E. T. Sterne of Brantford, in his own inimitable and admirable way, extended thanks and appreciation to the distinguished guest speakers.

The meeting was voted one of the most successful and worth while that had been held for some time.

Nine members from London were able to be there.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

The annual meeting of the Branch was held on May 31st, 1938. Chairman E. B. Martin, A.M.E.I.C., presided. The annual report and financial statement was presented, and approved, on motion of G. L. Dickson, A.M.E.I.C., seconded by R. H. Emmerson, A.M.E.I.C. At a meeting held on May 19th for the nomination of Branch officers for next season, no more than the number required were nominated and an election had, therefore, been unnecessary. The chairman announced that the following would constitute the Branch executive for 1938-39: Chairman, B. E. Bayne, A.M.E.I.C.; Vice-Chairman, F. L. West, M.E.I.C.; Secretary-Treasurer, V. C. Blackett, A.M.E.I.C.; Committee, F. O. Condon, M.E.I.C., G. L. Dickson, A.M.E.I.C., R. H. Emmerson, A.M.E.I.C., A. S. Gunn, A.M.E.I.C., C. S. G. Rogers, A.M.E.I.C., G. E. Smith, A.M.E.I.C.; Ex-officio, E. B. Martin, A.M.E.I.C.

A vote of thanks moved by T. H. Dickson, A.M.E.I.C., was extended the retiring officers.

Ottawa Branch

R. K. Odell, A.M.E.I.C., Secretary-Treasurer.

Roads in the Sky

The last regular noon luncheon of the season for the Ottawa Branch was held at the Chateau Laurier, at which Professor R. DeL. French, professor of Highway and Municipal Engineering of McGill University, spoke upon the subject of "Roads in the Sky."

Safety on the highways has a definite economic value, declared Professor French. He foresaw the day when many drivers of today would be told they were not fit to drive and if they wanted to travel on the highways it would have to be with a driver who met the qualifications. Statistics show that four per cent of accidents on the highways are due to defects in the vehicle, while five per cent are due to defects in the highway. The remaining 91 per cent are due to defects in the drivers and because of this he said licensing would become more strict and penalties for breaches of the traffic laws more stringent.

When engineers design roads on which it would be easier to drive safely than recklessly they will have accomplished something. Wide shoulders on roads, shallow ditches with a physical division between traffic lanes were desirable features for highways. Islands at intersecting highways force motorists to slow down and reduce accidents. He also advocated the greater use of traffic circles and said he did not know why there were not more of them in Canada. On heavily travelled roads he advocated grade intersections with one road passing above the other and "clover leaf" traffic circles with only right turns to change from one road to another. Provisions for parking off the travelled part of the roads also was necessary.

"It was surprising that in Canada, where efforts are made to attract tourists and where roads travel through beautiful country, the tourists cannot see the country because they have no place to pull up and park," Professor French said. Highway authorities should pay attention to this feature. The problem of bicyclists also was becoming greater and provision for cyclists on highways would be demanded.

Touching on illuminated highways, Professor French spoke of different methods of lighting roads and said the time would come when country roads would be illuminated. Lighting costs about $6,000 a mile, but this was not a high price for the safety which lighting brings by elimination of accidents.

In Canada there were 3,000 deaths and 40,000 to 50,000 accidents from motoring last year, while in the United States 39,000 were killed and there were 400,000 accidents in which there was lost time. The value of a man killed between the ages of 35 and 50 years, on an actuarial basis, Professor French said, had been set at $50,000, the amount necessary to invest in an annuity to provide the income that a man between these ages would earn had he not died. Then there were the medical, hospital, and other charges for accidents to be considered. In view of this, Professor French said the cost of improving highways to promote safety had a definite relationship to the economic value of such work.

W. F. M. Bryce, chairman of the Branch, presided.

Saguenay Branch

C. Miller, A.M.E.I.C., Secretary-Treasurer.
J. W. Ward, A.M.E.I.C., Branch News Editor.

At the regular monthly meeting of the Saguenay Branch held in Arvida on March 25th, 1938, some 30 members and guests were present. M. G. Saunders, A.M.E.I.C., vice-chairman, presided.

The first speaker of the evening, N. D. Paine, A.M.E.I.C., general electrical superintendent, Price Brothers and Company Limited, gave an illustrated address on "Operating Experience with Wood-Pole Transmission Lines in Saguenay District." Mr. Paine pointed out the economy and great adaptability of wood poles in transmission-line structures, discussed preservation practices and inspection routine. The great value of wood as an insulating medium was thoroughly presented, and experience data quoted.

One of the illustrations shown by Mr. Paine was most unusual, being a photograph of white-hot telephone line wires on a power-line telephone circuit carried on the same poles as a transmission line, the conductor of which had been struck by lighting about two miles from a large generating station.

The second speaker was F. L. Lawton, M.E.I.C., chief engineer of Saguenay Power Company, Limited, who spoke on "Operating Experience with Steel-Tower Transmission Lines in the Saguenay District." His address, illustrated with a number of slides, covered general features and insulation levels of three double-circuit steel-tower lines in the Saguenay district. The important part played in subsequent operating troubles by defects overlooked at the time of construction was noted, defects discussed being improper sagging of ground wires, kinking of cables, poorly-made joints or splices in cables, etc.

Failures encountered with certain component members of the steel towers, excellent performance of line insulation, relative freedom from conductor fatigue troubles, remedial measures available for vibration difficulties, data on sleet storms, etc., were touched on during Mr. Lawton's talk.

Exposure to lightning storms and operating records were analyzed. Lightning was shown to be the only important cause of service interruptions where good design, good construction practice and careful inspection were applied.

Following the two papers a most instructive discussion took place.

The regular monthly meeting of the Saguenay Branch of The Engineering Institute of Canada was held on May 4th; G. E. LaMothe, A.M.E.I.C., logging division engineer, Price Bros. and Company Limited, delivered an address on "Wood Preservation," before about 60 members and guests.

Wood Preservation

Mr. LaMothe said it was his intention to discuss wood preservation from the point of view of the engineer in Eastern Canada who often uses wood for minor construction where treated lumber is too expensive or in places where transportation is difficult or where it is economically prohibitive to employ pressure treated lumber.

Decay results from an organic process caused by low forms of plant life called fungi—whether the rot be wet or dry. Damage done by insects is not of any magnitude in the Saguenay district. Unseasoned sapwood contains food for fungi whilst the heartwood of many trees holds gum and other substances toxic in nature. Growth of fungi is dependent on the moisture content of the wood the limits between which life exists, being 25 to 150 per cent moisture by weight. Fungi thrive at temperatures between 75 deg. and 90 deg. F., are dormant below 40 deg. F. but cannot be frozen out. Moist heat above 100 deg. F. will kill them and this method of sterilization is sometimes used in completed structures. Air is required for fungus life.

Decay may be combatted by proper seasoning which will reduce moisture content to the safe figure of 12 to 15 per cent whereas green lumber contains 35 to 150 per cent. The use of wood where saturation is continuous or away from air removes the possibility of decay. Design of joints to shed moisture, use of a preservative coating where two surfaces meet, provision for air circulation and protection from the elements are also effective. Where timber roofs are used on heated buildings condensation should be guarded against.

Tree form timber is generally cut in summer. It should be thoroughly barked as this part is impervious to moisture, and, if possible should be skidded into well aired covered piles until hauling season. Cutting and hauling in winter and barking in spring followed by two years seasoning in the yards is the best method for this size timber but is costly.

Preservatives are even detrimental if applied to green lumber but are beneficial when used on seasoned wood. They consist chiefly of coal tar derivatives or water borne salts. The former are not fireproof while the latter are non-inflammable. Points containing hygroscopics help fungus growth due to their moisture attraction. Paint protects against weathering and changes in moisture content with consequent volume changes but is not a preservative. Aluminum paint is more effective as a moisture stop than ordinary paints or varnishes. A lime whitewash is fire retardant and appears to be toxic to fungi.

Of the Eastern Canadian trees within his experience the topic qualities of the heartwood contents decrease in the following order: cedar, pine, jackpine, yellow and black spruce, balsam and common white spruce. The sapwood of these trees is in about the same order for its resistance to fungi. Cedar is an excellent timber for sills and posts though pressure treated wood competition has reduced its popularity. Pressure treatment is the only really reliable method of preservation and should it become economically feasible in the Saguenay district would render many hardwoods useful that are at present weeds.

After this meeting two talkies, "Structural Shapes" and "Golden Gate Bridge," were shown through the courtesy of the Bethlehem Steel Export Corporation.

A meeting of the executive of the Saguenay Branch was held immediately after the general meeting of May 4th. The following members were present:—F. L. Lawton, M.E.I.C., chairman, M. G. Saunders, A.M.E.I.C., vice-chairman, J. S. Fisher, M.E.I.C., A. B. Sinclair, A.M.E.I.C., R. Rimmer, A.M.E.I.C., J. F. Layne, A.M.E.I.C., G. E. LaMothe, A.M.E.I.C., A. C. Johnston, A.M.E.I.C., Charles Miller, A.M.E.I.C., secretary-treasurer.

The following applications were recommended for admission:—

Mr. Omer Chaput as Junior, moved by Mr. Fisher and seconded by Mr. Layne.

Mr. Walter Dow as Junior, moved by Mr. Johnston and seconded by Mr. Rimmer.

The following applications were recommended for transfer:—

Mr. K. A. Booth, Student to Junior, moved by Mr. Johnston and seconded by Mr. Saunders.

Mr. W. P. LeBoutilier, Junior to Associate, moved by Mr. Layne and seconded by Mr. Sinclair.

Mr. Fisher moved and Mr. Johnston seconded the motion that the Saguenay Branch recommend that Julian C. Smith, M.E.I.C., be awarded the Sir John Kennedy Medal for 1938 and that the Secretary advise the St. Maurice Valley Branch accordingly.

Subjects for the Past President's prizes were then discussed. Mr. Saunders moved and Mr. Fisher seconded the motion that the following subjects be submitted.

(1) Use of Canadian Woods in Engineering Structures.
(2) Lack of Engineering Control in Public Work Expenditure.

The Secretary read a letter from the District Vice-President, Mr. Keay, requesting that the Branch Executive appoint members to the Papers Committee. Mr. Layne moved and Mr. LaMothe seconded the motion that the Chairman and the Secretary be appointed members.

The following members were appointed to the Nominating Committee:—

N. McCaghey, A.M.E.I.C., moved by Mr. Layne and seconded by Mr. Sinclair; R. Belanger, A.M.E.I.C., by Mr. LaMothe and Mr. Fisher.

The plans for the annual dinner were next discussed. Moved by Mr. Saunders and seconded by Mr. Layne that a sub-committee of Messrs. Fisher, Rimmer and LaMothe be appointed to investigate the arrangements at Port Alfred.

At a meeting of the Saguenay Branch in Arvida on May 13th, 1938, some 40 members and guests had the pleasure of hearing Dipl.-Eng. A. Leuthold, of Brown-Boveri Company, Baden, Switzerland, give a very interesting illustrated address on:

LATEST APPLICATION OF GRID CONTROL MUTATORS

Mr. Leuthold referred briefly to the origin of the term "mutator" for what we more commonly call "mercury-arc rectifier," and touched on the mutator plant just completed for the Aluminum Company of Canada Limited, at Arvida, Que., where there are 18 high-current mutators with complete static grid control of latest design. This plant constitutes one of the world's largest.

The mutator is an electronic valve, the arc of which burns from the anodes to the cathode in a partial vacuum containing mercury vapour. A fine mesh metal or carbon screen, known as the grid, is placed between each anode and the cathode. Control of anode firing is obtained by applying a potential to grids so that the polarity can be altered as desired. If a negative charge is applied to the grids, no anode current can flow from the anode to the cathode, even if the anode is at high positive potential. As soon as the grid of an anode is positively charged, the anode to the cathode, provided, of course, that the anode is still at positive potential.

By means of oscillograms, Mr. Leuthold demonstrated how shifting the ignition or firing point of the anodes permitted operation of the mutator for rectification with d.c. output or inversion with a.c. output. The limit to voltage regulation by means of grid control was shown to be the permissible power factor in the a.c. supply lines and smoothness of the d.c. voltage.

An additional very important function of the controlled grids is the suppression of backfires in mutators and clearing of short circuits on the d.c. side. A quick-acting grid relay is operated from a current transformer on the mutator transformer primary side, and cuts off the periodic positive charge to the grid as soon as a backfire in the mutator or a short-circuit on the d.c. side occurs. By leaving a negative charge continually on the grids a negative space charge is produced which acts as a brake upon the electrons and prevents the arc from being ignited even during the positive half-wave. The anode which is just firing at this moment extinguishes at the end of its respective half-wave and cannot strike again. In this manner the heaviest short-circuit may be interrupted within one cycle.

Controlled grids make possible the use of mutators for conversion of direct current into three-phase a.c. This development is utilized by the South African Railways at Van Reenen and Colworth substations where mutators for recuperation by regenerative braking have proved entirely satisfactory. The line served has grades of 3 per cent in places.

Another application is the conversion of three-phase current at 50 cycles into single-phase current at $16\frac{2}{3}$ cycles, for single-phase railway systems. The three-phase single-phase mutator loads the three-phase power supply system symmetrically. An adjustable amount of power can be exchanged between the two networks independently of variations in the frequency ratio and without distortion of the voltage curves in either network.

The speaker mentioned the possibility of using grid-controlled mutators in connection with commutatorless d.c. and single-phase motors, for speed regulation and, finally, the use of single-pole grid-controlled mutators as high-voltage direct-current breakers or switches, with a tripping time of 1/1000 to 2/1000 of a second.

In discussing d.c. high-voltage power transmission, Mr. Leuthold noted a mutator has been developed with an output of 2,000 kw. at 50,000 volts d.c.

A most interesting and instructive discussion was brought to a close by A. B. Sinclair, A.M.E.I.C., in expressing the thanks of the meeting.

Saskatchewan Branch

J. J. White, M.E.I.C., Secretary-Treasurer.

The last meeting of the season was held on April 22nd, 1938, under the joint auspices of the Saskatchewan Branch of The Engineering Institute of Canada, the Association of Professional Engineers of Saskatchewan and the Saskatchewan Section of the American Institute of Electrical Engineers. It was held in the King's hotel, Regina, in the form of a dinner meeting.

R. W. Jickling, A.M.E.I.C., the new President of the Saskatchewan Section of the American Institute of Electrical Engineers, was in the chair and the attendance was good for an April meeting, namely seventy.

The speaker, L. M. Howe, M.Sc., District Superintendent of the Saskatchewan Power Commission at Saskatoon, delivered a very unusual and instructive address on "Photographic Registration of Lightning Discharges." The subject matter had been prepared by the speaker from actual experiments under his personal supervision, he had developed his own equipment which was set up for inspection, and he explained in both technical and non-technical language the operation of the equipment and how it photographically recorded the various types of lightning discharges.

Following the technical paper by Mr. Howe the audience viewed some excellent coloured moving pictures of travel through the British Isles and British Columbia. These views were exceedingly well edited by their producer, Professor A. L. C. Atkinson, of the College of Engineering, University of Saskatchewan, Saskatoon. Although the films were designed to be of general interest rather than of special interest to engineers they were greatly enjoyed by the large audience.

During the winter months the executive of the Saskatchewan Branch appointed a committee with Professor R. A. Spencer, M.E.I.C., as Chairman and Messrs. Young, McCannel and Lovell, to prepare an agreement that might be negotiated with the Professional Association for some form of local co-operation. The agreement is now in draft form having been tentatively approved by Headquarters.

In a recent meeting the joint executives of the Saskatchewan Branch of The Engineering Institute of Canada and the Association of Professional Engineers of Saskatchewan gave the draft some further study and with the minimum of amendments approved of it. The draft will now be forwarded to Headquarters for Council approval.

The joint executives were rather proud of the draft agreement and thought that through the columns of The Journal appreciation should be extended to Mr. Spencer and all the members of his committee.

The Benjamin Franklin Memorial

On May 19th, the Franklin Institute of the State of Pennsylvania held dedicatory exercises for the unveiling of a new memorial to that remarkable man Benjamin Franklin. The ceremony occupied three days of stately ceremonies, including the unveiling of the heroic Fraser statue of Benjamin Franklin, lectures on pure and applied science, a two million dollar philatelic exhibition, military and naval displays, and exhibits contrasting the science of Franklin's time with that of to-day. The Journal is pleased to be able to give herewith a sketch of the events, which has been written for us by Dr. T. Kennard Thomson, M.E.I.C., the official representative of The Institute on that occasion.

"It was a great privilege to be the official representative of The Engineering Institute of Canada at the very interesting and impressive Dedication of the Benjamin Franklin Memorial of the Franklin Institute, at Philadelphia on May 19th, 20th and 21st, 1938.

The Government opened a temporary post office in the Franklin Institute and issued for the first time the new Benjamin Franklin half cent stamp.

May 19th—Roll call of the official representatives, over two hundred from all over the world. They were called in chronological order—some dating back over eight hundred years. When waiting to hear 'Our Institute' called I was wondering whether they would use the date of the E.I.C. or that of the Canadian Society of Civil Engineers, and was therefore glad to hear The Institute and my name called as of 1887.

General Charles H. Mitchell responded for the University of Toronto. It is always pleasant to see that University take rank with the first group in age of the universities of this continent.

The American Society of Civil Engineers was represented by Benjamin Franklin of Philadelphia, a consulting engineer and a direct descendant of the original Benjamin Franklin.

During the afternoon the huge and magnificent statue of Benjamin Franklin, by James Earle Fraser, was unveiled in one of the impressive halls of the building.

On Thursday evening the Poor Richard Dinner was held in Franklin Hall with Hon. Daniel C. Roper, Minister of Commerce, as chief guest, making an excellent speech.

On Friday and Saturday, a series of very interesting lectures were given. All were well delivered and on schedule time.

On Friday we were lunched by the Institute; heard the French Ambassador gracefully confer a Medal on the President of the Institute. From four to six o'clock Count Rene Moynel de Saint Quentin, the French Ambassador, gave us a very fine reception and tea at The Barclay, where we met many old friends and made new ones.

Friday evening—Awards of medals by the Franklin Institute and the conferring of degrees by the University of Pennsylvania (University was founded by Franklin). We all marched in wearing our academic gowns and hoods.

The final event was the Dedication Dinner held at Hotel Bellevue-Stratford, with former President Hon. Herbert Clark Hoover as guest of honour. He made an exceptionally interesting speech.

I wish space permitted a description of the magnificent new building and its contents which would require several weeks to carefully examine.

The Franklin Institute was founded in 1824 and is the oldest in the U.S.A. devoted to mechanics, arts and applied science.

Benjamin Franklin (1706-1794) left school to work for his father when he was ten years old. Two years later he was apprenticed to one of his brothers who paid him no wages but paid for his board. Young Benjamin, one of seventeen children and the youngest son of the youngest son for five generations, suggested that his brother give him in cash half the amount that he was paying for his board. This being done, he divided it into two parts, one-half of which he used to buy books. Small wonder he made a fortune, was the best educated, broadest and most inventive minded man of his time, if not of all time. He founded the *Montreal Gazette*; guaranteed the debts of the British Army under General Braddock, which was a great financial strain on him. Franklin probably saved Canada for the British Empire. It would take many books to cover his career, as a "Master of all Trades," he was a printer, author, patriot, diplomat, logician, resourceful in every sense, lucid in expression, past master of reasoning, statesman, scientist, humanitarian, philosopher and lucid debater. Never egotistical, but a Democrat in spite of all honours.

His sterling honesty and thrift are well known. In 1740 he founded the University of Pennsylvania, and in 1787 gave the land and laid the cornerstone for the Franklin and Marshall College, Lancaster, Pa.

The first letter postmarked in the Colonies was addressed to Col. George Washington, c/o Benj. Franklin, Phila., and delivered to Washington by the Weekly Post Rider Service established by Benjamin Franklin.

Franklin was deeply interested in and wrote clearly on aeronautics, agriculture, silkworms, astronomy, botany, chemistry, education, fire protection, geology, hydrostatics, hygiene, mathematics, medicine, lead poisoning, the Gulf Stream, tides, optics, musical tones, infection from dead bodies, meteorology, origin of the north east storms, natural history, navigation and magnetism of metals. He invented a flexible catheter to show circulation of blood, bifocal spectacles, watertight bulkheads for ships, the first smokeless fire place, the first wood burning stove, a new stove for burning pit coal, a washing mangle, a clock with only three wheels which gave hours, minutes and seconds, a coping machine, and devised a hydrometer for testing moisture in air.

His common sense seemed to guide him in matters which were far in advance of his times—for instance, he anticipated the 'germ theory' as causing colds, etc.

And still the wonder grew that one head (certainly not small) could carry all he knew."

Yours respectfully,

T. Kennard Thomson.

Changes at Manitoba

The University of Manitoba announces an interesting departure in its engineering curriculum. A course leading to a degree in Geological Engineering will be offered, thereby affording the necessary training for students who wish to enter the field of geological exploration and preliminary work such as surveying and mapping of geological formations and the proving of mining properties.

The first two years will vary but slightly from the existing engineering courses, but the third and fourth years will be taken up largely with geology and chemistry, and some general training in mining engineering, ore dressing, assaying, strength of material and structural design.

New and Revised C.E.S.A. Specifications

The Canadian Engineering Standards Association has issued the following new and revised Standard Specifications:

C 22.2—No. 48—1938

Construction and Test of Non-Metallic Sheathed Cable. Price $0.50

G30, G31, G32, G45 and G46—1938

Billet-Steel Concrete Reinforcing Bars; Rail-Steel Concrete Reinforcing Bars; Cold-Drawn Steel Wire for Concrete Reinforcement; Fabricated Steel Bar or Rod Mats for Concrete Reinforcement; Welded Steel Wire Fabric for Concrete Reinforcement. Price $0.75.

International Management Congress

On September 19th to 23rd, the Seventh Congress will be held in Washington, D.C. It is being held under the auspices of the International Committee of Scientific Management, an organization which represents seventeen countries, and which in the past twelve years has held Congresses in many European capitals. The President of the Committee is The Rt. Hon. Viscount Leverhulme, of Liverpool. It is expected that members of The Institute who are particularly interested in management will be in attendance. Further details of the programme and costs may be obtained from The Institute.

Meetings of Societies

The American Mining Congress, Western Division, will hold its annual Metal Mining Convention and Exposition at the Ambassador Hotel, Los Angeles, Calif., October 24th to 27th, 1938.

American Mathematical Society will hold their forty-fourth Summer Meeting and Semicentennial Celebration at Columbia University, New York City, September 6th to 9th, 1938.

Erratum

In the May Journal, The Combustion of Pulverized Coal by Henry Kreisinger, page 229, line 26, change 200 deg. to 2,000 deg.

A.S.M.E. Nominations

Word has been received of the nominations for Officers of The American Society of Mechanical Engineers for 1939 which were announced at a recent meeting of the Nominating Committee held at St. Louis, Mo., during the Semi-Annual Meeting. Election will be held by letter ballot of the entire membership closing on September 27th., 1938.

The nominees as presented by the Regular Nominating Committee of the Society are:

President............ (To serve 1 year)	Alexander G. Christie, Professor of Mechanical Engineering, Johns Hopkins University, Baltimore, Md.
Vice-Presidents...... (To serve 1 year)	Henry H. Snelling, Senior Member, Snelling & Hendricks, Washington, D.C.
(To serve 2 years)	W. Lyle Dudley, Vice-President, Charge of Design and Sales, Western Blower Company, Seattle, Wash.
	James W. Parker, Vice-President and Chief Engineer, Detroit Edison Company, Detroit, Mich.
	Alfred Iddles, Application Engineer, Babcock & Wilcox Company, New York, N.Y.
Managers.......... (To serve 3 years)	Clarke Freeman, Vice-President, Charge Fire Prevention Engrg. and Underwriting, Mfrs. Mutual Fire Ins. Company, Providence, R.I.
	Willis R. Woolrich, Dean of Engineering, University of Texas, Austin, Texas.
	William H. Winterrowd, Vice-Chairman, Franklin Railway Supply Company, Chicago, Ill.

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted after a lapse of one month, upon request.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Situation Vacant

YOUNG CHEMICAL ENGINEER. A vacancy will shortly exist in a manufacturing plant in Eastern Canada. Applications are invited from young chemical engineers having a university degree and about four years practical experience in industry. Applicants should give full particulars of training and experience to date as well as personal particulars. No references need be sent in first instance. Apply to Box No. 1774-V.

Situations Wanted

ENGINEER, A.M.E.I.C., Combustion specialist heat balance. Steam, Mechanical. Refrigeration. Office routine. Correspondence. Plant layout. Apply to Box No. 5-W.

ELECTRICAL ENGINEER, JR.E.I.C., B.SC.; age 31; at present employed, desires change in location. Experience includes; three summers experience in power conduit construction; two years in telephone engineering; four years experience in radio, both development engineering and production; two and one half years in a paper mill on electrical maintenance, with a short time in the cost accounting and draughting departments. Would be interested primarily in electrical maintenance. Apply to Box 12-W.

PAPER MILL ENGINEER: B.A., B.A.SC. Married. Age 34. A.M.E.I.C. Ten years experience in paper mill costs, maintenance, design and construction. Now employed as cost engineer in Southern States. Hard worker with excellent references. Available immediately. Apply to Box No. 150-W.

SALES ENGINEER REPRESENTATIVE. Mechanical graduate with fifteen years experience in Eastern Canada in sales and service of mechanical equipment; full details upon request to Box No. 161-W.

MECHANICAL ENGINEER, JR.E.I.C., with thorough training in England and wide experience for past eight and a half years in Canada, is seeking a permanent position as mechanical engineer in an industrial plant. Has had varied experience in mechanical engineering, heating, ventilating and power plant equipment. Excellent references. Apply to Box No. 270-W.

PAPER MILL ENGINEER. If you are willing to pay around $5,000 per year for the services of an engineer, age 36, with twelve years experience in paper mill design, construction and operation, apply to Box No. 482-W.

CIVIL ENGINEER, B.A.SC., A.M.E.I.C. Married. Experienced in engineering and architechtural design and in supervision, office management, etc., wants to round out experience in the contracting field. Ten years experience since graduation. Present location Toronto. Apply to Box No. 576-W.

ELECTRICAL ENGINEER, B.SC. E.E., Age 39. Married. Seven years experience in operation, maintenance and construction of hydro-electric plants, and sub-stations. Five years maintenance and installation of pulp and paper mill electric equipment. Reliable and sober, with ability to handle men. Best references. Any location, at once. Apply to Box No. 636-W.

Situations Wanted

ELECTRICAL ENGINEER, B.SC. '28. Two years student apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660-W.

ELECTRICAL AND CIVIL ENGINEER, B.SC. Elec. '29, B.SC. Civil '33. JR.E.I.C. Age 32. Experience includes four months with Can. Gen. Elec. Co., approximately three years in engineering office of large electrical manufacturing company in Montreal, the last six months of which were spent as commercial engineer, also experience in surveying and highway work. Year and a half employed in electrical repair. Best of references. Apply to Box No. 693-W.

CIVIL ENGINEER, B.A.SC. (Toronto '27), age 34, married. Five years railway and construction work as building inspector and instrumentman. Level engineer and on construction of a long timber flume for a pulp and paper mill. Field engineer for a sulphite company, in charge of the following mill buildings, acid, digester, blow pit, barker room, chip storage and acid towers. Available immediately. Apply to Box No. 714-W

MECHANICAL ENGINEER, JR.E.I.C. Technical Graduate. Bilingual. Married. Experience includes five years with firm of consulting engineers, design of steam boiler plants, mechanical equipment of buildings, heating, ventilating, air conditioning, plumbing, writing specifications, etc. Six years with large company on sales and design of power plant, steam specialties and heating equipment. Available on short notice. Apply to Box No. 850-W.

CONSTRUCTION ENGINEER, Grad. Toronto '07. Experience as resident engineer and superintendent on railroad, municipal, hydro-electric and industrial construction. Intimate with organizing, layout, survey, estimates and costs. Available immediately. Apply to Box No. 886-O.

CIVIL ENGINEER, B.SC. '29, JR.E.I.C., R.P.E.M. Age 31. Married. Experience includes railway and highway surveys and construction, land and mineral claim surveys, 4 years draughting, structural and hydraulic design, preparation of plans and estimates for hydro-electric development, sewage disposal project, water treatment plant, subway construction, buildings, etc. Experienced in reinforced concrete design including statically indeterminate frames. Also capable of preparing designs in steel and timber Desire permanent employment, preferably in structural design. Available immediately. Apply to Box No. 1023-W.

ELECTRICAL ENGINEER, B.SC. '29, age 30. Single. Eight and a half years experience on maintenance, on construction, floorman and operator on hydro-electric system. Desires construction, service, sales or research work. Any location. Excellent references. Apply to Box No. 1062-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

Situations Wanted

TECHNICALLY TRAINED EXECUTIVE. General experience administrative, organization and management in business and industrial fields, including; business, plant, property and estate management; plant maintenance, modernization, production and personnel; economic studies, company reorganizations and amalgamations, valuations; railroad, highway, hydro, pulp, newsprint, housing, industrial surveys, investigations and construction; B.Sc. degree in engineering, age 49, married, Canadian. Apply to Box No. 1175-W.

CHEMICAL ENGINEER, grad. McGill '34, experienced in meter repairs, control work; and also chemical laboratory experience. Apply to Box No. 1222-W.

CIVIL ENGINEER, B.A.SC. (Toronto '33), S.E.I.C., age 27. Married. Five years experience includes highway surveys, bituminous and concrete paving, steel and reinforced concrete building construction, instrument work, draughting, cost accounting and estimating and some experience as foreman. Available immediately. Apply to Box No. 1265-W.

FIELD ENGINEER AND DRAUGHTSMAN, A.M.E.I.C. Age 36. Married. Fifteen years experience in civil engineering, general draughting and instrument work. Experience covers office and layout work on construction of sewers, water mains, gas mains, (6" to 30" dia.) and transmission line structures; topographic and stadia surveys. Draughting covers general civil, reinforced concrete and steel design, mechanical detailing and arrangements, and mapping. Present location Montreal, but willing to locate anywhere. Available at once. Apply to Box No. 1326-W.

ENGINEER SUPERINTENDENT, A.M.E.I.C., R.P.E., Que. and Atla. Age 47. Twenty years experience as engineer and superintendent in charge of hydro-electric, industrial, railroad, and irrigation construction. Specialized in rock excavation and suction dredging. Intimate knowledge of costs, estimating and organizing. Available immediately. Apply to Box No. 1411-W.

CIVIL ENGINEER, graduate 1927, age 34 years, desires position as town engineer. Eight years municipal experience. Location immaterial. Apply to Box No. 1628-W.

CIVIL AND ELECTRICAL ENGINEER, JR.E.I.C. (Univ of Man.). Married. Age 25. Good draughtsman. Four months draughting, one year instrumentman on highway location and construction, inspection and miscellaneous surveying and estimating. Six months as field engineer on pulp and paper mill construction. Prefer electrical or structural design. Available at once. Apply to Box No. 1633-W.

ELECTRICAL ENGINEER, B.SC. E.E. (Univ. of Man. '37). Age 24. Single. Experience in highway construction as inspector. Also experience in sales work and petroleum refining. Available on short notice. Apply to Box No. 1703-W.

CIVIL ENGINEER, B.SC. in C.E. '34. S.E.I.C. Age 27. Five years experience, including harbour construction, highway paving, one and a half years paper mill construction, instrument work, draughting, estimating, interested in design. Available on short notice. Apply to Box No. 1737-W.

CIVIL ENGINEER, B.A.SC. '33. O.L.S. Age 27. Married. One year and a half in charge of power plant construction. Four summers on land surveys and one summer on mine survey work. Also experience in draughting, electrical wiring, and highway engineering. Apply to Box No. 1757-W.

ELECTRICAL ENGINEER, B.E. in E.E., N.S. Tech. Coll. Single. Age 25. Experience in sales, electrical installation, and construction work. Available immediately. Will go anywhere. Apply to Box No. 1758-W.

CHEMICAL ENGINEER, graduate, Toronto '31. Seven years experience in paper mill, meter maintenance, control work and chemical laboratory. Speaking French and English. Location immaterial. Available at once. Apply to Box No. 1768-W.

CIVIL ENGINEER, B.A.SC., JR.E.I.C. (Toronto '35). Age 24. Experience in structural design, construction and surveying, including one year in South America. Details on request. Apply to Box No. 1784-W.

Preliminary Notice

of Applications for Admission and for Transfer

June 23rd, 1938.

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in August 1938.

L. Austin Wright, General Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

BARRETT—MICHAEL JOSEPH, of Cheticamp, C.B., N.S., Born at East Saint John, N.B., March 11th, 1913; Educ., B.Eng. (Mech.), N.S. Tech. Coll., 1935; 1931-34 (summers), steelworker, Saint John Dry Dock; 1935-37, Diesel engine installn. and repair, Canadian Fairbanks Morse Co. Ltd., Saint John, N.B.; July 1937 to date, asst. mech. supt., National Gypsum Company, Cheticamp, Cape Breton, N.S.

THE ENGINEERING JOURNAL

VOLUME XXI, No. 8 AUGUST, 1938

Building Invisible Edifices

H. I. Knowles,

Chief Chemist, Atlantic Sugar Refineries, Saint John, N.B.

Presented before the Saint John Branch of The Engineering Institute of Canada on March 24th, 1938.

SUMMARY.—Here is chemistry written for the multitude. Beyond a doubt the average citizen has no idea of how the ingenuity of the chemist has created so many of the commodities that are now in every day use. Carbon, oxygen, hydrogen and nitrogen are the four principal elements that contribute to the existence of approximately 300,000 different organic compounds. The author makes a complex subject both interesting and simple.

During the early part of the 19th century, chemists believed that the products of animal and vegetable life could be created only within the body of a living organism. For this reason, these products were called organic substances. In due time, chemists began to investigate organic compounds and in the year 1828 the realm of science was startled by Wohler's discovery that the products of living organisms could be made in the chemical laboratory. Chemistry took on a new meaning and a new life. No longer was it regarded as only a science of analysis, destructive in its application. It was realized for the first time that chemistry could be constructive, that molecules could be constructed as well as torn apart. This was the beginning of creative or synthetic chemistry.

One hundred years have passed. Explorers in the vast and mysterious world of organic molecules have so far identified approximately 300,000 different organic compounds. The majority of these have yet to be found in nature. They are the children of creative chemistry. At one time, all of them were laboratory curiosities. Now many are important products of industry, entering into articles of commerce and adding a touch of their own complexity to the complexity of modern life.

Three hundred thousand compounds means 300,000 different molecules. Yet this vast army of molecules is fashioned from less than a dozen different kinds of atoms or elements. Most of them are made from only four elements, carbon, oxygen, hydrogen and nitrogen. Thousands contain only carbon and hydrogen. Many organic substances have the same chemical composition. There are at least sixty-six compounds of different physical properties with eight atoms of carbon, twelve atoms of hydrogen and four atoms of oxygen in each molecule. Substances so different in character as sugar, fats, alcohol and vegetable oils are composed of the same three elements, carbon, hydrogen and oxygen. These and similar observations so puzzled the early organic chemists that they were forced to go into a huddle and work out schemes to conquer the invisible empire of organic molecules. It was realized that a chemical analysis of an organic compound gave only a bill of materials; and that to distinguish and understand organic compounds an architectural plan of the molecule was required. Consequently, some amazing but workable theories regarding molecular structure were evolved. Chemists became molecular architects; they drew up the plans of molecules, making alterations and additions, like an architect working on the plans of a mansion. To carry out these plans there was developed a remarkable technique of molecular surgery. Molecules underwent operations to have certain atoms removed or others added. Then there was introduced into the molecular world the promoter's art of bringing about mergers. Two or more molecules of the same kind were caused to combine forming a larger, more useful molecule. Even molecules differing in kind were induced to join forces and make a new molecule of different design. By these and other equally amazing feats, the chemist has found out how organic molecules are constructed; how to build new ones; how atoms gang together forming definite groups which function like single atoms; and how these groups impart characteristic properties to the molecule.

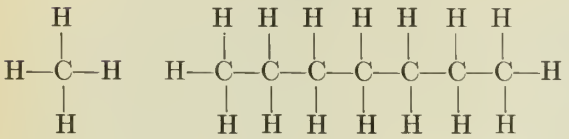
All truly organic compounds contain carbon. Indeed, carbon is the key element. Atoms of carbon constitute the skeleton or framework of organic molecules. The carbon atoms are linked together and to them are attached other atoms; the carbon atoms carry the structural load. For these reasons, carbon, either free or in combination with other elements, provides the basic raw material for the industrial synthesis of organic substances. The sources of carbon are manifold. The diamond is pure carbon but as a raw material it has certain obvious disadvantages. For practical sources there are petroleum oils, coal and vegetable matter.

An oil well houses the members of the petroleum family, compounds of carbon and hydrogen. This important family boasts of two branches, the paraffins and the naphthenes. The baby of the paraffins is methane, a gas, composed of one carbon atom decorated with four hydrogen atoms. The other paraffins are simply chains of carbon atoms with attached hydrogen atoms. As the chain is lengthened so the molecules change from gases to light oils like gasoline, heavier oils like lubricating oils and finally solids like paraffin wax. The naphthenes are ring compounds; that is, the carbon atoms are linked together in the form of a closed chain or ring. The smallest is triangular in shape having three carbon atoms, the next largest is a four sided figure and so on depending on the number of carbon atoms. The California naphthenes are the most elaborate in structure, having an endless variety of side chain attachments, highly fantastic and decorative, quite in keeping with the atmosphere of Hollywood. Naphthenes have associated with them an asphaltic substance whereas the paraffins have wax. Crude oil, then, is a complicated, indefinite mixture of complex molecules. This complexity causes the oil refiner many a headache and brings despair to the purchaser of petroleum products, especially if he is a stickler for specifications.

PLAN VIEW OF SOME HYDROCARBON MOLECULES
STRUCTURAL FORMULAE SHOWING IMAGINARY BONDS

C = Carbon atom H = Hydrogen atom

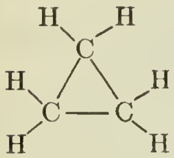
Paraffin Molecules



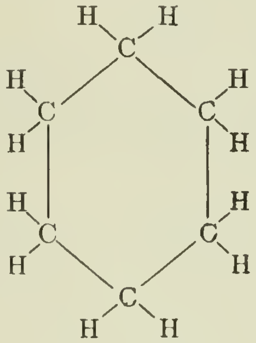
$C_{35}H_{72}$

Methane CH_4 (Gas) — Heptane C_7H_{16} (A gasoline molecule that tends to "knock") — Pentatriacontane (A solid that melts at 167 deg. F)

Simple Naphthene Molecules



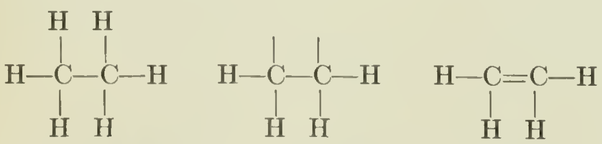
Trimethylene



Hexamethylene

Petroleum molecules do not lend themselves readily to changes in structure because they are saturated; that is, the carbon atoms are carrying a full load of other atoms; in this case hydrogen. For this reason the synthetic chemist has been inclined to let them alone. For the same reason the petroleum chemist has been inclined "to treat 'em rough." He scours them with sulphuric acid to remove gums and other molecular trash, then washes them with water and alkali. Being forced to produce more and more gasoline, he conceived the idea of breaking down the large less useful molecules and recovering from the wreckage smaller molecules coming within the group called gasoline. In this so-called cracking process, the heavier oil fractions are heated to about 1,000 deg. F. under a pressure of some 330 lb. per sq. in. This is quite a strain on molecular structure and the big fellows are so badly cracked-up that not only is gasoline produced but gases as well; and many of the molecules have hydrogen atoms knocked out of them. The molecules on losing hydrogen become another type. They are unsaturated and strange to relate they possess anti-knock properties. So cracked gasoline may be added to regular-run gasoline to impart anti-knock properties. Some of these unsaturated anti-knock molecules are present in gasoline as it comes from the refiner's still but they are removed by the acid wash. Therefore, the petroleum chemist has begun to mend his ways and use less drastic methods in refining. Today the trend is toward the production of gasoline with anti-knock properties, obviating the addition of anti-knock compounds like tetraethyl lead.

HOW ETHANE A "SATURATED" MOLECULE LOSES HYDROGEN ATOMS AND BECOMES ETHYLENE, AN "UNSATURATED" MOLECULE



Ethane C_2H_6 (Gas) — Ethylene C_2H_4 (Gas)

The synthetic chemist is always on the look-out for molecules showing a "To let" sign; for he known there is room for other atoms in the structure. One of the gases of this type, produced in large quantities in the cracking of oils, is ethylene. From ethylene the chemist has created a variety of useful organic compounds, prominent among which is ethylene glycol. Ethylene glycol has some of the properties of glycerine. It is sold as an anti-freeze and when treated with nitric acid ethylene glycol dinitrate is formed. As an explosive this compound is as effective as nitro-glycerine and is used in the manufacture of low freezing dynamite.

Coal is the most important raw material for the industrial synthesis of organic substances. Coal contains about 75 per cent of carbon in one form or another. From coal, limestone, air and water thousands of synthetic substances can be made. If you are an investor in the carbide industry you receive dividends, if you receive them at all, because of two simple chemical reactions. The first occurs when coal and limestone are heated together in the electric furnace with the formation of calcium carbide, a compound of the metal calcium and the element carbon. The second reaction takes place when carbide is dropped in water; acetylene gas is generated and hydrated lime is formed. In acetylene, we have an organic molecule composed of two carbon atoms and two of hydrogen. More important is the fact that the atoms of carbon are loaded to only one-third capacity; therefore, they are capable of carrying other atoms.

FORMATION OF ACETYLENE

$$CaC_2 + H_2O = CaO + HC{\equiv}CH$$

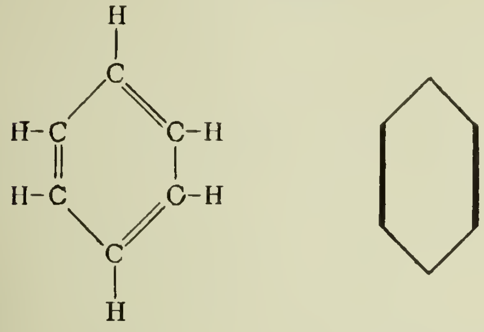
Calcium Carbide — Water — Lime — Acetylene

Note the triple bonds in the acetylene molecule.

Acetylene is the starting point for the creation of a multitude of important synthetic substances. There are several roads open to the traveller; the journey is full of amazing molecular changes; and at the end of the journey there is always a surprising product. One may find various alcohols used as solvents in the preparation of articles as quick drying paints and lacquers, such as Duco. One meets acetic acid and its offspring acetic anhydride, both of which are used to make cellulose acetate for photo films and celanese silk. Then there is acetone, an important solvent, used in manufacturing cordite, pyroxylin plastics and lacquers, artificial leather, celanese silk and book covers. One may get a whiff of butyric acid which gives to Limburger cheese its famous aroma; or have a taste of ethyl butyrate, a synthetic pineapple flavour made from ethyl alcohol and butyric acid. Over 20,000 tons of artificial rubber were made in Germany last year from acetylene. Plastics moulded into products ranging from dentures to radio cabinets, organic glass, safety glass, these and hundreds of others may trace their origin to acetylene gas.

Coal is the source of another class of valuable organic compounds. They belong to the benzene or aromatic family. This family inhabits coal tar, a product of the by-product coke oven industry. Benzene is both the baby and the daddy of the family, an unheard of state of affairs. It is the baby because the benzene molecule is the smallest; it is the daddy because all larger members of the family can be made from it. The benzene family is distinguished by a famous ring or closed chain structure that is a delight to the synthetic chemist, for there are offered exceptional opportunities for molecular construction. Other important members of the family are toluene, naphthalene, anthracene, xylene and phenol.

Structural Formula of the Benzene Molecule Also Abbreviated Form or Symbol Commonly Used for Convenience



Benzene Abbreviated Form

By performing two minor operations on the benzene molecule aniline is made. Aniline is the starting point for the synthesis of aniline dyes. Similar operations on the molecules of other members of the family combined with extensive molecular construction result in the creation of other dyes. These and the aniline dyes constitute a chemical rainbow of over 900 different colours, many of which for sheer beauty and permanence excel nature's best.

The essential elements of a dye are: (1) A group of atoms called a chromophore. (2) An organic body containing the chromophore known as a chromogen. (3) A salt-forming group of atoms called auxochromes, as (OH), (NH_2), and (COOH) in which N = nitrogen and O = oxygen atoms.

—N=N—

Chromophore

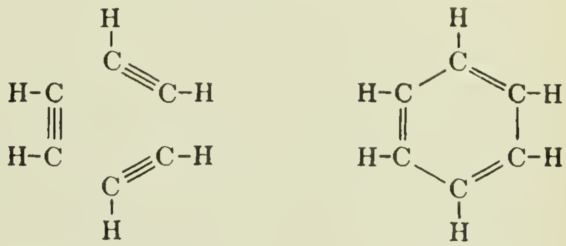
Chromogen
(Containing 2 benzene rings)

Butter Yellow Dye

The  NH_2 section is aniline. Generally, "by increasing the size of the molecule or by increasing the number of chromophores and salt-forming groups, the shade passes successively from yellow to orange, red, violet, blue, green and black."

Toluene is a liquid resembling gasoline. Yet when combined with chlorine, an evil gas, and treated with sodium cyanide, a deadly poison, the result is a wonderful smelling, non-poisonous substance called phenyl ethyl alcohol which is the principal constituent of rose water. When three molecules of nitrogen tetroxide are built into a molecule of toluene, trinitrotoluene or TNT is created. Picric acid, trinitrophenol, made in a similar way from phenol or carbolic acid, is a yellow dye, a remedy for burns and at the same time it is the proper thing to have in high explosive bombs. Phenol or carbolic acid is the source of salicylic acid, a powerful antiseptic, which when combined with poisonous wood alcohol forms methyl salicylate or oil of wintergreen used extensively in flavouring toothpaste, confectionery and so forth. Salicylic acid with a dash of soda water becomes a rheumatism remedy; or if the pain is in the head then salicylic acid is treated with acetic acid, made from acetylene, and Aspirin is made. Phenol, when heated with formaldehyde in the approved manner, forms a resinous liquid which on cooling becomes a solid capable of being moulded into various forms. This compound is known as polymerized oxybenzol methylene glycol anhydride. Some people call it Bakelite. Since the early days of Bakelite, numerous other synthetic resins have been created. Entering into the construction thereof are substances such as naphthalene (familiar to us in the form of moth balls); urea, an animal waste product, which is also produced synthetically; glycerine, derived from animal fats; ethylene glycol and formaldehyde. The final stage in the construction of synthetic resins is called polymerization or condensation, which is another way of saying that two or more molecules of a compound are caused to merge or amalgamate forming a larger, more complicated structure. The molecules which enter into the merger are called structural units and as the size of the molecular edifice is increased by the addition of a structural unit, the resulting resin changes from a liquid to a soft plastic and finally to a hard resinous substance. Synthetic resins may be an amber colour or colourless and as transparent as glass. They may be dyed, made oil-soluble, compounded with other materials, heat treated and moulded. Many find application in the paint and varnish industry, imparting properties not found in natural resins. They have become important as plastics furnishing a variety of articles as bottle caps, radio parts, lamp shades, dentures, safety glass, chemical tanks and piping to mention only a few. The important properties of these resins are resistance to water, acid and alkali; low temperature coefficient; high dielectric value; resistance to mechanical shock; low density; and structural strength. The hardened resins may be cut, threaded and machined.

A Simple Example of Polymerization is the Possible Conversion of Acetylene into Benzene



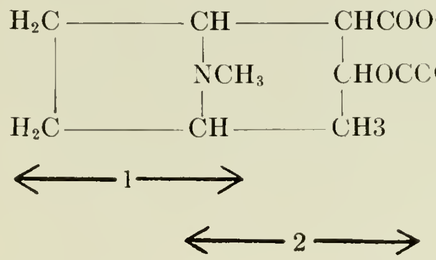
3 molecules of Acetylene polymerize Benzene

Atoms of carbon and hydrogen may be directly united forming hydrocarbons found in crude petroleum. This takes place in the hydrogenation or liquefaction of coal. Powdered coal is mingled with oil and the mixture is heated to 750 deg. F in an atmosphere of hydrogen under a pressure of 2,250 lb. per sq. in. in the presence of a catalyst. A catalyst is a chemical parson which brings about the union of elements or molecules without undergoing any permanent change itself. Catalysts are metals, metallic oxides, salts and organic compounds. They are used extensively in industrial synthesis and are of great importance in this age of synthetics.

Vegetable and fish oils may also be hydrogenated and when stuffed with hydrogen atoms they become fats. The commercial procedure is to suspend finely divided nickel in the oil heated to about 300 deg. F. and blow in hydrogen gas. The oil molecules are unsaturated and as hydrogen atoms enter into the structure the oil is transformed into a solid identical with the animal fats. In this manner edible oils may become lard and fish oils are made into soap.

Most natural substances are not chemically pure. The principal constituent is accompanied by various other substances. Wine is a natural fermentation product. But wine cannot contain more than about 18 per cent. alcohol because when this alcoholic content is reached the yeast gets drunk and quits work. So a man confined to wine or beer has to drink five to ten quarts of water to get one quart of what he is really after. The same is true of natural drugs. But the chemist has helped the situation by determining the active principle of many natural drugs, by devising ways of isolating the chemical in pure form and in many cases by finding a way to make it synthetically. Many synthetic drugs trace their origin to coal tar chemicals. Cocaine is one example. Brilliant researches revealed the structure of the complex cocaine molecule and how it could be made from benzoic acid, derived from coal tar chemicals. Although cocaine is a useful drug, it is extremely toxic and it is habit forming. To overcome these disadvantages, chemists disected the cocaine molecule and determined the groups of atoms which were toxic and those which were necessary to produce anesthesia. With this knowledge they set to work building new molecular structures and created several drugs like novacaine and butyn, both of which have the advantage over cocaine in being much less toxic, more stable in solution and not habit forming.

Cocaine



There are three important parts to the cocaine molecule. The ring group of atoms (indicated by 1) forming the left half is common with several alkaloids, such as nicotine; this part of the molecule is not necessary to produce local anesthesia. The righthand ring (indicated by 2) also occurs in other toxic alkaloids and plays a part in the anesthetic effect. The group —$OCOC_6H_5$ related to benzene, is very important for anesthesia. The righthand half, therefore, is the important one.

Another example is found in Veronal, a valuable sedative or hypnotic. Urea, an animal waste product, which as mentioned before is made synthetically, is a sedative, mild in action but safe because the body can tolerate it. Ethyl or grain alcohol, the principal constituent of whiskey, is also a sedative, as we may have observed, if not experienced, but alcohol is toxic. So the chemist built two ethyl groups of atoms into the urea molecule and made the powerful but not unduly toxic sedative called Veronal. Ethyl alcohol (C_2H_5—OH) is soluble in both water and fats. To the ethyl group C_2H_5— is attributed the property of penetrating the fatty tissues covering the nerves.

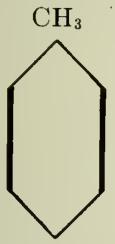
In nature a little perfume is made to go a long way. Twenty-five tons of violets yield only a single ounce of the violet oil which is worth $75 an ounce. It requires about 1½ tons of roses or approximately half a million blossoms to make a pound of rose oil or attar of roses. Musk is the most important single ingredient of a high grade perfume. Natural musk is obtained from certain glands of the musk deer that roams the mountain tops of Tibet. Crude musk is worth about $560 a pound, equivalent to $40,000 a pound for pure musk, if such could be obtained. The natural perfume of the lilac and of the lily-of-the-valley has never been bottled because no satisfactory means of extracting the perfume from these flowers has been found. In view of the high cost of the natural oils derived from flowers and other sources and because it is sometimes impossible to extract them, most of the natural perfumes have their synthetic substitutes. Some of these synthetics are made from coal tar chemicals; often the desired molecule is found in some inexpensive vegetable oil. The isolated molecules usually undergo a reconstruction or a remodelling and are often blended to give the desired imitation of the natural perfume. Oil of citronella, the mosquito's enemy and the fisherman's friend, is the source of the basic odour of synthetic lily-of-the-valley and also of synthetic rose oil. Synthetic violet perfume may be made from oil of lemon grass or from acetylene gas derivatives. What boy would believe that castor oil could furnish anything so delightful as the odour of peaches, the violet leaf odour or a jasmin perfume? From cocoanut oil is made a series of synthetics called aldehydes which are used in the preparation of the best French perfumes of today. A perfume is composed of four odour types: sweet, acid, burnt and what is known as the goat odour. This makes the modern perfume a symphony of odours, good and evil, skilfully blended by an artist from the extracts of leaves, wood bark, grasses, flowers, animal products and syntehtic creations. Synthetic perfumes have made it possible for industry to make inexpensive goods more attractive and to mask a disagreeable odour inherent in a product by incorporating a perfume.

Since time immemorial plants have synthesized chemical compounds and by so doing they have provided animals with food and clothing. The mulberry tree feeds the silkworm and this marvelous creature takes in mulberry leaves and turns out a thread of silk. Man's imitation consumes cellulose, the skeleton of plants, and turns out a thread of rayon, celanese or a sheet of cellophane. Cellulose as cotton or wood pulp is combined with a chemical to make it soluble in some solvent. The solution is forced through the minute openings of a spinneret immersed in an acid bath wherein the liquid thread is solidified. The several solid threads are combined and wound as a single thread on a bobbin. Later the chemical causing solution is removed. In the case of rayon silk the product is essentially the original cellulose, except that cellulose enters the process worth 5c a pound and comes out worth about $1.50 a pound. Cellophane is made in a similar manner using a flat aperture in place of the spinneret and the sheet is impregnated with glycerine; or if it is to be made waterproof a coating of lacquer is applied. Celanese silk is not cellulose but a compound of cellulose and acetic acid or vinegar and is called cellulose acetate.

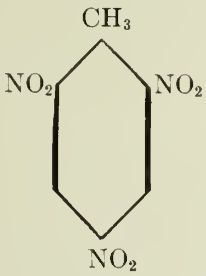
Our ancient ancestors fought each other with cellulose in the form of wooden clubs. Today nitrogen is the important thing; for this tempermental element is the key element of all explosives. The naval engagement off the Falkland Islands during the Great War was a battle over nitrogen. The important source of nitrogen then was the nitrate deposits in Chile and the Germans attempted to cut off the Allies' supply of this all-important war material. By winning the battle the British fleet cleared the nitrate route and saved the Allies' cause. Yet the air contains an exhaustless supply of nitrogen. We breathe in nitrogen only to lose it again, for which reason we are obliged to buy meat, eggs and other protein or nitrogen bearing foods. Free nitrogen costs nothing but it is good for nothing. It is fixed nitrogen that is in demand. Had not German chemists worked out a process for fixing atmospheric nitrogen in preparation for the last war, Germany might have been beaten within a year. Since then the fixation of atmospheric nitrogen has become of considerable commercial importance.

Nitrogen is not inclined to combine with other elements and in certain combinations it is liable to leave the party with explosive violence. This makes the capture of nitrogen from the air a difficult task and requires violent methods. In one process air is passed at a rapid rate through a broad or long electric arc, the temperature of which is about 6000 deg. F. The oxygen and nitrogen in the air combine forming oxides of nitrogen and these may be converted into nitric acid and nitrates. In another process a mixture of nitrogen and hydrogen gases sweep over iron oxide, a catalyst, under a pressure of 4,500 lb. per sq. in. at a temperature of about 900 deg. F. The ammonia produced may be used as such in refrigeration; or by catalytic oxidation converted to nitric acid; or it may be combined with sulphuric acid or phosphoric acid to make fertilizer. In the cyanamide process nitrogen is passed through heated calcium carbide forming calcium cyanamide. This compound finds application in fertilizers; or it may be steamed in an autoclave giving ammonia. Nitrogen fixed by these and other processes, is used in dye manufacture, fertilizers, various commercial chemicals and explosives.

The so-called nitro groups of atoms that put the roar in TNT and change so placid a substance as glycerine into dynamite are oxides of nitrogen derived from nitric acid. The more nitro groups built into the molecule of toluene or cellulose, for example, the more explosive is the compound. Nitrocellulose, used as a military powder, has 10 nitro groups in each cellulose molecule. Nitrocellulose used in preparing pyroxylin lacquers and celluloid contains less nitrogen. In this way the explosive property of nitrated compounds may be more or less regulated.



Toluene
$C_6H_5—CH_3$



Trinitrotoluene (TNT)
$C_6H_2—CH_3—(NO_2)_3$

Note that Toluene is benzene with the CH_3 group replacing the top H atom and that the nitro groups (NO_2) also replace H atoms.

The year 1856 was an important one in the history of applied synthetic chemistry. For it was in that year that William Henry Perkin, then only 18 years of age, discovered the first aniline dye and took steps to put the discovery to practical account. Perkin at the time was an assistant at the Royal College of Science, London, England, and he devoted his spare time to chemical research. The Easter holidays found him engaged on the very ambitious problem of making quinine synthetically from coal-tar chemicals. Each attempt ended dismally; the result was a black tarry mess. Starting again, this time with benzene, he converted it into aniline and oxidized this with bichromate of potash. He noted in the hopeless looking mixture a slimy precipitate which on further examination was found to be soluble in alcohol, giving a beautiful purple solution. Having satisfied himself by tests that the precipitate was a dye with practical possibilities, Perkin decided to give up his position, build a factory and manufacture the dye which he named aniline purple. Fortunately, his father was a contractor. Moreover, Perkin senior had a sublime faith in his son and he contributed the required financial backing. The factory was constructed and this apparently foolhardy enterprise got under way. Getting a laboratory experiment to work on an industrial scale is a difficult task under the most favourable circumstances. In this instance, Perkin and his associates were without industrial experience; they had nothing in the way of precedents to guide them. They were pioneers blazing a trail in new territory. Perkin had to design and test every piece of equipment. Even the raw material was practically unknown; and the coal-tar distillers had to be taught how to recover the benzene from which the aniline was to be made. Other chemicals required in the process were not being manufactured; and these had to be made specially for Perkin. After getting into production, Perkin was obliged to work out methods for applying the dye to different fibres and to instruct the dyers in the new methods. No wonder that at the age of 23, Perkin was regarded as the leading authority on coal-tar dyes and their application. Perkin's ability, courage and enterprise were rewarded with sufficient wealth to enable him to devote the remainder of a long, useful life to chemical research.

German chemists took up the trail where Perkin left off and built up a profitable business in dyes, drugs and other synthetic organic chemicals. By the year 1913, the German synthetic chemical industry had waxed so big and strong that one factory alone employed 8,000 workmen and 330 university trained chemists. Germany had practically a world monoply in dyes, drugs and organic chemicals which are essential to a well-balanced chemical industry. She lost this dominant position as the result of the World War. Other countries have since constructed their own organic chemical industry. Millions of dollars have been invested in synthetics. The Dupont Co., for example, spent forty million dollars to get into the dyestuff business and this company alone expends over six million dollars annually in research. Building invisible edifices is today a gigantic enterprise with many ramifications. The industry continues its forward march, replacing natural products with less expensive and often superior synthetics, fashioning countless new and useful articles of commerce, transforming luxuries of the past into commonplaces of the present.

The Petroleum Situation in Canada

G. S. Hume,

Bureau of Geology and Topography, Mines and Geology Branch, Department of Mines and Resources, Ottawa.

SUMMARY.—It is interesting to have in one place a concise description of Canada's petroleum situation. The paper deals principally with Alberta's present development and further possibilities, but touches on the other provinces as well. Canada's place in the world production picture is not too impressive, although there are prospects of it being improved.

WORLD PRODUCTION OF PETROLEUM

Petroleum has become an indispensable commodity of industry throughout the whole world. Not only has world production of crude oil from wells reached the enormous volume of 2,039,002,465 barrels for 1937 but in many countries substitutes are being artificially made to supply an ever increasing demand. In general, however, these manufactured petroleum substitutes are inferior in quality to products derived from crude oil or are produced at greatly increased costs. The main supply of petroleum, therefore, is still derived from wells in many countries as shown in Fig. 1 but with more than 60 per cent coming from United States and only a relatively small amount from Canada.

Production in Ontario

Production of crude oil began in Canada with the drilling of the first flowing well at Oil Springs in Lambton county, Ontario, in 1861. Discoveries at near-by Petrolia and at Bothwell in Kent county followed soon afterwards. These early wells in Ontario were only a few hundred feet deep but many flowed hundreds of barrels a day, some 1,000 to 2,000 up to 5,000 barrels and one as much as 7,500 barrels a day. At that time the demand for oil was mainly governed by the demand for kerosene or illuminating oil and in the distillation of the oil, the gasoline, as we

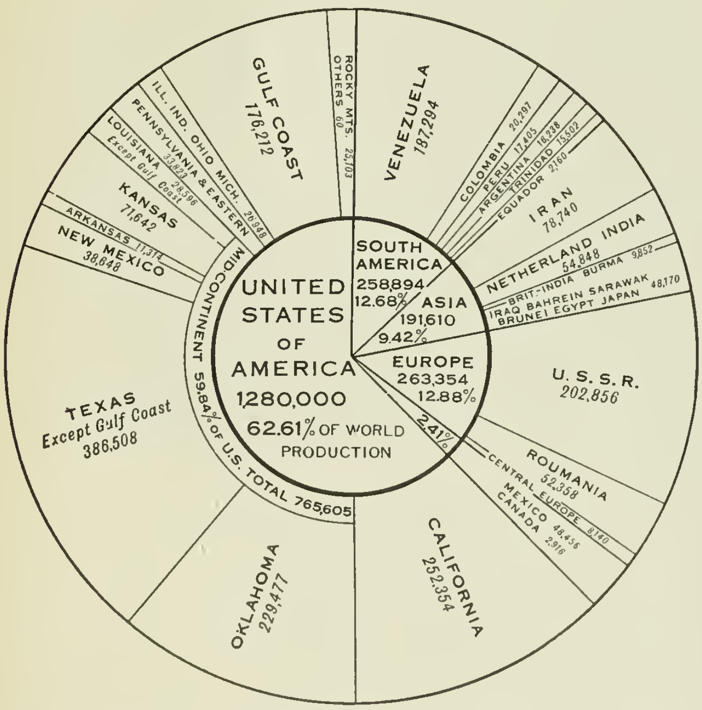


Fig. 1*—World Petroleum Production in 1937 (in thousands of barrels).

know it today, was a by-product that was driven off and wasted. After three-quarters of a century of continuous production the Ontario fields are still yielding crude oil and the main part of this comes from the earliest discovered areas at Oil Springs and Petrolia. Production per well is very low, in most cases not exceeding a few gallons a day, but the pumping operations inaugurated many years ago whereby a number of wells are pumped from one central power station are still profitable because of the very shallow depths at which the oil occurs. The production of Ontario now amounts to only 160,000 to 170,000 barrels a year with very remote prospects of materially increasing this yield.

*Through courtesy of World Petroleum, February 1938.

Production in New Brunswick

In addition to the Ontario production of oil there was in 1937 in eastern Canada a yield of 22,000 barrels from the Stony Creek field close to Moncton, New Brunswick. This field is primarily a gas field used to supply natural gas to Moncton, Hillsboro and other adjoining small centres of population. In the last few years the oil production of the Stony Creek field has been doubled and presumably some further increases may occur. In spite of this, however, the prospects of extending production from the field to any very large volume are not considered good.

Production in Northwest Territories

In the Northwest Territories, 50 miles north of Fort Norman on Mackenzie river two producing oil wells were drilled as a result of an exploration campaign inaugurated by Imperial Oil Company Limited, in 1920. These wells are on the east side of the river and quite close together. They were drilled in proximity to an oil seepage on strata which dip westward into the Mackenzie basin—a structure about 25 miles wide lying between the Norman range of mountains to the east of the wells and the Carcajou mountains at some distance west of the river. The dip of the strata at the wells is, therefore, monoclinal, i.e., in one direction only and the structure is not the usual arch or anticlinal fold with which most oil fields are associated. Eastward from the wells the west dip of the strata brings the bevelled edges of the formations to the surface and within three miles of the wells the oil horizons outcrop. A short distance east of this in the Norman range of mountains strata much lower than any reached in the wells are exposed. This is not the type of geological structure best suited for the retention of large volumes of oil although it is understood each of the two producing wells has still a capacity of about 125 barrels of a high grade crude oil per day. It is probable that the oil is held either in lenticular reservoir beds or in strata that have been sealed at their outcrop by a heavy tarry residue. With such evidence of oil, however, favourable anticlinal structures with the oil bearing strata buried under younger impervious beds would be highly regarded as prospects within the Mackenzie basin. The quantity of oil now available although relatively small is sufficient for local needs. A refinery is operated in the summer months and a considerable part of the mineral developments in the Northwest Territories, as for example the radium producing mines on the east side of Great Bear Lake, are dependent on this oil for fuel and power. During 1937 a pipe line to transport oil was built over the 8½ mile portage on Great Bear river. A storage of 2,000 barrels is provided at Fort Franklin at the head of Great Bear river and a 30,000 gallon barge is used to transport oil across Great Bear lake. During 1937 slightly more than 11,000 barrels of oil were produced. Thus although this oil on Mackenzie river is a highly valuable asset as far as the development of mineral resources in the Northwest Territories is concerned, it is not likely owing to its location, 1,200 miles north of Edmonton, to be speedily developed except as local need demands.

Production and Prospects in Alberta

The first drilling to be done for oil in southern Alberta was undertaken in the Waterton lake area. On Cameron Brook and Lineham Creek, a tributary of Cameron Brook, above Waterton Lake, there are active oil seepages. These seepages issue from very hard argillites that are now known to be late pre-Cambrian in age and which are known to have been thrust during the Rocky Mountain uplift over younger strata of Mesozoic and Palaeozoic ages. It seems entirely improbable that any oil originated in these pre-Cambrian strata so that it has been assumed that the seepages are due to the escape of oil from the younger rocks through fractures in the over thrust pre-Cambrian mass lying over them. In this early drilling only one well near Waterton Lake was able to get through the pre-Cambrian rocks into the underlying younger beds and this well is said to have obtained some oil. Other wells, however, got small flows of oil from fractures in the pre-Cambrian and some production resulted. The efforts at production were subsequently abandoned but in the last few years a further attempt has been made to drill a well at the former site of the production on Cameron Brook.

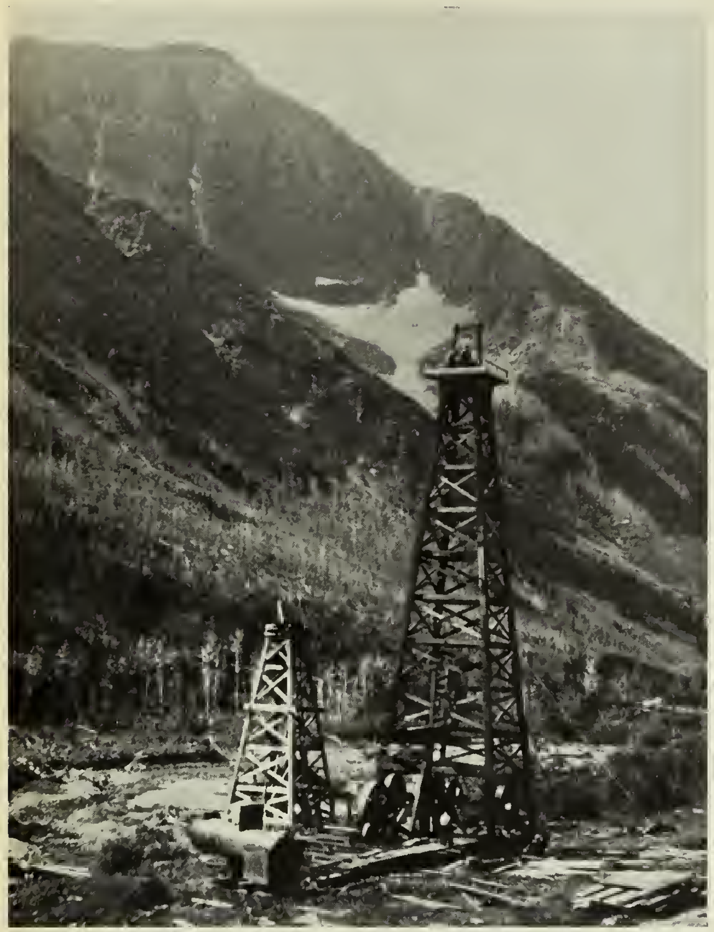
In many parts of the foothills there are seepages particularly of gas but to a less extent oil and it is not surprising that these attracted the attention of the early settlers. One such seepage existed on the north bank of Sheep river in what is now Turner Valley and in 1913 the first well, Dingman No. 1, was drilled close to this seepage. At a depth of 180 ft. sufficient gas to fire the boiler was obtained and in the autumn of 1913 some light oil was encountered in this well. This flow, however, soon exhausted itself and drilling was continued. On May 14th, 1914, oil was struck at a depth of 2,718 ft. This led to a frenzied oil boom in Calgary and although this collapsed some further drilling was done so that from 1914 to 1924 Turner Valley produced 65,945 barrels of light crude oil. A 6 in. gas main 15 miles long was laid from Turner Valley to Okotoks to join the trunk gas line to Calgary from Bow Island. Gas deliveries from Turner Valley began in 1922.

The second phase of development of Turner Valley began in the autumn of 1924 with the completion of Royalite No. 4 well at a depth of 3,740 ft. This well discovered a productive zone in the deep Palaeozoic limestone not hitherto reached by the drill and yielded about 20 million cu. ft, of gas with a content of high grade volatile naphtha of 500 to 600 barrels a day. Further drilling was immediately undertaken and up to June 1936 about 150 wells had been started of which 114 were successfully completed to the same productive limestone as in Royalite No. 4 well. These outlined a field 14 miles long by about one mile wide extending from a short distance south of the north branch of Sheep River to a short distance north of Highwood river. All of these wells produced large volumes of gas from which naphtha was extracted. During this period about 10,000,000 barrels of naphtha were recovered but since much more gas was produced than could be used, more than 750,000,000 thousand cu. ft. was burnt as waste. In heat value this waste is the equivalent of about 33,000,000 tons of good grade coal. Royalite No. 4, the first well drilled to this productive zone, was one of the best naphtha wells in the field producing from its inception in 1924 until it was abandoned in 1934 a total of 911,313 barrels of naphtha valued at over $3,-000,000.

During this period of naphtha production there was a marked decline in the pressures in the reservoir rock from a probable 2,000 lb. or more to the square inch to below 400 lb. in parts of the field where the gas had been heavily withdrawn. This decline allowed oil that originally was farther down the dip on the west flank of the structure but within the same reservoir zone as the gas, to migrate upwards into the gas area. This resulted in a number of wells that originally produced naphtha with gas turning into crude oil wells. This proof of crude oil was finally firmly established in June 1936 with the completion of Turner Valley Royalties well at a depth of 6,828 ft. and an initial flow of crude oil of about 850 barrels a day. This quickly led to further drilling and by the end of 1937, i.e., within 18 months, 26 additional wells had been completed to depths up to 7,475 ft. These with seven others that had originally produced gas with naphtha but had turned into crude oil wells, had a capacity of 26,803 barrels a day. In 1938 up to April 30th there have been nine additional crude oil wells completed and with the inclusion of two more that have changed from naphtha to crude oil wells the total number of crude oil wells now producing is 45. As announced at the end of April the potentials for these wells taken at two-thirds open flow capacity is 31,918 barrels a day. In addition about 2,000 barrels of naphtha a day are still being produced from wells yielding natural gas.

Brown No. 2 well coming into production. The mud fluid used in drilling, saturated with oil when the productive limestone was encounted, is being blown out and burnt at the end of a 6 inch flare line.

At the present time (April 30th, 1938) there are two separate crude oil producing areas in Turner Valley. The larger of these is in the south end of the field and embraces an area of slightly more than 3 sq. mi. which contains most of the wells. The other area in which Royalite No. 29 well was completed in March of this year is in the



The original discovery "John Lineham" No. 1 well (small derrick) drilled in 1902 on Cameron Brook, west of Waterton lakes and the modern drilling rig (large derrick) of Oil City Royalties Company.

north end of the field 14 miles north of the south end. Royalite No. 29 well has confirmed the conclusion that crude oil is present in the north end of the field. This had been previously demonstrated by the production of three wells of the Model Oil Company which originally produced naphtha with gas but which later turned to crude oil wells. Within the southern part of the field only one well has been completed that has not received an appreciable production. Three to five miles north of the producing south end two wells drilled on the west flank, where crude oil was expected, have been abandoned as dry holes. No satisfactory explanation for these dry holes is yet apparent because a former naphtha well, Advance No. 5A, situated in an intermediate position to them but somewhat higher structurally, is now producing crude oil. Recently also a well on the west flank of central Turner Valley has turned from a naphtha to a crude producer indicating crude oil prospects in that area. As far as structure is concerned the whole west flank of Turner Valley is favourable for production of crude oil but as demonstrated by the two dry holes already drilled, certain parts of it will be unproductive. In the south end of the field the area which has proved productive is more than 3 sq. mi. in extent with a width of about one mile and no limits are known except to the east where the oil is bounded by the gas area in turn sharply cut off by structural conditions. It is expected that the limit of the oil area to the west will be the oil-water line. In nearly all oil fields salt water occurs down the dip of the beds in the reservoir rocks. So far this oil-water line has not been reached on the west flank of Turner Valley but its presence west of wells now producing is to be expected. It can safely be said, however, that Turner Valley has excellent prospects for large production of oil. As yet reliable estimates of the oil content and recovery are impossible but petroleum engineers of the Alberta Departement of Lands and Mines have stated there may be an oil content of 500,000,000 barrels. Estimates by other authorities would place the recoverable oil in the best part of the oil area at 20,000 to 23,000 barrels an acre with perhaps 40 per cent of the total oil content recoverable. This then indicates a new major oil field for Canada and recent developments have been even more encouraging than when these estimates were made.

Turner Valley is the only producing oil field so far discovered in the foothills. The foothills, however, are a structural unit which extends 800 miles north from the International boundary to Liard river and have a width of 12 to 25 miles. Drilling to date outside of Turner Valley has not met with any success in the foothills but it will be singular indeed if within this large area, where already a few favourable structures are known, a number of fields like Turner Valley are not eventually found. In 1936 the Dominion Geological Survey undertook a sub-surface study of the Turner Valley field with the object of determining the details of the structural conditions and their relationship to oil production. Not only is such information of great value in the orderly development of any oil field but it is hoped by applying the knowledge of structure learned

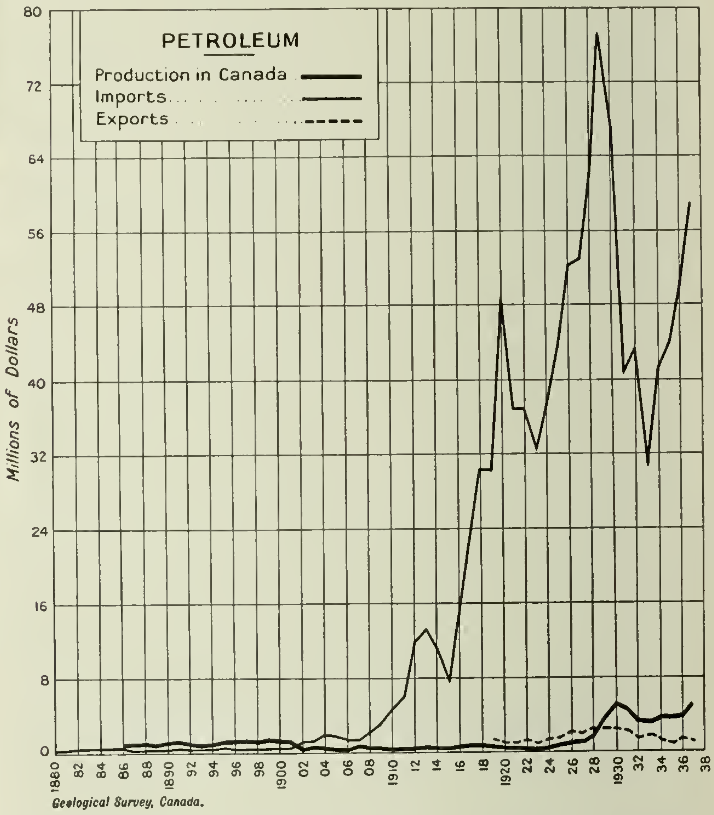


Fig. 2—Petroleum Production Imports and Exports of Canada.

in Turner Valley to other foothill areas to direct drilling to the more promising prospects. In comparison with the country in which oil fields are found the oil fields themselves are mostly confined to relatively small areas because of the fact that oil accumulations occur only under certain favourable geological conditions, in which the character of the structural features are the controlling factors. Thus it is hoped structural studies now being made will obviate much drilling in areas where drilling can hardly be expected to meet with success.

On the plains there has been production of oil from a few widely separated fields at Red Coulee and Skiff in southern Alberta to Wainwright and Ribstone in eastern central Alberta on the Battle river. Recently a promising oil field has been opened up at Taber east of Lethbridge and oil is now being shipped from this field to the Imperial Oil refinery in Regina. It is probable that more extensive developments will take place in the immediate future. Thus it can be said that never have prospects for large oil developments in Alberta looked so promising and never before has there been so much drilling and prospecting activity as at present.

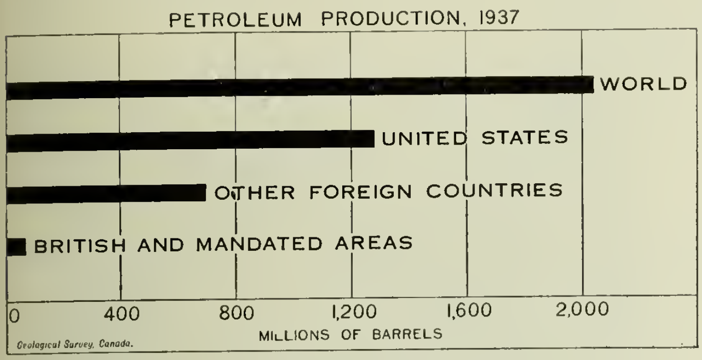

Fig. 3—Petroleum Production 1937.

MARKETS

The developments in Turner Valley have taken place so rapidly that transportation and market facilities could not be provided quickly enough to take care of the rapid increase in production. Under such conditions proration or restricted output has been put into effect. At present there are two 4 in. pipe lines from Turner Valley to Calgary and these have recently been handling about 13,000 barrels a day. An additional 6 in. pipe line now under construction will bring the capacity up to 24,000 barrels a day. The consumption of the Prairie market is said to be about 17,000 barrels a day on a yearly basis with a much larger volume used in summer than in winter. The pipe line capacity now available and under construction to Calgary will, therefore, take care of these needs and it is certain the volume of oil already indicated in Turner Valley is sufficient to supply the Prairie market for years to come. To insure expansion of markets beyond the Prairie Provinces there must be a guaranteed supply of a very large volume of oil over a long period of years so that the necessary transportation facilities and the refinery adjustments can be made with the assurance that they are warranted. Until the time when such market expansion is justified there will be a period when the output of the wells must be restricted below their capacity. The length of such a period will be dependent on the rate of development of reserves by drilling and there is no doubt the discovery of one or more other large fields like Turner Valley would quickly insure this stability.

The price paid for crude oil in Turner Valley by the major refining companies is $1.14 a barrel for oil with a gravity of 40 to 40.9 deg. A.P.I. increasing 2 cents for each degree Baumé to 1.62 for oil between 64 and 64.9 deg. A.P.I. Above 65 deg. A.P.I. the oil is classed as naphtha and brings $2.14 a barrel. The naphtha produced with the natural gas in Turner Valley had a gravity up to 73 deg. A.P.I. but the oil becomes progressively heavier down the west flank of the structure and oil just slightly more than 40 deg. A.P.I. is now obtained from some of the deeper wells. The costs for transportation by pipe line to Calgary are 15 cents a barrel. At Calgary there is a charge of 5 cents a barrel for loading onto railroad tank cars. By tank car the rates charged are 18½ cents a cwt. (51.8 cents a barrel) to Moose Jaw, 19 cents a cwt. (53.2 cents a barrel) to Regina and 39 cents a cwt. ($1.09 a barrel) to Winnipeg.

AVAILABLE CANADIAN MARKETS

United States with about 30 per cent of the world's automobiles consumes about 60 per cent of the world's petroleum production.* Russia ranks second and Great Britain third. Great Britain, however, does not consume as much oil in a year as United States does in a month. Canada ranks fifth with a consumption in 1936 of about 17,500,000 barrels of gasoline, 15,200,000 barrels of gas and fuel oil, 890,000 barrels of kerosene, 995,000 barrels of lubricants and 1,010,000 barrels of engine distillate, a total of 35,595,000 barrels of oil of various kinds in addition to other petroleum products. This consumption in 1936 was due to the use† of 1,035,198 passenger automobiles, 6,331 taxi cabs, 184,798 motor trucks, 2,154 buses, 10,825 motor cycles and 818 tractors, ambulances, service cars etc. It is difficult to accurately estimate what this means in consumption in relation to crude oil production since crude oil from different fields yield different volume of various products and in many cases the refinery can control the character and amount of the products according to market requirements. For example, by straight run distillation, i.e. without cracking, 100 barrels of Turner Valley crude oil will yield about 50 barrels of gasoline, 13 barrels of kerosene, 17 barrels of gas oil and 13 barrels of lubricants with some residues. If, however, the product left after the gasoline is taken off is "cracked" the same volume of crude oil can be made to yield more than 80 barrels of gasoline with a corresponding decrease of other products. From a comparison of consumption, however, it can be seen that Canada's requirements are many times in excess of the 2,995,025 barrels of crude oil produced in 1937. At the present capacity of Turner Valley which is at the rate of nearly 12,500,000 barrels a year it is

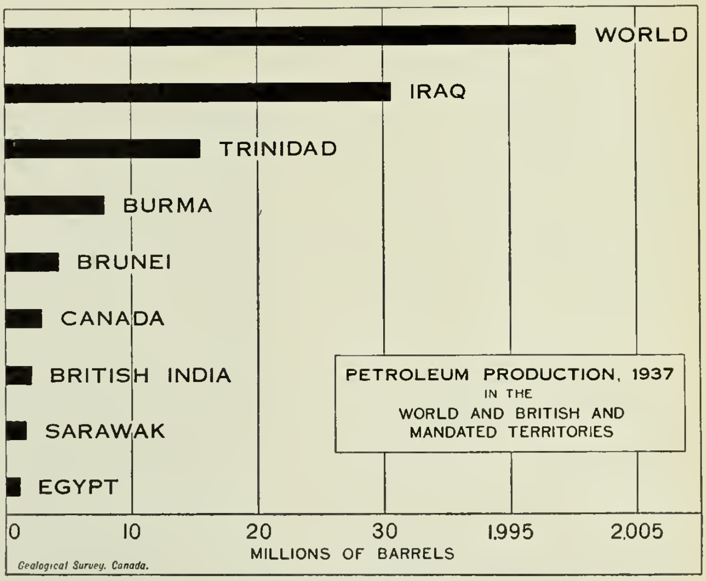

Fig. 4—Petroleum Production 1937, World, British and Mandated Areas.

probable that about one-third of Canada's needs could be met from this source alone. This development of a considerable domestic supply totally changes the situation in Canada from a few years ago. In 1924, when the naphtha zone of Turner Valley was first discovered, the total oil production of Canada, mostly from Ontario, amounted to only 160,773 barrels valued at $467,400, whereas the value

* Petroleum Times, London, Feb. 19, 1938, p. 230.
† Bureau of Statistics, Ottawa.

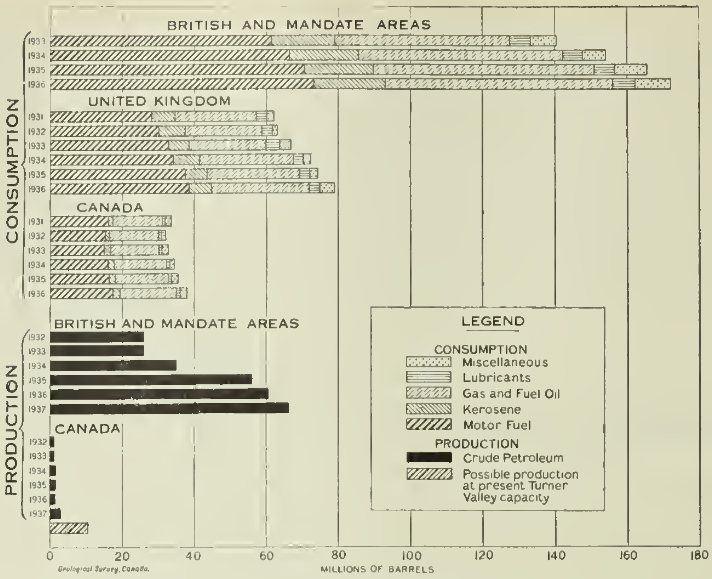

Fig. 5—Production and Consumption of Oil Lubricants and Petroleum in British and Mandate Areas.

of imports over exports amounted to $36,236,987. By 1929 owing mostly to the production of Turner Valley naphtha production in Canada rose to 1,117,368 barrels valued at $3,731,764 but the value of imports over exports rose to $75,111,338. Although the use of oil in Canada declined from 1929 to 1933 it is again rapidly increasing and will undoubtedly soon pass the record established in 1929 (See Fig. 2). Thus the development of a large supply of oil in Canada is an event of national importance and there seems little doubt as the reserves of oil are established in Alberta to justify market expansion, this will eventually take place.

Petroleum in the British Empire

During 1937 all Empire countries furnished about 5 per cent of British consumption of 70,000,000 barrels a year. These Empire countries with their yield in relation to world production are shown on Figs. 3 and 4. It is obvious that the British Empire is very deficient in oil supplies. Crude oil for refining in Great Britain in 1937 was supplied* by imports of 3,740,100 barrels from Venezuela, 2,373,300 barrels from Iraq, 2,242,100 barrels from Peru, 2,078,300 barrels from Iran, 408,100 barrels from Trinidad and other Empire territories and 283,500 barrels from Mexico. In addition to crude oil, however, Great Britain imports large quantities of refined products. A very considerable part of this comes from the Dutch West Indies which is the refining centre for Venezuelan oil. The remainder comes from Iran, United States, Trinidad, Mexico, Roumania, Iraq, Peru and U.S.S.R. The consumption of oil products for the British and mandate areas, the United Kingdom and Canada together with the production of crude oil within the British and protectorate areas and Canada are shown on Fig. 5. For comparison the possible production of Canada is shown provided Turner Valley was allowed to produce at capacity of 30,000 barrels a day (as in March, 1938). It can readily be seen that not only does Canada still fall far short of supplying domestic needs but that the production in all British and mandate areas including Canada has up to the present been insufficient for Empire requirements. It would appear, therefore, that in the expansion of production in Canada a market is offered by domestic consumption with a wider market within the Empire. In reaching these markets difficulties of transportation over long distances must be met but by modern methods of transporting large volumes of oil it is believed that much wider marketing facilities than at present will eventually be provided when sufficient reserves of oil are established.

The Collapse of the Falls View Bridge

P. L. Pratley, M.E.I.C.,
Monsarrat and Pratley, Consulting Engineers, Montreal.

Paper presented before the American Association for the Advancement of Science, Ottawa, June 27th, 1938.

SUMMARY.—The collapse of the Falls View Bridge was front page news for several days, but the newspaper accounts told nothing of it from the engineering point of view. This paper describes the unusual ice conditions that brought about the disaster, and the action of the bridge under the abnormal strain.

"There is probably no bridge site on the North American continent of greater technical and historic interest than that of the Niagara Arch." This is substantially a quotation from the opening words of a paper written forty years ago for the American Society of Civil Engineers by Major R. S. Buck, M.E.I.C., old friend and one-time chief of the writer, and now resident in Washington, D.C. What was true then is true still, and though no doubt many new and interesting sites have been found and crossed since 1898, as transportation conditions have changed and the touring automobile developed, the Falls View Bridge stood, and will stand again, on a site unsurpassed for historic, scenic, and romantic associations.

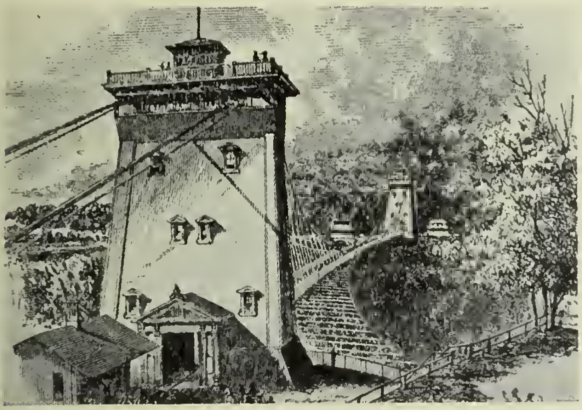

Fig. 2—Original Bridge 1868.

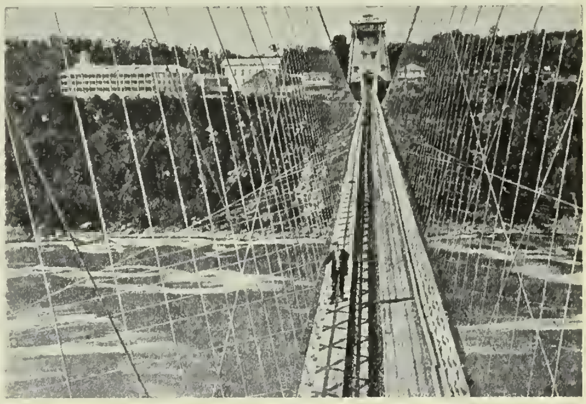

Fig. 3—Original Bridge 1868, Showing Span.

The Niagara river gorge from the Falls to Lake Ontario is in itself quite an interesting natural feature. This paper will not deal with the geology of the neighbourhood, but the geological data provided by the walls of this gorge with their sections of almost uniformly horizontal strata of deposited rocks, including clay, shales, limestones, and sandstones, is of outstanding value to those concerned with this science. The slow recession of the Falls during the centuries, the origin of the Whirlpool, and the evidences of an earlier channel north of this Whirlpool leading to the banks of the prehistoric Lake Iroquois, are some of the features which lead to the fascination which the Niagara gorge provides not only to the casual tourist or the 'honeymooner,' but also to the more seriously minded student of natural phenomena. The Niagara river is about thirty-two miles long by the international channel from Lake Erie at Buffalo to Lake Ontario at the Forts, but the gorge proper occupies only about seven miles from the Horseshoe Falls to the escarpment at Queenston-Lewiston. Below Queenston the river is quiet and navigable for its remaining six miles, and above the Falls on both sides of Grand Island there are navigable stretches used by boating clubs, etc.

There are several bridge sites on the Niagara river, some above the Falls and some below. The present paper is concerned particularly with one site, namely that just below the Falls, only a few hundred feet from the nearest part of the American cataract and ¾ of a mile distant from the furthest point of the Canadian, or Horseshoe Falls. The gorge in this neighbourhood is about 180 ft. deep from the banks to the average water surface, and the depth of the water reaches about the same figure in the area between the foot of the Falls and a point slightly downstream from the site of the Falls View bridge. North of this point the river bed rises, the gorge narrows, and the velocity correspondingly increases, giving rise to that stretch of rapids reaching down to the Whirlpool and beyond.

Fig. 1—Jan. 27th, 2.30 p.m., Showing Ice and Bowed Vertical.

The bridge that fell in January, 1938, was not the first occupant of its site and moreover two other sites along the gorge were occupied even before this one, namely those at Queenston-Lewiston (1850) and at "Suspension Bridge" across the Whirlpool Rapids (1848). The Queenston-Lewiston site was first bridged by a 1,040 ft. parallel-wire cable suspension span, designed by General E. W. Serrel (who also designed the old Suspension Bridge at Saint John, N.B., in 1862), and built by Mr. T. M. Griffith. This span was endangered by an ice-jam in 1864 but survived this experience only to be destroyed later in the same year by a gale. The

Fig. 4—Jan. 27th, 2.40 p.m., Showing Kink in Downstream Lower Chord.

collapse was directly due to its lateral cable guys not having been replaced after their removal during the said ice-jam. The bridge at Whirlpool Rapids thus stood alone until 1868, when the first crossing at Falls View was completed.

All these early bridges were of the suspension type, some of them being pioneers, and all of them being very light. Although the hope and intention of the promoters was to build a railway bridge at the Whirlpool Rapids site, the funds available in 1847 would not permit of this scheme, so Mr. Chas. Ellet constructed a carriage-way bridge only 7 ft. 6 in. wide, suspended from four cables each of which consisted of three ropes, each rope being composed of three No. 9 gauge wires. This bridge was however replaced in 1853-5 by a railway bridge 821 ft. in span carrying the Great Western (Grand Trunk) Railway, and Mr. John A. Roebling, the founder of that family so prominent in North American suspension bridge history, achieved a notable success on this occasion in applying mathematical studies to the practical problems of stiffness and erection. The old cable wires were absorbed into the new cables, and although certain repairs and some alteration work were carried out in 1877 and again in 1880 and 1886, this structure of 1855 stood until 1897-8 when it was taken down and the present arch span (lower arch) constructed to replace it.

The Queenston-Lewiston site seems to have stood empty from 1864 to 1898 when the present bridge at this location was erected, using for its cables those of the Falls View suspension bridge which had just been dismantled.

The Falls View site to which our attention will now be limited was first occupied in 1868 by the Clifton Suspension Bridge, 1,268 ft. in span, with its towers seated on the top of the banks of the gorge. The Clifton Suspension Bridge Company was chartered in Canada in May 1868, its American counterpart, the Niagara Falls Suspension Bridge Company having revived its powers in April 1867 although its charter actually dated back to March 1855. The companies merged in July 1868 and construction was completed by the end of that year, Mr. Samuel Keefer, M.Inst.C.E., being the responsible engineer. The bridge was opened on January 2nd, 1869, with appropriate ceremonial. The towers were of timber construction, each pylon being of pyramidal shape with four 12 by 12 in. sticks constituting each of its four legs. There were thus sixteen of these timbers brought together under each cable saddle.

Traffic on this structure was of the one-way type, the width of roadway being only 10 ft. and consisted principally of market gardeners taking fruit and vegetables from Ontario across to New York State. After sixteen years of service, the timber towers were replaced by iron or steel, of very similar design, and in 1887 work was commenced on new anchorages as part of a scheme for introducing additional cables and increasing the capacity of the structure by providing two-lane traffic and a 17 ft. wide roadway. Two new steel cables were placed, making four in all and new steel stiffening trusses were suspended from these to carry the new timber floor system. Traffic was apparently maintained without interruption, and the whole work of reconstruction was finished by December 15th, 1888.

Unfortunately it was less than a month later, namely, January 10th, 1889, when the whole suspended structure was destroyed by a severe storm which seemingly severed the horizontal sway-prevention cables and then swung the trusses and deck in the wind until the suspender ropes were severed by direct abrasion. Mr. L. L. Buck, the engineer responsible for the widening and reconstruction, describes this disaster in the following words. "The storm-cables or wind-guys were put up and adjusted during warm weather. During a high wind in severely cold weather in January, 1889, they became so taut that one end of that to windward broke loose from its anchorage, the suspended structure swung to leeward far enough to bring the upper chord of the steel truss against the suspenders, sawing them off at a distance of 300 ft. outward from the shore, and then the remaining suspenders gave way in succession like tearing cloth, and the stiffening truss fell into the river, leaving the cables intact." Another commentator states that the wind during that night blew through the gorge with such force and such noise that the gate-keepers, stationed in the bridge office 20 ft. from the end of the main span, neither heard the collapse nor knew anything of it until daylight the next morning.

Reconstruction of the suspender ropes, the stiffening truss, and the deck was immediately ordered, and 117 days later on May 7th, 1889, the span was again opened to traffic.

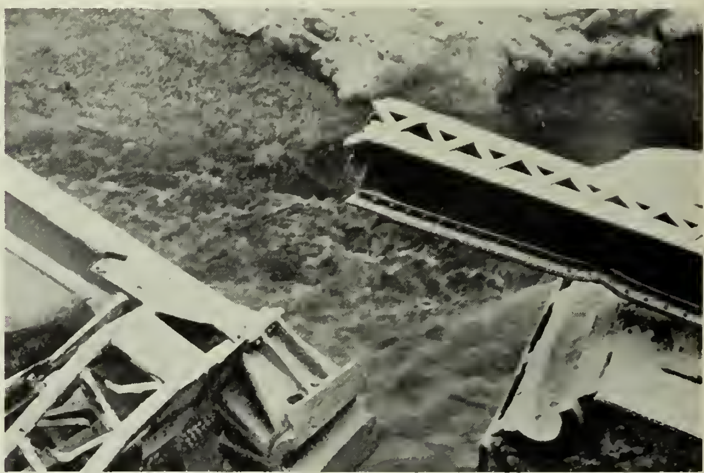

Fig. 5—Jan. 28th, 11 a.m., Downstream U.S. Corner.

During the next ten years great changes began to occur in the general conditions of life and travel. Electric railways were built, one such line being constructed on each side of the scenic portion of the Niagara [Gorge. It became desirable to connect these in order to provide a round-trip and therefore means had to be found to carry them across the gorge at approximately the site of the Falls View Bridge. This provision for the entertainment and the benefit of tourists, seemed to the owners to offer sufficient chances for profit to warrant the entire reconstruction of the Falls View Bridge, and the services of Mr. L. L. Buck were again retained for the purpose of preparing a new design. This time the suspension type was abandoned in favour of the arch and the Falls View Bridge, as we of this generation have known it, was built during the years 1895-98, being opened to traffic in August of the latter year. During the replacement it is recorded that the longest continuous period during which traffic was interrupted was about three days, and the aggregate time during the whole three years, was about 7 days.

Mr. L. L. Buck states, in describing this structure, that "The high-water level and the movement of the ice were investigated before fixing the span of the arch and the elevation of the abutments; according to the worst conditions previously known, danger from water and ice was amply guarded against, but on January 22nd, 1899, an ice-jam took place which exceeded all past experience. The ice-field, firmly anchored to both shores, then caught a heavy run of ice coming down the river, the water of which was greatly augmented by a stiff and long-continued southwest gale on the lakes. At about 4 p.m. the river-channel under the ice became choked, and within a few minutes the water near the head of the ice-field rose to a height of 25 ft. or 30 ft. above its level at the bridge, ¾ mile below, and began to pour over the pack for some distance below the Falls. The pressure caused the whole pack to move downstream. Not only was the ice piled up over the masonry abutments, but it was swept against the steelwork of the arch as high as the upper chord panel-point two on each side of the river. As it struck the rib-chords it was shaved off as with a knife and deposited in large masses upon the upstream truss members and the lower laterals. The bridge quivered from end to end as the ice ground against it, but did not sway. The pack moved about 250 ft. in about 10 minutes, after which the channel underneath the ice cleared and the water subsided as rapidly as it had risen. On each side of the river one main lateral and one sub-lateral, four members in all, were badly bent. The abutments were uninjured and no other damage was done. The bent struts were straightened immediately and served until they were replaced several months later. During the following summer, to guard against similar trouble in the future, heavy concrete walls were built around the abutments, extending as far out in front as possible, and the first two panels of laterals in the plane of the lower chords on each side of the river were changed from latticed struts to plate-webbed struts."

It is a matter of observation and record that great quantities of ice from Lake Erie come over the falls every winter, especially in January and February, and that in most years an ice bridge is formed across the gorge just about at the site of the Falls View bridge, which ice bridge or solid pack-ice extends itself up and downstream to greater or shorter distances, depending on the severity of the season.

The jam above-described as having occurred in January 1899 and being then without recorded precedent as to magnitude, seems to have been almost identical in many respects with that which occurred in January 1938, except that it persisted for a much shorter period of time, as will be appreciated later when recording the events leading up to the recent collapse.

The Falls View arch bridge continued to serve the local and travelling public for a generation, and actually outlived the electric railways which demanded its creation. In 1932 the gorge routes ceased to operate and in 1936 the rails were removed and the timber floor entirely renewed, being re-arranged at that time to carry modern bus traffic. This change however, unlike many changes which are due to modern developments, was not detrimental to the capacity of the structure, but actually eased conditions slightly as the writer, acting as consulting engineer, could quite confidently discontinue the practice of reserving a sensible percentage of the carrying capacity of the various structural members for the absorption of dynamic or impact stresses. Thus the bridge, although 39 years old, could, by virtue of its original sound design, the continued policy of proper maintenance, and the removal of trolley-car loading, be relied upon to furnish adequate and safe service for decades to come.

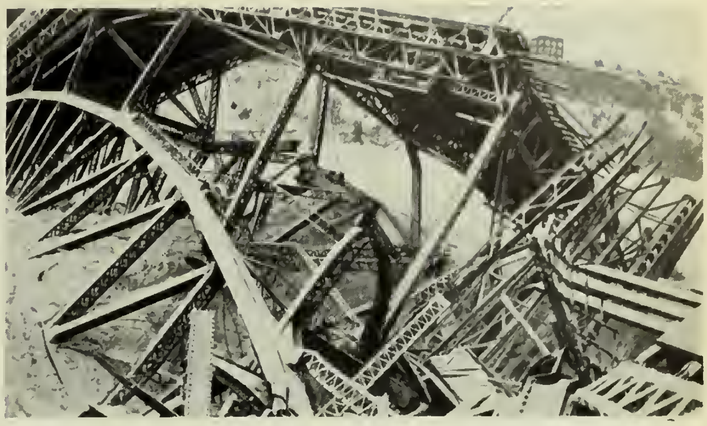

Fig. 6—Jan. 28th, 11 a.m., Wreckage at U.S. End.

However fate in the shape of natural phenomena, had the deciding voice, and to some of us was given the sorrowful experience of seeing an old and tried friend, although of steel and timber, go to its end, while we stood by helpless.

The immediate cause of the collapse was very obvious to spectators and is equally easy to explain. It was merely the enormous lateral pressure of the moving mass of ice brought over the falls in unusual quantities from Lake Erie. The more fundamental reason lies in the peculiar sequence of weather conditions and the successive changes in water-level experienced on Lake Erie during the two or three preceding days. During a cold snap of fairly short duration, ice of about 4 in. thickness formed over a large portion of Lake Erie, but a rise in temperature served to loosen this thin ice from the shores and strong winds from the southwest drove it to the east or Buffalo end of the lake. These winds were so persistent and so powerful that they not only broke up this ice and forced it into the mouth of the Niagara river, but they raised the water level at Buffalo on January 25th at quite an alarming rate, according to data supplied by the U.S. Engineers' office. (Fig. 14.)

Fig. 7—Jan 26th, p.m., Buckled Laterals.

Fig. 8—Jan. 27th, a.m., Kink in Downstream Bottom Chord.

According to the report on the St. Lawrence Waterways Project by the Joint Board of Engineers, page 90 of Appendix B, the formula for the discharge of the Niagara River would indicate that each foot rise of Lake Erie at Buffalo would increase this discharge by 22,000 cu. ft. per sec., so that the 3 ft. rise indicated in Fig. 14 would lead to a substantial increase in the amount of water coming over the Falls which water had to find its way through the limited channel left under the existing ice-pack in the gorge below the falls. Furthermore, at the normal rate of flow, the peak of this increased discharge would reach the Falls about 7 or 8 hours later than the time shown on the diagram at the Buffalo gauging station, which means that from approximately midnight to 6 a.m. on January 26th, the river was pouring over the falls with this augmented discharge, carrying a continuous load of 4 in. ice in small slabs which could only pass under the existing ice-pack if it were to reach Lake Ontario. In the early hours of the morning, this ice travelling at all depths in the turbulent waters, jammed this submerged channel and began to pack up solid beneath and behind the original ice-pack, extending this pack almost to the foot of the Falls. The orifice for passing water was thus gradually shut off, with the result that the augmented discharge over the Falls gathered enough energy to actually lift the whole of the ice-pack in the gorge below, and the entire sheet rose under this ever-increasing pressure until it cut loose from the bottom and the banks and moved in a mass downstream, the upper or more recently formed areas piling themselves onto the available shore space just south of the arch bridge and into the power-house on the Canadian side. This movement of course relieved the pressure somewhat and re-opened the submerged channel, allowing both water and ice to discharge through this orifice. The ice sheet over the river gradually sank again, leaving stranded on the shore all that ice, mostly small slabs of 4 in. thickness, that had been piled up during the movement.

Up to this time no visible damage appears to have been done to the steel bridge. Maintenance engineers of the International Railway Company, owners and operators of the structure, had been called to the site as early as 5 a.m. as observers reported that the ice field, including both the earlier pack-ice and the new Lake Erie ice, was rising. By 6.30 a.m. the movement above described had all taken place and these engineers began to clamber over the stranded ice south of the span on the U.S. shore in order to reach and examine the shoes of the structure which carried the thrust of the steel arch to the stone and concrete pedestals, familiarly known as "skewbacks." They found this stranded ice to be as high as 20 ft. above the shore and approximately the same amount above the elevation of the hinge-pins at the point where the arch bears on the masonry. But this was only true of the ice stranded on the shore. At the shore line just a few feet forward of the skewbacks there was then a sheer drop to the ice in the river of some 30 or 35 ft., and a definite crack or line of separation between the stranded ice and the river ice was visible up and downstream for several hundred feet, indicating that the river ice had moved north considerably more than the stranded ice, and had continued to so move as the river level was dropping and the ice that had overflowed the banks, was being left stranded.

The pile of ice directly against the upstream or south truss of the arch span was higher than elsewhere as it consisted partly of the shavings from the top of the ice that had moved down stream under the span, which shavings had been trimmed off by the steel members, and it was reported that the shaping effect of the steel arch on the ice could be seen several hundred feet downstream where the ice that had thus been shaved had come temporarily to rest as the first general movement ceased. The maintenance engineers' report states that at 6.30 a.m. the ice was no longer moving. This could only mean that the channel under the ice was temporarily open and that the discharge of the river was passing underneath the pack-ice once more. At the same time it could readily be recognized that this channel might block again and the whole incident repeat itself as the water and ice coming over the Falls was still abnormally high.

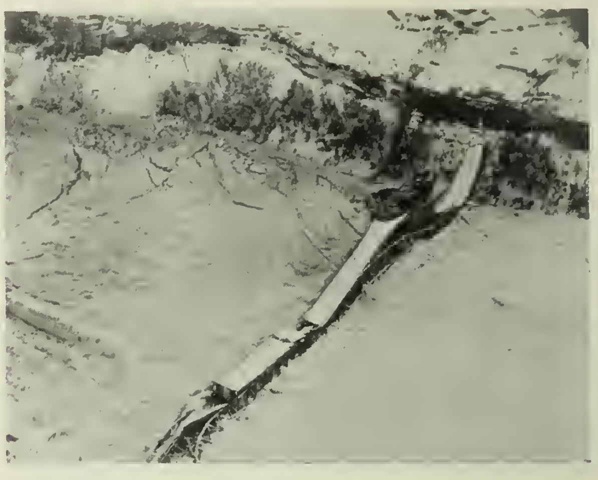

Fig. 9—Jan. 28th, a.m., Wreckage Looking Toward U.S. End.

A 30 minute inspection of the span was made but as far as could be seen no damage had occurred to the steel work and the maintenance engineers set out again on their return trip over the stranded ice to the stairway leading down from the Park concession to the shore. Before they could reach this point, however, and therefore at about 7.15 a.m. they noticed the river water beginning to overflow the new pack-ice, and new ice from the Falls being deposited on this pack or carried above it. This was evidence that a second jam had already begun to form under the ice-pack and the constriction apparently became very definite for the water rose rapidly, 10 ft. in 3 minutes being recorded, and a further 10 ft. in the next 7 or 8 minutes, at which time the stairway of the Park concession was actually flooded. However, the river ice immediately rose again and moved north, some of it climbing over the shore ice already stranded and pressing furiously against the bridge. It was at this moment, shortly before 8 a.m. on the 26th January, that the steel must have suffered its critical experience.

The submerged channel cleared again and the ice movement ceased. The river pack which now filled the whole area from the Falls to the bridge site and beyond this for several hundred yards, reaching almost to the rapids, settled down again and the discharge from above was diminishing. The new ice was carried under the pack-ice still in tremendous quantities and began to jam in the lower reaches of the river near Queenston. Between the hours of 8 and 11 a.m. on January 26th the steel could be seen to buckle and distort, and the Company's chief engineer, realizing that the safety of the structure was now in jeopardy, shut off all traffic at about 9.15 a.m.

Fig. 10—April 12th, 4.04 p.m., Last Portion of Wreckage Disappearing Below Water.

To explain the precise nature of the damage to the steel frame, which was confined to the eastern or U.S. end, and to sketch the sequence of failure, some general idea of the construction must be given. As diagrams and photographs will show, the bridge was of the "trussed-rib" type of arch, with end hinges only. The "rib" had upper and lower chords and a web framing between them consisting of alternate vertical and diagonal members. The upper and lower chord of each rib were so laid out at each end that their axes intersected on the hinge pin, the members themselves finishing on a common gusset plate, well stiffened and heavily reinforced and connected to a large shoe casting by bolts which passed through base angles (see Fig. 13). This casting also carried the end vertical post and was finished with a semi-cylindrical surface which bore on the 12 in. by 5 ft. 10 in. hinge-pin. This pin in turn bore against another semi-cylindrical surface furnished by a cast steel box which was built into and backed up by a structural steel shoe designed to spread the thrust to the masonry. These shoes, box-castings, and pins were not moved or even damaged by the ice pressure, and only in one instance out of four did the actual fall of the span displace the pin. This was at the northeast or downstream American corner, where the pin was lifted or pushed out of its bearing by some of the falling steel after the arch rib had pulled away.

The main span across the gorge was 840 ft. between hinge-pins, and the deck was carried at a height of about 167 ft. above these pins on a series of floorbeams and stringers supported by vertical posts, sway-braced together in pairs standing on the upper chords of the ribs. From each bank of the gorge to the end vertical posts above the shoes, was an approach span of bow-string truss construction, pin-connected to the top of the vertical posts, and provided with sliding roller-bearings at the abutments. These approach spans were not quite identical as the Canadian span was 210 ft. long and the American 190 ft. long. The whole bridge was thus 1,240 ft. long between end bearings, or about 1,244 ft. between the natural rock backwalls. The weight of steel in the structure as originally designed was 4,532,047 lb. to which some 30 or 40 tons may have been added during maintenance

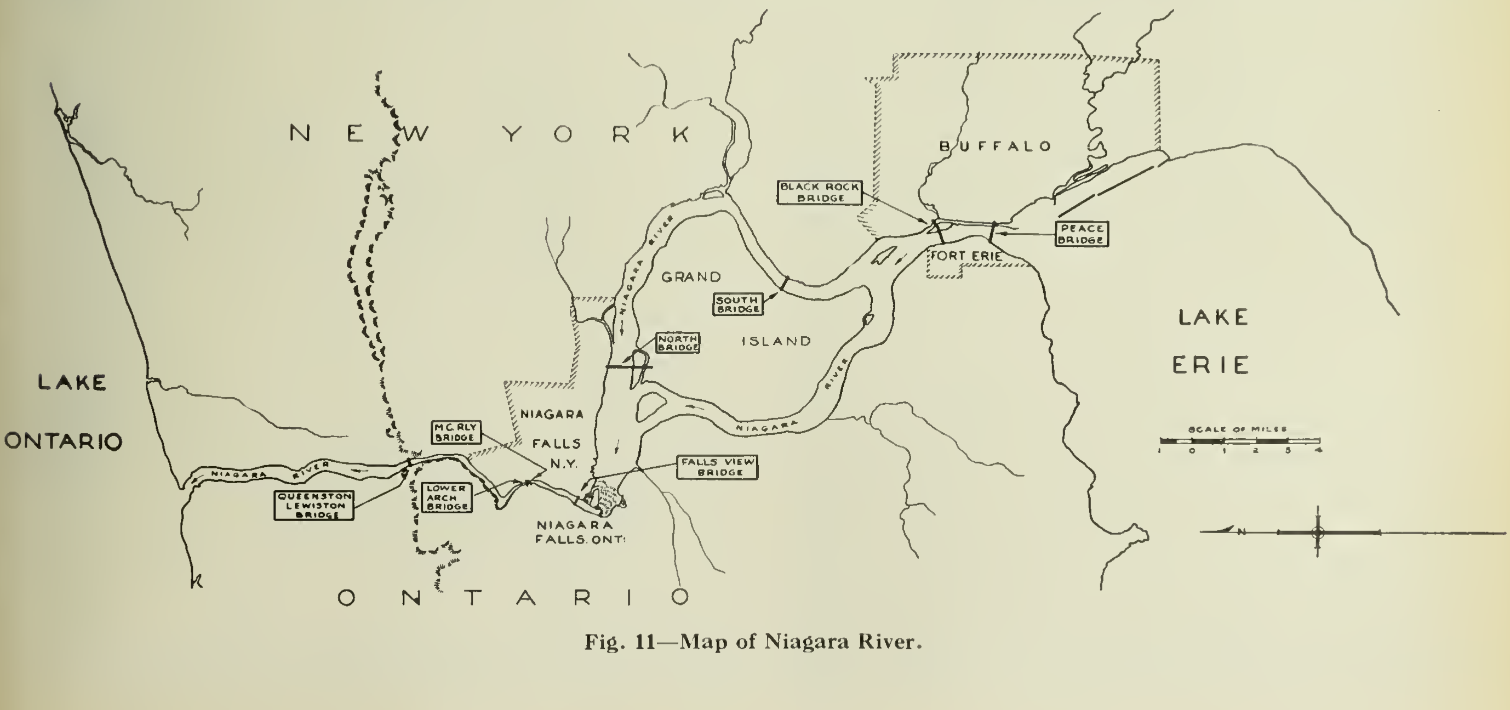

Fig. 11—Map of Niagara River.

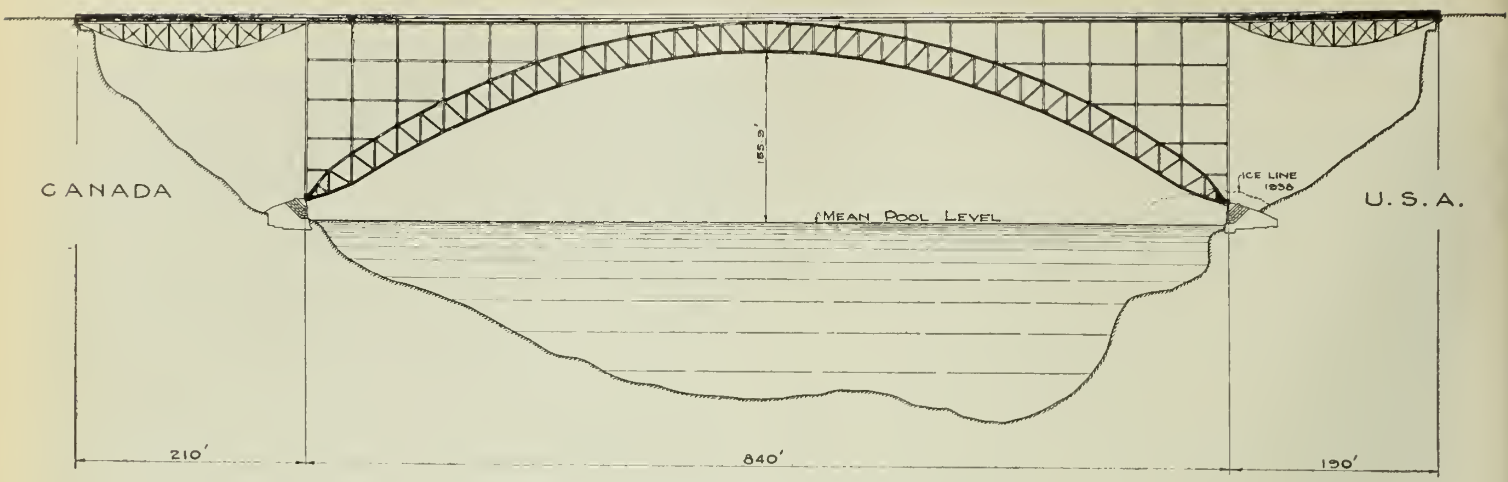

Fig. 12—General Diagram of Falls View Arch.

operations over the 39-year period. The timber deck as renewed in 1936 amounted to about 265M f.b.m., weighing possibly 500 tons.

The upper chords of the two ribs were braced together by a lateral system and the lower chords by another lateral system, each of these systems terminating in a transverse strut located close to the hinge-pin. A third transverse strut which formed part of the sway bracing of the end vertical posts also crossed from one side to the other, just above the shoe castings. The first panel of the lower chord laterals are those which were reinforced in 1899 when the webs were made of solid plate instead of lacing bars as is the case in all other members of the lateral system, and it is worthy of note that the main lateral diagonals of both the upper and lower systems are sub-trussed to shorten the otherwise long members, and that in both chords two short sub-members meet at a point midway between the main truss panel points.

As the ice pressure against the end lengths of the upstream lower chord at the American end developed, these chord members acted as continuous beams supported to various degrees at the connection to the shoe, the panel points of the vertical truss, and the panel points of the lateral system. The reactions at these points of partial support travelled by devious routes to the masonry, two or three per cent perhaps going to the Canadian end via the bridge as a whole, but by far the greater part to the two American shoes. The almost direct path to the downstream shoe via the lateral system, lasted only until the end laterals buckled, which was probably a matter of a few minutes. The path via the second set of panel laterals to the downstream chord at $L\,1$ also lasted a very short period until these laterals buckled. In each of these cases the resistance at the downstream end of the laterals was greater than the capacity of the laterals in compression, so that the buckling occurred quickly with little or no adverse effect on the downstream truss. At the mid-point $L\,1\frac{1}{2}$, where there was no other main truss member to assist, the downstream lower chord was not able to furnish sufficient resistance to the lateral thrust and the chord began to buckle before the lateral sub-diagonals were overloaded. Pressure travelling to the upper chord of the upstream truss, via the vertical and diagonal members, met little effective resistance from the top lateral bracing which readily collapsed in compression. The yielding of all these secondary paths meant that the remaining path, namely, that through the connection of the upstream truss to its shoe-casting, was compelled to bear the whole load. This it could only do if the two lateral end struts stood firm, but apparently they also began to fail, and crushed in toward their upstream ends, probably in succession, the lower lateral strut first. After this the whole load came onto the connection angles and their rivets. The enormous concentration at this point gradually bent these angles and pushed the gusset plates downstream firstly without severing the connection either from plates to angles or angles to casting. The failure was progressive and rivets began to shear, material to tear, and heads to fly off, so that as the gusset plates bent further and further downstream (Fig. 13) the normal dead load thrust became more and more eccentric and thus hastened and intensified the distortion. The upstream truss thus moved definitely eastward toward the U.S. skewbacks as the yielding of the gusset plates permitted, until the latter actually bore against the bottom lateral strut. It was this constant movement that forced the short horizontal strut from $U\,1$ to the end vertical post to push the latter out of line (Fig. 1). Meantime the buckling of the downstream chord at the midway panel point $L\,1\frac{1}{2}$ was increasing and the normal dead load in that member, approximately 822 kips, together with any unfavourable wind load, was acting with an ever growing eccentricity and thus creating a progressively increasing buckling moment. The two critical points were therefore the upstream chord-to-shoe connection and this point of buckling at $L\,1\frac{1}{2}$ downstream. Each of these had reached a state absolutely beyond hope of repair at 10.30 a.m. on January 26th.

The yielding of the upstream chord near the shoe, after the cessation of ice movement, most probably resulted in some decrease of the active ice pressure and furthermore the ice jammed in between the trusses probably assisted to some slight degree in delaying the severance of this connection. But in spite of these factors, the severance continued very gradually to develop, ominous sounds of tearing were heard, and sharp reports, as rivet heads flew off, but the process slowed down and the other critical point seemed to exhibit for a while more signs of immediate failure. The amount of buckling at $L\,1\frac{1}{2}$ downstream gradually increased during the 26th, and developed a component in the upward direction which introduced some distortion into the vertical posts above the truss and into the deck construction immediately overhead. The tearing of metal was also heard at this point occasionally during the afternoon and noticeably about 1 p.m., but matters all seemed to ease as with the approach of night. In the early morning of the 27th, observations and measurements showed some further displacement of the deck structure above the point $L\,1\frac{1}{2}$ in the downstream truss and also some further degree of severance of the connections at the upstream shoe. Examinations at noon revealed the fact that there remained some connection between the gussets and the casting at the lower extremity, but exactly how much could not be determined due to it being buried in ice. It was also noted at this time that the buckling of the downstream chord at $L\,1\frac{1}{2}$ had reached the amazing dimension of about 3 ft. horizontally and 17 in. vertically, but had apparently steadied down at these figures. The chord had tilted about 40 deg., the upper coverplate was ripped across for about three-fourths of its width from the south edge, leaving just a few inches in contact with the north upper flange angle.

The lower flange plates were almost entirely torn off and both the south flange angles badly crushed at the point of buckling. The outstanding leg of the lower flange angle on the north side was cracked through a rivet hole and the crack was slowly creeping past the fillet into the upstanding leg. An instrument was set up on the bank at the writer's request to observe any further movement at this point as he felt that this would be the place where final failure must inevitably occur. The figured stresses from dead load thrust, dead load eccentricity, and the much reduced and damaged cross-section were definite indications leading to this opinion, but no more movement was recorded between noon and 3.45 p.m. when the last reading was made.

In the meantime however further inspection at the upstream shoe showed continued slow movement and the observers reported that occasional tearing and shearing could be heard to take place. At 2.40 p.m. it became obvious to the writer that further observations were likely to be dangerous so that all men were ordered away from underneath the bridge except one observer who from a safe distance, was instructed to record any serious change in the situation or any ominous noise. At 4.10 p.m. this observer approached the upstream shoe with the idea of making some check measurement, but heard a distinct tearing report from the other truss and saw the structure begin to fold up. He naturally ran southwards and was about 20 ft. clear when the downstream truss collapsed, bringing after it the approach span and the whole structure. As mentioned above this downstream truss left its bearings, but the upstream truss just quietly lay down. The Canadian end was pulled forward as the American end dropped and the bridge went down to its rest at 4.12 p.m. with a rattle like distant light artillery. When the snow cloud cleared it could be seen that the axis of the deck as it lay on the fallen arch, was almost directly below its proper alignment for a distance of two-thirds of the length from the Canadian end toward the American end, after which it dipped northwards or downstream, partly due to the fact that the downstream truss failed first and partly because of the hole in the ice which had been caused by the water from the tail-race emptying alongside the downstream skewback. It was also noticed that a number of the lamps were still intact, both globes and glass shades being unbroken.

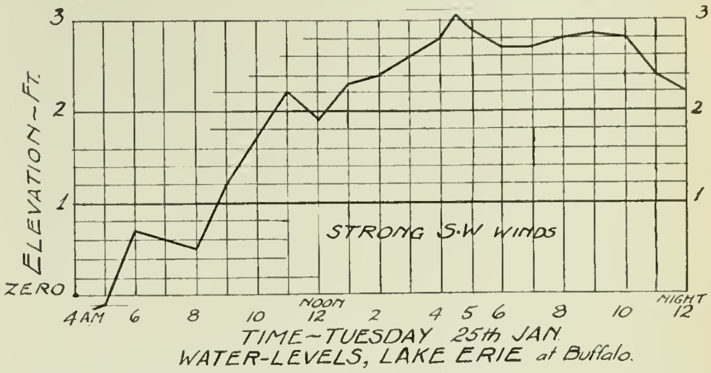

Fig. 14—Diagram of Water Levels, Lake Erie, on Jan. 25th, 1938.

In conclusion a brief statement as to the ultimate fate of the wreckage may be of interest. Arrangements were promptly made by the owners to cut the wreckage into sections and to cut it loose from the shores so as to minimize the danger of any quick movement of the ice leaving the span as a whole on the bottom of the river between the two sets of skewbacks. Local opinion was that the ice would remain for a goodly number of weeks, particularly on the Canadian side where it was apparently thick enough to rest on the bottom of the river profile. Further arrangements were made for the removal of the Canadian approach span, the salvaging of some of the timber and later on of some of the main span steel near the west or Canadian shore. The condition of the ice at the American end made it absolutely unsafe to carry out any operations in this vicinity. During the first few days of February, the hole in the ice caused by the tailrace near the downstream American corner enlarged itself and let the wreckage sink in this neighbourhood, but no really serious movement occurred until the beginning of April, when approximately half of the bridge at the American end dropped through the now rotting ice, and the remaining portion began to move downstream. A series of photographs taken on the 4th April record these movements and the last sight of any portion of the main structure was obtained about 4.04 p.m. on this day, several hundred yards downstream as the ice which carried a 200 ft. section upset and the steel sank to the bottom. The wreckage of the American approach span was finally removed during May and June so that the shore could be cleared as a preparation for the erection of a new bridge.

The New Viewpoint in Lighting

J. W. Bateman, B.A.Sc.,
Manager, Lighting Service Department, Canadian General Electric Company Limited, Toronto, Ont.

Presented before the Niagara Peninsula Branch of The Engineering Institute of Canada, December 16th, 1936.

SUMMARY.—With the constant increase in the number of people with defective eyesight, the problem of lighting becomes more and more important. The author points out how bad lighting contributes to this condition and indicates the standards which should apply in order to enable persons to maintain their normal eyesight for a greater number of years.

Illuminating engineering is continuously embracing new fields of application. At no time has the practice of the art and science of illumination been so interesting and so expansive as in the present era. At no time has illuminating engineering served so broad a viewpoint—in eyesight conservation and human welfare, in decoration and aesthetics, in safety and convenience—as it does today.

The first and fundamental question on lighting design is as to the real objective to be accomplished by lighting. In seeking an answer to this question, it is necessary to depart from the traditional engineering boundaries and enter a totally different realm—that of human reaction—of likes and dislikes—of health, heritage and habits; only here can we find the full significance and purpose of lighting.

Lighting specifications, both as to quantity of light and quality of lighting, must be based logically first, on how lighting affects visual processes, following through to the contribution to human welfare. Definite and measurable scientific facts have come out of an orderly programme of research on seeing, which have placed new responsibilities on the designer of lighting. These new responsibilities deal directly with the conservation of eyesight, health and safety of those who use the lighting. This is the new approach to lighting: this is the new viewpoint in lighting.

This new viewpoint is founded upon the new science of seeing. Seeing is a partnership of light and vision. The science of vision is relatively old. It has to do with our eyes, their function, limitations, and the visual sense. The science of seeing is much broader. It extends the viewpoint of vision to an activity of the whole human organism, its behaviour, efficiency and its welfare. It treats of human beings as human seeing machines. No science can be more universally important, since seeing is something in which everyone is interested. It is of prime importance in our everyday activities and therefore worthy of careful thought, consideration, study and action. It is for this reason that lighting research has been directed to the investigation of seeing, and the light by which we see. Dr. Matthew Luckiesh and his co-workers in the Lighting Research Laboratory at Nela Park, have during the past 25 years developed many significant facts and have presented much new knowledge which is just being accepted today.

One is inclined to think that because we live in a modern civilized world of machines, concrete buildings and motor cars, we are well fitted to our work of today. Actually, civilization imposes a considerable burden on many parts of our body and only through ages and ages of accommodation and evolution could we ever become completely adapted to modern times and the conditions we have made for ourselves. Outstanding among out bodily functions not yet adapted to our living conditions, are our eyes, which through inheritance are still best fitted to work under the seeing conditions of several thousand years ago.

How many years has it taken man to develop into what he is today? Some say five million years, some two million years. Let us say half a million years to be conservative. Let us assume that the 12 hours on the clock from noon to midnight represents the half million years down through the ages and during which man has been developing into what he is today, and follow the hands of the clock around hour after hour to a point just before midnight—5 seconds before midnight. If we did this, these 5 seconds would represent your lifetime and mine. What a small fraction of man's total existence we are living today! Within the last minute or so of this journey of ours upon the clock man started to use his eyes for closer vision—pottery, weaving; and later, within the last 30 seconds, to reading books and papers.

Fig. 1—The Illuminating Engineering Society type study and reading lamp, built by several manufacturers to specifications issued by the I.E.S., provides an adequate amount of glare-free lighting for its designed purpose. Inside the shade is a translucent bowl with the open end upwards, containing but concealing the source of light. The light that passes through the bowl is reflected downwards by the shade and the balance goes upwards to the ceiling and walls, thus reducing the difference in intensity of illumination between the well lighted area and the balance of the room; such differences are a definite source of eyestrain.

Nature's Plan—Man's Plan

For the thousands and thousands of years that man has been developing, he has been essentially an outdoor creature. His eyes, for instance, were evolved to function under the high illumination of daylight. He used his eyes primarily for long-distance seeing, and when the sun went down, he went to bed. But what has happened now? Within the last two generations, we have become modern. We have developed all kinds of indoor-located machinery, which we run night and day, on dark days as well as on sunny ones.

Let us contrast the difference between nature's plan and modern man's plan. We moderns, tossing lightly aside the fact that our eyes have been in the process of development for hundreds of thousands of years, bring ourselves indoors, accelerate our tempo of living, and create all sorts of jobs for those eyes under conditions vastly different from those nature intended. Instead of distant vision, we have for most of our visual tasks close vision, 15 to 30 inches. Instead of broad daylight, we have relatively low levels of indoor natural and artificial light, and, not content with all this, we have, on the average, lengthened the working day that our eyes must serve.

Our eyes are so formed that the ideal distance for seeing is probably a range of 20 feet or more—no doubt because so far as our remote ancestors were concerned, objects seldom required close scrutiny at shorter distance than this. The eye is provided with muscles for converging the eyeballs into position for near vision, but nature intended these to be used for intermittent concentration and not to be under strain for many hours each day. Therefore, it is just as logical that fatigue should result from this continuous concentration as from any other unnatural action, such as holding your hand at arm's length for more than a few minutes' time.

Nature planned for the eye to cease functioning at nightfall and have a long period of rest. In the present century, while we have been busy shortening the hours of labour for the body, we have steadily increased the hours of hard labour for the eyes, to about 16 hours per day. Not long ago there was no daily newspaper to read and no magazines. There were no movies, no automobiles, no basement machine shops—all of which give us mental relaxation but plague our eyes and increase their burden. The contrast of nature's plan with modern man's plan begins to suggest some of the reasons back of the statistics on defective eyesight. But, you ask, how does this relate to lighting and the Science of Seeing? If modern civilization has chosen to impose such handicaps, what is there that we can do about it?

Outdoor Footcandles

Nature is very generous and on a bright sunny day gives us as much as 10,000 footcandles of illumination, and we moderns find no real discomfort in this amount as we engage in out of doors work or play; there is something really pleasant about it. Even on a dreary, rainy day, there are several hundred footcandles outdoors. In the shade of a tree there is an illumination of perhaps 500 footcandles.

Indoor Footcandles

When we come indoors the story is quite different. Take a modern building with large windows covering most of the sides. Surely there is a bright cheerful daylighting inside on a sunshine day. Measurement of the illumination inside with the light meter would probably show that near the window there is only about 100 footcandles, even though there are several thousands outside. At ten feet from the window, this value would have dropped to approximately 20 footcandles and at a distance of 20 feet would have dropped as low as five footcandles. Even on bright days in most of our interiors the light is poor, except at the windows. The use of light meters which detect lighting conditions is needed vastly more than the thermometers, the use of which is commonplace in offices, schools, and other work places. With a good modern system of lighting, automatic photo-electric lighting control is one sure safeguard again abusing the eyes by failure to turn lights on when needed. Tests in two schoolrooms showed that the lights in one classroom with automatic control set to maintain a minimum footcandle level, were on 40 per cent of the time. In an adjacent classroom with the same daylight exposure, the manually-controlled lighting was, through inattention, turned on only about 10 per cent of the time.

Light is the One Controllable Factor in Seeing

What are the elements which go into this process of seeing? They are three: the eye, the seeing task, and the light which makes it possible for the eye to see. We can do very little for the eyes themselves, beyond sharpening them with the aid of glasses, if these eyes need such aid. We can do very little about the seeing task. If we are typing in an office, we must continue to type. If we are working on a lathe, we must continually keep our eyes on this task. If we are reading a newspaper, we cannot change the type, or the colour of the paper.

The one big variable is the light, and that we can control in almost any manner we wish. We can make it high or we can make it low; we can make it harsh and glaring or we can make it soft and comfortable. How important it is, therefore, to study the effects of this one factor, to know how much light we should have, and how much light we are actually getting. The slow processes of evolution are inadequate to compensate for the changes man has made in his method of living. The eyes are not receiving the assistance from lighting that they should.

As people grow older, more and more of them have to turn to eyeglasses to help out an increasing percentage of defective eyes. Surely it is a rather startling fact that among people sixty years of age, only one in twenty has normal vision. A study of the progress of nearsightedness in school children and college students reveals appalling conditions. If 40 per cent of the adults we meet on the street were hobbling along on crutches, we would bend every effort to correct so distressing a situation. And yet, many of us give slight consideration to our eyes which probably all of us will admit are our most valuable possession.

How Much Light Do the Eyes Want?

For long years we have been recommending intensities of illumination based largely on guesswork, tempered with good engineering judgment, satisfying the question "Can you see?", rather than the more important one "How *well* can you see?" Now with the findings of researches in seeing, we have a rational basis upon which to base our recommendations. Even so, had we in previous years given our eyes a chance to judge how much light they want rather than theorize, we would have determined long ago that the footcandles intensities being recommended and used were pitifully inadequate.

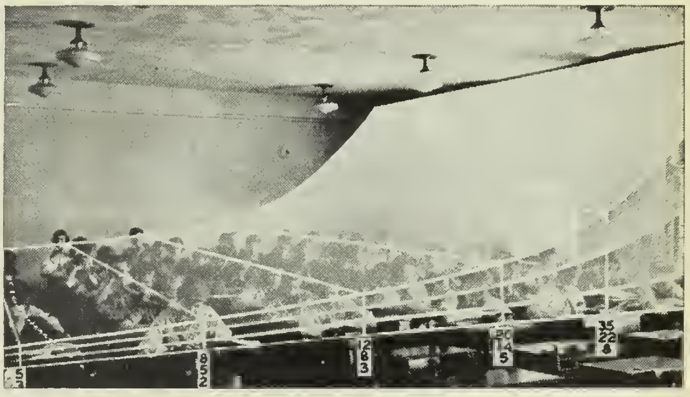

Fig. 2—Composite photograph showing the rapid falling off in natural daylight as the distance from the window increases. Top line represents a bright day, middle line a cloudy day, lower line a dark day. Good classroom lighting has been receiving much attention lately.

There has been adopted a device whereby any person can select for himself any intensity his eyes ask for between 1 and 1,000 footcandles. A summation of the results obtained by a number of people on a simple visual task such as reading a newspaper produces astonishing results: a few are satisfied with 10 and 20 footcandles, most ask for 50 footcandles; some want 100 and 200 footcandles, with an occasional one asking for 500 or more. In the light of the 2.5 to 10 footcandles we have been making our eyes work under, perhaps we would demand more, if our pocketbooks or past practices had not played a more important part in our judgment than our eyes.

There are Four Factors in Seeing

The Science of Seeing now tells us very definitely the proper amount of light recommended for the several grades of visual tasks. Also that every time we see an object, four principal factors come into play: the size of the object, the contrast, the time and the brightness. The first three of these factors are usually more or less uncontrollable in any specific instance; the fourth, brightness or the amount of light, can be controlled and its proper intensity is dictated largely by the other three factors. The second fundamental factor is that of contrast. Often our selection of clothes, shoes, wallpaper, and things of that character is influenced by the statement, "It won't show the dirt," but everyone will agree that in lighting laundries and food factories, we ought to be able to see the dirt. A dark hairline crack or flaw hiding in the grey background of a casting in a foundry doesn't show the dirt either, but it is quite vital to see it before it gets into the cylinder block of your automobile.

The third factor of vital importance in seeing is that of time—for it takes time to see. The eye is very much like a camera in its action. When the illumination is high the eyes take a snapshot; when the illumination is insufficient, they must take time-exposures.

More Light is Only Part of the Story

In the majority of instances, improving seeing demands higher levels of illumination. But this is just one factor that is under the control of the lighting engineer. Other elements of quality, control, direction, surroundings, enter into the problem and require an intelligent selection of reflecting and diffusing equipments and their proper location.

Probably the most apparent and at the same time the most undesirable factor of quality is that of glare. Glaring lights are hazardous to eyesight and positively wasteful because they reduce visibility. Similarly, reflected glare, that is brightnesses reflected from shiny work surfaces, glasstopped desks, store counters, and the like, may prove even more annoying and interfere with vision to an even greater extent than direct glare. The illumination of the surroundings, so as to relieve severe contrasts, is of extraordinary importance in relieving eye muscles and obviating the necessity for frequent adaptation of the pupils of the eyes.

Consider the many cases of serious complaints of factory and office workers, suffering from headaches and nervousness, with consequent loss of time, where the solution has time and again rested purely and simply on the matter of providing an adequate system of illumination with respect to both quality and quantity. The prevalence of defective eyesight will never be alleviated if we continue to install lighting systems in accordance with primitive notions and on a false basis of economy. Good lighting is not only a matter of saving eyesight. It is a matter also of stopping needless waste of untold quantities of nervous energy. The statement has been made that the office worker who uses his eyes all day under inadequate light may be actually more tired at night than the man who spends a day digging ditches. The Science of Seeing indicates quite clearly that it does take energy to see. In testing this in our Lighting Research Laboratory, we have discovered, after thousands of tests, that there is a direct relationship between low illumination and increased muscular tension. The higher the illumination, the greater the relaxation.

Good Lighting Helps Those Who Need It Most

It is a generally accepted fact that improved lighting increases efficiency. Fast workers with normal vision are enabled to produce more useful work when provided with the advantages of good lighting. Slower workers and those with subnormal vision receive even greater assistance from good lighting. The eyes are entitled to carefully designed lighting adequate for all periods in the life of the individual. During the formative period of childhood, young eyes are easily injured by the strain of inadequate and improper lighting. As the eyes grow older, physiological changes occur which impair vision, for example, the pupils of a 50-year old person admit slightly more than one-half as much light as those of a 20-year old person. In this, and in other ways, higher levels of illumination serve to offset the handicap in seeing imposed by advancing age.

In general, more and better lighting improves visibility, makes visual work easier, reduces eyestrain and fatigue and enables a greater proportion of the energy available for work to be converted into useful work. Increasing the amount of illumination, utilized in accordance with known relationships of lighting and seeing, is the most generally efficacious means at the command of the light specialist for assisting vision. In the business of lighting, many compromises are often made with respect to types of units, systems employed and lamp sizes, yet there can be no compromise with eyesight.

Application of the New Science of Seeing

Now let us give some consideration to the application of the principles of the new science of seeing to our modern lighting installations. The school lighting field is one which is of interest to the entire community and educators and lighting men have been giving much attention in the last year or two to the significance of adequate lighting in our schools. A survey indicates that even on a bright day the natural illumination in the inside row of desks is entirely unsuitable for the work which the pupils have to do. A carefully conducted test of the progress of students in a poorly lighted room and in a well lighted room in one particular school, showed the following results:

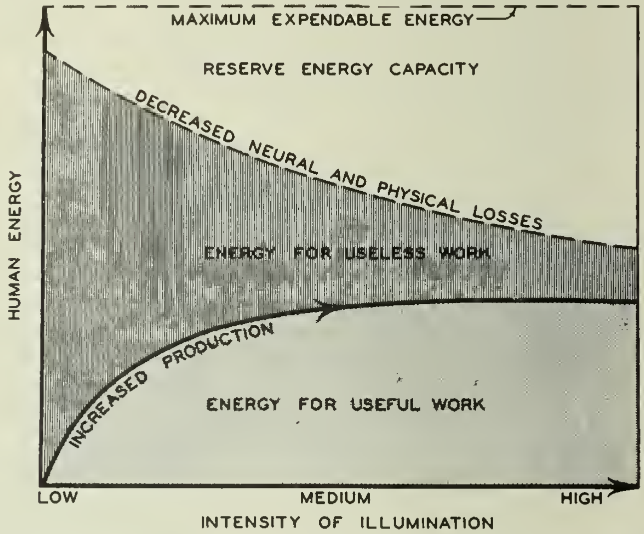

Fig. 3 — Curve showing the proportion of human energy available for useful work under various intensities of illumination.

1. The pupils in the well illuminated room showed approximately 28 per cent more improvement than those in the poorly lighted one.
2. The pupils in the better lighted room were more alert and more responsive.
3. The teachers commented on several occasions that the better lighted room was a much more pleasant location in which to teach.

Another three year study of the effect of adequate classroom lighting contrasted with poor lighting in schools was conducted. Over the three years an average of nine pupils per year failed in a poorly lighted room, compared with three in well lighted room. The total electrical energy used in each room was metered and the average cost for the additional consumption for the well lighted room was $24.33 per school year. The cost of educating each pupil in that location is about $28.00 per year for actual operating expenses. The results of this investigation indicated that better lighting paid for itself six times over when the additional cost of the higher lighting was compared with the cost of instruction for the pupils.

By far the largest amount of school money goes for formal instruction. Although learning is chiefly received through the eyes—psychologists tell us that 87 per cent of our knowledge comes through the sense of sight—only a tiny sum is spent for the one medium which can help the eyes and an analysis of the actual operation expenditures of the school system serving a city of 40,000, with average lighting in its schools, shows that even doubling the present lighting bill would increase the budget only ½ of 1 per cent. Improved lighting is a cheap way to reduce failures and protect the eyes of the school children.

Office Lighting

One can't very well move his desk outdoors under the shade of a tree, much as he may wish to have at his work the 500 or more footcandles of comfortable, well-diffused illumination that is to be found there. What can be done, however, and what is being done today by many business executives, is to provide for themselves and their employees lighting systems that produce illumination comparable in quality, if not in quantity, to that found in the shade of a tree.

As a matter of fact, it is not necessary to provide the quantity of foot candles indoors that nature provides outside. To do this would tax the ingenuity of the engineer and probably could not be justified from an economic point of view. What is desirable, however, is to provide illumination values indoors far in excess of the starvation levels that are to be found in the average office today. For not only does good lighting help to conserve human energy and human eyes, but adequate illumination also helps to increase the efficiency of the workers by enabling them to do more work with less effort.

There are three kinds of lighting systems applied to offices—indirect, semi-indirect and semi-direct. In the first two mentioned systems all or most of the light is directed from the luminaire to the ceiling, whence it is distributed as useful illumination throughout the office. In these systems, since the ceiling becomes the main source of light, distribution illumination to the desks, and being large in expanse, somewhat similar to an overcast sky, comfortable illumination of good quality results. In general, semi-direct systems of lighting which direct most of the light directly downward to the desks are only recommended where the ceilings are unsuitable as a secondary source of light.

The present recommended standards of illumination for office work are as follows: 20 footcandles for ordinary desk work; 30 to 50 footcandles for prolonged close work, computing, designing, and so forth; 30 footcandles for bookkeeping and accounting; 30 footcandles for drafting rooms.

Industrial Lighting

To understand factory lighting problems and solve them successfully demands that we have a knowledge of the Science of Seeing and appreciate the significance of light in relation to eyesight. The scientific knowledge is all-important and constitutes the basis for the specifications of lighting for every job where quick, accurate and safe seeing is involved.

Let us forget for the moment any ideas or notions about lighting we may have, and approach the discussion with an open mind and with simple logic; it seems we must consider these three questions:

1. Do we need better lighting for industrial work?
2. Do we have the knowledge and equipment to apply better lighting?
3. Can we afford better lighting?

Those of us who have been concerned with supplying artificial lighting now realize that light in itself has no value but becomes important only as a function of the processes of seeing. The Science of Seeing indicates the levels of illumination desirable for the many tasks which our eyes have in a factory. Surveys which have been made indicate that the present lighting is far below useful values. The results of tests made in measuring the illumination in the work areas of nearly 3,000 factories show the average value to be only of the order of about three footcandles.

During the past few years many industrial executives have been realizing the very definite need for higher intensities of illumination. Results have shown that a good number of outstanding installations have been accomplished. The practical results indicate that the present knowledge of illuminating engineering and the wide choice of lighting equipment are adequate to provide the advance of lighting needed. General illumination of the order of 10, 20, 30 or even 50 footcandles is now very practical, and even 100 to 500 footcandles over special local areas.

And now, as to the question "Can We Afford Better Lighting?" Some of its values are so far-reaching and complex as to defy measurement in dollars and cents. Humanitarian values in conservation of eyesight and benefit of the health and well-being of the workers, cannot be thus appraised. But, let us look at the cost of lighting. This is usually so small that in the majority of cases it is not known nor is it usually set down as a separate accounting item. From the best estimate it is possible to make it is indicated that factory lighting costs today are less than .3 of 1 per cent of the total production cost. Even the best lighting that we think of today would cost only a very small proportion of the total cost of doing business. And then, when we consider the benefits of better lighting which spread themselves over every phase of plant operation, and the values which come from any one phase, may more than offset the entire lighting bill. We must conclude that we have in lighting a commodity which cannot help but be a profit.

The fact that all plants use artificial light to some extent today indicates the inadequateness of natural lighting to provide the illumination required. The difference between the cost of poor lighting and good lighting is so small, coupled with the overwhelming evidence of its benefits, that judged either from the standpoint of investment required or operating expense, the conclusion that it is worth more than it costs appears almost inescapable.

Home Lighting

The lighting in the home is something in which everyone is interested. The lighting provided affects every member of the family. During the past few years we have heard much of the "better light—better sight" activities which has spread knowledge of better lighting into a good many of our homes throughout the country. This knowledge of better lighting has been warmly welcomed as has been indicated by the increase in the use of improved types of portable lamps and other lighting equipment. The advantages which will acrue in the conservation of priceless eyesight and human resources and the comfort and joy of a more restful, cheerful, inspiring and safe environment, in the sheer pride of a more attractive and up to date home, are worth thoughtful consideration in the lighting which we plan for our own residence.

Simplified Performance Calculations For Aeroplanes

Elizabeth M. G. MacGill, A.M.E.I.C.,
Aircraft Department, Canada Car and Foundry Limited, Fort William, Ont.

Presented before the Aeronautical Section of the Ottawa Branch of The Engineering Institute of Canada, March 22nd, 1938.

SUMMARY.—Through the use of two simple, generalized logarithmic curves, one representing Power Required, the other representing Power Available, the ceilings and high speed, climbing speed and maximum rate of climb at any altitude are determined rapidly for any aeroplane. The curves are in terms of general propeller and aeroplane parameters: shifting their positions relative to one another provides change of altitude.

The tools of the method are two generalized curves, prepared beforehand, and which relate to any aeroplane. The generalized Power Required curve (Fig. 1) is in terms of a variable K_{HP}, expressing the ratio of any power to minimum power, and a variable K_v expressing the ratio of any speed to speed at minimum power. The generalized Power Available curve is also in terms of the ratios of power and speed: in this case the ratio of any power available to maximum power available and any speed to maximum speed.

While the development of the two generalized equations upon which the curves are based is quite straightforward, it is not necessary to follow it through as the desired performance figures can be obtained by using the routine mechanically. It is proposed to demonstrate the use of the method first and to develop the equations later.

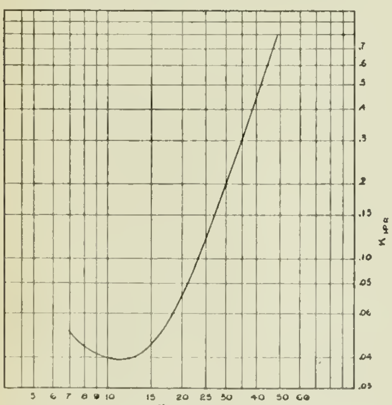

Fig. 1—Generalized Curve of Power Required.

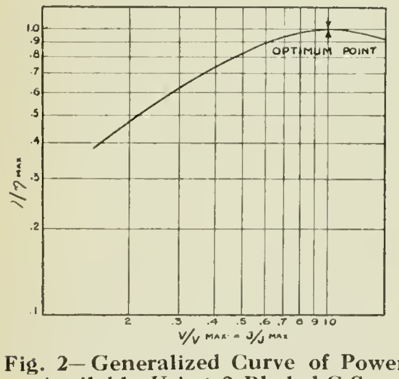

Fig. 2—Generalized Curve of Power Available Using 2-Bladed C.S. Propeller.

Assume we have given:

1. The generalized curve of Power Required plotted in terms of K_{HP} on K_v on logarithmic paper (Fig. 1).
2. The generalized logarithmic curve of Power Available (Fig. 2) cut from celluloid.
3. The usual working charts for propellers, such as References 5 and 6.
4. The general characteristics of the aeroplane, such as listed for the Sample Aeroplane in Table Ia.

From the figures of Table Ia, calculations are carried out to determine one value for K_v and one value for K_{HP} for each altitude. This locates a point for each altitude on the generalized Power Required sheet, Fig. 1 (see Fig. 5). The Power Available curve (assuming a constant speed propeller) for the desired altitude is then drawn by setting the Optimum point of the celluloid curve on the specified point of the Power Required graph and tracing out the curve—one curved line for each altitude. This set of curves may then be treated as an ordinary set of aeroplane power curves: their intersection represents the high speed at the specified altitude; their vertical differences represent Excess Power, from which the maximum rate of climb at the altitude may be determined, and hence the service and absolute ceilings obtained. The case of a fixed pitch propeller is treated in the same general manner, with slight differences.

Sample Calculations

Using the data given in Table Ia, the simple calculations of factors and sea level values of the parameters S_v and P_v are carried out as shown in Table I.

Case A. Sample Aeroplane with Constant Speed Propeller.

In Table II, the Sea Level values of S_v and P_v (as calculated in Table I) are listed in the Sea Level Altitude column: their values at various altitudes are obtained by multiplying the Sea Level value by $1/\sqrt{\sigma}$, as shown. Item 5 is taken from the engine power curve, or, if this is not available, the values are estimated by methods given in Reference 1. Items 7 and 8 are taken directly from Fig. 3 for the values calculated for Item 6. Item 9 is calculated as shown, the 2 being introduced because there are two engines. Items 9 and 10 give the ordinates and abscissae for the points marked on Fig. 5. On each of these points in turn is set the Optimum point of the Power Available celluloid curve, and the curve traced out and labelled with its altitude. This set of curves then represents the power curves for the sample aeroplane with constant speed propeller.

The high speed at any altitude is obtained by reading the value of K_v at the point where the power curves for that altitude intersect (Item 11) and multiplying this value $K_{v\,\max.}$ by the speed variable S_v (Item 3), relating to that altitude (Item 15). To determine the maximum rate of climb for a given altitude, the greatest distance between the Power Required curve and the Power Available curve *at the desired altitude* is determined (by subtraction of the ordinates) as set out in Item 13, and this value is multiplied by 3.3 P_v (the P_v used being that related to the desired altitude), giving the maximum rate of climb in feet per minute directly. The reader is cautioned that the figure 3.3 is peculiar to this sample calculation. The figure by which $P_v(K_{HP\text{av}} - K_{HP\text{req.}})$ is multiplied is 33,000 per gross weight, which in this case is 33,000 per 10,000 equals 3.3. The value for best climbing speed is that value for K_v (Item 12) at which Item 13 is measured. Then the value of the maximum climbing speed at the desired altitude is this value of K_v multiplied by the value of S_v for the altitude.

The results of the calculation have been plotted on Fig. 7.

Case B. Sample Aeroplane with Fixed Pitch Propeller.

Power curves for the same sample aeroplane with a fixed pitch propeller are now determined.

Here the propeller is assumed to be designed for full B.hp. at the critical altitude, and the blade angle is chosen to give the values at 5000 ft.,

$C_p = .0371$ $\qquad J$ at η max. $= .702$ $\qquad \eta$ max. $= .818$

using Reference 6, i.e. Fig. 3 as before. The value m is also read off from Fig. 3, where m is a function of C_p as explained later.

In Table III, the first six items are determined in the same manner as in Table II. Item 7 is calculated, being the ratio between C_p at η max. and the C_p value at altitude

Item 8 is read from Fig. 4. Item 9 is determined by multiplying Item 8 by the design J at η max. Item 10 is read from Fig. 4. Item 11 is calculated by multiplying Item 10 by η max. Items 12 and 13 are then calculated as shown, the figure 2 being introduced in Item 12 *in this case* because there are *two* engines. Items 12 and 13 then give the ordinates and abscissae for the points marked in Fig. 6.

$\frac{\eta}{\eta_{\text{max.}}} = \left(\frac{V}{V_{\text{max.}}}\right)^m$ Now the curve of propeller efficiency when plotted logarithmically is a straight line of slope m. Hence, through the marked points on Fig. 6, we draw lines of slope m which represent the Power Available at the stated altitudes. Since the power drops off at the same rate when the optimum point is passed, beyond the optimum point the power available will be represented by a straight line of the same slope m, but m will be negative.

The remaining calculations of Table VI are carried out from Fig. 6, in a manner similar to that of Case A. The speed and climb and ceiling values are plotted in Fig. 7.

Comparison of Calculated Values with Flight Test Figures

Performance figures obtained by this method were checked against flight test data for three aeroplanes (all high winged monoplanes, two single-engined, one twin-engined) and the following characteristics noted:

1. There was excellent agreement for speeds at all altitudes and for maximum rate of climb at sea level and critical altitude.
2. There was poorer agreement for maximum rates of climb above the critical altitude, and hence for ceilings. The method gave results about 7½ per cent. too optimistic for the absolute ceiling.

Discussion of Graphs

Before proceeding to the development of the equations, some points regarding the graphs and tables will be discussed.

Figure 1 is plotted from Table IV, and represents the equation $K_{HP\text{req'd}} = .00000683\ K_v^3 + \frac{.3329}{K_v}$ and is applicable to any aeroplane.

Figure 2 is plotted from Table V. These values were taken from Reference 1, and apply to 2-bladed propellers.

Figure 3 is plotted from References 5 and 6. The data of Reference 5 related to full-scale tests of a cabin fuselage with J-5 engine and N.A.C.A. type cowling. The propeller diameter was 9 ft. and the Blade No. Navy Design 4412, section R.A.F. 6. Similar curves for open biplane types, etc. may be obtained from this reference. Reference 6 gave data applicable to a 4 ft. propeller, Blade 4412, situated 30 per cent. of the chord ahead of the leading edge of a wing of 60 in. chord and maximum thickness 20 per cent. of the chord.

Values of m plotted on Fig. 3 were taken from Reference 4.

Figure 4 is plotted from Reference 6, the values being given in Table VI.

Reference 9 is useful in determining corrections to the blade angle for a fixed pitch propeller.

In adopting References 4 and 6 for general use, the inaccuracy, as noted in Reference 9, is introduced—namely, that test data which applies to specific propeller blade form and section used in connection with certain aircraft bodies, is applied regardless of blade form, section, etc. of the problem aeroplane. However, as more suitable data is obtained, the inaccuracy will dwindle.

The general Power Available curve of Fig. 2 applies to 2-bladed propellers only. It would be desirable to obtain a similar curve for 3 and 4 bladed propellers.

Table Ia lists as requisite data for calculation, the value of C_{D0} and the slope "a" of C_L^2 on C_D. These values presumably are obtained from wind tunnel tests of the aeroplane model, corrected for scale effect. Our generalized Power Required curve assumes a straight line variation of C_L^2 on C_D throughout its range. If, however, as seems sometimes to be the case, when C_L^2 is plotted on C_D, below a certain low value of C_L the slope of the curve increases suddenly, we take the value of C_D at this C_L as being the true value of C_{D0}. This brings our calculations in line with the peculiarities of the particular case.

Development of Generalized Power Required Equation

The development of this equation is from first principles and can be worked up from any standard text, as for example, p. 365 Reference 1.

$$C_D = C_{D0} + C_{Di} \qquad q = \frac{1}{2}\rho V^2 = .00256\ V^2\sigma$$

$$\begin{aligned} D &= C_D \cdot q \cdot S \\ &= C_{D0} \cdot q \cdot S \cdot + C_{Di} \cdot q \cdot S \cdot \\ &= .00256\ V^2\sigma C_{D0} S + .00256\ V^2\sigma S C_{Di} \quad \ldots\ldots\ldots (1) \end{aligned}$$

From Prandtl wing theory

$$C_{Di} = \frac{C_L^2 S}{\pi b^2 e^2}$$

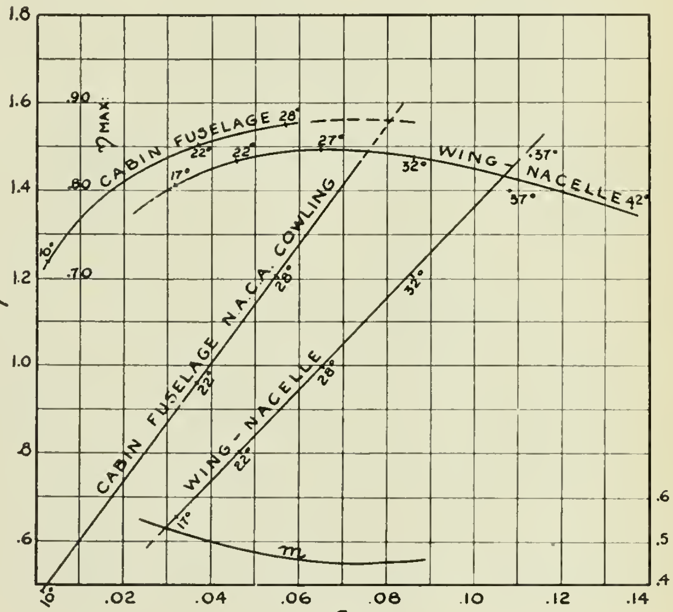

Fig. 3

But at small angles

$$L = W = C_L \cdot q \cdot S \cdot$$

or

$$C_L^2 = \frac{W^2}{q^2 S^2}$$

Hence

$$C_{Di} = \frac{W^2}{q^2 S^2} \times \frac{S}{\pi (b e)^2}$$

Substituting in (1)

$$\begin{aligned} D &= .00256\ V^2\sigma C_{D0} S + .00256\ V^2\sigma S \frac{W^2}{q^2 S^2} \cdot \frac{S}{\pi (b e)^2} \\ &= .00256\ V^2\sigma C_{D0} S + \frac{.00256\ V^2\sigma W^2}{(.00256)^2\ V^4\sigma^2\pi (b e)^2} \\ &= .00256\ V^2\sigma C_{D0} S + \frac{124.8\ W^2}{\sigma V^2 (b e)^2} \quad \ldots\ldots\ldots\ldots (2) \end{aligned}$$

Now HP required $= \frac{D \times V}{375}$

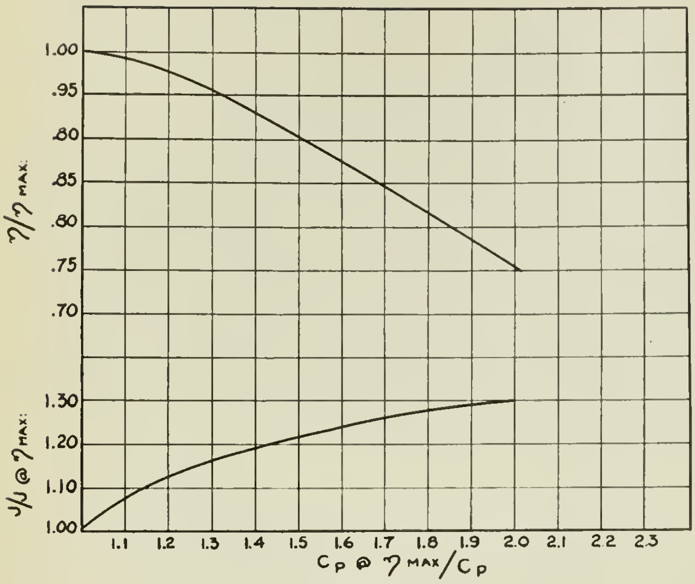

Fig. 4

Hence converting (2) into a power equation

$$HP_{\text{req'd}} = \frac{.00256}{375} V^3 \sigma C_{D0} S + \frac{124.8\ W^2}{375\ V\ (b\,e)^2 \sigma}$$

$$= .00000683\ V^3 \sigma C_{D0} S + \frac{.3329\ W^2}{(b\,e)^2\ V \sigma} \quad \dots\dots\dots\dots (3)$$

Differentiating (3) with respect to V

$$\frac{d\,HP_{\text{req'd}}}{d\,V} = 3 \times .00000683\ C_{D0} S \sigma V^2 + (-1) \frac{.3329\ W^2}{(b\,e)^2 \sigma V^2} \quad \dots (4)$$

If the power is a minimum, this equals zero, hence

$$V_{P.\min.}{}^4 = \frac{.3329\ W^2}{.00002049\ C_{D0} S \sigma^2 (b\,e)^2}$$

$$V_{P.\min.}{}^4 = \frac{11.28\ W^{1/2}}{(\sigma b\,e)^{1/2} (C_{D0} S)^{1/4}} \quad \dots\dots\dots\dots\dots\dots\dots\dots (5)$$

Equation (5) gives the flight speed for minimum power in terms of the air density and known aerodynamical characteristics of the aeroplane. We now express any other flight speed V as a multiple of $V_{P.\min.}$:

i.e. $V = K \cdot V_{P.\min.}$

or $$V = \frac{K \times 11.28\ W^{1/2}}{(\sigma b\,e)^{1/2} (C_{D0} S)^{1/4}}$$

or $V = K_v S_v$ where $K_v = 11.28\,K$

$$S_v = \frac{W^{1/2}}{(\sigma b\,e)^{1/2} (C_{D0} S)^{1/4}}$$

Substituting this value of V in Equation (3), we express the Power Required at any speed V in terms of variables and aeroplane characteristics.

$$HP_{\text{req'd}} = \frac{.00000683\ C_{D0} S \sigma W^{3/2}}{(\sigma b\,e)^{3/2} (C_{D0} S)^{3/4}} K_v^3 + \frac{.3329\ W^2 (\sigma b\,e)^{1/2} (C_{D0} S)^{1/4}}{(b\,e)^2 \sigma\ W^{1/2} K_v}$$

$$= .00000683 \frac{W^{3/2} (C_{D0} S)^{1/4}}{(b\,e)^{3/2} \sigma^{1/2}} \cdot K_v^3 + \frac{.3329\ W^{3/2} (C_{D0} S)^{1/4}}{(b\,e)^{3/2} \sigma^{1/2}} \frac{1}{K_v}$$

To simplify this unwieldy form, write

$$P_v = \frac{W^{3/2} (C_{D0} S)^{1/4}}{(b\,e)^{3/2} \sigma^{1/2}} = S_v^3 C_{D0} S \sigma$$

hence

$$HP_{\text{req'd}} = .00000683\ P_v K_v^3 + \frac{.3329\ P_v}{K_v}$$

or

$$\frac{HP_{\text{req'd}}}{P_v} = .00000683\ K_v^3 + \frac{.3329}{K_v}$$

Now $\dfrac{HP_{\text{req'd}}}{P_v}$ is simply a factor, which we will represent by K_{HP}

Then

$$K_{HP_{\text{req'd}}} = .00000683\ K_v^3 + \frac{.3329}{K_v} \quad \dots\dots\dots\dots\dots\dots (6)$$

Equation 6 is a general equation for Power Required applicable to any aeroplane, expressed in terms of variables which depend upon the aerodynamic characteristics of the aircraft. Figure 1 shows the generalized curve and is plotted from the values of K_{HP} and K_v as listed in Table IV.

Development of the Generalized Power Available Curves

From Reference 4, p. 18, we obtain a general equation for Power Available (for values of $V/V_{\max.}$ greater than .5) for aeroplanes using gasoline engines. This equation is written $T_v = R_v^m$ or $\dfrac{T_{HP}}{T_{HP\,\max.}} = \left(\dfrac{V}{V_{\max.}}\right)^m$.

The relation of the variables of this equation is in the form of a power function, hence the points of the curve, when plotted on logarithmic paper will lie on a straight line of slope "m". This means that, knowing the value of m, we can represent the Power Available curve by a straight line of given slope m.

The value of the exponent m varies with the engine. From the information given in the tables of Reference 4, we can cross plot and obtain values of m for values of C_p. These values we have plotted on Fig. 3. Hence having determined the value of C_p for the design condition of maximum speed from the equation $C_P = \dfrac{550\ B.HP}{\rho\, n^3 D^5}$ we read the value of m directly from the figure, and can reproduce a curve of the Power Available by a straight line on logarithmic paper. This line, of course, applies only to the altitude at which the design C_p applies.

The above applies to the case of an aeroplane with fixed pitch propeller, where, as the speed of the aeroplane

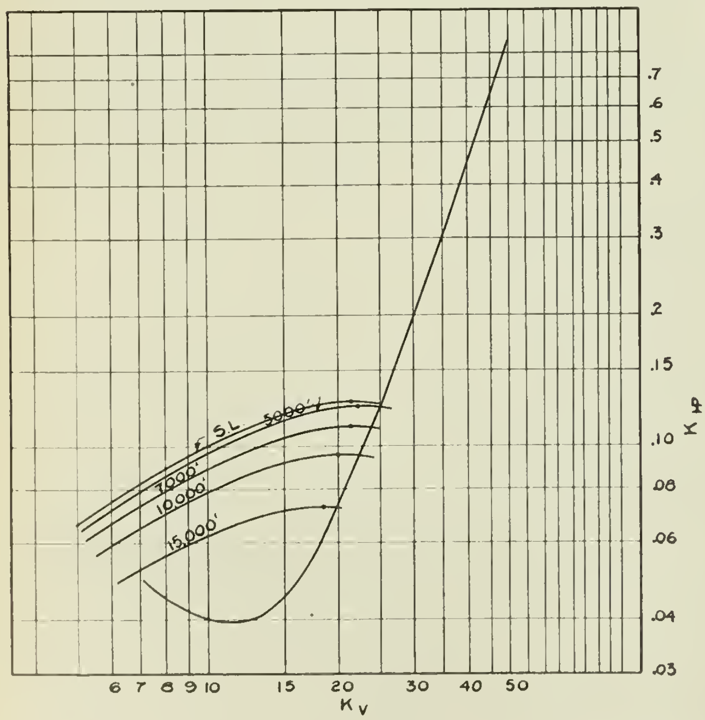

Fig. 5 – Sample Power Curves Using Constant Speed Propeller.

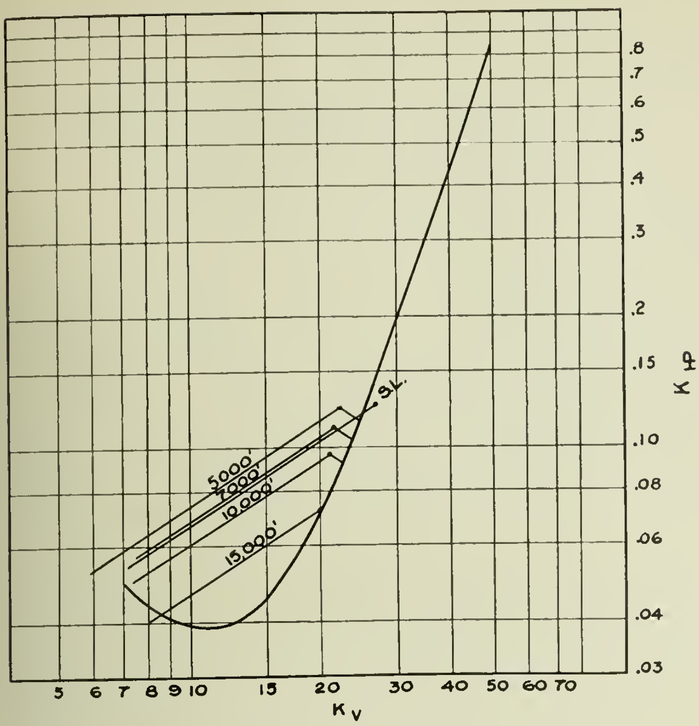

Fig. 6—Sample Power Curves Using Fixed Pitch Propeller.

changes, the r.p.m. changes. We need now a curve of Power Available for the constant speed propeller. In the equation $\frac{T_{HP}}{T_{HP\,max.}} = \left(\frac{V}{V_{max.}}\right)^m$ we can write, for the constant speed propeller,

$$\frac{T_{HP}}{T_{HP\,max.}} = \frac{\eta}{\eta_{max.}} \frac{B_{HP\,max.}}{B_{HP\,max.}} = \frac{\eta}{\eta_{max.}}$$

hence

$$\frac{\eta}{\eta_{max.}} = \left(\frac{V}{V_{max.}}\right)^m.$$

But $J = V/nD$, and both n and D are constant, so that J varies directly as V. Thus we can write, as shown in Reference 1,

$$\frac{V}{V_{max.}} = \frac{J}{J_{max.}}$$

and

$$\frac{\eta}{\eta_{max.}} \propto \frac{J}{J_{max.}}$$

This general Power Available curve as determined from N.A.C.A. full scale propeller test data is plotted in Reference 1, p. 337, and has been replotted on logarithmic paper as Fig. 2.

Superposition of the Power Curves

We have now two generalized curves, one of Power Required (Fig. 1), the other of Power Available (Fig. 2). If we can superimpose them in their proper relation to one another the point of their intersection will give values of K_{HP} and K_v which can be converted easily into horsepower and velocity values by multiplying by the variables shown, such power and speed values representing maximum speed at maximum power available. The point of maximum efficiency on the Power Available curve is the Optimum point, as marked on Fig. 2. The propeller-engine combination has been designed to give maximum efficiency at some particular value of propeller characteristics C_p at a specific B.hp., r.p.m. and altitude.

For the particular aeroplane we calculate the design value of C_p from $C_p = \frac{550\, B.HP}{\rho\, n^3 D^5} = \frac{.05105\, B.HP}{\sigma\, N^3 D^5}$. This C_p value has a certain value of J (at $\eta_{max.}$) and $\eta_{max.}$, which we read from Fig. 3. Then the power available and the speed of the aeroplane under these conditions are

$$HP_{av.} = \eta_{max.}\, B.HP$$

and

$$V_{max.} = \frac{J \text{ at } \eta_{max.}\, ND}{88}$$

But we can convert HP into a K_{HP} term by dividing by P_v; and we can convert a V into a K_v term by dividing by S_v. Carrying out these divisions we are able to locate the optimum point of the Power Available curve on the sheet Fig. 1.

In both cases, the fixed pitch propeller case and the constant speed propeller case, the curve shape for various altitudes will be the same as for the sea level altitude. In the case of the F.P. propeller it is a straight line; in the case of the C.S. propeller it is the curve of Fig. 2. To determine the position of the Power Available curve at various altitudes it is only necessary to determine the position of the optimum point for each altitude. This is simply

$$K_{HP} = \frac{K_{HP0}}{\sqrt{\sigma}} \text{ and } K_v = \frac{K_{v0}}{\sqrt{\sigma}}$$

since

$$V = V_0 \sqrt{\frac{\rho}{\rho_0}} = \frac{V_0}{\sqrt{\sigma}} \text{ and } HP = HP_0 \sqrt{\frac{\rho}{\rho_0}} = \frac{HP_0}{\sqrt{\sigma}}$$

Thus we are able to superimpose the curves upon one another in their proper relationship.

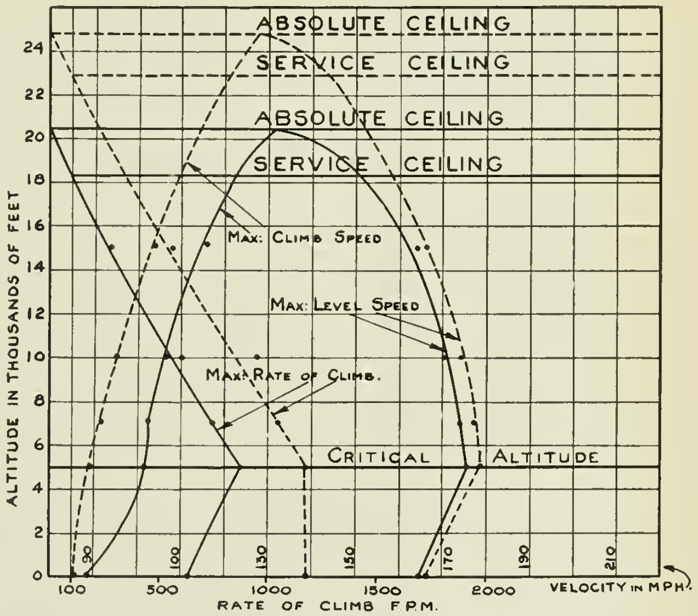

Fig. 7

Effect of Differences of Scale in Fig. 1 and Fig. 2

The curves of Fig. 1 and Fig. 2 have been plotted on logarithmic paper.

Now if we have an equation $y = ax^n$ where a is the scale factor, if we plot on log paper we are taking mechanically the log of both sides

$$\log y = \log a + n \log x$$

where $\log a$ is a constant representing the log of the scale factor. Hence changing the scale simply results in the addition of a constant representing the log of the multiplying factor.

While the scale factor of Fig. 1 may differ from that of Fig. 2, it will be constant for its own figure. Thus, locating correctly one point of Fig. 2 with respect to Fig. 1 will result in all points of Fig. 2 being located correctly with respect to Fig. 1. In our routine we have located the point called the Optimum Point of Fig. 2, correctly with respect to Fig. 1, hence the other points of Fig. 2 are located correctly.

Possible Advantages of this Method

Once the generalized curves have been prepared, the routine, the author believes, is as simple and rapid as that of References 4 and 7 (since Reference 4 is out of print, the value of the above method is increased), and it has the added advantage that curves of actual Horsepower upon Velocity can be determined readily if desired. The results obtained by the method are as accurate as those determined by the more laborious arithmetical methods of References 2, 3 and 10, and the generalized curves are developed from the same fundamental relationships as References 2 and 3.

Acknowledgments

The germ of the idea for the above development came from References 11 and 12. The author also gratefully acknowledges the assistance of Dr. J. J. Green and Mr. K. F. Tupper, both of the National Research Council, Ottawa, for corrections and suggestions regarding the presentation of this material.

List of Symbols

C_D	= Absolute coefficient of drag.
C_{D_0}	= Absolute coefficient of profile drag.
C_{Di}	= Absolute coefficient of induced drag.
S	= Area of wing in sq. ft.
q	= Dynamic head $= \frac{1}{2}\rho V^2$.
V	= Speed in mi. per hr.
ρ	= Density of air.
σ	= Relative density.
C_L	= Absolute coefficient of lift.
b	= Span of wing in ft.
e	= Span efficiency factor for aeroplane $= \frac{1}{\sqrt{\pi R a}}$
W	= Gross weight of aeroplane in lb.
D	= Drag in lb., also
D	= Diameter of propeller in ft.
HP	= Horsepower.
η	= Propeller efficiency.
n	= Engine speed in revolutions per sec.
N	= Engine speed in revolutions per min.
R	= Aspect ratio $= b^2/S$.
J	= V/nD.
C_P	= Propeller power coefficient $= \frac{550\ B.HP}{\rho n^3 D^5}$
$B.HP$	= Brake horsepower.
a	= dC_L^2/dC_D from wind tunnel curve of aeroplane.
THP	= Thrust horsepower.

A Parking Survey in the Capital City

R. M. Simpson,
Survey Director for the Citizens' Parking Committee, Ottawa.

Presented before the Ottawa Branch of The Engineering Institute of Canada, April 12th, 1938.

SUMMARY.—A short account of the first comprehensive attempt of a Canadian city to scientifically solve its parking problem. The paper deals only with the survey and the recommendations.

Canada's first comprehensive parking survey was completed in the downtown business section of Ottawa in November, 1937. The project was originated by the Automobile Club of Ottawa which invited 34 public spirited organizations to join with them in the formation of a Citizens' Parking Committee. Civic officials cooperated by supplying the services of 240 relief men for a total of 3,000 hours of field work. A staff of six qualified assistants was obtained for the survey director and work started on October 15th.

As the guiding principle, the committee decided that all recommendations would be developed from the factual basis evolved from the survey findings.

The chart presented here indicates the first step (Fig. 1). It is interesting to note that Ottawa possesses fewer motorists and considerably more pedestrians than cities of similar size.

As the survey principally dealt with automobile congestion, the second step was to determine just what situation resulted from the fact that the majority of the persons using the central business district were automobile drivers or passengers. By measuring the street space, it was found that the district had a legal capacity of 1,728 parked automobiles on the streets with sufficient room for 2,026 off-street—a total capacity for 3,754 parked motor vehicles.

The accumulation of motor vehicles is illustrated (Fig. 2). That is, the number of vehicles left in the district; shown by half-hour periods. It is quite true that these figures include all vehicles either in motion or parked, but since all cordon counts are conducted in this manner, comparative purposes are served. On the three main business streets, Bank, Sparks and Rideau, 86 per cent of the vehicles parked were within the legal time limits but the 14 per cent who exceeded the allotted time of 30 minutes, used up 41 per cent of the total number of hour spaces. Flagrant violations, to the extent of four and five hours parking, existed in these locations where space is at a premium. Strict and impartial enforcement throughout the area under survey would give an increase of 28.97 per cent in space hours.

A further unestimated increase in capacity would be obtained if the practice of office employees being sent down to move several parked cars was eliminated.

Violations

The fact that out of 14,146 parked automobiles observed in one day 5,869 violated the civic ordinances speaks for itself. The percentage of violations is 41.49 per cent.

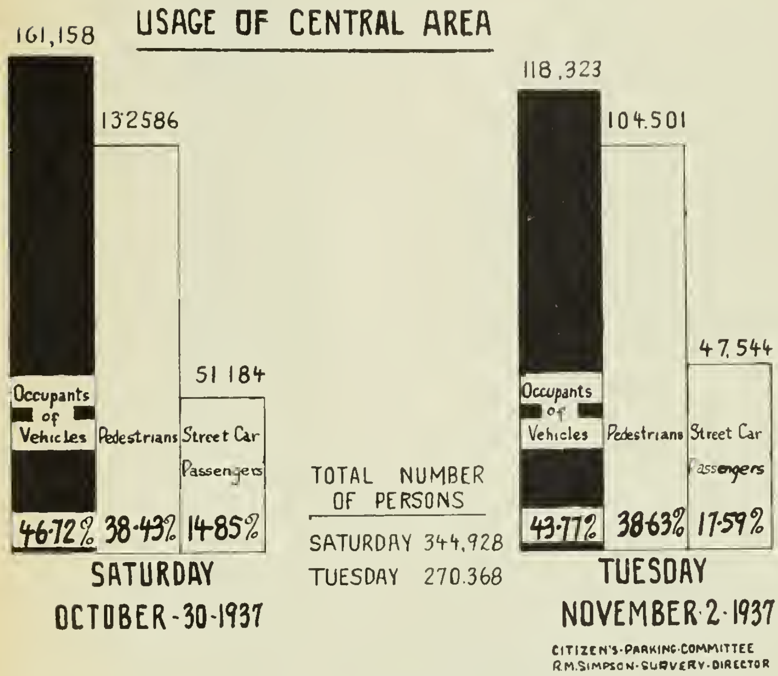

Fig. 1—Usage of Central Area.

This is a situation of vital concern to any citizen or group of citizens concerned with the unfortunate increase in the number of automobile fatalities. Beyond a doubt the practice of allowing vehicles to brazenly park under "No Parking" signs, too near corners, beside hydrants or improper parking, creates a disregard or disrespect for other motor vehicle laws such as those covering a vehicle in motion. Seventy-four photographs covering these conditions were secured by the survey staff.

That such a disregard for regulations and a lack of common courtesy on the part of motor vehicle drivers exists in Ottawa is amply borne out by two things. First, an increase of 46 per cent in the number of fatalities in 1937 over the previous year. Secondly, a death rate of 13.38 in a city where the registration is only seven persons per vehicle. The attempt made to ascribe the high death rate to the admitted slippery conditions of the street during the winter period was not confirmed by an examination of the accident statistics. Out of the 19 persons killed by motor vehicles during the last year, only one fatality occurred as a result of icy road conditions. A 25 per cent decrease in the number of fatalities could be obtained by strict and impartial enforcement of the parking regulations alone!

Parking Infractions

The following excerpt from the 1937 report of the police department presents a reason for some of the congestion in Ottawa.

Warnings issued	14,950
Persons summoned	883
Percentage of persons summoned	5.9

The committee recommended the adoption of the "cafeteria court" plan. Tickets are to be in triplicate, serially numbered, and issued by the City Treasurer to the police department. An audit is to be made each thirty days and shortages accounted for. Fines are $1.00 for each infraction, payable within 48 hours at the police station—failing compliance, a summons is issued and the regular fine of $3.00 plus $2.00 costs is applied if the motorist is found guilty of breaking the ordinance. This system is in vogue in nearly every city of size in the United States and Canada and was developed by the International Association of Police Chiefs.

The present system of two warnings with a summons on the third offence leads to too much abuse.

Business

The effect of the parking congestion on business was indicated by the tabulation of the questionnaires. Out of nearly 14,000 persons answering the questionnaire and who work in the downtown area, 4,580 or 33.9 per cent have definitely changed their shopping habits and now do their buying elsewhere.

The committee recognized the fact that any recommendations which they might make would not restore this lost business to the downtown merchants but, at least, the situation would be eased and further losses avoided. As a matter of general policy, it was decided that "Congestion causes decentralization, destroys values and creates hazards."

The fact that the majority of persons using the central business area employ automobiles for transportation purposes has been proved. A classification of the transportation methods used by the customers of the downtown retail establishments is now shown.

Classification of Business

	Pedestrians	Street Car	Auto
Uppertown department stores	35.9 per cent	30.9 per cent	33.15 per cent
Lowertown department stores	27. " "	30. " "	43. " "
Specialty stores	25.3 " "	29.3 " "	45.2 " "

In addition, the automobile trade has been established as being the most valuable class for the retail merchant to have. In a survey of a large American city, automobile passengers made up 40 per cent of the total number of customers but bought 60 per cent of the total value of the sales.

Thus, automobile congestion becomes a serious problem for the merchant. All business districts must be regarded in the light of a market. Political boundaries mean nothing to a motorized buyer and most important of all, the prosperity of any business or business section is enhanced by easy accessibility—or, if it is difficult to find a parking space—loss of business results.

Therefore, retail merchants are vitally concerned with congestion and parking regulations.

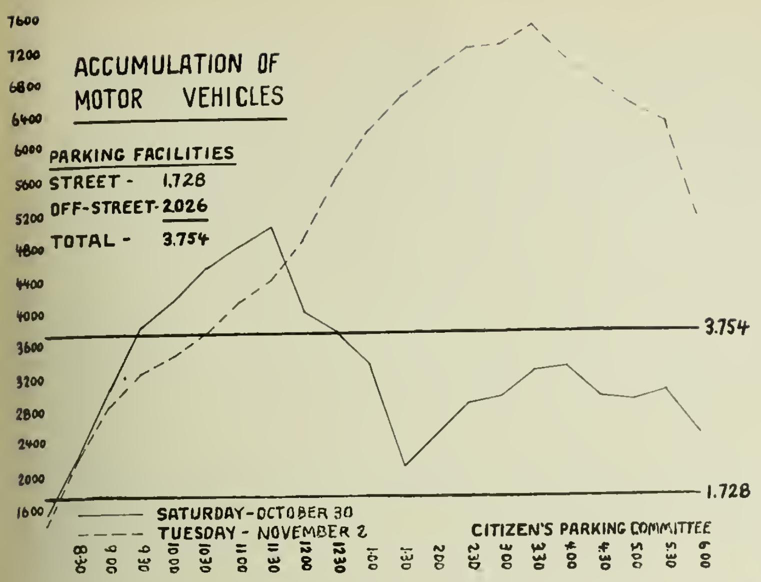

Fig. 2—Accumulation of Motor Vehicles.

Large Office Buildings

A serious situation with respect to the large office buildings was discovered. Taking one building as an example, 149 tenants or employees drive their cars, 118 additional people would drive provided space was available. Of the 149 first mentioned, 79 parked their cars on the streets and 70 off-street.

The fact that these 79 cars were parked on the streets within a radius of 460 ft. from the building means that prospective customers of the tenants have difficulty in finding a parking space in order that they may conduct the business which provides the livelihood of the tenants and makes the office space rentable. Similar information was complied for each large building.

There is an expressed willingness on the part of motorists to pay a reasonable charge for convenience, 2,877 or 72.39 per cent of those answering the question stated that they would be willing to pay on an average of $2.06 per month for off-street space.

In addition, the concentration of the Dominion Government offices within a small area presents a problem peculiar to Ottawa. 37.8 per cent of the civil servants drive to work in their automobiles.

In the city of Washington, the government decided as follows:—

> "While it is recognized that the government is not legally responsible for the facilitation of any means of transportation that the civil servants may desire to use—it is equally apparent that the concentration of the government buildings in a small area presents a problem—impossible of solution other than by the government itself. Therefore, provision shall be made for off-street parking facilities in any new buildings and open air lots shall be provided for certain existing buildings."

A delegation headed by Chairman W. G. Keddie interviewed the Minister of Public Works, Honourable P. J. A. Cardin, and received an extremely favourable hearing. Evidences of the success of the appeal were obtained in the provision of off-street facilities as included in the plans of M. Greber, who had been commissioned by the government as a town planning expert.

Conclusions

It was quite evident to the committee that the parking problem would never be solved at the curb. That is, the amount of curb space would never increase but the demand for its use would. Since the principal characteristic of the area under survey was the prevalence of retail establishments, a general policy along this line was adopted:—

"Parking on the streets during the business hours should be confined to short time parkers of one hour or less. Those persons requiring more than one hour should park off-street."

The four main recommendations of the committee to relieve the situation are as follows:—

(1) Recognition of the Dominion Government and large office buildings of their responsibility in providing off-street space for employees and tenants.

(2) Removal of the business tax amounting to 10 per cent of the regular assessment at the current tax rate on vacant property devoted to the sole use of parking automobiles.

(3) Installation of mechanical policemen or parking meters to assist in the enforcement of regulations. The

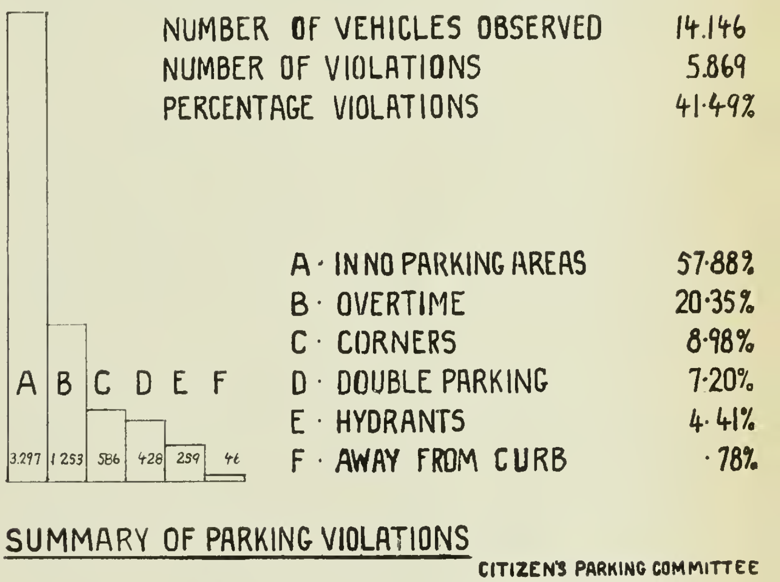

Fig. 3—Summary of Violations.

committee after an exhaustive study of the metered system of parking control and as a result of some 89 letters received from Traffic and Civic officials, Retail Merchants Associations, Automobile Clubs and Chambers of Commerce of cities where meters were installed, recommended that immediate consideration be given to the installation of these devices.

(4) A $1.00 fine applied to every parking infraction; tickets in triplicate, serially numbered; issued by the City Treasurer to the Police Department with a 30 day audit.

Fines payable within 48 hours at the police station. Failing compliance, summons issued in the usual manner and the regular fine of $3.00 plus $2.00 costs applied if the motorist is found guilty.

THE ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

VOLUME XXI AUGUST, 1938 No. 8

The Saskatchewan Agreement

Negotiations with the Association of Professional Engineers of Saskatchewan have advanced to the stage that the proposed agreement is now published in The Journal for the information of all members, and in compliance with By-law No. 76. It will be found on page 396. Members are asked to read it carefully, and see for themselves the simplicity with which such far reaching agreements can be worded and executed.

This agreement has been unanimously approved by the local executive committee of each body, at a joint meeting held in Regina in April 22nd. It now only remains for The Institute to submit it by ballot to all Councillors and to members resident in Saskatchewan. This will be done in such time that results can be disclosed to Council at the September meeting.

This is a very important document. When it is finally accepted by both organizations and put into effect, it will be the first firm step towards full co-operation between engineering bodies in Canada. It will be the first tangible result of years of thought and effort on the part of many members of the several engineering organizations which have been interested. Its final consummation will be very gratifying and encouraging to them and to engineers at large.

Membership List

Usually mere lists of names do not make very interesting reading, but judging from the number of inquiries that are received at Headquarters the membership list of The Institute has a very definite interest to many people. The last list was issued in 1935, and the supply is now exhausted, but inquiries continue to come in from all points of the compass, and many parts of the world. A new list is urgently required.

The preparation of such a list is not as simple as it may seem. There is a great deal of detail work and an unbelievable amount of checking and rechecking. Already the task is under way, and will be worked at continuously, and yet it will not be completed until December. The list will appear as a supplement of The Journal, as was done with the last one, and will therefore reach every member.

Members are asked to co-operate in this effort. Do what you can to make sure that the right details are on the records. After all, you are the only authoritative source from which such information can be secured, and if it does not come from you, there is some chance that it may not be accurate or up-to-date. Cards were circulated not long ago, but many were not returned. To those who did not reply, and to those whose position or address has changed recently, we particularly direct our inquiry. Right now, before it is forgotten, will you please turn to page 403 and fill in the form that is provided there for your convenience. Your co-operation will make it possible to prepare an accurate and complete list that will be a reliable source of information for all members.

Tragedy Strikes Mining Engineers

The sympathy of the entire profession will go out to the families of the five young engineers who lost their lives so suddenly on July twenty-eighth in a mine catastrophe at Bourlamaque, Quebec.

On behalf of The Engineering Institute of Canada The Journal extends the heartfelt sympathy of its officers and members to the relatives and friends of Peter Downey, James Crocker, Arthur Hewat, Harry Field and Clarke Isbister.

Minutes of Council

The decision to send minutes of all Council meetings to past-presidents, branch chairmen, and ex-councillors, in the latter case for one year after their term of office, will be received with general approval. The decision was reached at the Ottawa meeting, after the announcement of the return of a ballot from all councillors, which showed an almost unanimous approval of the suggestion.

This more than doubles the number who formerly received the report, and will thereby make possible a wider dissemination of the decisions and actions of the governing body. It was felt by Council that an increase in the number who were familiar with the aims and activities would result in an increased interest in Institute affairs, and would eventually react to the benefit of Council itself.

Montreal Branch Makes Generous Gift Towards Headquarters Renovation

In spite of the fact that members of the Montreal Branch pay an extra $3.00 over and above the fees paid by any other branch, the executive offered Council a contribution of $250.00 to assist with the cost of the work of "rejuvenation" of the building. Council accepted the offer at the June meeting and, on a motion by Colonel L. F. Grant, M.E.I.C., and W. R. Manock, A.M.E.I.C., placed itself on record as being very appreciative of the assistance.

The work is already under way, and it is expected will be completed before the Fall activities commence. The record of the last time the building was overhauled and redecorated is beyond the memory of the oldest "inhabitant," and it is painfully evident that the work is long overdue. From the point of view of depreciation alone, it is good business to have the work done now in order to arrest the ravages of time, and to bring the building up to the standard that is expected of The Institute.

Past-Presidents' Prize

An unusual number of subjects has been submitted by branches for this competition, the total running to more than forty. The regulations say "Council shall confer with the branches, and use its *discretion*, with the object of selecting a subject which may appear desirable in order to facilitate the acquirement and the interchange of professional knowledge among the members of The Institute." More than discretion is required in making a selection from such an extensive list. A degree of judgment such as made Solomon's name a by-word, would be more useful and more welcome.

The committee, appointed by the President, on behalf of Council, to make the selection, has given the subject a great deal of consideration. The purpose of the competition, as disclosed in the regulations, has been kept in mind. The possibility of finding some phase of engineering to which our members could make a definite contribution, and the hope of selecting a subject upon which many members could write, have also influenced the decision. It will be interesting to watch results and to see how closely the committee comes to its objective.

The subject is

"Highway Planning"

Highways are something in which all engineers as citizens are interested. Traffic problems are essentially engineering problems. Therefore it appears that many members will be able to write on this subject. Mistakes in planning and absence of planning are evident to all of us. We all suffer from them—both because of the waste of money and because of the attendant inconveniences. Surely we can contribute something that will assist in the solution of at least some portions of this problem.

The subject referred to most often in the branch recommendations was highways, three branches including it in their lists. The committee believes that all the recommended titles, as well as all others that go to make up the complete subject, can be included under the title selected. It is therefore somewhat of a composite selection which, it is hoped, will make it acceptable to all branches.

The title may be construed very broadly. The only definite restrictions are that papers must deal with Canadian roads and problems, and that the actual type of construction or design of the roadbed is not to be considered as part of the subject. The term "highway" may be taken to cover any road for motor traffic, either in the city or in the country.

The paper may deal with the situation in one particular city, or in one province, or may cover the national situation and take in the whole Dominion. Whatever the geographic limits may be, the paper should contribute something to the solution of the present and future traffic problems of that area.

It may include something on the economics of transportation, and deal with safety and speed of travel, real estate values, tourist considerations, and, from the national point of view, the utility of the roads in time of war. This latter consideration has been recommended as of sufficient importance to justify a full paper in itself, and if any contributors feel specially qualified to deal with this particular division of highway planning, such a paper will be considered as coming within the scope of the subject. If any prospective contestant has a phase of highway planning upon which he would like to write, and is in doubt as to its suitability, it is suggested that he write to Headquarters for a ruling.

There is a prize of one hundred dollars and much honour awaiting the winner of this competition. The closing date is June 30th, 1939.

Journal Cover Competition

The Publications Committee is having difficulty in picking out any one of the many designs as being superior to all of the others. It had been hoped that a selection could be made in time for an announcement in this Journal, but it is now evident that, in fairness to all competitors, much more time must be spent in judging. The committee is very pleased with the quality and quantity of the designs, and is confident that the new cover—when decided upon—will merit the approval of all readers.

Council Entertains Engineers from England

Joint Gathering in Canada Affords Opportunity to do Honour to Distinguished Delegates

The Council of The Institute was quick to seize the opportunity to entertain some of the well known engineers from England who were in Canada attending the Fifty-Seventh Annual Meeting of the Society of Chemical Industry in Ottawa in June.

On Thursday, June 30th, a luncheon was given at the University Club, Montreal, in honour of Dr. W. E. Cullen, President of the Institution of Chemical Engineers, Dr. R. E. Stradling, C.B., M.C., Ph.D., Councillor of the Institution of Civil Engineers, and Director, Building Research Station of the Department of Scientific and Industrial Research, and Mr. H. V. Potter, Councillor of the Society of Chemical Industry, and Managing Director of Bakelite Limited. Other guests included Victor G. Bartram, newly elected President of the Society of Chemical Industry, and E. J. Carlyle, Secretary-Treasurer of the Canadian Institute of Mining and Metallurgy.

Dr. Cullen is one of those quiet speaking, modest little Englishmen who impress you instantly as having great reserves of poise and ability. He has a cheerful voice and a merry twinkle in his eye that attract you to him immediately. To him belongs that magic word "charming." He makes a fine ambassador for his homeland.

This was Dr. Stradling's first visit to Canada. He remarked that he had never before been in a country that had impressed him so favourably. He said "My admiration for Canada is such as I thought I should never have for any other country than England." He spoke of the advantages of laboratory work in conjunction with practical engineering, and referred to the research work being done in his department. He was greatly interested in the work of the National Research Council at Ottawa, and found a great similarity with what was being done in England. He said "The subjects are the same, but the emphasis is different."

Mr. Potter will be remembered for his part in the Semicentennial celebration. He presented an illuminated address on that occasion from the Society of Chemical Industry. It was renewed pleasure to have him with us again. He spoke most kindly and enthusiastically of Canada, and made an emphatic reference to his last visit here. He said he had never seen a celebration carried out so well as was the Semicentennial.

Mr. Victor Bartram spoke very briefly, giving as justification for the brevity, the fact that he was already a half hour late for his golf appointment with a group of chemists from the Old Country. He was excused.

President J. B. Challies was in the chair. He mentioned the great pleasure and satisfaction it gave councillors to have so many past-presidents at the luncheon, particularly Dr. Herrick Duggan, who is the senior of them all. Dr. Surveyer and Dr. Lefebvre were the others who were present. Guests, councillors and past-presidents made up a party of twenty-two.

Proposed Agreement Between The Engineering Institute of Canada and the Association of Professional Engineers of Saskatchewan

The agreement printed herewith is in the form recommended by accredited representatives of the Council of The Institute and of the Association of Professional Engineers of Saskatchewan. It is now published in The Journal in accordance with the requirements of By-law No. 76.

The executive of the Saskatchewan Branch of The Institute, and the executive committee of the Association have both approved of this agreement.

MEMORANDUM OF AGREEMENT made in duplicate at the City of Montreal, in the Province of Quebec, this day of 1938,

By and Between

THE ENGINEERING INSTITUTE OF CANADA having the head office at the City of Montreal, the Province of Quebec, hereinacting by its President and Secretary, duly authorized for the purpose hereof by a resolution of its Council passed at a Meeting duly called and held on the day of 1938, hereinafter called "The Institute,"

Party of the First Part

and

THE ASSOCIATION OF PROFESSIONAL ENGINEERS OF SASKATCHEWAN having its head office at the City of Regina, in the Province of Saskatchewan, hereinacting by its President and Registrar, duly authorized for the purpose hereof by a resolution of its Council passed at a Meeting duly called and held on the day of 1938, hereinafter called "The Association,"

Party of the Second Part.

Whereas it is desirable in the interest of the Engineering Profession that there be close co-operation between the Institute and the Association, and

Whereas such close co-operation will be promoted if, so far as it is practicable, there is effected:

(*a*) A common membership in the Province of Saskatchewan of the Institute and the Association;

(*b*) A simplification of existing arrangements for the collection of fees;

(*c*) A reduction in the total fees payable by those who are members of both the Institute and the Association;

(*d*) Management by a common executive.

Now, Therefore, the parties hereto agree with each other as follows:

1. All persons who are, on the date of this agreement, or who may be hereafter during the term of this Agreement, registered as Professional Engineers under the provisions of Chapter 173 of the Statutes of the Province of Saskatchewan for the year 1930, and any subsequent amendments thereto, and who are not on the date of this Agreement, nor on the date of such future registration, as the case may be, Corporate Members of the Institute, shall under the provisions of this Agreement automatically become Corporate Members of the Institute on and after said date, subject to the terms and conditions of this Agreement, as hereinafter set forth.

2. Any person registered as a Professional Engineer in the Association shall be accorded the class of membership in the Institute warranted by the age, experience and professional qualification of such person, according to the By-laws of the Institute and the decision of the Council of the Institute. Any person dissatisfied with such classification shall be entitled to have his classification and qualifications for the same reviewed by the Council of the Institute.

3. All persons who are, on the date of this agreement or who may be hereafter during the term of this Agreement, registered under the By-laws of the Association as Engineers in Training and who are not on the date of this Agreement, nor on the date of such future registration, as the case may be, Junior Members of the Institute, shall, under the provisions of this Agreement, automatically become Junior Members of the Institute on and after the said date, subject to the terms and conditions of this Agreement as hereinafter set forth.

4. All persons who are, on the date of this Agreement or who may be hereafter during the term of this Agreement, registered under the by-laws of the Association as Students and who are not on the date of this Agreement, nor on the date of such registration, as the case may be, Students in the Institute, shall, under the provisions of this Agreement, automatically become Students of the Institute on and after said date, subject to the terms and conditions of this Agreement as hereinafter set forth.

5. The entrance fee of the Association shall be remitted to any Corporate Member of the Institute, who, at the date of this Agreement, is a bona fide resident of the Province of Saskatchewan and who applies for membership in the Association within 12 months. The entrance fee shall also be remitted to any Corporate Member of the Institute who, after the date of this Agreement, becomes a bona fide resident of the Province of Saskatchewan, provided application for membership in the Association is made within twelve months of the date of such residence.

6. The Association will collect one Joint annual subscription fee from each of its members from which the Association shall pay to the Treasurer of the Institute, in lieu of the ordinary membership fees of the Institute, the sum of six dollars ($6.00) per annum for each member of the Association having the Institute classification of Member (M.E.I.C.); the sum of Five Dollars ($5.00) per annum for each member of the Association having the classification of Associate Member (A.M.E.I.C.); the sum of Three Dollars ($3.00) per annum for each member of the Association having the Institute classification of Junior, and Two Dollars ($2.00) per annum for each member of the Association having the Institute classification of Student. These fees shall entitle the members of the Association to those privileges of the Institute membership provided by its By-laws and shall include the annual subscription to the Institute Journal.

These fees shall be due and payable to the Institute by the Association annually in advance on the 31st day of March of each year. The provisions of this Section 6 of this Agreement shall not be effective until the 1st day of January, 1939.

7. The Saskatchewan Branch of the Institute shall consist of all members of the Institute resident in the Province of Saskatchewan and all members of the Association.

8. During the term of this Agreement, the officers and the Council of the Association shall *ipso facto* be and become the officers and the members of the Executive Committee of the Saskatchewan Branch. Any Saskatchewan member of the Institute elected president or vice-president or councillor of the Institute, shall be an ex-officio member of this Executive Committee. The Executive Committee as so constituted will be responsible for the financing and the management of the Saskatchewan Branch.

9. The Councillor representing the Saskatchewan Branch will be nominated and elected in accordance with the By-laws of the Institute.

10. As a principal objective of this Agreement is the achievement of a common membership between the Saskatchewan Branch and the Association, all meetings will be announced as a "Meeting of the Engineering Institute of Canada and the Association of Professional Engineers of Saskatchewan," with the exception of any legally required special or annual meetings of either the Branch or the Association.

11. The term of this agreement shall be the period commencing on the date hereof and ending on the 31st day of December, 1941, on which date this Agreement shall terminate provided either party has given to the other a notice of termination at least six months prior to the 31st day of December, 1941, and if no such notice is given this Agreement shall continue after the 31st day of December, 1941, from year to year, but may be terminated at the end of any calendar year by either party giving notice in writing to the other of such termination at least six months prior to the end of any calendar year.

12. The terms and provisions of this Agreement may be amended by mutual agreement, in writing between the parties hereto, duly executed by them.

13. Any changes in nomenclature of the various classes of membership in the Institute will automatically apply to the provisions of this Agreement.

In Witness Whereof these presents have been duly executed on behalf of the parties hereto on the date and at the place first above written.

Presidential Activities

On Friday, July 1st, the President and a group of Headquarters engineers were down at the *Duchess of Atholl* to say good-bye to Dr. and Mrs. Cullen and to Dr. and Mrs. Stradling. Both these distinguished engineers, who are members of the British delegation to the recent meeting of the Society of Chemical Industry, promised to take home to the Councils of their own Institutions the loyal, friendly greetings of The Engineering Institute. In spite of the short notice which made it quite informal, it was a rare pleasure and a delightful privilege for the Headquarters of The Institute to honour the presence in Canada of Dr. Cullen, the President of the Institution of Chemical Engineers, and of Dr. Stradling, a member of Council of the Institution of Civil Engineers of Great Britain.

At London, on Tuesday, July 19th, the President conferred with the chairman of the Nominating Committee, H. F. Bennett, M.E.I.C. He also discussed with the Management Committee of the London Branch the plans which the London and the Border Cities Branches are making for an appropriate engineering celebration at Sarnia shortly after the formal opening, on August 19th, of the new international highway bridge across the St. Clair river.

At the "Soo" on Wednesday, July 20th, President Challies entertained at luncheon the Management Committee of the Sault Ste Marie Branch, when Institute matters were discussed at length. Following a dinner at the Golf Club he addressed a well attended meeting of nearly sixty engineers. As many of those present were recent graduates, the President took advantage of the occasion to urge an active interest in and a loyal support for both the Ontario Provincial Professional Association and The Engineering Institute of Canada.

A few notes and some correspondence just received as we go to press indicate the President's enthusiasm for the future of the Sault Ste Marie Branch as a robust centre of Institute activities.

Mr. Challies' visit to the "Soo" at this time was made possible by the fact that he was spending a short vacation in Ontario.

Air Raid Precautions Exhibition

An interesting exhibition dealing with the subject of air-raid precautions was arranged by the Building Centre, 158, New Bond Street, London, W.1, at the Charing Cross Underground station of the London Passenger Transport Board. This exhibition, which was opened by Wing-Commander E. J. Hodsoll, C.B., Inspector-General of Air Raid Precautions, on Thursday, May 5, and remained open for the next few weeks, consisted mainly of a room such as might be found in any house. This room on the ground floor, had been treated against air raids in accordance with the recommendations of the Home Office publication *Protection of Your Home Against Air Raids*, and the various methods of treatment were distinctly labelled. The ceiling was supported in the centre by timbering in order to protect the occupants as far as possible from falling debris. The windows were sealed and protected on the outside by sand bags. The fire-place and door were also sealed against gas and all cracks in the plaster and skirtings filled in. A transparent material was pasted over the windows and fixed with cellulose varnish as a protection against glass splinters. It is not suggested that the room shown was bomb proof. It was merely treated for protection against demolition splinters and gas.

Among the other exhibits were three types of shelters, one in steel and two in pre-cast concrete. These were built below ground. Various alternative methods of protecting windows and doors were exhibited, as well as covers for underground shelters such as have been described in *Engineering*. In fact, how protection can be obtained against every form of damage except that caused by a direct hit was shown.

We understand that the exhibition was a preliminary to a permanent exhibition and information centre on air raids precautions in buildings, to be opened at the Building Centre.—*Engineering.*

Alternative Firing of British Men-of-War

In all quarters concerned with maritime affairs, increasing attention is being directed to the risks inseparable from the complete dependence of the Navy upon a foreign fuel supply. The similar dependence of half of our Merchant Marine, of the Air Force and mechanized Army, and of a large proportion of our land-transport and industry, has necessarily accentuated the growing disquiet. Many well-known flag-officers, as well as other authorities in the shipping and engineering worlds, have shown that in the unhappy event of war, against which this nation is so expensively re-arming, the oil supply, upon which every branch depends, will be endangered at its source, in transport through pipe-lines and on its long ocean passages, and while in storage in the great tank-farms in Home territories. No one seriously disputes that risks are being accepted; indeed, the Government has explicitly admitted that some risks do, in fact, exist, and it is known that this question is engaging the unremitting attention of the authorities.

But on the purely naval aspect of this difficult problem, and the aspect which the author desires to examine, there are two opposed schools of thought. One school, while admitting some risk, regards that risk as sufficiently slight to justify its acceptance for the sake of the technical advantages claimed for the ship designed exclusively for oil-firing. The other school considers the risk so serious that it should be eliminated altogether, if this can be done without crippling the fighting power of the Navy, or unduly extending its commitments in tonnage or personnel. The latter school, however, is itself loosely divided into two groups. One of these groups shares, more or less, the prevailing conviction that the very high speed and great mileage endurance, for which provision has been made in post-war ships, are necessary characteristics of up-to-date British men-of-war. This group therefore advocates that all future men-of-war, while retaining their existing, or contemplated, speeds and mileage endurances as exclusive oil-burners, should, by dual-firing, and by an appropriate modification in design, be equipped with the safeguard of coal-burning, so that, in the event of an interruption of oil supplies, the vessel can steam at economical speed for a reasonable period.

The other group disputes the fighting value of the extremities of speed and what it regards as excessive mileage endurance, in view of the sacrifice in guns and armour which, on any given tonnage, these two characteristics entail. It therefore advocates a reduction in speed and endurance, and the restoration of native fuel, either as the basic fuel in a dual-firing system or as the sole fuel.

The author's own conviction is, when the worship of the speed god becomes out of date among seamen, that future British men-of-war should rely entirely upon coal. Need it be doubted that British marine engineers and constructors, if called upon to do so, will be able and anxious to apply to men-of-war the remarkable advances in coal-combustion and engineering which, since coal went out of fashion at sea, mechanical engineers have so remarkably achieved on land?

In the past nine years, as can be seen from perusal of official statistics, the improvement in steam generating stations has been about 45 per cent, and it is estimated that at least 6,000,000 tons less coal would be needed to generate the electricity sold in 1936 at the higher efficiency now attained than at the lower efficiency of only nine years ago. The dirt and exertion of coal-firing and bunkering can, furthermore, be eliminated by up-to-date practice. An alternative fuel would, in addition, increase the likelihood of obtaining oil, and at prices which the nation might be able to afford to pay.—Captain B. Ackworth, D.S.O., R.N. (ret.). in *Engineering.*

Performance Code for Air-Conditioning Equipment

A "Code of Minimum Requirements for Comfort Air Conditioning" just adopted by the American Society of Heating and Ventilating Engineers, and developed jointly with the American Society of Refrigerating Engineers, has set up a uniform procedure for establishing the fundamental basis for the design of conditioning installations.

In the making for the past two years, its sponsors aim at establishing minimum design standards by which purchasers can judge the performance of equipment.

For winter air conditioning, 70 deg. indoor temperature with 35 per cent relative humidity, when outdoor temperature is 30 deg., is set as a minimum design standard. For summer air conditioning, an indoor design schedule of "effective temperatures" (which are index of comfort based on a combination of temperature, relative humidity and air motion) is established ranging from 71 deg. "effective temperature" when it is 80 deg. outside to 75.5 deg. "effective temperature" when it is 105 deg. outdoors.

The code specifies the introduction of outside air for ventilating purposes at a rate of not less than 10 cu. ft. per hr. per occupant, or not less than 15 cu. ft. in premises where smoking is permitted, with removal of 95 per cent of ordinary dust particles to provide requisite air purity.

Air velocities which account for drafts and are a frequent cause of complaint in air conditioning systems, are limited to not more than 50 lin. ft. per min., according to the new code. Control of air temperatures within 3 deg. at the five foot level or the "breathing zone" is also specified in the code.

—*American Society of Heating and Ventilating Engineers.*

Ottawa Branch Entertains Council

Head Table (left to right): President J. B. Challies, W. F. M Bryce, A.M.E.I.C., T. H. Hogg, M.E.I.C., G J. Desbarats, HON.M.E.I.C., de Gaspe Beaubien, M.E.I.C., Dr. C. Camsell. M.E.I.C., J. L. Busfield, M.E.I.C., F. S. B. Heward, M.E.I.C., W. R. Manock, A.M.E.I.C., A. B. Gates, A.M.E.I.C., F. Newell, M.E.I.C.

Others who may be easily identified are: General Secretary L. Austin Wright, W. E. Bonn, M.E.I.C., H A. Lumsden, M.E.I.C., J. A. Vance, M.E.I.C., L. F. Grant, M.E.I.C., J. A. McCrory, M.E.I.C., F. A. Gaby, M.E.I.C.

John Murphy, M.E.I.C.

It is news of interest to members of The Institute, that John Murphy is retiring from active service with the Federal Government. Mr. Murphy has been so closely associated with the Ottawa Branch, and the general activities of The Institute that events which are of importance to him become of importance to The Institute at large. Fifty-four years of service and usefulness to society surely entitles a man to the privilege of at last becoming master of his own time. Mr. Murphy is just about to enter that Elysian field, and no one will acknowledge his stirling qualities, or wish him more happiness therein than members of The Institute.

It is not possible within the present limitations to give a satisfactory account of such an active life. Only certain mileposts and highlights can be mentioned. Such things as his intense interest in athletics—particularly tennis—service clubs, his church, and so on must be passed by and yet they tell so much about the man himself. The following paragraphs give a brief account of the business end of his life and will be of interest to all engineers, both old and young.

John Murphy, M.E.I.C., senior electrical engineer of the Department of Transport and the Board of Railway Commissioners, and acting superintending engineer of the Rideau Canal, has recently completed 32 years of service with the government. He has been receiving expression of the high regard in which he was held by officials of the Department of Transport but his outstanding ability as an electrical engineer draws admiration from fellow members of the profession as well.

His career is linked with the early development of the hydro-electric power industry in Ottawa. At the age of 16 he entered the employ of the Bell Telephone Company. He was here only a year when he was placed in charge of an electric light plant at Chelsea. Two years later, in 1887, he was placed in charge of the newly established Chaudière Electric Light and Power Company. His duties and responsibility were increased in 1891 when he was given charge of the Ottawa Electric Railway Company and the Chaudière Electric Light and Power Company. He continued in this position for the next 20 years.

When Mr. Murphy joined the staff of the Department of Railways and Canals in 1906 as electrical engineer he brought with him wide experience gained as a consulting engineer. Later he was promoted to the position of senior electrical engineer to the Department as well as to the Dominion Board of Railway Commissioners.

Mr. Murphy has identified himself prominently with numerous technical associations, among which are The Engineering Institute of Canada (Chairman of Ottawa Branch 1916-17), Canadian National Committee of the International Electro-Technical Commission (President 1927-1937), Canadian Committee of the World Power Conferences, Illuminating Engineering Society, Canadian Electric Railway Association, Railway Signal Association, American Electrical Railway Association, Professional Engineers of Ontario, American Institute of Electrical Engineers, Canadian Electrical Association, Canadian Engineering Standards Association (member of several committees), the National Research Council, the Professional Institute of Civil Service and the Civil Service Association. He has also acted as official delegate to the World Power Conference at Wembley in 1924, and to the International Electro-Technical Commission plenary meetings at Bellagio and Rome in 1927, to Japan in 1929 and to Germany and Scandinavia in 1930.

Mr. Murphy will be seventy years of age on December seventeenth this year.

W. L. Malcolm, M.E.I.C., Goes to Cornell

In the July Journal an announcement was made of the appointment of Dr. William Lindsay Malcolm, M.E.I.C., of Queen's University as director of the School of Civil Engineering at Cornell University. The following information, which augments that previously given, will be of interest to our readers.

Dr. Malcolm has a brilliant record as a teacher, an army engineer, and a practising engineer in civil life. Entering Queen's University in 1902 with scholarships in mathematics, physics, and chemistry, he received the M.A. degree in 1905, and the B.S. in Civil Engineering in 1907. Cornell awarded him the degrees of Master of Civil Engineering in 1934 and Ph.D. in Civil Engineering in 1937. He has been a member of the Faculty of Queen's University since 1907, including five years overseas during the World War.

During 1914-1919 he served with the Canadian Engineers, attaining the rank of lieutenant-colonel, and command officer of engineers, successively, of the Fifth and Fourth Divisions of the Canadian Army. He is now a member of the Advisory Board of the Royal Military College.

Since 1905, Professor Malcolm has also been acquiring varied experience in municipal engineering, construction, and other phases of engineering practice. He has been city engineer of Stratford, associate city engineer of Guelph, and a consultant on highway construction and building design and construction. He designed and built the stadium and ice hockey rink and the sanitary engineering laboratory at Queen's University, as well as numerous factories and other structures.

He is a member of The Engineering Institute of Canada, the American Water Works Association, the Canadian Institute of Sewage and Sanitation, the New York State Sewage Works Association, and the Professional Engineers Association of Ontario, and holds licenses as Ontario and Dominion land surveyor.

The news of this appointment will be well received by engineers throughout Canada. Beyond a doubt Queen's is suffering a serious loss, but they can be proud of the fact that their staff is strong enough to contain engineers of this calibre. All Canadians, and particularly members of The Institute, will share with Dr. Malcolm, in the pride and pleasure that can be taken from such an appointment. The Journal wishes him great success and much happiness in his new field.

Annual Western Meeting C.I.M.M.

The Canadian Institute of Mining and Metallurgy holds this important annual meeting in Vancouver this year on November 9th to 12th. President E. A. Collins of Copper Cliff, Ontario, has arranged to attend, and The Journal is informed that he expects many others from central and eastern Canada to do likewise.

President J. B. Challies and the General Secretary L. Austin Wright have been specially invited by the President and Council of the C.I.M.M. The schedule of Mr. Challies' western trip will permit his party to be in Vancouver at that time, so that it has been possible to accept the invitation. Mr. Challies has expressed himself as being delighted at the prospect of participating in the proceedings of the Mining Institute.

The entire arrangements for the western meeting are in the hands of the British Columbia Division. Each year this division renders this valuable service to the profession and the industry, and in spite of the great amount of work involved is satisfied with the recompense of a satisfactory attendance.

Meetings of Council

A meeting of Council was held at Headquarters on Friday, May 20th, 1938, at eight o'clock p.m. President J. B. Challies and twelve other members of Council were in attendance.

Considerable discussion was given to a report from the chairman of the Committee on Membership and Management, Professor R. A. Spencer, dealing with the subjects of Council reorganization and classification of grades of membership. It was decided that the committee's first proposal be submitted to all branch executives for their consideration during the summer, with a view to their considered opinions being available early in the fall.

Councillor Newell reported on behalf of the Committee on Professional Interests. He referred to the legislative difficulty which had arisen in Nova Scotia, thereby delaying the consummation of the co-operative agreement with the Professional Association of that province. He also indicated how this obstacle would be overcome in the near future. He touched on the situation in the provinces of New Brunswick, Manitoba, and particularly Saskatchewan, where an agreement has been approved of in principle. Mr. Newell was authorized to proceed with further negotiations.

Consideration was given to a suggestion which had come from many sources that copies of the minutes of Council meetings should be sent to past-presidents, branch chairmen, and ex-councillors for one year after the expiry of their term. It was decided to consult all councillors by means of a ballot to be returned in time for the next Council meeting.

The Sir John Kennedy Medal award was discussed, and it was decided to send out a preliminary ballot so that the final ballot would contain only one name.

The chairman of the Finance Committee, Mr. J. A. McCrory, reported that revenue and expenditure to date were keeping well within the budgeted amounts. Four resignations were accepted; one Member, four Associate Members and one Junior were reinstated; Life Memberships were granted to two members on the recommendation of their branches, and consideration was given to two special cases.

Mr. Gordon McL. Pitts, A.M.E.I.C., was appointed as The Institute's representative on the C.E.S.A. Committee on Fire Tests for Building Construction and Materials.

Councillor D'Aeth reported for the Library and House Committee, with particular reference to the maintenance and alteration work which was being planned for the Headquarters building. He was authorized to proceed with the work in consultation with the chairman of the Finance Committee and the General Secretary.

Mr. D'Aeth also reported on the suggestion which had been made that the practice of other societies might be followed and a per diem charge made for the use of books in the library. He reported that it did not seem an opportune time to make such a change. It was felt that the small financial benefits which might accrue would not justify the proposed new procedure. Council endorsed his recommendation.

At the President's suggestion it was decided that a special meeting of Council should be held in Regina at the time the President and the Headquarters party would be there on their western trip.

The programme of the Annual Meeting was discussed, and the President and Mr. Gaherty gave reports of the progress which had already been made. It was also agreed that a Council meeting should be called during the Annual Meeting under such circumstances that sufficient time could be given to the many important items of business that would develop.

A letter from E. P. Muntz, M.E.I.C., The Institute's representative on the National Construction Council of Canada, was read. In this he reported on the Construction Council's brief which had been presented to the Royal Commission on Dominion-Provincial Relations. The Commission had asked for a further report as to how the recommendations might be implemented, and Mr. Muntz asked that an emergency stand-by committee be appointed to co-operate with him in the preparation of such a supplementary draft. Past-Presidents J. M. R. Fairbairn and F. A. Gaby, Councillor W. E. Bonn, and the President, were appointed as this committee.

It was unanimously agreed that Mr. Muntz be asked to continue as The Institute's representative on the National Construction Council of Canada, with Dr. A. H. Harkness, M.E.I.C., as alternate.

In response to an invitation from the Canadian Society of Chemical Industry, Mr. Challies was appointed official delegate to the President's Reception and the Convention's Dinner and Dance at Ottawa.

Mr. F. A. Combe, M.E.I.C., was asked to represent The Institute on the Committee dealing with the Safety Code for Mechanical Refrigeration, this in response to a request from the C.E.S.A.

The following elections and transfers were considered and approved:

Elections		*Transfers*	
Members	3	Associate Member to Member	2
Associate Members	4	Junior to Associate Member	5
Juniors	7	Student to Associate Member	1
Students admitted	7	Student to Junior	5

One application for admission as Associate Member was approved, subject to the passing of The Institute's examinations, and one special case was considered.

The Council rose at eleven o'clock p.m.

Ottawa Meeting

A meeting of Council was held at the Chateau Laurier, Ottawa, Ontario, on Friday, June 24th, 1938, at two thirty p.m. President Challies, sixteen members of Council, and fifteen guests were in attendance. The guests were past-presidents, ex-councillors and the present officers of the Ottawa Branch.

The President expressed his appreciation of the excellent attendance at Council meetings this year, and he invited all the guests to participate freely in the discussions of the meeting. He particularly welcomed Councillor A. B. Gates, of Peterborough, who had recently recovered from a long and serious illness.

After considerable discussion it was decided that an invitation be sent to the Institution of Mechanical Engineers to visit Canada either before or after the joint meeting with the American Society of Mechanical Engineers which is being held in New York in September 1939.

Past-President Desbarats reported on the work which is being done by the engineering societies in England to improve the prestige of the profession with the public. It was thought that some similar movement might be undertaken in Canada.

Councillor Busfield reported progress for the Publication Committee, and dealt with the designs for a new cover, and with the formation of a Technical Advisory Board for The Journal.

Considerable discussion was given to the progress report of the Committee on Membership and Management. Eventually it was pointed out by the President that Professor Spencer, chairman of the committee, was on his way east, and suggested that no action should be taken until the members of the committee in the east should have an opportunity of discussing the situation with him. This was agreed upon.

The Secretary reported that the ballot of Council, dealing with the matter of sending minutes of Council meetings to others than councillors, had carried almost unanimously. It was therefore decided that minutes of all Council meetings should go to all past-presidents, branch chairmen, and ex-councillors for one year after their term of office.

Councillor Newell reported for the Committee on Professional Interests, touching on conditions in Nova Scotia, New Brunswick and Manitoba. He also reported that negotiations with the executive of the Saskatchewan Branch and the Council of the Saskatchewan Association had reached a complete understanding on the form of agreement. The proposed agreement was examined clause by clause, and unanimously approved. It was hoped that the agreement would be ready in time for the President's signature at the time of his visit to Regina in October.

Council made special recognition of the appointment which had come to Dr. W. L. Malcolm, M.E.I.C., of Queen's University. Dr. Malcolm has been made Director of the School of Engineering at Cornell University.

The chairman of the Library and House Committee submitted a report on the renovation of the Headquarters building. It was expected that the work would be under way by the 1st of July.

Particular reference was made to the offer of a contribution from the Montreal Branch towards the cost of the Headquarters renovation. The sum of $250.00 was offered by the branch and, on the motion of Colonel Grant, seconded by Mr. Manock, was accepted with sincere thanks.

The President submitted a draft itinerary of his visit to the western branches, and pointed out how it had been arranged that his party would be in Regina at the time of the Semi-Annual Open Meeting of the Association of Professional Engineers of Saskatchewan.

The Annual Meeting received much attention. The President reported that Colonel Wilfred Chevalier had accepted the invitation to be the guest speaker at the Annual Dinner. It was also hoped that Sir Gerald Campbell, the newly appointed High Commissioner to Canada from the United Kingdom, would be able to take a part in the proceedings.

Mr. Gaherty, chairman of the Committee on Western Water Problems, made a very full report dealing in detail with the negotiations he was able to complete while on his western trip, with many speakers who were to take part in the papers and discussions. Mr. Gaherty's revised programme was approved of, and the arrangements were left in his hands in consultation with the President and the General Secretary.

The advisability of including papers other than those on western water problems was discussed, and it was decided that other subjects should be included, but action was delayed until the matter could be given proper consideration.

The Past-Presidents' Prize competition was reported on by the General Secretary, and a committee was named by the President to finally select a subject from the many which had been suggested by the branches. The committee consisted of the Treasurer, the General Secretary, and the Secretary Emeritus.

Past-President Gaby drew the attention of the meeting to the recent announcement of the honour which is to be conferred upon the President by the University of Toronto. A Doctorate of Engineering is to be given to him on October 14th.

Vice-President McCrory reported for the Finance Committee, and stated that the financial condition was still very favourable, and that it was expected that the year would finish as it had been planned when the budget was originally drawn up.

Seven resignations were accepted; two Associate Members and one Junior were reinstated, and the names of eight over age Students, in arrears for two years, were removed from the list of members.

A joint meeting of the Border Cities and London branches at Sarnia in September was reported on by Councillor Vance. It was hoped that a large number would be in attendance, and that the President and members of Council would make a special effort to be present. The special occasion was the opening of the new bridge between Canada and the United States at that point.

Councillor Bonn reported in detail for the Membership Committee, and made particular reference to the comprehensive information which has been gathered by Mr. Huet Massue, one of the members of the committee. Particular reference was made to the membership situation in the province of Ontario. Mr. Bonn made some definite recommendations which it was hoped would be of assistance to the membership committees of the Ontario branches. A discussion of our relationship with the Technical Service Council resulted in a decision that Mr. Bonn, along with Mr. Busfield and Mr. Heward and the General Secretary, should go into this whole question thoroughly and report to a subsequent meeting of Council.

The Secretary reported on the Seventh International Management Congress which is to take place in Washington in September 1938, and drew attention to the interest which has developed in Industrial Management by members of The Institute. Members of the Montreal Branch Industrial Management Group had urged that The Institute should have official representation at the Congress, so that Council could decide on the share of the participation which The Institute should take in this development. Following some discussion it was resolved that the General Secretary be authorized to attend the Congress, and that T. M. Moran, A.M.E.I.C., of the Montreal Industrial Management Group, be also accredited as an official representative.

In compliance with the request of the C.E.S.A., it was decided to ask Colonel C. S. L. Hertzberg, M.E.I.C., to represent The Institute on the Committee on Building Materials.

Councillor Heward reported on the meetings of the Canadian Chamber of Commerce with particular reference to the convention which is to be held at the Seigniory Club in September.

Past-President Desbarats presented a report of the Annual Meeting of the Royal Society of Canada in Ottawa, at which he officially represented The Institute.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

Elections		*Transfers*	
Associate Members	8	Associate Member to Member	8
Juniors	5	Junior to Associate Member	4
Students admitted	4	Student to Associate Member	1
		Student to Junior	3

One application for admission as Associate Member was approved, subject to the passing of The Institute's examinations, and four special cases were considered and disposed of according to their merits.

It was decided that the next meeting of Council should be held in September, it being understood that the President would call a special meeting during July or August if such should become necessary.

The Council rose at six o'clock p.m. to attend the President's dinner at the Rideau Club.

OBITUARIES

Paul Baily, A.M.E.I.C.

The death of Paul Baily, A.M.E.I.C., occurred July 14th in Montreal, where he had been residing. Mr. Baily was born in Namur, Belgium, on July 23rd, 1890. He received his technical education in Belgium at the University of Ghent, from which he was graduated in 1912. After a year's engineering work with the Belgium Government and a year with the Fabrique Nationale d'Armes de Guerre at Herstal, Liege, he left Belgium for England where he was connected with Aerators Limited of London. Coming to Canada in 1915, he entered Canadian Vickers Limited, Montreal, as assistant chief engineer and naval architect. He remained in this position until 1920 when he accepted the position of designing engineer with the Belgo Canadian Pulp and Paper Company, Shawinigan Falls, for a year. Since that time he has held the positions of assistant city engineer of Verdun, Que., and designing engineer with John Stadler, consulting engineer, Montreal.

Mr. Baily joined The Institute in 1922 as an Associate Member.

Conway Edward Cartwright, M.E.I.C.

On July 4th in Vancouver, Conway Edward Cartwright, Life Member of The Institute, died at the age of 74.

Mr. Cartwright was born in Toronto, Ont., on October 14th, 1864. He graduated from the Royal Military College, Kingston, Ont., in 1884 and began his career as a railroad engineer even before this date. Between the time of his graduation and his location in Vancouver in 1899 as a consulting engineer he was engaged in railroad work in various parts of Canada and the United States. From 1885 to 1887 he was on location and construction surveys and works for Pontiac Pacific Junction and Gatineau Valley Railways. From 1887 to 1890 he was in charge of the draughting office of the Norfolk and Carolina Railroad at Norfold, Va. In 1890 he left railroad work for a time and became resident engineer of improvement works at Salem, Va. From 1891 to 1892 he was principal assistant engineer, Nashua, N.H. In the latter year he returned to railway work and was on location and construction of the Vandalico Line, Indiana. In 1896 he began his connection with the New York and Ottawa Railroad, at first in the capacity of surveyor and later as assistant chief engineer.

In 1912 Mr. Cartwright entered the firm of Cartwright and Matheson and Company, Vancouver. He formed his own company in 1920, but later became divisional engineer for the Canadian Pacific Railway in Vancouver.

Mr. Cartwright joined The Institute as a Student in 1887, becoming a member in 1898. He served as a member of Council from 1912 to 1914.

William Thomas Thompson, M.E.I.C.

The tragic death of William Thomas Thompson, M.E.I.C., was confirmed, July 18th, 1938. He set out July 8th to survey quartz mineral claims in the Cold Lake district, 450 miles northwest of Winnipeg, and was to have met two companions at Cranberry Portage. When he did not appear they spread the alarm and for ten days Indians, fishermen and trappers joined in an exhaustive search. On July 18th the body of Mr. Thompson was discovered on the shores of Cold Lake a few feet from where he had mounted his large surveyor's blue prints on a short stick. This distress sign had been blown down.

Mr. Thompson was born at Cannington, Ont., on November 1st, 1853. He received the degree of B.A.Sc. from McGill University in 1877 and that of M.A.Sc. from the same university in 1882. He was engaged on base line and principle meridian surveys for the Dominion Government from 1879 to 1884 in what are now the Provinces of Saskatchewan and Alberta. He then undertook surveys for the Dominion Government in Western Canada, subdividing townships, with correction and inspection work in connection with the townships. In 1896 he became one of the first surveyors and engineers appointed by the Old North West Territories Council and on organization of the Provinces of Saskatchewan and Alberta he continued in that appointment for Saskatchewan, resigning during 1922 to take up private practice in The Pas, Man. He remained here until 1931 when he removed to Cranberry Portage, Man., where he made his home until the time of his death.

Mr. Thompson joined The Institute as an Associate Member in 1894, becoming a Member in 1910.

The following items refer to deaths which occurred some time ago, notice of which has just reached headquarters.

John William Burke, M.E.I.C.

The death of John William Burke, M.E.I.C., occurred in New York, on August 29th, 1937. Mr. Burke was born at Westford, Mass., on May 7th, 1865. He received his technical education at the Worcester Polytechnic Institute, being graduated in civil engineering in 1887. In 1895 he began his practice as consulting engineer in New York and was still in active practice at the time of his death.

Mr. Burke joined The Institute as a Member in 1903.

Major Alan Bruce Ritchie, A.M.E.I.C.

Word has just been received of the death of Major Alan Bruce Ritchie, A.M.E.I.C., in a mine accident at Kimberley, B.C., in December last. Major Ritchie was born at Halifax, N.S. on August 15th, 1882. He was graduated from McGill University in mining engineering in 1906. He was employed with various mining companies but since 1921 held the position of general superintendent of the Consolidated Mining and Smelting Company of Canada Limited at Kimberley.

His service during the war was acknowledged by the Military Cross.

Major Ritchie joined The Institute as a Student in 1904, becoming an Associate Member in 1911.

George R. Wright, A.M.E.I.C.

We have just received notification of the death of of George R. Wright, A.M.E.I.C., in Vancouver, B.C., on January 1st, 1938. He was born at Salisbury, N.B., on September 28th, 1882. He received his B.A. degree from Mount Allison University, Sackville, N.B., in 1903 and that of B.Sc. from McGill University in 1907. In this latter year he entered the Canadian General Electric Company in Peterborough, Ont. Serving in various departments he became district manager in 1916 and was at that time located in Winnipeg. In 1925 he was transferred to Vancouver, B.C., and remained there until his death.

Mr. Wright joined The Institute in 1920 as an Associate Member.

April, May and June Journals Required

Copies of the April, May and June 1938 issues of The Engineering Journal are required for binding and it would be appreciated if members having no further use for these issues would forward copies available to Headquarters at 2050 Mansfield Street, Montreal, Que.

PERSONALS

Professor R. A. Spencer, M.E.I.C., Chairman of the Committee on Membership and Management, is making a lengthy visit to Toronto. He will be in Montreal for the Council meeting of August 19th. His Toronto address is 166 Balsam Avenue.

Lesslie R. Thomson, M.E.I.C., has again made a substantial contribution to the solution of one of Canada's great economic problems. The Macmillan Company of Canada announces the printing of his book "The Canadian Railway Problem," shortly to be available to the public. The prospectus describes a very interesting publication, and certainly one whose table of contents indicates a very broad and thorough treatment of the subject. A review will appear in a later number of The Journal.

John F. Plow, A.M.E.I.C., former Assistant Secretary of The Institute, has recently qualified for the rank of provisional lieutenant-colonel. At present he is major in the 1st Medium Battery Royal Canadian Artillery.

Lt.-Col. T. S. Morrisey, D.S.O., M.E.I.C., has recently been appointed secretary-treasurer of the Associated Screen News, Montreal. Col. Morrisey is commanding officer of the McGill University C.O.T.C.

Jules LeBlanc, A.M.E.I.C., has been appointed engineer with the Provincial Electricity Board, Montreal. Mr. LeBlanc was graduated from the Ecole Polytechnique in 1928 with the degree of B.A.Sc. and from the Massachusetts Institute of Technology in 1929 with the degree of B.Sc. He was formerly assistant chief engineer of the Provincial Relief Works of the Ministry of Labour.

H. A. Matheson, Jr.E.I.C., is now with the Tropical Oil Company in Barranca-Bermeja, Colombia, S.A. Mr. Matheson is a graduate of the University of Saskatchewan, Regina, in 1933 with the degree of B.Sc. He entered the Imperial Oil Company in 1935, as engineer of maintenance and construction at Regina. The following year he was transferred to Sarnia, Ont., remaining there until accepting his present position.

F. C. Jewett, A.M.E.I.C., has been recently appointed chief engineer of the Newfoundland Airport. Prior to going to Newfoundland he was resident engineer of the Capitol Works, National Harbours Board, Saint John, N.B.

G. R. Langley, M.E.I.C., has been appointed to succeed **L. De W. Magie,** M.E.I.C., who is retiring after having held the position of works engineer at the Peterborough plant of the Canadian General Electric Company for 38 years. A native of Toronto where he attended Upper Canada College, Mr. Langley is a graduate of Union University at Schenectady, N.Y., in electrical engineering. Following graduation he became associated with the General Electric Company in the Test Department, Research Laboratory and Switchgear Engineering Department. Since 1913 he has been the engineer in charge of the Switchboard Engineering Department at Peterborough. For many years he has taken a keen interest in athletics. Before going to Peterborough as works engineer in 1900, Mr. Magie gained wide experience with the Stanley Electric Company in Pittsfield, Mass., and the Royal Electric Company in Montreal. He is a member of the E.I.C., the A.I.E.E., and the Engineering Club in Toronto. He is a well-known member of the Peterborough Library Board and is a great lover of books and flowers.

J. W. Stafford, S.E.I.C., who has been located at Arvida, Quebec, with the Saguenay Power Company Limited as junior engineer has been transferred to the company's Isle Maligne Station as plant engineer. Mr. Stafford graduated from the University of Alberta in 1937 with the degree of B.Sc. in electrical engineering.

REQUEST FOR INFORMATION

To all members of The Engineering Institute of Canada

It is proposed to publish a membership list before the end of the year. In order that complete and up-to-date information may be available, will you kindly fill in this form and return it to Headquarters. The work is already under way; therefore a prompt response will be appreciated.

L. Austin Wright, *General Secretary*

Name in full..

Residence address..

Business address..

(*Underline the one to be used for mail*)

Membership classification in Institute..

Name of Employer..

Position occupied..

College, Degrees and year..

Military or Civil titles and honours..

Visitors to Headquarters

Brig.-Gen. Sir Godfrey Rhodes, C.B.E., D.S.O., M.E.I.C., was in Montreal for a few days on his way to England. We were very pleased to have him visit Headquarters on July 7th. He is general manager of the Kenya and Uganda Railways and Harbours, Kenya Colony, British East Africa. He is a graduate of the Royal Military College, 1907. The Vancouver Branch had the pleasure of entertaining him at luncheon on June 13th.

Major-General A. Clyde Caldwell, Master-General of the Ordnance, Department of National Defence, Ottawa, was a welcome visitor on July 15th. General Caldwell is having a paper prepared dealing with an important phase of industry which is to be printed in an early edition of The Journal.

Special Meeting Planned for Sarnia

The opening of the new bridge from Port Huron, Michigan, to Sarnia, Ontario, has been seen as an opportunity for a special celebration on the part of the London and Border Cities branches. The President and the General Secretary intend to be present, and councillors and officers of other branches are also expected.

The date is set for late September and the meeting will be in Sarnia. The tentative programme includes a visit to the Imperial Oil Refinery, with one of the officials of that company as speaker at the luncheon; a visit to the bridge and a dinner at night when it is expected that a prominent engineer of the highway department will be the speaker. Visitors from across the border are expected.

Council Entertains English Engineers

Dr. W. E. Cullen
President of the Institution of Civil Engineers.

Dr. R. E. Stradling, C.B., M.C.
Councillor of the Institution of Civil Engineers.

ELECTIONS AND TRANSFERS

At the meeting of Council held on June 24th, 1938, the following elections and transfers were effected:

Associate Members

BRYDEN, Donald Charles, B.Sc. (E.E.), (Univ. of Alta.), power sales engr., Winnipeg Hydro Electric System, Winnipeg, Man.

CLARKE, Robert Arthur, (Crystal Palace School of Engrg.), res. engr., highway divn., Dept. of Public Works of N.B., Lewisville, N.B.

COOK, Clarence Arthur, B.Eng. (Civil), (Univ. of Sask.), teacher, Bedford Road Collegiate, Saskatoon, Sask.

DESLOOVER, Jean Raymond, B.Sc. (E.E.), (McGill Univ.), engr., Provincial Electricity Board, Montreal, Que.

HUBER, Albert Lloyd, (Ottawa Collegiate Institute), chief engr., Link-Belt Ltd., Montreal, Que.

JONES, Allan John, B.A.Sc. (Civil), (Univ. of B.C.), engr., purchasing agent and asst. mgr., B.C. Bridge and Dredging Co. Ltd., Vancouver, B.C.

MINSHALL, Harry Hugh, (Hamilton Technical Institute), engr. of erection, Dominion Bridge Co. Ltd., Vancouver, B.C.

STROYAN, Philip Bateman, B.A.Sc., (Univ. of B.C.), asst. supt. and engr., Board of Park Commissioners, Vancouver, B.C.

Juniors

CHAPUT, Omer, Jr., B.Sc. (E.E.), (Queen's Univ.), ap'tice engr., Aluminum Co. of Canada, Arvida, Que.

DOW, Walter Kerr, B.A.Sc. (E.E.), (Univ. of Toronto), ap'tice engr., Aluminum Co. of Canada, Arvida, Que.

DRIEDGER, Edwin Wilfrid, B.Eng. (Civil), (Univ. of Sask.), dftsman., Canadian Bridge Company, Windsor, Ont.

FLEMING, Frederick Alexander, B.A.Sc. (E.E.), (Univ. of Toronto), asst. meter engr., Can. Gen. Elec. Co. Ltd., Peterborough, Ont.

SUTHERLAND, Gordon Alexander, B.Sc. (E.E.), (Univ. of Man.), designing engr., Kipp-Kelly Ltd., Winnipeg, Man.

Transferred from the class of Associate Member to that of Member

ARMSTRONG, Arnold Victor, B.Sc. (E.E.), (McGill Univ.), sales mgr., Canadian Cutler-Hammer Ltd., Toronto, Ont.

CRASE, George Hobart, B.C.E., (Univ. of Mich.), gen. sales mgr., Horton Steel Works Ltd., Toronto, Ont.

DICKENS, Harry Blundell, co-ordinating officer, Royal Arsenal, Woolwich, England.

MANNING, Ralph Clark, B.A.Sc., (Univ. of Toronto), engr. and mgr., Canadian Institute of Steel Construction, Toronto, Ont.

MICHAUD, J. Arthur, (Univ. of Toronto), Dept. of Public Works, Toronto, Ont.

O'HALLORAN, James, B.Sc. (Mech.), (McGill Univ.), plant engr., Anglo-Canadian Pulp and Paper Mills Ltd., Quebec, Que.

RYBKA, Karel Rudolf, Mech. Engr., D.Sc., (Technische Hochschule, Prague), engr. in charge and mgr., Walter J. Armstrong, M.E.I.C., Consltg. Engr., Toronto, Ont.

WHITAKER, Albert William, Jr., Chem. Engr., (Univ. of Penn.), gen. supt., Arvida works, Aluminum Co. of Canada, Arvida, Que.

Transferred from the class of Junior to that of Associate Member

BAIN, Archibald Marcus, B.Sc., (Univ. of Man.), M.Sc., (McGill Univ.), struct'l. designer, Dominion Bridge Co. Ltd., Lachine, Que.

LeBOUTILLIER, William Percy Cecil, B.Sc. (Civil), (McGill Univ.), asst. groundwood supt., Price Bros. & Co. Ltd., Kenogami, Que.

RICHARDSON, William Gordon, B.Sc. (E.E.), (Queen's Univ.), engr., Canadian Broadcasting Corporation, Montreal, Que.

VICKERSON, George L., B.Sc. (Civil), (McGill Univ.), i/c of contracts, G. R. Locker Co. Ltd., Montreal, Que.

Transferred from the class of Student to that of Associate Member

SANDILANDS, Adam, Jr., B.Sc. (E.E.), (Univ. of Man.), elect'l. and sales engr., Power and Mine Supply Co., Winnipeg, Man.

Transferred from the class of Student to that of Junior

BARNHOUSE, Frank William, B.Sc. (E.E.), (Univ. of Alta.), wire and cable sales engr., Can. Gen. Elec. Co. Ltd., Toronto, Ont.

BOOTH, Keith Alexander, B.Sc. (E.E.), (Univ. of Man.), B.Eng. (Mech.), (McGill Univ.), engr. i/c records office, Price Bros. & Co. Ltd., Kenogami, Que.

CROTHERS, Donald Coverdale, B.Sc. (Mech.), (Queen's Univ.), sales engr., Canadian Ingersoll-Rand Co. Ltd., Vancouver, B.C.

Students Admitted

DAVIS, Samuel, B.Sc. (Civil), (Univ. of N.B.), 42 Spring St., Saint John, N.B.

HARLAND, Robert Thompson, B.Sc. (E.E.), (Univ. of Man.), 241 Waverley St., Winnipeg, Man.

LOW, Ernest Gerald, B.Sc. (E.E.), (Univ. of Man.), 830 Hillcrest Ave., Calgary, Alta.

VATCHER, Chesley Holmes, (Univ. of Toronto), 65 St. George St., Toronto, Ont.

ADDITIONS TO THE LIBRARY

Proceedings, Transactions, etc.

Association of Ontario Land Surveyors: Annual Report and Proceedings of the Forty-Sixth Annual Meeting; Toronto 1938.

Canadian Institute of Surveying: Proceedings of Thirty-First Annual Meeting, Ottawa, 1938.

Institution of Electrical Engineers: List of Members, 1937.

Asphalt Institute and Association of Asphalt Paving Technologists: Eleventh National Asphalt Conference, Memphis, Tennessee, 1937.

Society of Naval Architects and Marine Engineers: Transactions, Vol. 45, 1937.

U.S. National Research Council Highway Research Board: Proceedings of the Seventeenth Annual Meeting, 1937.

Reports, etc.

American Foundrymen's Association: Silicosis in the Foundry Industry, by Dr. Leonard Greenburg (Reprint No. 38-35).

American Institute of Electrical Engineers: Standards, Oil Circuit Breakers (rev.).

American Standards Association: Relays Associated with Power Switchgear; Automatic Stations.

Bell Telephone System: Recent Development in Hill and Dale Recorders; Microgasometric Analysis with the Dilatometer; High-Speed Motion Picture Photography Applied to Telephone Apparatus Design; Fatigue Properties of Non-Ferrous Sheet Metals; Transmission Measuring Systems for Telephone Circuit Maintenance; Cable Carrier Telephone Terminals; On the Theory of Space Charge Between Parallel Plane Electrodes; A New Single Channel Carrier Telephone System; A Carrier Telephone System for Toll Cables; Crystal Channel Filters for the Cable Carrier System; The Impedance Concept; Crosstalk and Noise Features of Cable Carrier Telephone System; An Application of Number Theory to Gear Ratios; A Theory of Noise for Electron Multipliers; Theory of Order for the Copper Gold Alloy System; Composition and Structure of Hevea Latex; Ultraviolet Microscopy of Hevea Rubber Latex; Sorption of Water by Rubber; Dielectric Losses in Polar Liquids and Solids; Mixed Linear Condensation Polymers. (Monographs B-1047-64, B-1066, B-1068.)

Canada Civil Service Commission: Annual Report, 1937.

Canada Bureau of Mines: The Canadian Mineral Industry in 1937.

Kenya and Uganda Railways and Harbours: Report of the Genera Manager of the Administration of the Railways and Harbours for the year ended 31st December, 1937, Pts. I and II.

Ontario Hydro-Electric Power Commission: Annual Report, 1937.

U.S. Bureau of Mines: Crushing and Grinding, Coal-Mine Accidents in the United States: 1935 (Bulletins 402, 409); A Study of a Solvent Analytical Separation of Waxes from Petroleum and its Lubricating Fractions (Technical Paper 583).

University of Illinois: Pressure Losses Resulting from Changes in Cross Sectional Area in Air Ducts, A. P. Kratz and J. R. Fellows; Papers Presented at the Short Course in Coal Utilization, Univ. of Illinois May 25-27, 1937. (Bulletin Nos. 52, 55.)

University of Nevada: Effects of High Voltage on the Bacterial Content of Milk. (Engineering Experiment Station Bulletin No. 3.)

Technical Books, etc.

The Golden Gate Bridge, Report of the Chief Engineer to the Board of Directors of the Golden Gate Bridge and Highway District, California. San Francisco, 1938. 246 pp., front. illus., tables, charts, 11¼ by 8½ in., cloth.

U.S. Works Progress Administration, **Bibliography of Aeronautics**, Pt. 1 Air Transportation; Pt. 3 Insurance; Pt. 5-6-7 Seaplanes, Flying Boats, Amphibians; Pt. 11 Medicine; Pt. 27 Aircraft Propellers; Pt. 46 Gliding and Soaring; Pt. 48 Parachutes.

Vibrations Caused by Blasting and Their Effect on Structures. By E. H. Rockwell. Wilmington, Del., Hercules Powder Company 1934. 69 pp., fig., tables charts, 6¼ by 9 in., paper.

BOOK NOTES

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet, the books are not in The Institute Library, but inquiries will be welcomed at Headquarters, or may be sent direct to the publishers:

Air Conditioning, Heating and Ventilating. By J. R. Dalzell and C. L. Hubbard. Chicago, American Technical Society, 1938. 571 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.00.

A practical treatise on the principles and general application of steam, hot water, vapour, vacuum, and forced air for heating; split systems for heating and ventilating; and air conditioning for all types of buildings. Calculations have been made as simple as possible, and a profusion of diagrams, tables, and practice problems increases the utility of the book.

Applied Thermodynamics. By V. M. Faires. New York, Macmillan Co., 1938. 374 pp., illus., diagrs., charts, tables, 10 x 6 in., lea., $3.90.

An elementary textbook covering the theories of thermodynamics involved in engineering problems. It includes the material contained in the author's "Elementary Thermodynamics," plus further chapters on entropy, combustion, steam engines and steam power plants, steam flow, and heat transfer.

Autographic indicators for Internal Combustion Engines. By J. Okill. London, Edward Arnold & Co., 1938. 88 pp., illus., diagrs., charts, tables, 8 x 5 in., cloth, $1.80 (obtainable from Longmans, Green & Co., New York).

Only indicators of the combined piston, spring, and pencil-lever type are considered, thus limiting the discussion to moderate-speed large cylinder engines with crank-shaft speeds under 500 r.p.m. History, development, descriptions of actual instruments, diagrams, calculations, disturbing factors, and errors are included in the discussion.

The Chemistry and Technology of Rubber Latex. By C. F. Flint. New York, D. Van Nostrand Co., 1938. 715 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $14.00.

Based on the translation of a French book on latex, but considerably enlarged, this book covers the various phases of rubber latex in industry. The gathering, composition, properties, and handling for shipping of latex are discussed; the numerous applications in manufacturing fields are considered in detail; and information is given concerning artificial dispersions of rubber.

Design of Machine Members. By A. Vallence. New York and London, McGraw-Hill Book Co., 1938. 514 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.00.

This textbook, the first of a series devoted to production development, is intended for students with some training in kinematics, mechanics and factory processes. With this basis, the work explains the theory involved in the design of the elements of operating machines and points out the variations from theory required by practical operations.

Direct and Alternating Currents, Theory and Machinery. By E. A. Loow. 2 ed. New York and London, McGraw-Hill Book Co., 1938. 730 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.50.

This volume is intended primarily for students desiring a short survey course in the theory of the electric circuit and the operating principles of electric machines. The author stresses fundamental principles rather than mere factual information. Alternating-circuit theory is stressed largely in terms of vectors. Mathematical discussions are omitted or reduced to simple forms. The new edition has been thoroughly revised. New material has been added and new problems presented.

Electrical Engineering. By C. V. Christie. 5 ed. New York and London, McGraw-Hill Book Co., 1938. 717 pp., diagrs., charts, tables, 9 x 6 in., cloth, $5.00.

This standard textbook has undergone a fifth revision, which has incorporated additional details of a practical nature to make the book of more permanent value. New material includes the two-reaction method for analyzing the operation of synchronous machines; an outline of the theory of the three-winding transformer; additional information upon induction motors; and a chapter on symmetrical components. The book aims to present a logical development of the theory of electrical circuits and machinery which will give a background for advanced study in any special field.

Elementary Thermodynamics. By V. M. Faires. New York, Macmillan Co., 1938. 225 pp., illus., diagrs., charts, tables, 9 x 6 in., lea., $2.60.

A presentation of the topics of importance for short courses in thermodynamics. These topics include energy equations, reversible non-flow gas processes, thermodynamic cycles, compression and expansion of air, liquids, vapours and vapour cycles, refrigeration, nozzle flow, and the properties of mixtures. Many problems are appended.

Elements of Mechanism. By P. Schwamb, A. L. Merrill and W. H. James. 5 ed. New York, John Wiley & Sons, 1938. 400 pp., diagrs., charts, tables, 9 x 6 in., cloth, $3.50.

Intended to give familiarity with the application of the fundamental principles of kinematics in the field of mechanical movements, this book treats of vectors, velocity analysis, motion transmission by various means, and the characteristics of gears, wheel, trains, cams, wedges, belts, and other such transmitters of power.

Essays in Science and Engineering, compiled by F. Montgomery and L. N. Backlund. Rev. ed. New York, Farrar & Rinehart, 1938. 523 pp., charts, tables, 9 x 6 in., cloth, $2.00.

A collection of essays and articles on scientific and technical subjects designed to provide reading material for engineering English courses. The first part comprises a selection of more general essays, while the second and larger part consists of "expository models" for various kinds of technical composition.

Foundations of Wireless. By A. L. M. Sowerby. 2 ed. London, The Wireless World, Iliffe & Sons, Limited, 1937. 266 pp., illus., diagrs., charts, tables, 8 x 5 in., cloth, 4s. 6d. + 5d. postage.

An elementary textbook on radio fundamentals and the radio receiver in particular. Circuits, tubes and the process of detection are considered fully, and new material contained in this edition includes negative feed back, automatic tuning and automatic selectivity control.

Gas Analysis. By A. McCulloch. London, H. F. & G. Witherby, Limited, 1938. 166 pp., illus., diagrs., charts, tables, 9 x 6 in., lea., 7s. 6d.

The construction and manipulation of five well-known types of gas analysis apparatus are described in this book for students taking laboratory courses in fuel technology. Calorific value and other miscellaneous determinations, absorbents, and sampling of gases are also discussed.

Great Britain. Scientific and Industrial Research Dept. Chemistry Research Special Report No. 4. **An Investigation into the Causes and Prevention of the Corrosion of Tar Stills.** By D. D. Pratt with H. C. K. Ison and R. G. Wood. London, H.M. Stationery Office [obtainable from British Library of Information, 270 Madison Ave., New York, $0.30], 1938. 30 pp., charts, tables, paper.

The objectives of this investigation were to identify and isolate the tar constituents responsible for corrosion and to suggest means for reducing or eliminating the latter. The methods of investigation are described and the conclusions reported.

Handbook of Aeronautics, Vol. 1. By Royal Aeronautical Society, 3 ed. enl. London, Sir Isaac Pitman & Sons; New York, Pitman Publishing Corp., 1938. 639 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $10.00.

This handbook, which is issued under the authority of the Royal Aeronautical Society, has an established place as an authoritative collection of data needed by designers and builders of aircraft. In the new edition, of which this is the first of three volumes, the material has been brought up to date by specialists. Aerodynamics, airplane performance, construction, materials, instruments, air surveying and photography, meteorology and the design and construction of gliders and sailplanes are covered in volume one.

Hearing, Its Psychology and Physiology. By S. S. Stevens and H. Davis. New York, John Wiley & Sons, 1938. 489 pp., illus., diagrs., charts, tables, 9 x 6 in., lea., $4.50.

This book discusses fundamentals of the science of sound, analyzes the auditory process, and describes the systematic relations between stimulus and sensation. Later chapters offer a study of the functional anatomy and physiology of the ear. The relations of the science of audition to architectural acoustics, phonetics, noise and music have been omitted. A glossary and long list of references are appended.

Jigs and Fixtures. By F. H. Colvin and L. L. Haas. 3 ed. New York and London, McGraw-Hill Book Co., 1938. 354 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $3.50.

A complete, practical manual dealing with the fundamentals of jig and fixture design. Includes new material on economies of design and standard practices from large concerns which is of importance in figuring costs. There are also new details of various features to assist the designer in producing efficient and economical work-holding devices.

Machine Guns. By G. S. Hutchison. New York and London, Macmillan & Co., 1938. 349 pp., illus., maps, 9 x 6 in., cloth, $7.00.

The development and tactical employment of the repeating weapon is traced from antiquity to modern times, with special emphasis on three major operations: the Franco-German War; the Russo-Japanese War; and the Great War. A history of the British Machine Gun Corps, 1915-1922, is included with the more general context.

Men and Iron, the History of the New York Central. By E. Hungerford. New York, Thomas Y. Crowell Co., 1938. 424 pp., illus., tables, 10 x 6 in., cloth, $3.75.

This history of the New York Central Railroad is mainly concerned with the beginnings, development, and consolidation of the smaller rail units east of Buffalo which went to form the original New York Central. The book is to a great extent written around the men whose foresight and energy carried on the work, and demonstrates the importance of railroad men and events in the progress of the country as a whole.

The Mind of the Ancient World. By H. N. Wethered. New York, Longmans, Green & Co., 1937. 302 pp., tables, 9 x 6 in., cloth, $4.00.

A review of Pliny's "Natural History," presenting many excerpts from a famous Elizabethan translation with critical comment by the author. In two appendices appear short discussions of medieval natural history and ancient science in literature.

(A) **Modern Spanish-English and English-Spanish Technical and Engineering Dictionary.** By R. L. Guinle. New York, E. P. Dutton & Co., 1938. 311 pp., 10 x 6 in., cloth, $4.00.

There are relatively few dictionaries of Spanish and English technical terms, and still fewer that have been revised recently. As a result, any modern one is a useful addition. This one is a well-printed volume of convenient size, the work of an English engineer with long experience in South America. The vocabulary covers the terms used in civil, mechanical and electrical engineering.

Motion Picture Sound Engineering, a Series of Lectures presented to the classes enrolled in the courses in Sound Engineering given by the Research Council of the Academy of Motion Picture Arts and Sciences, Hollywood, Calif. New York, D. Van Nostrand Co., 1938. 547 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, $6.00.

The material included in this book is taken from a series of lectures presented to a selected group of employees of various motion picture studios. The lecture subjects varied from fundamental discussions of sound, electricity, and the chemical elements, through the mechanical processes of recording and projecting, to highly technical descriptions of filters, networks, amplifiers, etc.

The Physics and Chemistry of Surfaces. By N. K. Adam. 2 ed. Oxford, Clarendon Press; New York, Oxford University Press, 1938. 402 pp., illus., diagrs., charts, tables, 10 x 7 in., cloth, $7.50.

A comprehensive, detailed account of present knowledge in the field of surfaces and surface films. The sections on capiliarity, molecular properties, and the measurement of surface tension have been revised, and much new material has been added to the sections dealing with insoluble films, adsorption on liquid surfaces, and the structure and properties of solid surfaces, including lubrication. A new chapter has been added on electrical phenomena at surfaces.

The Principles and Practice of Lubrication. By A. W. Nash and A. R. Bowen. 2 ed. rev. New York, Chemical Publishing Co., 1937. 345 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $7.25.

A presentation of the salient features of the subject of friction and lubrication, covering the chemistry, characteristics, testing and care of lubricants, friction fundamentals and testing machines, and the design and lubrication of bearings. Useful tables and charts are appended.

Principles of Engineering Economy. By E. L. Grant. rev. ed. New York, Ronald Press Co., 1938. 431 pp., diagrs., charts, tables, 8 x 6 in., cloth, $3.75.

Demonstration of a practical technique providing an engineering basis for making economic decisions is the purpose of this book. Interest, valuation, and rate of return calculations are explained. The making of estimates for new enterprises, replacement problems, and the planning of future developments are discussed. Appendices contain notes on cost estimating, interest tables, and a list of selected references.

Problems on Applied Thermodynamics. By V. M. Faires and A. V. Brewer. New York, Macmillan Co., 1938. 137 pp., charts, tables, 9 x 6 in., paper, $1.40.

Contains 1,403 problems designed especially for use with Faires' "Applied Thermodynamics," but usable with other textbooks as well. Tables of the properties of fluids and charts depicting those properties are included in the volume.

Reinforced Concrete Bridge Design. By C. S. Chettoe and H. C. Adams, with a foreword by Sir H. Maybury. 2 ed. new and enl. London, Chapman & Hall, 1938. 412 pp., illus., diagrs., charts, tables, 10 x 6 in., 42s.

Detailed information on the design of reinforced concrete bridges. There are four introductory chapters on structural theory, concrete, design essentials, and live load on highway bridges. The next five chapters contain practical design data with all details. The concluding chapters cover such allied subjects as piling, excavation, curves, expansion, bridge strengthening and widening, aesthetics of design, and location problems.

Standard Plumbing Details for Architects, Engineers, Contractors, Plumbers and Students. By L. J. Day. New York, John Wiley & Sons, 1938. 119 pp., diagrs., charts, tables, 12 x 9 in., cloth, $6.00.

A collection of 119 plates intended to show the connections required in plumbing installation and how they fit together, so that proper spaces may be provided in a building. The drawings are drawn to scale. They cover fixtures, equipment, installations and layouts, for all usual requirements, and conform to general codes.

Steels for the User. By R. T. Rolfe. New York, Chemical Publishing Co., 1938. 280 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $8.50.

Carbon steels, with particular reference to bright and free-cutting steels, are the subject of this expansion of material which appeared in a series of articles in "Iron and Steel Industry." Composition, heat treatment, case hardening, mechanical testing, and the selection of steels are discussed, with a special chapter on the use of steels at elevated temperatures.

Testing and Grading Foundry Sands and Clays, Standards and Tentative Standards, adopted by the American Foundrymen's Association, 222 West Adams St., Chicago. 4 ed. 1938. 208 pp., illus., diagrs., charts, tables, 9 x 6 in., lea., $4.00.

Standards for sampling, analyzing and testing foundry sands and clays, including descriptions of the testing equipment. There are also foundry sand grading classifications, a short glossary, and a large bibliography on sand testing and control.

Year Book on Coal Mine Mechanization, 1937. Ed. by American Mining Congress, Washington, D.C. 428 pp., illus., diagrs., charts, maps, tables, 9 x 6 in., lea., $2.00.

"Listard" Processed Cylinders and Liners
(*Van der Horst Patents*)

Consolidated Engines and Machinery Co. Ltd., Read Bldg., Montreal, have available for distribution a 12-page booklet describing the "Listard" process of chrome hardening cylinders and cylinder liners. It is illustrated by photographs and graphs which describe tests comparing the wear of "Listard" and ordinary hardened iron cylinders, which showed 400 per cent increased wear resistance in favour of "Listard."

BRANCH NEWS

Border Cities Branch

J. F. Bridge, A.M.E.I.C., Secretary-Treasurer.
F. J. Ryder, Jr.E.I.C., Branch News Editor.

The April monthly meeting of the Border Cities Branch was held on April 29th, 1938, with dinner preceding the meeting. Thirteen were present for dinner and twenty-two for the meeting.

Professor H. O. Warner, of the University of Detroit, was introduced by the Chairman as the speaker of the evening. His topic, "The Mysteries of Electrical Sciencc," did not prove so mystifying as the title would lead one to believe. He defined engineering as "the science of controlling forces and utilizing the materials of nature for the benefit of mankind." Electric current is merely a flow of electrons. He described thc transmitting system invented by himself for transferring voice waves from the linesman on a football field to the scoreboard. A telephone transmitter is used in series with a thoroid coil and a set of telephone batteries by the linesman. He remains immediately over a pair of No. 14 wires strung longitudinally up the field and tied in to an audio amplifier at the scoreboard. So long as the coil is carried at right angles to the pair of No. 14 wires, reception is good. Professor Warner also described the body resistance of a human being. This value is 2,500 ohms of an average. Twenty milliamp. are sufficient to produce muscular contraction and two amp. will cause death if it passes through a life-giving vital organ. The current destroys tissue either by burning or causing vital organs to fail to function.

Professor Warner proved himself to be a scholar versed in many fields of engineering by answering all questions in the discussion following the lecture.

A hearty vote of thanks was moved by Boyd Candlish, A.M.E.I.C., and responded to by all.

The meeting adjourned at 10.30 p.m.

There were 32 persons present at the regular monthly meeting held Friday, May 27th, 1938. E. Krebser, A.M.E.I.C., chairman, introduced the speaker, Major C. V. Brunett, manager of the Detroit City Airport. The subject of his talk was:

The Operation of a Modern Airport

Planes today leave very little for the pilot to do compared with the earlier flights. The air is criss-crossed with directional radio beams which guide the pilot as surely as a railroad track. The intersection of one beam with another tells the pilot his location even though he may not be able to see the ground. When coming into an airport, the beam that he is following intersects a vertical beam from the airport and he then knows his exact location. Then by following the rules laid down for that airport as to altitude, flying speed, etc., it is possible to bring his ship to the ground even though he cannot see it or the landing lights. At present, research work is being done on a curved radio beam which will take from the pilot all the responsibility of landing a ship. For once he arrives at the airport, he will switch over to the automatic pilot which will bring the plane down following the curved beam. Very few accidents have been caused by forced landings due to lack of fuel as the cruising radius of a plane is greater than actually required.

One cause of air accidents has been the formation of ice on the wings. It is not the added weight that causes the harm. The manner of changing the contour of the air-foil causes a loss of lifting power. The Goodrick de-icer has overcome this harmful effect. A rubber membrane along the leading edge of the air-foil is inflated which raises the edge of the ice layer and the rushing air rips in under and tears it off. Propellers are kept free of ice by using glycerine which is introduced onto the whirling propeller through openings in the hub and the centrifugal force spreads it over the face of the propeller. The development of the full-feathering propeller has overcome the harmful effect of "windmilling" of a propeller on an engine that has gone dead. The blades can be rotated at right angles to their flying position thus preventing the turning of the propeller as it is forced through the air.

The Airway Traffic Control Station, which is under government control, directs the landings and take-offs of planes at the airports thereby avoiding confusion between the various companies. When a plane arrives at the airport the company reports to the Control Station. The pilot is assigned a cruising altitude if there is another plane ahead of him, if not he is given the o.k. to land. At times, there may be five or six planes over the airport waiting to land.

Present day transports are equipped with dual and even triplicate equipment and though much is made of and heard of airplane crashes, the insurance rates on travellers in planes is nearly as low as that on railroad travellers and in some cases is the same.

Many interesting questions were asked and answered and doubtless the air-mindedness of most those present was considerably increased by this paper.

The meeting then adjourned until the fall.

Lakehead Branch

H. Os, A.M.E.I.C., Secretary-Treasurer.

The annual meeting was held at the Prince Arthur hotel, Port Arthur, June 22nd, 1938. The meeting took the form of a dinner meeting and thirty-four members and guests were present. The chairman, G. R. Duncan, A.M.E.I.C., presided at the meeting.

Reports by the chairman and secretary of the year's activities were read and adopted.

The following slate of officers were proposed by the Nominating committee and elected to the Executive committee for the coming year:—Chairman, E. L. Goodall, A.M.E.I.C.; Vice-Chairman, K. A. Dunphy, A.M.E.I.C.; Secretary-Treasurer, H. Os, A.M.E.I.C.; Executive, J. R. Mathieson, Jr.E.I.C., D. Boyd, A.M.E.I.C., B. A. Culpeper, A.M.E.I.C., S. E. Flook, M.E.I.C., H. Olsson, A.M.E.I.C., M. Gregor, E. A. Kelly, M.E.I.C. (Outside West), A. T. Hurter, M.E.I.C. (Outside East).

A vote of thanks to the outgoing chairman and executive was moved by R. J. Askin, M.E.I.C., and seconded by H. G. O'Leary, A.M.E.I.C.

Ottawa Branch

R. K. Odell, A.M.E.I.C., Secretary-Treasurer.

LUNCHEON TO COUNCIL

At the Chateau Laurier on June 24th, 1938, the Ottawa Branch held one of the largest attended and most interesting luncheon meetings of the year. The Branch took advantage of the presence in Ottawa of many members of the Council of The Institute who were in Ottawa to attend a council meeting during the afternoon. It was the first occasion for a meeting of The Institute Council in Ottawa, apart from the times when an annual convention of The Institute itself was held in the city.

The chairman of the Branch, W. F. M. Bryce, presided, with the following guests at the head table: President J. B. Challies; Vice-President J. A. McCrory; the new Treasurer, de Gaspe Beaubien; the new General Secretary, L. Austin Wright; Past Presidents Dr. F. A. Gaby, of Toronto; Geo. J. Desbarats, of Ottawa, and the Chairman of the Hydro-Electric Power Commission, Dr. T. H. Hogg, of Toronto; Councillors J. L. Busfield, R. H. Findlay, F. S. B. Heward, and Fred Newell, all of Montreal; Councillors J. A. Vance, of London; A. B. Gates, of Peterborough; Major L. F. Grant, of Kingston; W. E. Bonn, of Toronto; H. A. Lumsden, of Hamilton; W. R. Manock, of Niagara Falls; Dr. R. W. Boyle and E. Viens of Ottawa.

In his address President Challies sketched the great progress made by the engineering profession since Confederation. In 1867, he pointed out, there was no purely engineering faculty in the Canadian universities; today there are 11 Canadian engineering colleges with over 3,500 students in attendance. Fifty-two years ago, there was no purely professional national engineering body in the Dominion; today The Engineering Institute is the envy of the American and British engineer. Thirty years ago, the engineer in the federal public service had no more status than that of a clerical clerk; today he is an officially recognized member of one of the leading professions and rewarded as such. Twenty-five years ago there was no licensing body in any of the provinces; today in every mainland province there is a provincial professional association that is protecting the public from the quack and the charlatan, just as acceptably as do the Bar Associations or the Medical Councils. Ten years ago, there were no engineers among our political leaders and very few occupied key executive positions in the public service anywhere; today in the political world and in the public service everywhere engineers are bearing a prominent share of the responsibilities of government.

Mr. Challies paid an eloquent tribute to Sir Wilfrid Laurier for establishing in 1908 the Civil Service Commission and thus rescuing the Civil Service from the blight of political interference. He praised Sir Robert Borden for forcing upon the Civil Service, in 1918, the scientific classification of all professional positions, and he made generous reference to all succeeding prime ministers—the Rt. Hons. Arthur Meighen, W. L. Mackenzie King and R. B. Bennett—for refusing to remove the ban from political interference in the public service.

Following the address of the President the new Secretary, Mr. L. Austin Wright, spoke briefly on matters pertaining to The Institute and particularly with reference to The Engineering Journal. This was the first visit of Mr. Wright to the Ottawa Branch in his official capacity as General Secretary.

At the conclusion of the afternoon meeting of the Council of The Institute, a dinner was held at the Rideau Club at which Past Presidents, Honorary Members of The Institute and Councillors were the guests of President Challies.

Vancouver Branch

T. V. Berry, A.M.E.I.C., Secretary-Treasurer.

The Vancouver Branch, on June 13th, 1938, entertained at luncheon Brigadier-General Sir Godfrey Rhodes, C.B.E., D.S.O., M.E.I.C., General Manager of the Kenya-Uganda Railroad, East Africa. Sir Godfrey Rhodes, who is a native of British Columbia, for a number of years subsequent to the war, was chief engineer of the Kenya-Uganda Railroad, later becoming general manager. Following the introduction of the guest of honour by Lieut.-Col. J. P. Mackenzie, Sir Godfrey, in an interesting manner, described life in Kenya.

A number of questions by the members, more particularly relative to railroad engineering in East Africa, were answered by Sir Godfrey. A vote of thanks was proposed by Major F. P. V. Cowley, R.M.C., M.E.I.C.

On the occasion of this luncheon, the Vancouver Branch were very pleased to welcome Elizabeth Muriel Gregory MacGill, A.M.E.I.C., the recently elected lady member of The Institute, who has also been spending a holiday with her parents in Vancouver.

Colonel Mackenzie also introduced to the meeting Group Capt. G. O. Johnston, A.M.E.I.C., officer commanding R.C.A.F. Stations, Western Canada, who has recently been moved to Vancouver from Ottawa.

Twenty-six attended the luncheon.

Meetings

American Society of Civil Engineers—Fall Meeting, October 12th-14th, 1938, at Rochester, N.Y.

American Society of Mechanical Engineers—Fall Meeting, October 5th, 6th and 7th, at Providence, R.I.

Canadian Chamber of Commerce—1938 Convention, September 28th-30th and October 1st, at the Seigniory Club, Montebello, P.Q.

The Canadian Institute of Mining and Metallurgy—Annual Western Meeting, November 9th, 10th, 11th, at Vancouver. H. Mortimer Lamb, Vancouver Secretary, British Columbia Division.

The Engineering Institute of Canada—Annual General and Professional Meeting, February 20th-22nd, 1939, at Ottawa.

The Seventh **International Management Conference**—September 19th-23rd, 1938, at Washington, D.C.

The Iron and Steel Institute, and The Institute of Metals (London, England), Autumn Meeting, September 22nd Quebec; 23rd Shawinigan Falls; 24th and 25th Montreal; 26th Ottawa; 28th and 29th Toronto. Canadian Institute of Mining and Metallurgy are acting as hosts for Canadian visit.

Additional information about any of these functions may be secured from the General Secretary.

American Association for the Advancement of Science Meets in Ottawa

Starting on June 27th, the Association held its Summer Meeting as a series of papers occupying three days and dealing among other things with many phases of engineering and aeronautics. The chairman of the Canadian Committee for arrangements was Dr. Charles Camsell, M.E.I.C. F. E. Lathe was in charge of the programme committee. Norman Marr, M.E.I.C., was Canadian representative of the Engineering Section.

The Section on Engineering held one session with four papers on widely diverse subjects. About 80 persons attended. The first paper by P. L. Pratley, M.Eng., M.Inst.C.E., M.I.Struct.E., M.E.I.C., F.R.S.A., dealt with the collapse of the Falls View Bridge at Niagara Falls during extraordinary ice conditions in the Niagara river in January 1938. The second paper delivered by Mr. F. B. Friend for Dr. Marcel Pochon, chief chemist of Eldorado Gold Mines Limited, Port Hope, Ontario, discussed mining, concentration and transportation operations in connection with mining and treating radium bearing ores on Great Bear lake in the sub-arctic region of Northern Canada. The third paper by R. H. Field, A.M.E.I.C., described some instrumental aids to mapping from air photographs as practised in Canada. The fourth paper by Mr. W. B. Buchanan, B.A.Sc., M.Am.Inst.E.E., dealt with some aspects of applied science from the viewpoint of an electrical engineer.

Serving for Mr. A. A. Potter as chairman was G. J. Desbarats, Hon.M.E.I.C., immediate past-president of The Engineering Institute of Canada, and for Secretary F. M. Feiker, Norman Marr, M.E.I.C., chief hydraulic engineer, Dominion Water and Power Bureau, Department of Mines and Resources, Ottawa.

Preliminary Notice

of Applications for Admission and for Transfer

July 20th, 1938.

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in September 1938.

L. Austin Wright, General Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BLOXHAM—HORACE WILLIAM, of 116 Aberdeen Ave., Hamilton, Ont Born at Coventry, England, Sept. 18th, 1889; Educ., 1906-08, Coventry Technical Institute; 1912-13, instrument work, C.P.R., Calgary; 1914-16, dfting and field work, Welland Ship Canal; 1917, instrument work on highway constrn., Toronto-Hamilton Highway Comm.; 1918-19, transitman, rly. mtce., G.T.R.; 1920-21, asst. engr., i/c field party, G.T.R.; 1922-23, City of Toronto, valuation of street rly., field engr.; 1925-33, C. S. Boone Dredging Co. Ltd., Toronto, Ont., engr. for rock drilling and dredging of Port Colborne Harbour and rebldg. of breakwater; responsible for layout and checking of quantities and estimates; Apr. 1936 to Oct. 1937, Ontario Paper Co. Ltd., Thorold, Ont., field engr. on rly., wharf and mill yard on Baie Comeau Quebec development; responsible for constrn. and quantities; mill yard contained water supply, sewers, steel girder bridge, coaling plant, and conveyors for coal and pulp wood; at present, res. engr., subway constrn., C.P.R., Toronto (Bruce Divn.)

BRADLEY—JOSEPH GERALD, of Cap de la Madeleine, Que., Born at Sydney, N.S., May 13th, 1904; Educ., 1925-26, first year engrg., McGill Univ., not completed. 1927-28, first year, School of Commerce at McGill, completed; 1926-27, cost accting and mech. dfting., Fraser Brace Engrg. Co., Gatineau, Que.; 1928 R.C.A.F., Prov. Pilot Officer; 1928-29, supervision of 75 mile freight route, Island Falls, Sask., and 1929-30, inspn. of pipe and pump installn. of concentrator plant, Copper Cliff, Ont., for Fraser Brace Engrg. Co.; 1931 to date, asst. supt., i/c of mtce., calcining furnaces and milling plant at Red Mill, Que. for The Sherwin Williams Co. of Canada Ltd.
References: W. M. Mitchell, K. S. LeBaron, G. R. Stephen, J. M. Mitchell, L. Sterns.

JONES—REGINALD ELSDON, of Toronto, Ont., Born at Toronto, Oct. 18th, 1891; Educ., Univ. of Toronto (S.P.S.), 1911-13; R.P.E. of Ont.; Member, A.I.E.E.: 1909-11, fixture dept., Toronto Elec. Light Co.; 1912, Miller Lake O'Brien Mine, Gowganda; 1913-15, distribution dept., Toronto Elec. Light Co.; 1915-19, overseas, C.E.F.; 1919-20, distribution dept., Minneapolis Gen. Elec. Co.; With the Hydro-Electric Power Commission of Ontario as follows: 1920-29, i/c rural distribution constrn. in eastern Ontario, investigation and development of improved design of lines; 1929-37, i/c rural line specifications and development of new methods of installn. of rural lines; 1938 to date, i/c design and installn. of highway lighting and traffic signals for Dept. of Highways.

Memory of Sir Casimir Gzowski to be Honoured

Word has been received that a special service is to be held in Toronto on Sunday, August 28th, probably in Massey Hall, commemorating the fortieth anniversary of the death of the great Canadian Sir Casimir Gzowski, who was President of The Institute in 1889, 1890 and 1891. His Excellency the Governor-General, the British High Commissioner, and the Ambassador of Poland in London, Count E. Raczynski, are Honorary Patrons of the function. The same day a wreath will be laid on the grave of this famous engineer and citizen.

The History of the Canadian Forces in the Great War

by an Engineer

The following article appeared in the editorial page of the Montreal Gazette. Colonel Duguid is a member of the Ottawa Branch of The Engineering Institute and therefore the article will be of particular interest to our readers.

The first volume of the long-awaited Official History of the Canadian Forces in the Great War, 1914-1919, has been issued. Volume I (accompanied by a volume of appendices and maps) deals with the outbreak of war, the raising of the First Contingent, the crossing to England, the winter on Salisbury Plain, the first appearance in the British battle line; also with other Canadian forces raised and sent overseas prior to the formation of the Canadian Corps in 1915. Hence it will be of particular interest to the Originals and to members of earlier subsequent forces sent overseas.

In this volume (there are eight others to follow) the compiler, Colonel A. Fortescue Duguid, D.S.O., B.SC., R.C.A., A.M.E.I.C., announces that his purpose has been "to assemble established facts and figures into a form that can be readily grasped, to reproduce verbatim typical or important documents, and to arrange in pertinent relation a series of significant pictures, so that in the light of ordered testimony the reader, relieved of the speculative drudgery of groping in the dark after elusive facts, may be free to follow the action closely, to draw his own conclusions and to form his own opinions."

The formation, the campaigning and the disbandment of the Canadian Expeditionary Force provide a theme of national importance to the people of this Dominion. Proudly the achievements of Canada's citizen soldiers were followed during the war, and in this history these achievements are set down clearly, dispassionately analyzed, and always with the hallmark of authenticity.

The work is well indexed, and the sketches and maps cover all sections of the battlefields in which Canadian soldiers were engaged. This official history is published by authority of the Minister of National Defense.

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted after a lapse of one month, upon request.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Situations Wanted

ENGINEER, A.M.E.I.C., Combustion specialist heat balance. Steam. Mechanical. Refrigeration. Office routine. Correspondence. Plant layout. Apply to Box No. 5-W.

ELECTRICAL ENGINEER, Jr.E.I.C., B.Sc.; age 31; at present employed, desires change in location. Experience includes; three summers experience in power conduit construction; two years in telephone engineering; four years experience in radio, both development engineering and production; two and one half years in a paper mill on electrical maintenance, with a short time in the cost accounting and draughting departments. Would be interested primarily in electrical maintenance. Apply to Box 12-W.

PAPER MILL ENGINEER: B.A., B.A.Sc. Married. Age 34. A.M.E.I.C. Ten years experience in paper mill costs, maintenance, design and construction. Now employed as cost engineer in Southern States. Hard worker with excellent references. Available immediately. Apply to Box No. 150-W.

SALES ENGINEER REPRESENTATIVE. Mechanical graduate with fifteen years experience in Eastern Canada in sales and service of mechanical equipment; full details upon request to Box No. 161-W.

MECHANICAL ENGINEER, Jr.E.I.C., with thorough training in England and wide experience for past eight and a half years in Canada, is seeking a permanent position as mechanical engineer in an industrial plant. Has had varied experience in mechanical engineering, heating, ventilating and power plant equipment. Excellent references. Apply to Box No. 270-W.

CIVIL ENGINEER, M.A.Sc., A.M.E.I.C. eight years survey and municipal engineering experience, and three years draughting, detailing steel, concrete, and timber structures. Apply to Box No. 467-W.

PAPER MILL ENGINEER. If you are willing to pay around $5,000 per year for the services of an engineer, age 36, with twelve years experience in paper mill design, construction and operation, apply to Box No. 482-W.

CIVIL ENGINEER, B.A.Sc., A.M.E.I.C. Married. Experienced in engineering and architechtural design and in supervision, office management, etc., wants to round out experience in the contracting field. Ten years experience since graduation. Present location Toronto. Apply to Box No. 576-W.

ELECTRICAL ENGINEER, B.Sc. E.E., Age 39. Married. Seven years experience in operation, maintenance and construction of hydro-electric plants, and sub-stations. Five years maintenance and installation of pulp and paper mill electric equipment. Reliable and sober, with ability to handle men. Best references. Any location, at once. Apply to Box No. 636-W.

ELECTRICAL ENGINEER, B.Sc. '28. Two years student apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660-W.

Situations Wanted

ELECTRICAL AND CIVIL ENGINEER, B.Sc. Elec. '29, B.Sc. Civil '33. Jr.E.I.C. Age 32. Experience includes four months with Can. Gen. Elec. Co., approximately three years in engineering office of large electrical manufacturing company in Montreal, the last six months of which were spent as commercial engineer, also experience in surveying and highway work. Year and a half employed in electrical repair. Best of references. Apply to Box No. 693-W.

CIVIL ENGINEER, B.A.Sc. (Toronto '27), age 34, married. Five years railway and construction work as building inspector and instrumentman. Level engineer and on construction of a long timber flume for a pulp and paper mill. Field engineer for a sulphite company, in charge of the following mill buildings, acid, digester, blow pit, barker room, chip storage and acid towers Available immediately. Apply to Box No. 714-W

ELECTRICAL ENGINEER, B.Sc. '31 (U.N.B.), Jr.E.I.C. Age 30 years. Single. Experience in electrical wiring, construction of concrete wharves, inspection of piling, rip rap, concrete reinforcing, forms, and dredging. Also junior engineer. Available at once. Apply to Box No. 722-W.

MECHANICAL ENGINEER, Jr.E.I.C. Technical Graduate. Bilingual. Married. Experience includes five years with firm of consulting engineers, design of steam boiler plants, mechanical equipment of buildings, heating, ventilating, air conditioning, plumbing, writing specifications, etc. Six years with large company on sales and design of power plant, steam specialties and heating equipment. Available on short notice. Apply to Box No. 850-W.

CONSTRUCTION ENGINEER, Grad. Toronto '07. Experience as resident engineer and superintendent on railroad, municipal, hydro-electric and industrial construction Intimate with organizing, layout, survey, estimates and costs Available immediately. Apply to Box No. 886-O.

CIVIL ENGINEER, B.Sc. '29, Jr.E.I.C., R.P.E.M. Age 31. Married. Experience includes railway and highway surveys and construction, land and mineral claim surveys, 4 years draughting, structural and hydraulic design, preparation of plans and estimates for hydro-electric development, sewage disposal project, water treatment plant, subway construction, buildings, etc. Experienced in reinforced concrete design including statically indeterminate frames. Also capable of preparing designs in steel and timber Desire permanent employment, preferably in structural design. Available immediately. Apply to Box No. 1023-W.

ELECTRICAL ENGINEER, B.Sc. '29, age 30 Single. Eight and a half years experience on maintenance. on construction, floorman and operator on hydro-electric system. Desires construction, service, sales or research work. Any location. Excellent references. Apply to Box No. 1062-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 41. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experience in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

Situations Wanted

TECHNICALLY TRAINED EXECUTIVE. General experience administrative, organization and management in business and industrial fields, including; business, plant, property and estate management; plant maintenance, modernization, production and personnel; economic studies, company reorganizations and amalgamations, valuations; railroad, highway, hydro, pulp, newsprint, housing, industrial surveys, investigations and construction; B.Sc. degree in engineering, age 49, married, Canadian. Apply to Box No. 1175-W.

CHEMICAL ENGINEER, grad. McGill '34, experienced in meter repairs, control work; and also chemical laboratory experience. Apply to Box No. 1222-W.

CIVIL ENGINEER, B.A.Sc. (Toronto '33), S.E.I.C., age 27. Married. Five years experience includes highway surveys, bituminous and concrete paving, steel and reinforced concrete building construction, instrument work, draughting, cost accounting and estimating and some experience as foreman. Available immediately Apply to Box No. 1265-W.

FIELD ENGINEER AND DRAUGHTSMAN, A.M.E.I.C. Age 36. Married. Fifteen years experience in civil engineering, general draughting and instrument work. Experience covers office and layout work on construction of sewers, water mains, gas mains, (6" to 30" dia.) and transmission line structures; topographic and stadia surveys. Draughting covers general civil, reinforced concrete and steel design, mechanical detailing and arrangements, and mapping. Present location Montreal, but willing to locate anywhere. Available at once Apply to Box No. 1326-W.

ENGINEER SUPERINTENDENT, A.M.E.I.C., R.P.E., Que. and Atla. Age 47. Twenty years experience as engineer and superintendent in charge of hydro-electric, industrial, railroad, and irrigation construction. Specialized in rock excavation and suction dredging. Intimate knowledge of costs, estimating and organizing. Available immediately. Apply to Box No. 1411-W.

CIVIL ENGINEER, graduate 1927, age 34 years, desires position as town engineer. Eight years municipal experience. Location immaterial Apply to Box No. 1628-W.

CIVIL AND ELECTRICAL ENGINEER, Jr.E.I.C. (Univ. of Man.). Married. Age 25. Good draughtsman. Four months draughting, one year instrumentman on highway location and construction, inspection and miscellaneous surveying and estimating. Six months as field engineer on pulp and paper mill construction. Prefer electrical or structural design. Available at once. Apply to Box No. 1633-W.

ELECTRICAL ENGINEER, B.Sc. E.E. (Univ. of Man. '37). Age 24. Single. Experience in highway construction as inspector. Also experience in sales work and petroleum refining. Available on short notice. Apply to Box No. 1703-W.

CIVIL ENGINEER, B.Sc. in C.E. '34. S.E.I.C. Age 27. Five years experience, including harbour construction, highway paving, one and a half years paper mill construction, instrument work, draughting, estimating, interested in design. Available on short notice. Apply to Box No. 1737-W.

CIVIL ENGINEER, B.A.Sc. '33. O.L.S. Age 27. Married. One year and a half in charge of power plant construction. Four summers on land surveys and one summer on mine survey work. Also experience in draughting, electrical wiring, and highway engineering. Apply to Box No. 1757-W.

ELECTRICAL ENGINEER, B.E. in E.E., N.S. Tech. Coll. Single. Age 25. Experience in sales, electrical installation, and construction work. Available immediately. Will go anywhere. Apply to Box No 1758-W.

CHEMICAL ENGINEER, graduate, Toronto '31. Seven years experience in paper mill, meter maintenance, control work and chemical laboratory. Speaking French and English. Location immaterial. Available at once. Apply to Box No. 1768-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C. (Toronto '35). Age 24. Experience in structural design, construction and surveying, including one year in South America. Details on request. Apply to Box No. 1784-W

THE ENGINEERING JOURNAL

VOLUME XXI, No. 9 SEPTEMBER, 1938

Welding in Ship Construction

William Bennett,

Principal Lloyd's Surveyor for the United States and Canada, New York.

To be presented before the Montreal Branch of The Engineering Institute of Canada, October 27th, 1938.

SUMMARY.—The field for welding has expanded so much in recent years that no one would dare attempt to describe its ultimate limit. This paper goes back into the history of welding in ship construction, and also describes the most successful practice of today as indicated in modern specifications.

Such a paper as this may very easily start with a bit of the history of the earliest examples of welded ship construction. Therefore we will begin with the M.S. "Cedros" ex "Fullagar," the first sea-going vessel to be constructed in which electric arc-welding was used to the total exclusion of riveting. She was built in 1920 by Messrs. Cammell Laird and Co., Ltd., of Birkenhead, and was classed "+100 A1," with the notation "electrically welded," "subject to annual survey," "experimental."

For some years she was engaged in the coasting trade and in 1924 she grounded on a sandbank in the Mersey, but, floating off the next tide and remaining intact, although showing signs of serious damage, she proceeded on her voyage. When dry-docked on her return to Liverpool it was found that the bottom plating was set up over a length of about 50 ft. After this examination the vessel proceeded under her own power to Leith for repairs, which were effected by pressing the bottom back into position by means of shores and hydraulic jacks. It is interesting to note that in spite of the damage received, the repairs proved satisfactory, the vessel later (in 1928) being classed with the amended notation, "subject to biennial survey."

Subsequent to the foregoing repairs, the vessel was purchased by a Canadian cement company, was taken across the Atlantic and out to British Columbia, where she was again placed in coasting service, but this time the service was of a distinctively different type. The welding was carefully examined at each special survey, and no failures have been reported. In addition, the Vancouver surveyor made the interesting statement, that corrosion was entirely absent throughout the vessel, except in some shell rivets in way of the double bottom fuel oil tank. This was a tank which had been repaired by riveting.

In 1930, when the vessel was about 10 years old, she ran head-on into a cliff at full speed in fog, in consequence of which extensive damage was done to her stem and bow plating. It was reported by the surveyor that the welded seams withstood the impact of this damage equally as well, if not better, than the solid plates. Shortly after this repair (in 1933) the confidence established in the welded construction of this vessel induced the Committee to eliminate the word "experimental" in the vessel's class.

Fig. 1—All Welded Motor Lake Freighter "Franquelin."

Recently sold to a firm in Mexico, this famous pioneer in arc-welded ship construction was renamed the "Cedros," and as proof of the confidence of the Committee of Lloyd's Register in this type of construction, it may be stated that in 1935 the condition "subject to biennial survey" was withdrawn, thus enabling the vessel to be surveyed at her regular four-yearly periods. Unfortunately the "Cedros" was recently involved in a serious collision off the west coast of Mexico, as a result of which she sank, after a successful period of service of seventeen years.

Motor Lake Freighter

Figure 2 shows the midship section of an all-welded motorship, and Fig. 1 gives a photograph of the vessel when completed. Built by Messrs. Swan Hunter and Wigham Richardson, Ltd. at the Wallsend Shipyard in 1936, the vessel had a successful crossing of the North Atlantic to Canada, and was delivered to her owners, the Quebec and Ontario Transportation Company, the same year. She was the fourth all-welded vessel built by Messrs. Swan Hunter, to the design of Messrs. Lambert and German of Montreal. The vessel was designed for carrying pulpwood, newsprint, or grain, on the Great Lakes. Her dimensions are as follows: length overall, 259 ft.; breadth moulded at deck, 42 ft. 10 in.; depth moulded, 22 ft.; deadweight about 3,100 tons on 14 ft. draft in fresh water.

She was built to Lloyd's class, +A1 "for service on the Great Lakes and Gulf of St. Lawrence," "electrically welded" and, as may be seen from her plans, she is designed with a "conduit bilge." It is claimed this protects the bilge from damage and leakage due to contact with canal sides and dock walls.

The framing is arranged transversely except in the fore peak, where a system of cant frames has been substituted for the more usual arrangement, and extra stiffening has been incorporated at the fore end to meet the conditions encountered in the particular trade in which the ship will be employed.

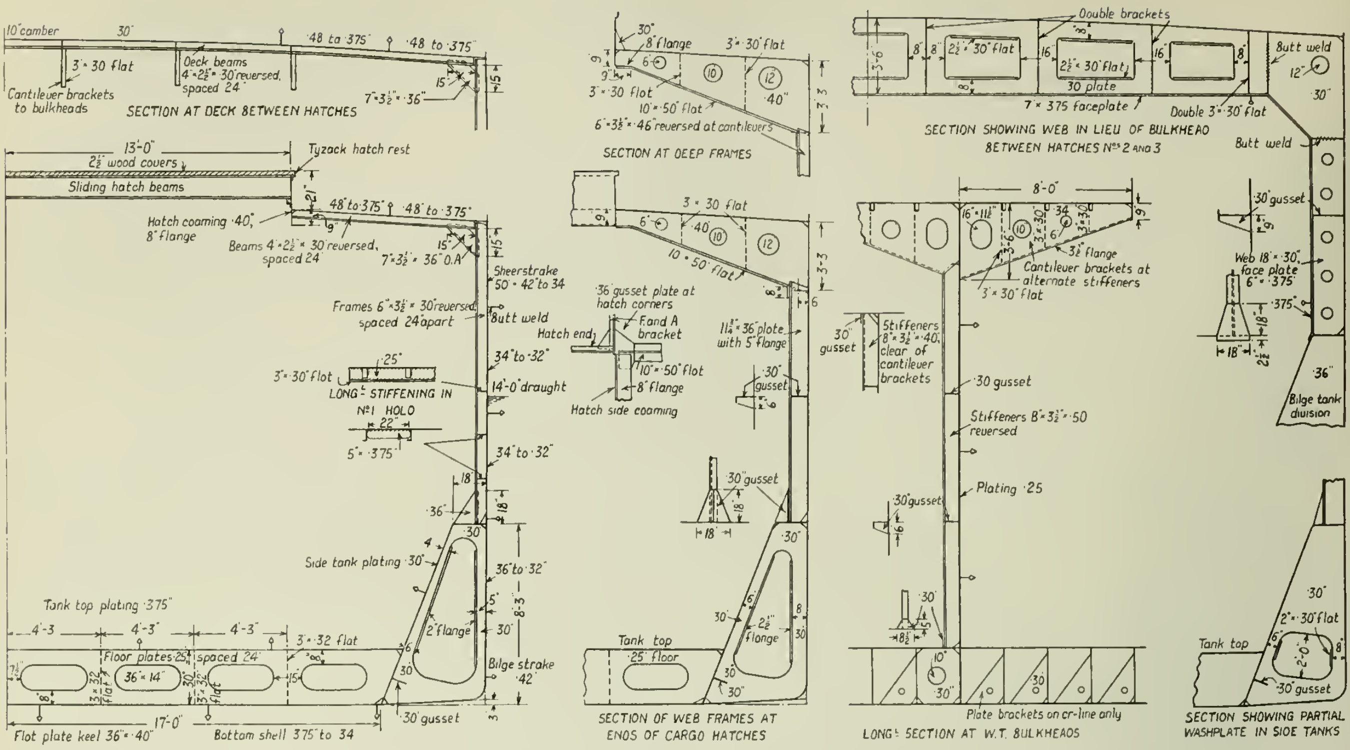

Fig. 2—Midship Section of the "Franquelin."

The system of fabrication adopted to suit the welding of the structure, was based on the builders' experience in constructing all-welded ships. Butt-welding was adopted throughout the main structure generally, lap-welding being used only for such items as beam knees and the large brackets in way of the hatches where welding to the side frames or to the bulkhead stiffeners was followed.

The keel and outer bottom plating were erected plate by plate on the berth, faired up and welded together, the plate edges being veed 60 deg. on their upper edges. The welding was thus carried out in the "down" direction, except the closing weld on the underside.

The inner bottom plating, complete with floors and centre girder, was welded in large panels on the welding skids upside down to obtain a "down" welding position for the floor connections, and turned over on erection in position on the berth.

The bilge tank was also welded complete with shell, bottom and side plating, in sections about 30 ft. long, and afterwards erected in position on the berth.

The side shell and deck were similarly treated, all butts being flush. Each transverse bulkhead was welded complete with stiffeners on the skids, lifted into position on the berth, and welded direct to the inner bottom shell and deck, no boundary bars being fitted.

245 ft. Oiltanker

This vessel is 245 ft. B.P., 42 ft. 2 in. beam, 18 ft. moulded depth, 2,240 tons deadweight, and 16 ft. 9¾ in. draft. She was built by Messrs. Swan Hunter and Wigham Richardson, Ltd. and delivered to her owners the Dampskibsselskabet Marna A/S Company, Oslo, Norway, in 1935.

The vessel was built to Lloyd's highest class, +100A1 "carrying petroleum in bulk," "longitudinal framing in double bottom," "electrically welded." The construction is quite novel, providing smooth surfaces inside all tanks to allow for easy drainage and cleaning. This is provided by the fitting of a double skin to the shell, deck and bottom. There are five main tanks divided by a centre-line bulkhead into 10 compartments. The design of the transverse and centre-line bulkhead consists of a series of "trough" or corrugated plates welded together, thus dispensing with all projecting stiffeners. A special tank-cleaning apparatus is installed in which steam, water, caustic soda solutions or cleaning oil, may be sprayed over the internal surfaces of the tanks.

The shell plating is butt welded, with the exception of the joint at the bilge, which is lapped onto the side plating and welded in a "down" position. This vessel has made several North Atlantic crossings in both summer and winter, and her all-welded construction has shown no weakness so far.

Motor Tanker

Another interesting example of an all-welded vessel is an oiltanker, built in 1937 by the Pennsylvania Shipyard, Inc. of Beaumont, Texas, to the designs of George B. Drake of New York. She is owned by the Cleveland Tankers, Inc. of Cleveland, Ohio, and classed by Lloyd's Register +100 A1 "for service on the Great lakes, etc.," "carrying petroleum in bulk," "longitudinal framing," "bracketless" and "electrically welded."

Her principal dimensions are:—Length (overall) 258 ft.; length (B.P.) 251 ft. 3 in.; beam 43 ft.; moulded depth 16 ft. 6 in. These dimensions are the maximum possible to permit transit through the New York State Barge Canal. On her maiden voyage she took a cargo of oil from the Gulf via New York, up the Hudson river, through the barge canal to Oswego, into Lake Ontario, and thence through the Welland Canal into Lake Erie. She will be used for the carriage of petroleum products generally, from Chicago to Great Lakes ports.

The vessel's framing is longitudinal and bracketless, and she has a continuous expansion trunk over the oil tanks. Five pairs of main cargo tanks are arranged, with a continuous centre-line bulkhead. The total carrying capacity of the tanks is stated to be about 22,000 barrels on a draft of 13 ft. 4 in. Figures 3 and 4 show some photographs of this interesting new tanker, whose structural plans clearly show her all-welded construction. This applies from stem to stern, to the total exclusion of rivets.

The shipyard welding specifications required: the plate edge overlaps to be not less than 1 in. plus twice the thickness of the plate, and both edges continuously welded; all plate butts to be lapped, with both edges continuously welded, and having fillets equal to the thickness of the plates joined; the bulkhead plates to have continuous weld on both sides to shell and deck, each fillet being of size equal to the thickness of the bulkhead plating; the extreme ends of the unbracketed longitudinals to be double continuously welded to shell or deck for one-tenth the spacing of the transverses; the unbracketed bulkhead stiffeners to be double continuously welded for one-tenth their length each end, and intermittent welded elsewhere; all brackets to be continuously welded all around.

Motor Tanker, Made in Canada

Another interesting vessel, and one recently constructed in Canada, is an oiltanker, the "Beeceelite," built by Marine Industries, Ltd., Sorel, Quebec, to the order and designs of the Imperial Oil Shipping Co., Ltd. of Toronto. This interesting single screw Diesel tanker is intended for oil and gasoline distributing service on the British Columbian coast, and reflects much of the latter company's wide experience in tanker requirements. She is the largest all-welded vessel of this type to be built in a Canadian shipyard, and was classed with Lloyd's Register +100A1 "British Columbia coasting service," "carrying petroleum in bulk," "longitudinal framing," and "electrically welded."

With a length B.P. of 120 ft., beam 27 ft., and moulded depth 12 ft. 6 in., this vessel follows very closely standard tanker practice, with cargo tanks amidships and a dry hold forward. Immediately forward of the engine room a large pump room is arranged, the pumps being driven by motors placed in the engine room. A feature of the vessel is the elaborate cargo transferring arrangements which permit independent pumping of all tanks. A considerable number of drums may also be carried on the deck, with substantial retaining stanchions and chains.

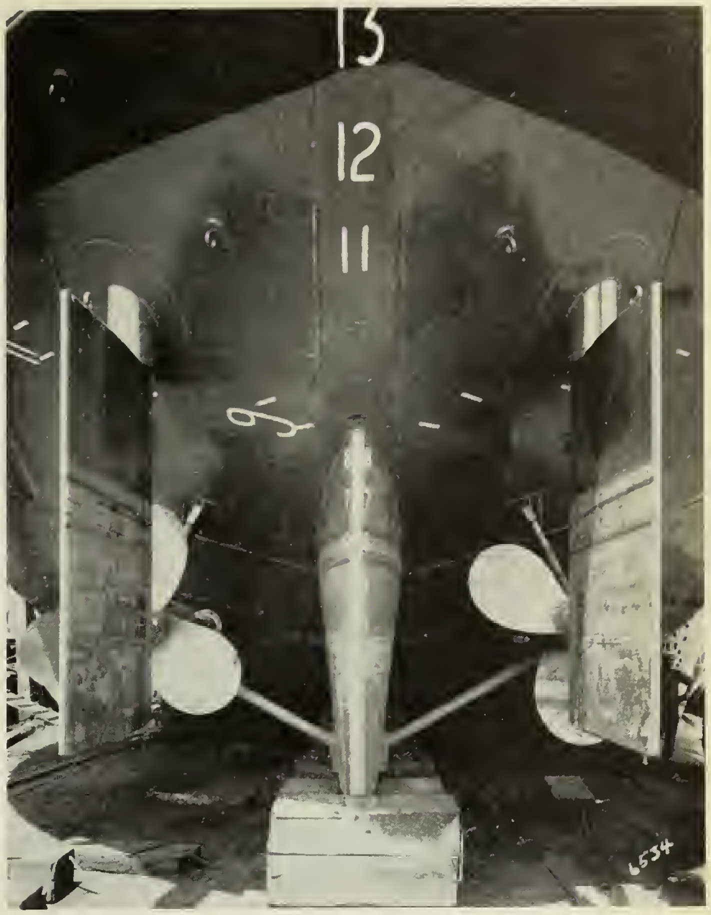

Fig. 4—All Welded Oiltanker "Mercury," Stern View.

Fig. 3—All Welded Oiltanker, "Mercury," Bow View.

The cargo tank space, as may be seen from her plans (Figs. 5, 6 and 7), is closely subdivided, six tanks port and starboard being arranged within a length of about 43 ft., with an oiltight centre-line bulkhead their entire length. Each pair of tanks has a common circular oiltight hatch on the centre-line, relief valves being fitted to the hatches.

Being completely welded, this vessel presents many interesting ideas in construction, with closely spaced transverse bulkheads, longitudinal framing in way of tanks and transverse framing at the ends. The bulkheads are fitted with boundary angles fully welded at both toe and heel, while all shell frames have faying flanges in order to reduce the area of unsupported plating, and are tack welded to the shell. The bulkhead stiffeners have no faying flanges, thus providing an economy in weight. An interesting feature is the fitting of the brackets on the ends of the shell longitudinals in way of the bulkheads. These brackets are slotted through the bulkheads and welded on both sides of the latter.

Butt welding was generally adopted, the V-butts being about 60 deg. angle, and the plates about $\frac{1}{8}$ in. open at the root of the V prior to welding. The electrodes were coated $\frac{3}{16}$ in. rods, used generally on all "down" work, and $\frac{5}{32}$ in. rods elsewhere, with about five runs in the average butt or seam. As much of the work as possible was welded on the skids, the transverse and longitudinal bulkheads having the horizontal stiffeners welded first, and the plates then being fully welded out from the centre of the bulkhead. In constructing the shell, all plates were erected and tacked before starting the welding. The butts were welded first, working out from the centre-line on both sides simultaneously, and finally the seams were welded, working from midships forward and aft.

Generally speaking, very little serious distortion was experienced, the bulkheads being quite satisfactory. The shell plates which had considerable curvature, such as in the bow, showed very fair when completed. Below the

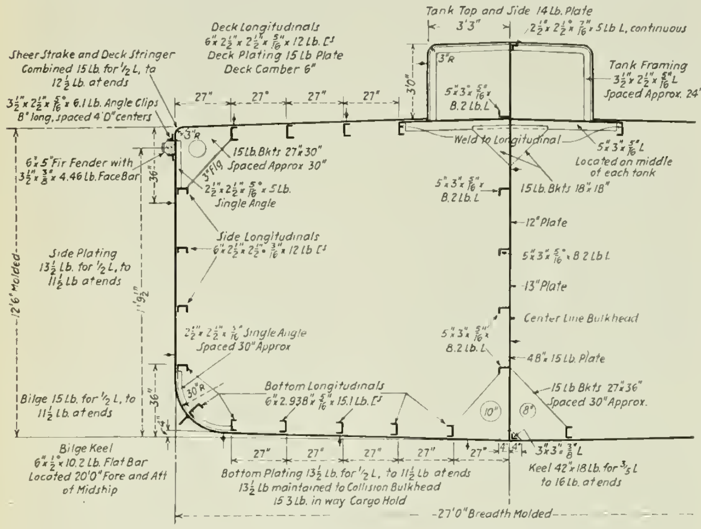

Fig. 5—"Beeceelite," Cross section Through Cargo Tank.

waterline all beads on the seams and butts were left full, and not buffed off, in order to provide a margin against corrosion. Where some rivets were necessary, such as in the shell connections to the stem and stern frame and in the plate rudder, these attachments were fully welded before drilling and finally riveted up. Figure 8 gives some indication of the work entailed in the construction.

The equipment used in the construction of this vessel consisted of sixteen 300-ampere welding machines with 20-25 volts open arc. The steel masts were all-welded, as were also many miscellaneous items, such as goose-neck vents, air pipes, strum boxes, skylights, etc.

Some Recent Vessels

Such great strides have been made in recent years in this subject that it is difficult to make a condensed statement which would do justice to it. Naturally the use of welding was first confined largely to the smaller types of vessels such as barges, scows, tugs, etc., but within recent years the construction of new oiltankers has developed more and more along electric-welding lines, until today we find that all oiltankers are being constructed, partially or wholly electrically-welded.

There are being built in the United States at the present time three large oiltankers of dimensions: 521 ft. by 70 ft. by 40 ft., and of 18,500 tons deadweight, the first of which has already been launched; and most of the other oiltankers presently being built in the U.S. are being constructed with all-welded bulkheads. The three all-welded oiltankers above mentioned are being constructed at the Sun Shipbuilding and Drydock Company, Chester, Pennsylvania, and it is not the writer's intention to go into details regarding their construction as this has already been very ably done in a paper entitled, "Recent Practice in Welding Large Oiltankers," written by J. W. Hudson and T. M. Jackson. The builders have introduced a new method of automatic welding which is being used in the shops for the construction of the bottom, side, deck, and bulkhead panels; the boundaries on the ship being done by hand-welding. Lloyd's Register of Shipping has carried out a series of tests on this type of welding with very satisfactory results, the essential particulars of which are quoted in detail in the above-mentioned paper. This is the only automatic method of welding that has been submitted to and approved by Lloyd's Register of Shipping in the United States to date.

Of the other oiltankers recently built, or presently being built, all have incorporated more or less welding to suit the owner's requirements. Most of this welding has been done by hand, but in the Sun Shipyard, the bulkheads are all being done by the automatic welding process. In most of the vessels now referred to, the shell has been riveted and, as already stated, all bulkheads welded. Sometimes the longitudinals have been welded to the shell and deck. Either flanged-plate longitudinals are used or, as in some cases, ordinary rolled channel or other sections have been used.

The various methods of connecting the longitudinals at the shell on either side of the bulkheads are of interest in passing. The method most frequently used has been the well known "bracketless" system (see Figs. 9 and 10).

A system was recently adopted whereby the longitudinals on opposite sides of the bulkheads were linked by means of a thick plate which is slotted through the bulkhead, afterwards welded on both sides of the bulkhead, and along the top of the longitudinals. This is clearly illustrated in Fig. 11, in which detail the longitudinals are cut quite clear of the bulkheads.

Another method is shown in Fig. 12, but in this case the longitudinals are brought close up to and welded to the bulkheads, and in addition, plates are slotted through the bulkhead, and welded similarly to that mentioned in the previous paragraph.

In Fig. 13, instead of the slotted plate shown in Fig. 11, a round bar is used and similarly welded. The illustrations clearly show the essential points of these connecting systems. All have been approved by Lloyd's Register of Shipping and each has its adherents and its claimed advantages.

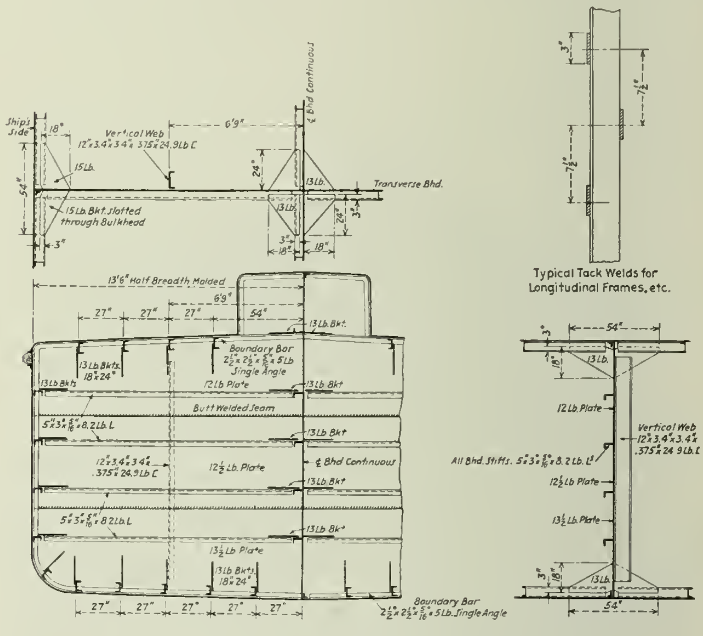

Fig. 6—"Beeceelite," Oil Tight Transverse Bulkhead.

In the case of some vessels building in Canada at present, the welding specifications contain the following interesting items:

1. All electrodes must be of the heavily coated variety and to the owners' and Lloyd's approval.

2. As far as practicable, the welding is to be performed in the "down" position.

3. Shell: The bottom is to be welded in the "down" position, the open side of the "V" joint being to the inside of the vessel. The actual welding of the "V" joint is to be made from the inside, after which a finishing reinforcing run is to be applied from and on the outside, and dressed off smooth.

On the side shell the welding may be from the outside or inside at the builder's option, but the owners prefer that as much of the shell plating as practicable be welded from the inside. In either case the welding of the "V" joint is to be done from the open side of the "V" first, and then a finishing run is to be applied from the opposite side. When the welding of a joint is completed, the outside of the joint is to be dressed off smooth. In welding a vertical butt joint or a vertical fillet-weld, the operator is to work from the bottom up, and never from the top down.

4. A careful record is to be kept of all welding, how performed, kind and size of electrode for each pass, also voltage and amperage. A periodic check of the individual welders is also to be made.

5. The current used during the welding is to be kept to a minimum to prevent undercutting, and all joints are to be thoroughly cleaned to bright metal before commencing to weld. After each pass, the surface of the weld is to be brushed clean, and is to be entirely free from slag before commencing the next pass.

6. In all cases the ground connections are to be as near the actual weld as practicable, and it is preferable to have the operators work away from the ground connection, instead of towards it, to avoid a "bent" arc and excessive slag deposit.

7. To avoid distortion, as much of the welding as possible is to be applied from the centre of the vessel outwards, and from amidships towards the ends.

8. Prior to water testing, all oiltight and watertight welding is to be painted with distillate. Faulty welding will show an oily stain on the reverse side, and all faulty work is to be cut out and re-welded.

9. Sample welds of all types are to be made up as specified by Lloyd's and to be submitted for testing and approval, before commencing work on the vessel.

It will be observed in paragraph 3 of the above that the root of the V in the shell joints is on the outside, the joints being welded from the inside. This gives a smaller area of exposed welded joint from the appearance and corrosion standpoints, and a smaller area to grind off, if a flush surface be desired.

In connection with the above welding specification the following suggestions are offered for consideration:

(1) All surfaces to be welded should be cleaned (or ground if necessary) to bare metal and should be free from scale, rust, paint, or dirt. In the Unionmelt automatic method of welding adopted at the Sun Shipyard, the bulkhead plates are ground before the stiffeners are automatically welded thereto.

(2) Where several beads are laid in a welded joint, each layer should be wire brushed and cleaned of all slag, before the next bead is laid down.

(3) As far as possible, all welding should be done under cover, or at least shielded from wind, rain, and low temperatures.

(4) In an all-welded ship-structure the welding should, as far as possible, proceed equally and simultaneously on both sides of the vessel, commencing amidships and working uniformly towards the ends, and towards the sides.

(5) The shell butts on any one plate should be welded first, before any seam welding is commenced, to allow for contraction.

(6) The welding procedure, as well as the technique and the sequence, should be given careful consideration by the welding superintendent, and instructions delivered to the welders, prior to the work being started. A staggered or back-stepped welding procedure should be used in the seams to eliminate residual stress, contraction, and distortion. No standard procedure in this respect can be prescribed. This must be decided upon after careful study of the details in each case.

(7) The welding of the shell should be completed, and the welding of the internal structure should be completed, before the shell and structure are welded to each other.

(8) The smaller the electrode, the less is the heat disturbance in the adjacent plates. This statement should not be construed, however, as a recommendation to use small electrodes, without full consideration of all the circumstances of the case. Generally speaking, the amount of distortion is somewhat increased if the number of runs is increased; and the relative cost is decreased by using a larger rod. A saving of about 15 per cent is obtained by the use of a $\frac{3}{16}$ in. rod, as compared with a $\frac{5}{32}$ in. rod.

(9) Where several beads of welding are laid in a joint, the second and subsequent beads impose a slightly heat-treated effect on those previously run; and in a welded V-butt the weld at the root should be chipped out, and a final back run made.

(10) Care should be taken not to over-weld any joint; and in fillet welds the welding should preferably be concave rather than convex.

(11) Careful examination should be made with a view to condemning or preventing all undercutting, distortion, residual stresses (as far as possible), porosify, inclusions, lack of penetration, and lack of uniformity in the finished weld.

GENERAL

Generally speaking, a combination of welding and riveting should be avoided in the joints of a structure such as a ship, due to the difference in their elastic properties under stress. If such a joint be subjected to stress, the joint will, in general, be resisted by the welding, and the rivets will offer little assistance.

In some cases the shell butts have been welded and the seams riveted, which eliminates scarping of the shell plates at the junction of butts and seams. Some authorities

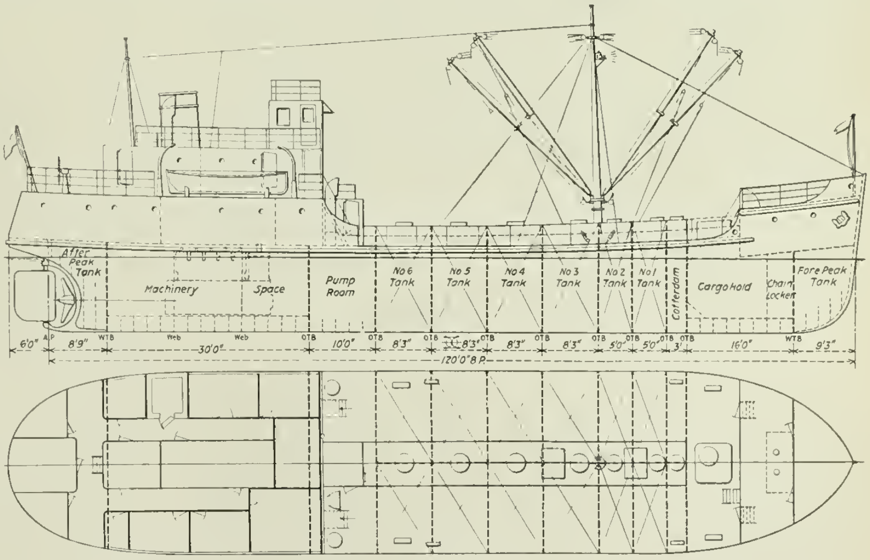

Fig. 7—"Beeceelite," Elevation and Deck Plan Showing Cargo Tank Layout.

contend that the welding of shell seams should be avoided.

The practice of using intermittent welding in joining frames to shell, stiffeners to bulkheads, etc., has recently been superseded in some shipyards by the fitting of a light continuous weld on both sides, which is stated to be desirable both for strength reasons and for reduction of buckling, although there appears to be some difference of opinion on this point.

Some owners, such as in the 120 ft. tanker described, prefer to use frames with the usual shell flange, whereas others prefer to take advantage of the saving in weight, by eliminating the use of this shell flange, and simply welding the toe of the shape to the shell. Undoubtedly the former practice provides better support to the shell and is to be recommended for vessels which frequently come in contact with piers, lockwalls, canal banks, etc.

Oiltight bulkheads are now almost universally welded in the U.S.A. and the experience gained with such bulkheads in service would seem to point to the universal adoption of welding for all such bulkheads in the near future.

A question which arises is whether the butts should be fitted edge to edge or overlapped. There again the

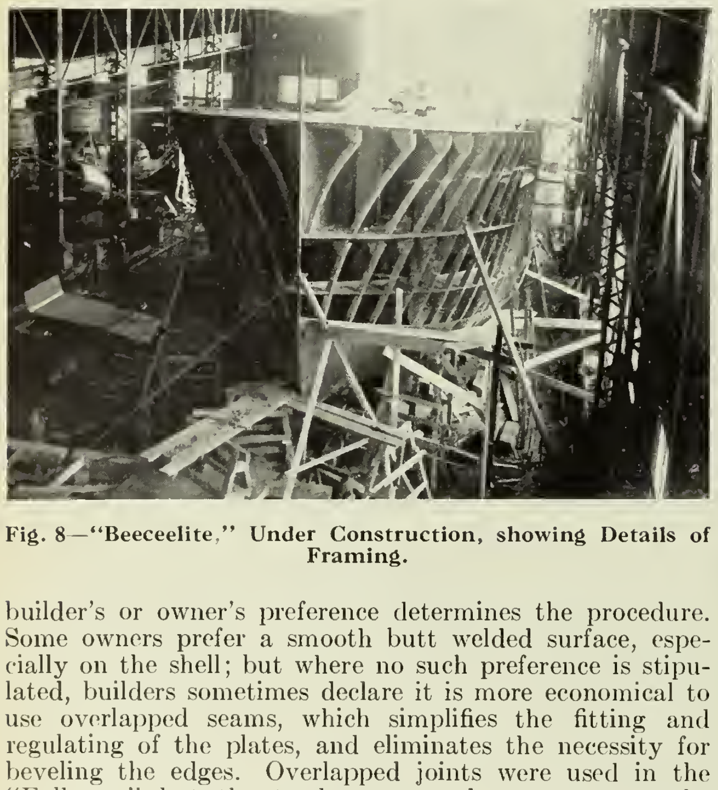

Fig. 8—"Beeceelite," Under Construction, showing Details of Framing.

builder's or owner's preference determines the procedure. Some owners prefer a smooth butt welded surface, especially on the shell; but where no such preference is stipulated, builders sometimes declare it is more economical to use overlapped seams, which simplifies the fitting and regulating of the plates, and eliminates the necessity for beveling the edges. Overlapped joints were used in the "Fullagar," but the tendency nowadays appears to be towards butt welded joints throughout. This applies particularly to the bottom shell in oiltankers for the purpose of better drainage, absence of pockets where residue can remain, and consequent corrosion prevention. The plate edges are now commonly flame-cut in the U.S.A. instead of planed.

The welding of engine seatings, rudders and tank tops which are required to be flush, is quite common.

Fractures After Welding High Tensile Steel

While we might report innumerable cases of satisfactorily welded vessels, unfortunately now and again cases of difficulty arise, and one of these is quoted here as a matter of information. This vessel was not built to Lloyd's classification, but the writer was invited into the discussion which ensued during construction, in behalf of the owners. This was the case of a small tanker which had been in the gasoline service for years, and for which it was decided to build a new midship body; the old midship body throughout the oil tanks having become thinned out by corrosion.

The vessel was transversely framed with overlapped butts and seams, and with full welds on same, inside and outside. The transverse frames had full welds on both sides. It was originally intended to construct this new midship body of mild steel, but later it was agreed to build it of a high tensile steel; the tensile strength being in the range of 65,000 to 75,000 lb. per sq. in.

During the building, several cracks developed, mostly at the proximity of a butt and seam, until some seven shell plates were affected and in need of repair.

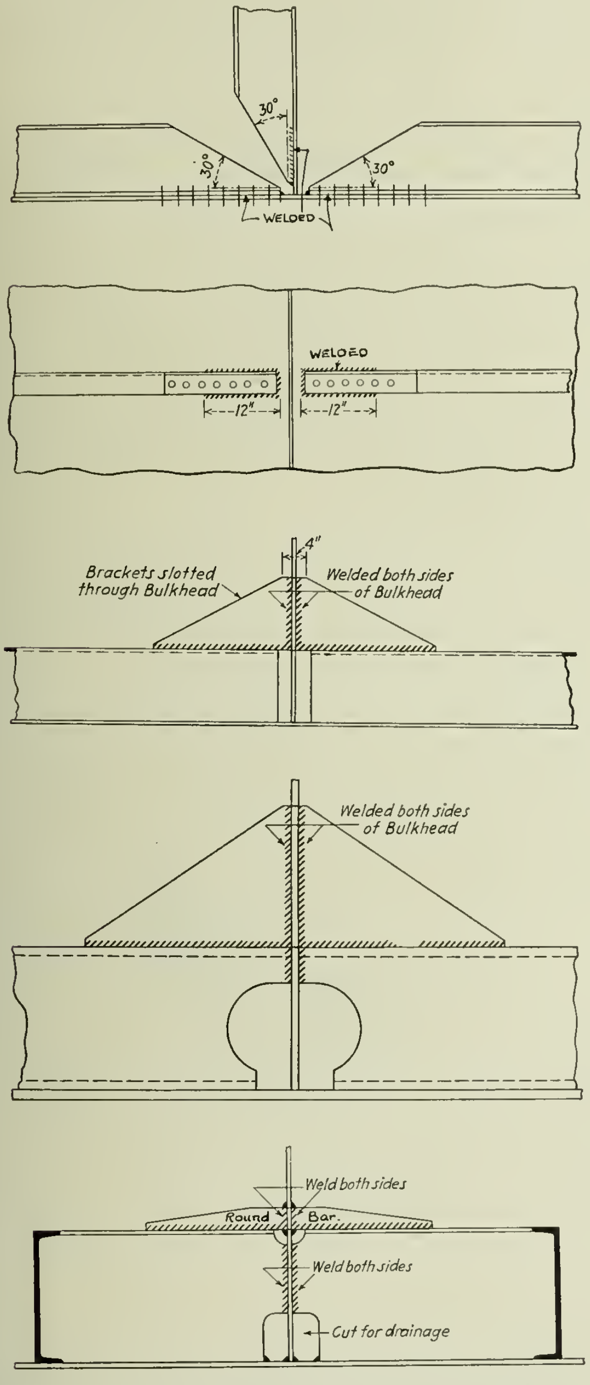
Investigations were made into the physical properties of the material and the welding, with the result that the cause of the trouble was laid to the welding. It was the opinion that either the electrode, the procedure, technique or sequence was at fault (one or more), these not having been fully developed for this particular material, prior to the structure being commenced. These difficulties, too, were accentuated by the excessive amount of welding at the joints. At the welded butts there were two and sometimes three full vertical continuous welds in close proximity to each other. The seams had also two continuous welds in close proximity, and each frame too, was continuously welded on both sides. Lloyd's rules require full welds on both sides only on shell and deck butts; on the seams the rules call for a full weld outside and a light weld inside; and on frames to shell plating, Lloyd's requirements are, an intermittent weld each 3 inches in length, spaced 7½ in. centre to centre. My own experience with welded construction indicates that it is just as important, if not more so, to prevent overwelding (with consequent locked-up stresses), than to prevent underwelding.

In the case under review, tests were made by removing 3 in. dia. discs from the shell to ascertain the amount of the locked-up stresses at various points of the shell plating. For this purpose, five positions were selected, the necessary measurements taken, and the discs drilled out. It was found that the readings varied to a considerable extent, some tensile and some compressive; the maximum being a compressive stress of about 27,000 lb. per sq. in. The centre of the discs were about 6 in. away from the nearest edge of the welds, and had they been close up to the edge it is possible the maximum stresses would have been larger, probably up to the breaking point of the material.

It is obviously impossible to ascertain with any degree of certainty the maximum stresses operating in a welded structure, the exact amounts and directions being unknown and therefore indeterminable. If, however, there is an elastic strain locked up in various parts of a welded ship, the stress corresponding to this strain will represent the actual starting point for any further superimposed stresses caused by working loads. This will, therefore, initially at any rate, reduce the margin of safety provided. Note the word "initially" in the preceding sentence, as it is uncertain whether these locked-up stresses eventually dissipate, either by slight buckling of the plates, or by slight permanent extension of the plates (i.e., beyond the yield point).

There is a considerable difference between a riveted and a welded floating vessel. The riveted ship is essentially a jointed structure with a certain amount of freedom to relieve itself of residual stresses, by slippage of the riveted joints or otherwise. On the other hand, a welded structure is a unit structure, rigidly held at all parts through the welded butts and seams. In the welded structure, if the physical properties of the welds are higher than those of the plate or parent metal the rigidity is accentuated, thus rendering the finished structure more susceptible to failure under impact, and more so with high tensile alloy steels.

In a welded joint, the aim is to produce a weld which has the same physical properties as that of the plate, in order to provide a homogeneous structure, all parts being equally elastic and able to take the same deformation under any type of loading; each plate and joint thus working in harmony with each other. This is much more essential in a welded, than in a riveted ship. A riveted ship after a few months is said to "shake down," and the riveted joints are supposed to readjust slightly to suit any unequal stress condition at any part. In reality this readjustment is more likely to be wholly or partially due to a form of stress relief under service conditions. In a welded structure, however, it is evident that no such "shaking down" process can be predicted, certainly not to the same extent. Locked-up stresses, due to the unity and non-slipping nature of the joints, can only be relieved in the early stages by change in contour, and if this does not take place, the stresses will remain locked-up indefinitely, or until they are relieved in some such manner as already mentioned. In other words, a riveted ship may relieve itself of residual stresses due to faulty construction or misalignment of holes, whereas a welded ship cannot do so initially. This may take place over a period of time, of which we have little experience at present.



Figs. 9, 10, 11, 12, 13—Methods of Connecting Longitudinals at the Shell on Either Side of Bulkheads.

Another consideration of interest is whether the full strength of the weld material itself can be used in computing the available strength of welded joints in a ship. There may be a possible change in the structure of the material adjacent to the weld, i.e., say along the edge of a seam, due to material changes resulting from the welding, of an indeterminable magnitude. This change might lower the physical properties of the material locally adjacent to the weld to such an extent that it is almost at the breaking point, due to the locked-up stresses above-mentioned.

Mild steel is, in my opinion, the best all around material at present on the market for a welded structure. High tensile steels have higher ultimate strengths than mild steel, but the elongations are less. In the former, the plates are stiffer, less subject to distortion, but by the same token are much more susceptible to locked-up stresses. In mild steel, any stresses imposed by welding are naturally relieved (altogether or to a large extent) by a slight weaving of the plate and the greater ductility of the material. In the high tensile plating, where the plates are stiff enough to withstand the buckling tendency, locked-up stresses are more likely. While these locked-up stresses may not in themselves be such as to cause the plate or welding to fracture, the fact that they are there raises the question in our minds whether a sudden shock, added to the stresses already locked-up, will cause the plate to fail later. Unfortunately, stress-relieving is impossible in a ship's structure.

Weather conditions are also important. There is no doubt that better welding can be done in summer than in the extreme of winter, but if care is taken, mild steel has proved its ability to withstand satisfactorily being welded under all conditions.

In the vessel referred to, the fractured plates were repaired, the tanks re-tested and hammer-tested, and the vessel was placed "experimentally" in the Coastwise service. No further cracks have developed, which leads one to the conclusion that severe locked-up stresses in welded structures may become relieved in course of time, probably by readjustment of the plating; i.e., either by slight local weaving, or by slight permanent stretching of the material, in way of the stressed conditions.

The Structure of the Earth as Revealed by Seismology*

Ernest A. Hodgson, M.E.I.C.,
Chief, Division of Seismology, Dominion Observatory, Ottawa.

Presented before the Niagara Peninsula Branch of The Engineering Institute of Canada, April 5th, 1938., and before the Ottawa Branch, April 21st, 1938.

SUMMARY.—The author has succeeded in discussing a very technical subject in simple terms that permit an untechnical audience to understand and enjoy it. The importance of earthquake study is explained and the methods used in Canada are described in clear detail.

You remember what Doe said of Dopey,† "He don't know if he can talk or not; he ain't never tried." For the same reason I do not know whether I can succeed or not—having never tried to deal with this phase of seismology before a general audience—but I hope it will be possible for me, without recourse to technical details, to present a clear and convincing picture of the means by which we have learned something of "The Structure of the Earth as Revealed by Seismology."

As usual, "The Greeks had a word for it." Their word for earthquake was seismos; hence, seismology, the study of earthquakes.

Why study earthquakes? Coming closer home, let us ask the very pertinent, perhaps sometimes disconcerting, question, "Why study earthquakes in Canada?" Earthquakes merit study. According to good authority approximately 800 earthquakes, strong enough to destroy cities and towns, have occurred on land since the beginning of the Christian era. History shows that an average of 30,000 persons have been killed each year during the past two centuries by these phenomena. More than 20,000 earthquakes occur each year; a widely recorded shock each fourteen hours; a destructive earthquake each six and one-half days—on the average of course.

Perhaps, then, it may be assumed without argument that major earthquakes should be studied. Why be prepared to study them in Canada? Since Cartier's first voyage in 1534 an earthquake of major proportions has occurred, in Canada, every fifty or sixty years—on an average. These earthquakes have been, in general, more severe than the one which, in 1933, caused fifty million dollars damage at Long Beach, California. It has just so happened that structures liable to damage were not situated near the origins or epicentres of these shocks. Canada is building up rapidly; the earthquakes will continue. You may draw the obvious and inevitable conclusion.

It was an attempt to ameliorate in some measure the damage caused by earthquakes that led initially to their being studied by scientifically trained men. Progress was slow at first, but there has gradually evolved a branch of the subject which may be called "engineering seismology." Considerable progress has been made of late years, particularly in Japan, in Italy, and in California. It is now possible to design houses which, except in the most extreme cases, will not be destroyed by an earthquake, will not be set on fire thereby, and will not kill their inmates or passers-by with falling débris. Moreover, the specifications for such structures are now written into some building codes, for example those in parts of California.

Taking for granted part of that which we shall later find to have been revealed by seismology, we may consider the earth to be a sphere consisting of three main divisions: a central core, with a radius of about 2,200 miles; surrounded by the mantle, a concentric sphere a little less than 1,800 miles thick; which is, in turn, surrounded by a crust of a varying thickness which may be set down roughly as 25 miles. We take in our stride the responsibility for the approximations as to the sphericity of the earth and the various dimensions given. We shall discuss the theory and the technique of determining earth structure under four different conditions and in the order named: the crust; the

†Walt Disney's "Snow White and the Seven Dwarfs."

mantle; the core; and, finally, returning again to the upper part of the crust—that region which is within reach of the drill.

One of the first things that men learned about the crust of the earth is that it does not have uniform stability. Earthquakes occur frequently only in certain seismic zones. One of the routine activities of seismological investigation is that of locating as accurately as possible all recorded earthquakes. To do this, international co-operation is necessary. At the present time more than 250 seismic stations are in operation, reporting regularly to each other and to a central station at Oxford, England, where an agency under the joint auspices of that University and of the International Union of Geodesy and Geophysics determines the position of all locatable shocks and publishes a statistical summary of the data. We now know that the most active seismic regions of the world may be defined as a belt about the Pacific with an offshoot zone across Asia and Europe north of India and along the north shore of the Mediterranean to meet another belt running north and south through the relatively shoal water of the mid-Atlantic. We know, further, that all earthquakes are not confined to these more active belts. We have very good reason for saying that there is no region of the earth in which a major earthquake might not take place. This international service was begun in 1895 and has been growing steadily ever since. Canada has participated since 1897.

How then can seismic stations determine from their records where an earthquake has occurred? It would take much too long to sketch the slow degrees by which men learned to construct seismographs and deduced the method of interpreting from their records the distance from the recording station to the source of an earthquake. The abstract mathematical foundations of the theory were laid as early as 1849, but it was not until 1889 that, by chance, the first record of an earthquake was made at a distance. At that time an earthquake in Japan was found to have been recorded on a very sensitive instrument at Potsdam, Germany, set up for the purpose of determining to what extent the earth itself has tides similar to, though smaller, than those caused on the sea. Not until 1900, however, was such a distant earthquake record interpreted to yield a value of the distance from station to origin.

Before explaining how distance can be read from the record, we must know just a little about the instrument known as a seismograph. Suppose someone asked you to describe a ladies hat—not some particular hat—just a hat. That difficulty is comparable with an attempt to describe the appearance of a seismograph. Such instruments vary in size from one you could hold in your hand to one which stands more than six feet high and weighs twenty tons. One thing, however, seismographs have in common. A relatively-heavy weight is held very delicately suspended from a framework which is, itself, in firm contact with the earth.

When the earth moves, the weight stays behind as you tend to do when the street car starts suddenly. The relative motion of the weight and the frame attached to the earth is recorded continuously and gives the record. When the earth is at rest the record line is straight. When a shock impulse arrives, the line is deflected. At regularly-timed intervals, normally once a minute, a slight motion is given the recording mechanism so that a small, recognizable, offset (or in some cases a short interruption) occurs on the line. A diagram of one sort of seismograph is shown in Fig. 1 together with a small section of a record showing the timing marks. All we wish to emphasize here is that an instrument has been developed which enables the inertia of a weight to give us a record indicating that an impulse has arrived at the recording station and telling us the exact moment of its arrival.

The earth is an elastic body—almost as elastic as steel. That is to say, if any part of it be deformed by force, that deformation will vanish when the force is removed. It is the elastic properties of steel which, for example, cause a suspended bar of the material to give off a ringing note when struck by a hammer. It is the elastic properties of the earth which cause it to transmit earthquake waves.

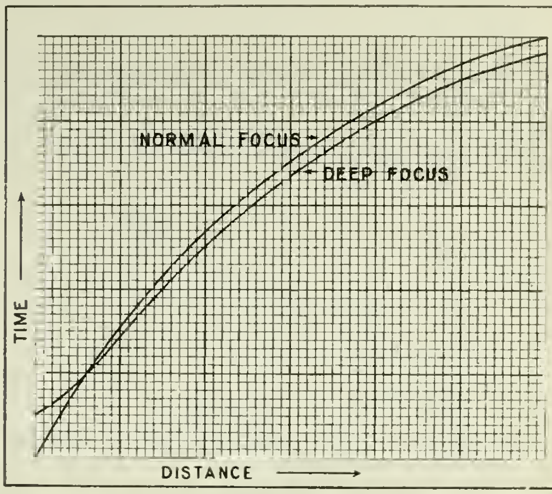

Fig. 3—Characteristic form of the time-distance curve for normal focus and for deep focus.

As early as 1849 it was deduced mathematically that an elastic body should transmit two kinds of waves and mathematical expressions for the speeds of the two waves were found. These two classes of waves are known as longitudinal and transverse. The first is propagated by the back-and-forth motion of the earth particles in the direction of the wave, somewhat after the manner in which a bump from an engine is transmitted down a long

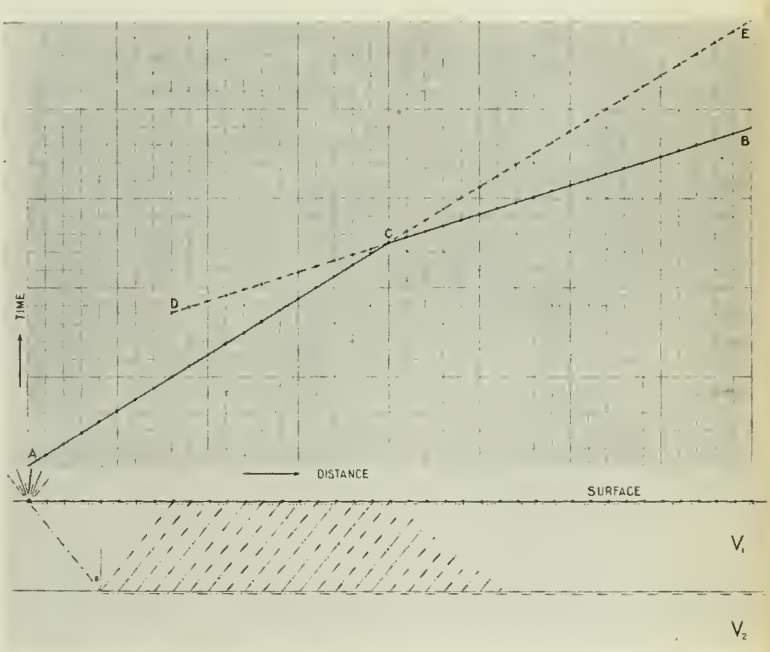

Fig. 4—Diagram illustrating the refraction method of probing surface layered structure. Velocities in the upper and lower layers are respectively V_1 and V_2. At distance C the energy by surface and sub-surface paths arrives simultaneously. For lesser distances, the earlier arrival is by the surface path. For greater distances, the earlier arrival is by the sub-surface path. The critical angle a depends on the velocities V_1 and V_2 which are given by the two graph slopes. Having V_1, V_2, C, and a the thickness of the upper layer may be computed.

line of freight cars. The second is propagated by a transverse motion of adjacent particles somewhat after the manner in which a water wave travels; the floating débris shows that the water particles move at right angles to the direction of propagation of the wave.

The difference in velocity depends on the elastic properties of the body through which the waves travel. For short distances it is a sort of neck and neck race. No laboratory is large enough to enable the waves to separate sufficiently for the fact to be established experimentally. So for many years there was no experimental verification of the two types of waves. After earthquakes were registered at considerable distances, it was found that a second burst of energy showed on the record among the

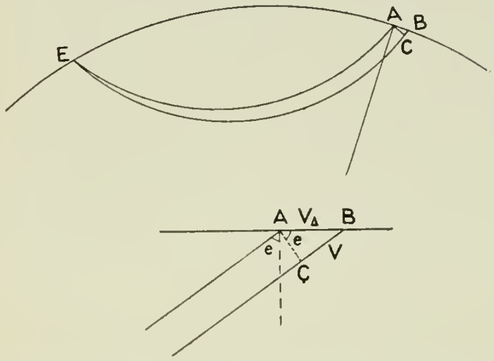

Fig. 5—Diagram illustrating the method of deducing the angle of emergence e of a ray at any chosen epicentral distance EA.

dying vibrations of the first impulse (see Fig. 1). The greater the distance from earthquake to station the greater was found to be the separation of these two impulses. It was finally established that these were the arrivals of the two types of waves which had left the origin of the earthquake together but had travelled at different speeds. The difference in time of arrival is thus a measure of the distance.

The two types of waves of which we have been speaking are designated, respectively, P and S waves by seismologists since, in point of time of arrival, they are primary and secondary. It is readily seen that, if observers possess a time table showing the time required for the P-wave to reach various distances on the earth's surface and a similar one for the S-wave, a table could be prepared showing the relation between S-P times and the epicentral distances. The first table of this sort was prepared by Oldham in 1900, since when a steady improvement has been effected. Such compilations are called time-distance tables or if plotted on graph paper, time-distance graphs. Given the table, it is easily seen how the distances from each station to the epicentre can be deduced. Now, if it be known how far the epicentre lies from any station then the epicentre must lie on a circle drawn about that station with the proper distance radius. If the circles for all the stations be drawn, their point of intersection makes the X which marks the spot (see Fig. 2).

A well defined earthquake can be located no matter where it may have occurred. Thus, routine statistical seismology is piling up accurate records of where earthquakes occur and when. Furthermore, we are now able to deduce the depth at which the shocks originate.

The point within the earth from which the earthquake energy is liberated is called the focus; the point vertically above it on the earth's surface is the epicentre. Now if the focus be on the surface we have what may be called, for want of a better name, a normal earthquake. To simplify our discussion we shall from this point confine our attention to the P-wave—the first impulse on the record. Obviously, the time-distance graph of a normal earthquake begins at the zero-zero point—at the origin of coordinates. Suppose another earthquake should happen with the focus at a depth of, say, 100 miles. All distances for our time-distance graph are measured from the epicentre. The epicentre is thus at zero distance. The time required for the impulse P to reach the epicentre at distance zero is in this case more than nothing and the time-distance graph must begin a certain distance up on the time axis, i.e., it must begin above the graph for a normal earthquake. But, at the antipodes of the epicentre, the shock must arrive earlier for a deep focus than for a normal one and the second curve must here lie below the first. The curves must cross. If the focal depth were 200 miles the new time-distance graph would start even later and arrive earlier than before—and so for successively-greater depths of focus. A typical pair of graphs is shown in Fig. 3. If the arrival times of the P-wave at a sufficient number of stations can be obtained, it is possible to determine from such a set of curves not only the distance to the epicentre but also the focal depth. In passing, let us note that Canada with her great expanse of territory would leave a wide gap in many of these curves did she not maintain a certain number of stations at strategically spaced positions. Her seven stations are little enough coverage for a country of such dimensions.

Depths of focus as great as 500 miles and more have been established and are a distinct contribution to the knowledge of the structure of the earth. They show that the earth can sustain built-up strain at depths previously considered impossible. We can no longer maintain that the crust alone is crystalline and that the mantle is plastic. At least the mantle is not plastic in the sense it was thought to be until deep focus earthquakes were established as a

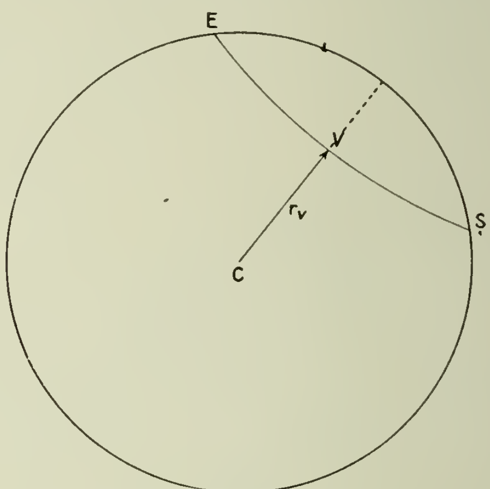

Fig. 6—The Herglotz-Wiechert method applied for any chosen epicentral distance ES yields the value of the vertex radius r_v, and the true velocity of the earthquake waves V at that depth.

fact. Probably no contribution of the science has aroused a greater interest among those concerned with learning something of the structure of the earth.

Suppose that the upper stratum of the earth transmits elastic waves at a velocity which is less than that for the deeper lying material. In this case, deeper means something of the order of fifty to a hundred feet. The diagram in Fig. 4 shows the approximate path of two rays of the waves propagated from an explosion at the surface. Let us take for granted that the rays are of the form shown and concentrate on visualizing the speed with which the nose of the advancing wave radiates over the surface.

If the surface were a calm lake, we could see the water waves radiate in ever-widening circles from the shock. Those waves would be gravity waves not the elastic waves which we are now considering but the same sort of ever-widening circles marks the progress of the energy transmitted by the earth. If the surface were covered with a thin layer of mercury we could actually see the nose of the disturbance spreading out from the source. If we were to put a dish of mercury on the ground at not too great a distance we could see a segment of the expanding circle pass over it. If we wish to know very exactly when the energy passes regularly-placed points on a line outward from the source and extending to a considerable distance, say twenty miles or more, we place sensitive seismographs at those points and have them record on a strip of moving paper which carries time marks. In this way we can tell when the initial impulse reaches each station and, if the seismographs be properly designed, we can also discern the arrival of later impulses —points on the common radius through the source, of the familiar circles within circles which can be seen when gravity waves radiate from a stone thrown into still water.

A little reflection is sufficient to show that, near the source, the arrival of the wave at successive stations will be at the rate v_1, if we may so designate the velocity in the upper layer. At a particular distance from the source is some station at which the energy, travelling along the surface with velocity v_1, will arrive at the same instant as that which has travelled down to the surface of discontinuity at velocity v_1, along the under surface of that layer at velocity v_2, to a point from which it rose again to the surface with velocity v_1. The greater distance travelled is just compensated for, by part of the path being traversed at greater velocity.

Let us suppose that we are equipped with properly designed seismographs at each station, from the source outward. The records for the very near stations will show only one arrival—the wave through the surface layer. At a certain minimum distance (which depends on the angle with which the ray reaches the surface of discontinuity, which again in turn depends on the ratio of the two velocities v_1 and v_2) energy will begin to arrive via the lower path; but it will arrive after the surface transmitted energy and will appear on the record as a second impulse. Farther out will be a station at which the energy by the two paths arrives simultaneously. Beyond that point, the first impulse will be that arriving via the lower stratum; but there will still be a second impulse on the records, due to the energy via the upper stratum. The arrival times of the two classes of impulse may be plotted and will result in defining two intersecting straight lines as shown in the diagram. The slope of these lines gives the velocities v_1 and v_2. The point of intersection defines the distance at which the arrivals by the two paths are simultaneous. The two velocities enable us to define the angle with which the ray impinges on the surface of discontinuity. Knowing the distance to the point of intersection, the two velocities and thence the angle of incidence, we can determine the depth of the upper stratum.

Considerable time has been devoted to explaining this seismic method of determining the thickness of a surface layer and the velocities in upper and lower strata because it is so important and far reaching in its application. The method can be extended to more than two layers—three, four, or even more—yielding the thicknesses of the layers and the velocities in each. It can also be used to determine whether the surfaces of discontinuity are parallel to the surface or tilted and will give the angles of tilt. It is known as the refraction method and will, henceforward, be referred to by that name.

In attempting to explore the entire thickness of the crust (about 25 miles) a difficulty presents itself—the explosions we can safely and economically use are inadequate to produce energy sufficient to travel to the depths and

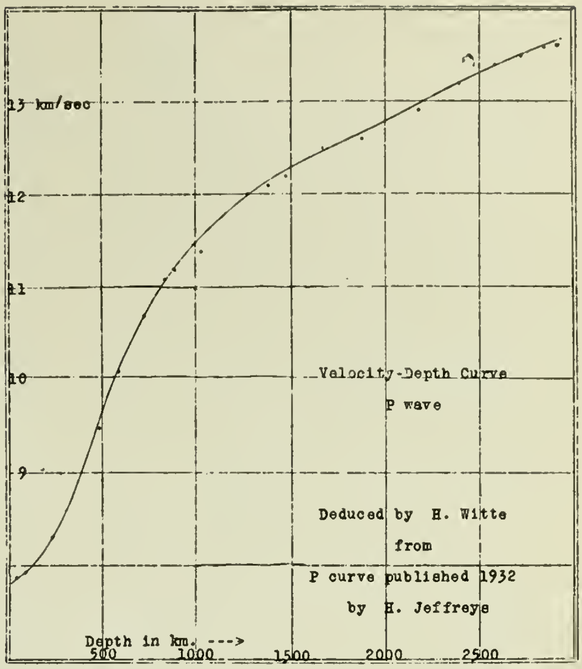

Fig. 7—Velocity-depth curve by Witte, 1932, based on Jeffreys' *P* curve.

distances required. Recourse must be had to earthquakes —not severe, but well located. Such small shocks usually follow a severe earthquake and are known as aftershocks. Immediately after a major earthquake, portable seismographs may be rushed to the epicentral region, a timing system arranged, and continuous records made. The aftershocks will originate not far from the original source. Several hundred of these, sharply-defined, will often be experienced. The data obtained yield much information as to the structure and thickness of the earth's crust in that particular vicinity.

Studies of this kind have been made in Japan, in central Europe, and in California. The crustal structure determined for Japan seems to be the simplest, that in California the most complex. No such studies have been made in Canada, but the data obtained from the records of the Timiskaming earthquake of 1935 show that the velocity in the outer edge of the mantle immediately under the crust is higher in Canada than in the outer edge of the mantle under Japan, central Europe or California. However, we are here considering the methods of determining earth structure not the results obtained, so we shall pass on to the methods of probing the mantle of the earth, that spherical shell about 1,800 miles thick below the crust and above the central core.

Before doing so it is necessary to note one further very necessary contribution from crustal analysis. In speaking of the methods used for locating earthquakes care was taken to say: "given a dependable time-distance graph." Science gives nothing gratis and yields her most valued and most valuable data only to those who seek; sometimes, it is true, not knowing exactly for what they are looking nor why they require it. One of the difficulties of obtaining a time-distance graph has been mentioned—the great areas on both land and sea unserved by seismograph stations at which to record the exact time of arrival of the elastic waves from an earthquake for which is accurately known the epicentre, focal depth, and time of occurrence. Even had we the optimum distribution of stations, it would still be necessary to have, for each of a series of selected earthquakes, the position of the epicentre, the focal depth, and the focal time. In other words, to locate an earthquake we must have accurate time-distance graphs and to con-

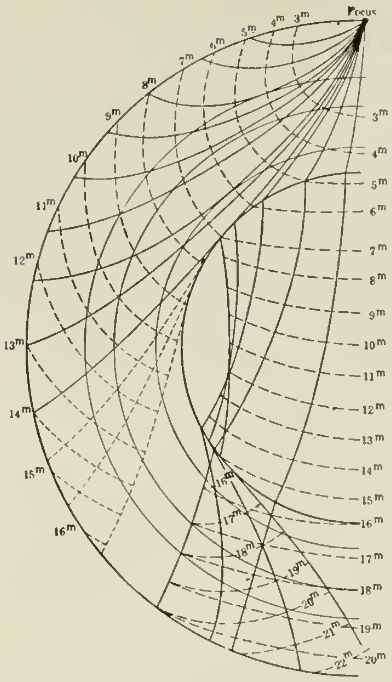

Fig. 8—Cross section of the earth showing rays and wave fronts of earthquake waves and the "blind zone." The last direct *P*-wave to emerge at the surface is the one grazing the core whose wave front is marked 14*m* indicating that the transmission time from the focus to this point is 14 minutes.

struct such graphs we must accurately locate an earthquake or earthquakes. It appears to be an impasse; but seismology has advanced, nevertheless, by a series of approximations—applications of the method of "cut-and-try."

Progress has been slow but steady over the years, as seismologists have gradually arranged for more stations, devised more efficient seismographs, and perfected timing arrangements. We may not here enter into details. Suffice it to say that remarkably good time-distance graphs are now available—so good that it is becoming necessary to take account even of the fact that the earth is not quite spherical.

The location of epicentral position and the determination of focal depth and focal time (for earthquakes which can serve to improve the existing time-distance graphs, yielding more accurate values for focal depth which we have seen to be of so much interest) are to be accomplished only by means of seismographs concentrated over an actively seismic area. The instruments must be in place at stations situated near a prospective earthquake source and must operate continuously until a shock occurs sufficiently strong to be recorded up to great distances. The near-station data can then be used, after the manner of the refraction method previously described, yielding definite knowledge of the epicentral position, focal depth and focal time. These, with accurately timed registration at stations over the entire distance range (or as much of it as possible), will permit a new refinement of existing time-distance graphs.

A sufficient concentration of seismographs over a seismic area is found at only a few places in the world—Japan, central Europe and California at the present time. Now, for an earthquake at any one of these places, some parts of the distance range must lie over water-covered areas where seismographs cannot be placed and also over other regions where, as yet, no stations are in operation. It is for this reason that efforts are being made by all seismologists to continue the operation of existing stations at as high an efficiency as possible and also to arrange for the inauguration of new stations at strategic points. Canadian stations are particularly valuable, as yielding data for parts of the distance range otherwise not covered, for earthquakes in Japan and California.

In order to co-operate in the attack on this major problem of seismology—the perfecting of the basic time-distance tables—a seismologist may decide to make a complete study of all records of some earthquake which appears from preliminary reports to be a promising source of fresh data. Requests are sent out to all the seismograph stations of the world asking for the loan of their records for this particular earthquake. Such a thorough study may extend over as much as two years. Canada has made complete studies of three major earthquakes and has loaned records of many others to seismologists engaged in research. Studies of this kind are most efficient means of obtaining data for furthering our knowledge of earth structure.

Let us, however, take for granted that we have a perfected time-distance graph for the *P*-waves of a normal earthquake. That is taking a great deal for granted but we already have very good graphs and we fully expect to have better ones as time goes on. The hypothetical, perfect graph tells us the rate at which the nose of the ever-widening circle of *P*-waves is radiating outward from the epicentre about the surface of the earth. That is all we ask to know. It is this which we crave to apprehend better year by year.

If we knew the varying velocity with which this surface circle of energy progresses throughout the entire distance range from the epicentre to its antipodes, we should be able to deduce the rate at which the waves travel at various depths within the earth and through what surfaces of discontinuity they pass. We may speak of the nose of surface energy as the trace of the wave and speak of its velocity as the trace velocity or apparent surface velocity in contradistinction to the true wave velocity at any point within the earth.

The time-distance graph gives the data for determining at any given distance the trace velocity; for we have only to find the rate at which distance varies with time at that particular distance range. For example we can take as our distance say 2,500 miles. We find how long it takes the trace to reach a distance of 2,500 miles by simply reading the ordinate of the graph for this distance. Now we read off the time it takes to go to 2,600 miles. The difference in these gives the time it takes the trace to travel 100 miles at the distance 2,500 miles. For those who are used to the process we simply say that the tangent to the time-distance curve at any distance value gives the apparent surface velocity or trace velocity at that distance. Suffice it to note that it may be deduced from the time-distance graph.

The most difficult part of the task set by this discussion now appears, that which the speaker so far "ain't never tried yet." It is hoped, however, that it may prove feasible to present, without recourse to technical details, a clear and convincing picture of just how the time-distance graph contains in its very shape the data from which may be deduced the velocity at any given depth within the mantle of the earth.

Before doing so, it is necessary to take drastic liberties with the earth. We have a time-distance curve for an earth, the crust of which varies from one point to another. We require for consideration a time-distance curve for an earth stripped of its outer crust. We may not be able to do this physically but we can use our knowledge of surface structure to cut off a little bit of distance and a little bit of time from each end of every focus-to-station path, obtaining time-distance values for that part of the earth which lies below the crust.

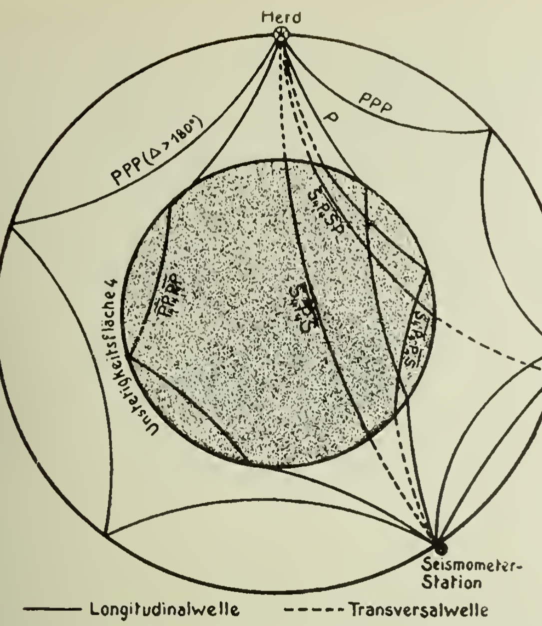

Fig. 9—Some typical complex earthquake rays from the focus (herd). The subscript 4 indicates the passage of the so-called fourth surface of discontinuity within the earth (Unstetigkeitsflache 4), which marks the boundary of the core.

After a procedure of this nature, we may assume we now have a new and hypothetically perfected time-distance graph for an earth stripped of its crust. We know that by applying the refraction method we can obtain the time velocity just at the bottom of the crust and in the outer edge of the mantle. We assume that, throughout any part of a concentric spherical shell defined by any given radial distance from the earth's centre, the conditions are the same—the true velocities are uniform over the whole shell. Thus, the velocity deduced just below the shell is taken as uniform over the entire earth.

You will remember that it has been stated that we have recently learned that this is not so. The true velocity at the outer edge of the mantle under Timiskaming is greater than that for the outer edge of the mantle in Japan. Very well! we shall have to continue this process of stripping the earth and adjusting our time-distance curve to a still greater depth until our premised conditions are satisfied. It will be sufficient if it is here made plain that we can use seismological methods to get a time-distance curve for an earth stripped of all lack of uniformity throughout any concentric shell; that we can find the trace velocity at any distance from the tangent to such a curve; and that we can determine the true velocity at the very surface of our stripped earth by application of the refraction method described for surface conditions. We have also, in effect, moved the origin from some point within the earth—the focus—to a point exactly in the surface of our stripped earth. Our amended time-distance graph begins at zero-zero—at the origin of co-ordinates. We may choose any point on the surface of our stripped earth and image an earthquake focus there. Proceeding to some distance about the surface of the stripped earth, we come to a point where the conditions of Fig. 5 obtain. Here two separate rays from the focus emerge at the hypothetical surface of the stripped earth. It is assumed that they are chosen so that the second ray reaches *B* just one second after the first ray reaches *A*. Thus the distance *AB* is a measure of the trace velocity; for it is the distance travelled by the trace in one second. We draw the line *AC* perpendicular to *CB*; thus the distance *CB* is a measure of the true velocity at the surface; for it is the distance travelled by the wave along the ray *CB* in one second. Now if we know the sides *AB* and *CB* of a right-angled triangle we can measure the angle of emergence, *e*, defined as angle *CBD* or *CAB*. We know the trace velocity from the amended graph and the true velocity from the refraction method so we can in this way find the angle of emergence of the rays at all distances, provided they do not dip into the core and become deflected. Up to more than half the distance around the earth from the epicentre chosen, we can deduce the angle of emergence of the rays.

As we saw in the refraction method, a ray passing from a stratum of lower velocity to one of higher velocity is bent toward the surface. If the true velocity increases at successively-deeper levels the ray will be bent more and more until it is at right angles to the radius. This is its deepest point. It then traverses the second half of its path which is the mirror image of the first half; and it emerges at the surface (of the stripped earth let us remember) at the same angle of emergence with which it started. That is to say, the ray is symmetrical about its centre radius through the vertex (see Fig. 6).

Clearly the amount of bending to which the ray is subjected is the sum of all the effects within its path; and the angle of emergence of the ray at any given distance is determined by the velocity at every depth through which the ray passed. If we could set up a mathematical expression giving the value of the depth of vertex and the velocity at that vertex of any chosen ray defined by its epicentral distance of emergence in terms of the emergence angle for that epicentral distance we could get one value of a true velocity at a known depth. For, as we have seen, we can determine emergence angles at every epicentral distance on the stripped earth. That, very briefly, is exactly what has been done. It is known as the Herglotz-Wiechert method.

Applying the Herglotz-Wiechert method once, we get one depth and the one corresponding true velocity. Applying it repeatedly, we get other depths and their corresponding velocities and thus bit by bit we get the complete graph which shows the variation of velocity with depth at all distances, down to the core. The velocity depth curve deduced by Witte in 1932 is reproduced in Fig. 7.

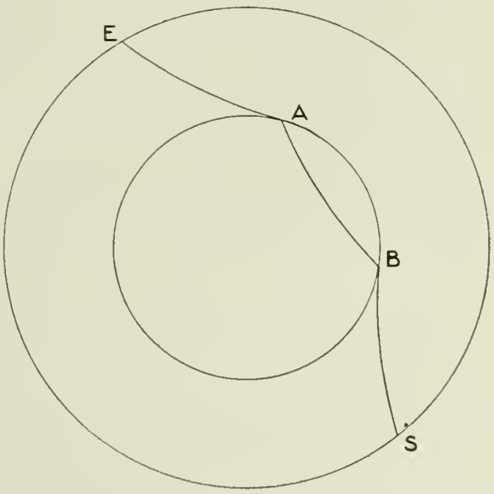

Fig. 10—**Path of *PKP*-ray, sometimes designated P_4P_4P or P_cP_cP.**

Down to the core, why not farther? Because the ray which barely grazes the core is the last direct *P*-wave to reach the surface. All others are deflected into the core in such a way that, beyond a certain distance range, no direct ray emerges at the surface. There exists a "blind zone" as shown in Fig. 8. No single part of the earth structure defined by seismology is quite so certain as the presence of the core. The blind zone is very clearly demarcated. It is possible to read off directly from a velocity-depth curve, such as that of Fig. 7, the depth to the core. The fact that the blind zone begins abruptly shows the surface of discontinuity to be sharply defined.

If a mathematician is given the dimensions of the earth, the structure of the crust, the variation of velocity in the mantle, and the depth to the core, he can compute the time it should take various waves, reflected within the earth, to reach the surface and the seismograms may be searched to see if they confirm the work which gave us

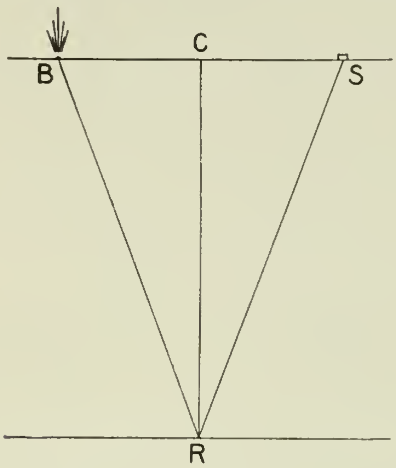

Fig. 11—Ray from blast to seismograph. The average velocity from the reflecting layer at *R* to the surface is found from shots fired in dry wells in the region, or by refraction shooting. The elapsed time shot to seismograph is known. Hence the distance *RS* is known. The distance *BS* is measured. Hence the depth *CR* may be calculated.

the velocity-depth curve. Not only the reflected *P*-waves but the *S*-waves of which we have nearly forgotten; for, as we got a velocity-depth curve for the *P*-waves, so we can get one for the *S*-waves. Furthermore, when an elastic wave either of *P* or *S* type is reflected or refracted it generates other waves of both types. Thus we may have a *P*-wave reflected at the under side of the surface as an *S*-wave and so on. The number of such possible, complex wave paths is very great and the times once computed may, as we have said, be checked on seismograms. Some of the possible paths are shown in Fig. 9.

So, step by step, by cut-and-try, by modification of theory and data, we have the means of probing the earth not only in the crust but in the mantle down to a depth of about 1,800 miles. But we stand at the barrier—the margin of a core of radius 2,200 miles. What can we learn about the core?

We can learn something of the nature of the material in the crust and mantle by knowing the velocity with which earthquake waves traverse them. We know from gravity measurements the total mass of the earth. The mantle and crust do not nearly make up their share of mass per volume (density). The core must be very heavy; the density must be great. We can deduce the approximate average density of the core. If we had a time-distance curve for the core and knew the true velocity just inside its boundary, we could apply the Herglotz-Wiechert method again to an earth stripped to the core and find a velocity-depth curve for that greater depth. So far no means has been found to do this. We know the total time for a wave such as that shown in Fig. 10 to reach the surface. We can compute the time required for the sections outside the core and we can find the end points of these branches at the core boundary. We know thus the time required for a wave to traverse the core along a path which has its end points fixed. But, not knowing the variation of velocity with depth in the core, we cannot say what shape the path has therein.

However, to make a long story short, there are, as we have partly indicated, a certain number of conditions which must be met if an assumed variation of velocity with depth within the core can be true. Over twenty such variations have been assumed by Gutenberg, checked with end data, and the most probable one selected. The research continues. We have still much to learn about the core.

Returning to the surface, let us see how we may use seismographs to probe the outer layers of the crust to depths which the drill may reach and confirm. We may use the refraction method which was described; and indeed it was used to excellent effect up to about 1929, when researches in radio made possible a new method which is now so useful that, in the United States alone, more than a million dollars a month are being spent in applying it to probe the upper earth strata in search of oil.

It is known as the reflection method. A shock generated from the explosion of from a quarter to a half pound of dynamite is recorded on a series of seismographs placed a measured number of feet apart at a measured distance from the blast. A very common "spread" is to have six seismographs at intervals of fifty feet with a thousand feet from the nearest seismograph to the shot point. The shot is buried in a hole drilled, usually, fifty feet deep; and the recording is done on very rapidly moving paper with time marks each tenth of a second. Time fails here to do more than say that this method uses electrical seismographs which feed their impulses through wave filters and amplifiers

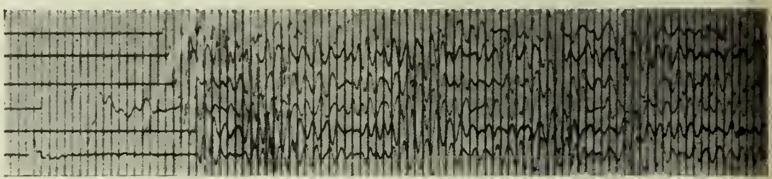

Fig. 12—Section of a typical six instrument seismogram.

so that the direct ground motion is killed out and those waves enhanced which have been reflected from a selected subsurface stratum which is thought to have oil-bearing possibilities.

The average velocity within the upper strata above the reflecting layer being studied can be measured by the refraction method or, where dry wells exist in the area, by measuring "up-hole time" from a shot in the well. Knowing the average speed and the elapsed time, and the distance from shot to seismograph, we have sufficient data to solve the conditions shown in Fig. 11 and learn the depth to the reflecting surface.

The crews work over the networks of country roads, finding the depth from point to point to the selected layer or "horizon" within the earth, until they find some place where it up-bulges about the same way as a large carpet would up-bulge if you were to put an inverted soup plate in its centre. Imagine a carpeted dining room with a table on the centre of the carpet and with an inverted plate under the carpet and under the table. The table top represents the earth's surface—the carpet represents the oil-bearing reflecting layer. The geophysicist seeks the invisible, up-bulged part represented by that hump in the carpet pushed up by the inverted plate. In practice, the layer may be at any depth up to a couple of miles. The bulge may be only fifty feet above the general level of the layer. But if such a bulge exists in those invisible depths, to learn of it is worth money; for that is where the oil will be—if there is any.

Figure 12 shows a typical record in the field. To deal adequately with this subject would take a whole series of lectures, for it is a very live business; and new technique and new discoveries are being reported every month. Some idea of the magnitude of the business may be given when it is stated that more than 200 seismograph crews are working in the United States alone, and that it costs at least $30,000 to equip a crew and $3,500 a month to run it. Crews with equipment may be hired at an inclusive charge of $9,000 per month. No companies are organized for this work in Canada, but some United States companies have operated here and also some from Germany.

It has been a long story, with many very summary and sketchy flights over details. We have seen how seismology penetrates to depths of a mile or two so quickly and surveys wide areas so rapidly that the expensive wielding of pick or drill need not be resorted to without some reasonable hope of reward. Aftershocks permit the extension of such methods to the bottom of the crust, which we have found to be of varying stability, varying thickness, and varying structure. The work on the crust permits us to arrive at a time-distance curve for an hypothetically stripped earth, after which the Herglotz-Wiechert method enables us to obtain a velocity-depth curve for the mantle. With these data at hand, we may compute the arrival times for various complex waves which should record at the surface, thus checking the previous deductions. We know some things about the core but it still remains to a large extent an unsolved problem—by no means the only one in seismology of course.

So, step by step, year by year, slow but steady progress is being made, by co-operative international effort, toward a more accurate knowledge of earth structure. This is one of the main reasons for studying earthquakes, whether in a seismic region or in relatively-quiescent Canada.

Railways Progressing Toward Continuous Rails

H. C. Drake,

Director of Research, Sperry Products, Inc., Hoboken, N.J.

Presented before the Montreal Branch of The Engineering Institute of Canada, April 21st, 1938.

SUMMARY.—An interesting description of welding methods and equipment, that facilitate a new development in railway practice. The elimination of rail joints is considered from the angle of construction and from the angle of maintenance and operation. It is possible that this development is pointing the way to a whole new chapter in railway history.

Continuous rail has been the dream of railway engineers since the introduction of the iron rail more than a century ago. The forces of expansion and contraction, as potent in 1830 as in 1938, lengthened those early rails in summer and shortened them in winter, compelling the engineer to make provision for rail movement at the joint. Throughout the evolution of the rail joint, from the first splice bar to the present modern joint bars, will be found the ever present provision for longitudinal rail movement.

In the year 1889, an intrepid engineer on the Lynchburg and Durham Railway decided to prevent rail expansion by brute force. He riveted 56 lb. rails together into a 3 mile stretch of track with no allowance for expansion. The ties were buried to provide maximum resistance to movement and the rail was kept in service 17 months. At the end of this period no buckling or movement of the rail was apparent although the track had not been surfaced or lined. This first stretch of continuous rail was discontinued due to deterioration of the covered ties.

In more recent years many electric railways have made use of continuous welded rails buried in street paving where the temperature changes are relatively small and the forces resisting rail movement large. The steam railways have also installed many stretches of welded rail in crossings, platforms and tunnels, where similar favourable temperature conditions obtain.

Continuous large section rail in open track became a reality in 1933, with the pioneer installation of welded rail by the Delaware and Hudson Railroad at Albany, New York. In this initial installation 131 lb. 39 ft. rails were welded in lengths up to 2,700 ft. by thermit pressure welds and were held to the ties by M. and L. construction. This type of rail fastening consists of double shoulder canted and crowned tie plates fastened to the ties by compression screw spikes. The rail is held by two spring clips bolted to the tie plates at the centre of the crown and bearing on the face of the rail. Each clip exerts a pressure of approximately 2,500 lb. on the rail base. This first installation of continuous rail proved entirely satisfactory and was followed by one mile in 1934, four miles in 1935, two miles in 1936 and some 35 miles of track in 1937. This latter figure represented their entire new rail programme for 1937, and brings the total mileage of continuous rail on the Delaware and Hudson Railroad up to approximately 43 miles. Of this total mileage approximately 65 per cent of the welds were flash welds and the remaining 35 per cent were thermit pressure type.

Included in the 1937 programme was a 7,700 ft. stretch of flash welded rail, the longest continuous rail on record.

Behaviour of Continuous Rail in Service

From 1933 to 1937, many tests were made on the Delaware and Hudson welded track, covering rail lengths ranging from 2,665 ft. to 7,700 ft. The object of these tests was to determine:—

1. The amount and distribution of rail movement throughout the long lengths.
2. Tie movement.
3. Stresses in rail and insulated joint bars.

The results of these tests may be summed up in the following statements:

1. Longitudinal movement of the ends of these continuous rails due to wide temperature changes was practically the same as for 39 ft. rail. There was no evidence of rail creepage.
2. There was no noticeable movement of the ties.
3. The insulated joints at the ends of these long lengths of rail at times exerted a restraining force of possibly 75,000 lb. on the rail end. Thus no particular difficulties were experienced from contraction or expansion of continuous rail on the Delaware and Hudson Railroad.

In May, 1937, Mr. F. R. Layng, Chief Engineer, Bessemer and Lake Erie Railroad, mentioned some interest-

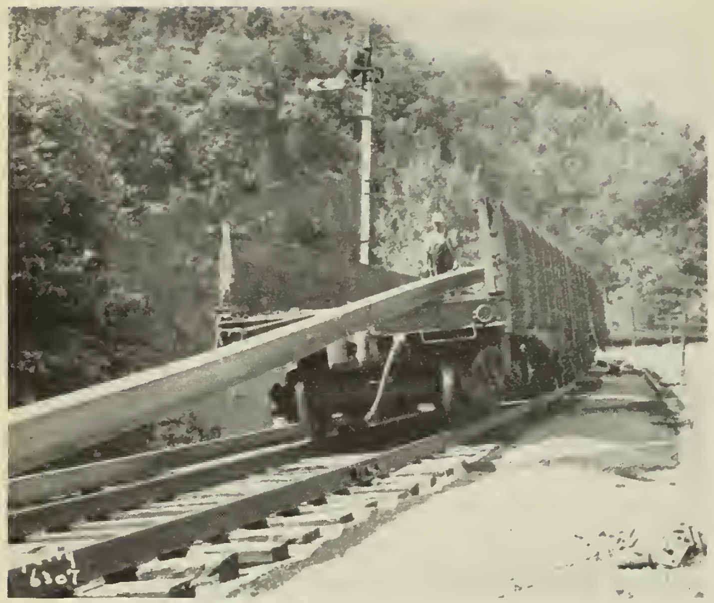

Fig. 1—Unloading Welded Rail.

A cable fastened to the end of a string of welded rail is anchored to the ground, then the flat cars are pulled forward and long welded rail appears to unload itself. Even around curves, it gives no difficulty in unloading as it naturally conforms to the curvature of the track over which it is drawn.

ing facts about the experimental welded rail installed by his road.* Tests were carried out on a stretch one mile in length, a little less than half of which represented tangent track; the remainder being a 1 deg. 30 min. curve and a compound curve having a maximum curvature of 5 deg. 43 min.

The traffic over this rail, at the time of tests, consisted of eight to ten heavy tonnage freight trains, containing up to 125 cars, daily. These trains operated at an average speed of about 30 m.p.h. One local passenger train also used this track, operating at a maximum speed of 50 m.p.h. It was estimated that the average annual gross tons which would be hauled over this rail was between 12 and 15 million; 18 million gross tons had been hauled over it at the time of test, with standard locomotives of the Texas types having a maximum weight per axle of 75,900 lb. and 70-to 90-ton capacity cars. The rail concerned was welded by the thermit process; the tie-plates were of the G.E.O. type, secured to ties with four screw spikes. Permanent monuments were set at appropriate locations along the track to record longitudinal and transverse movements of the rail, readings being made monthly.

*Official Proceedings, New York Railway Club, May 1937.

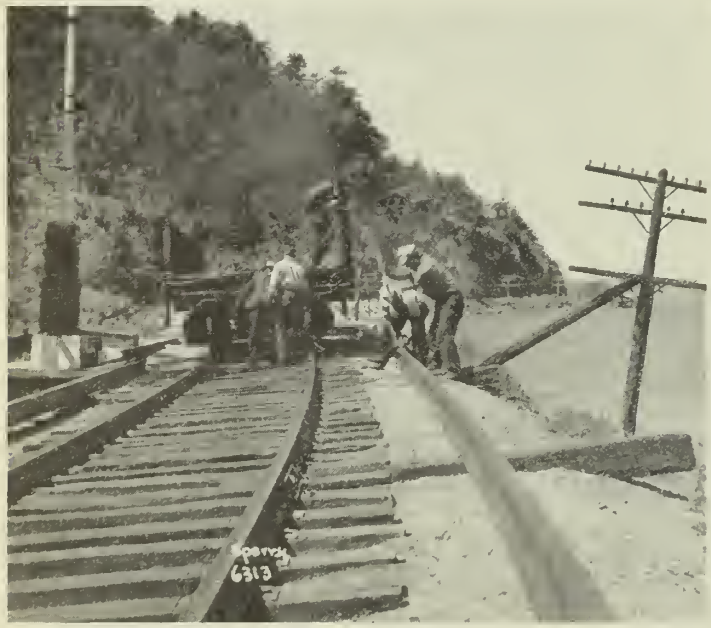

Fig. 2—Spiking down welded rail in temporary position, prior to placing it in permanent track. (Welded rail can be left thus until a convenient time for substituting it in track for the short length rails.)

This welded track was turned over for service November 9th, 1935. By May 1937, at the time Mr. Layng summarized results, this welded track had been in operation through two winters, one quite severe, and one summer during which there was an unusually long period of hot weather. The minimum temperature recorded was minus 15 deg. F., while the maximum was 104 deg. F. No longitudinal movements of special interest were recorded during this period, except at the extreme ends of the installation. Here, the rail movement covered a range of 1 in. at the south end, and $\frac{3}{4}$ in. at the north end. The following transverse movements were recorded: $\frac{5}{16}$ in. to the west, at a point 100 ft. from south end; $\frac{3}{16}$ in. to the east, at a point near the north end of compound curve; $\frac{3}{16}$ in. at the north end of the welded rail. To quote Mr. Layng: "As a whole, the track remained in excellent line and surface." No lining or surfacing was necessary throughout the above period—November 1935 to May 1937.

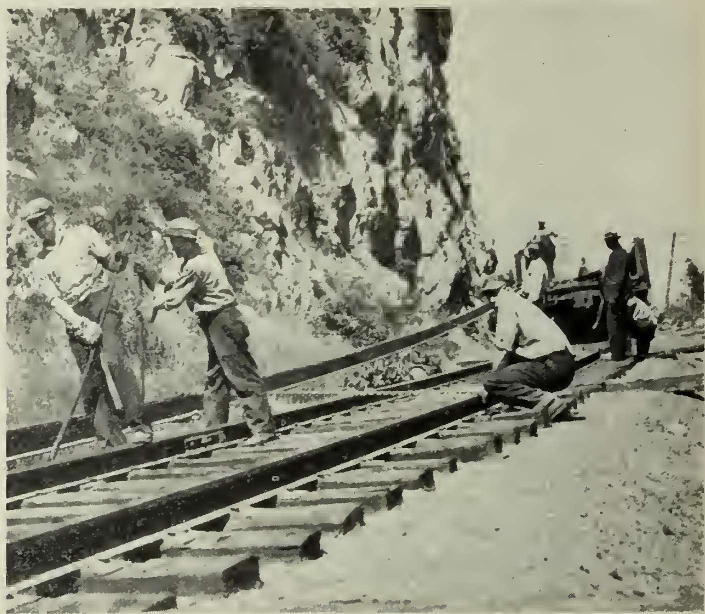

Fig. 3—Distributing Welded Rail Beside Curved Track.

Welded rail is hauled off flat cars and distributed alongside the permanent track until such time as it is convenient to substitute the conventional jointed rail with the welded rail.

A trial installation of 112 lb. continuous rail on the Central of Georgia Railroad is receiving considerable attention from railway engineers throughout the country. This welded track, located about 30 mi. from Atlanta, Georgia, is 2,180 ft. long and is the only open continuous rail with conventional type of fastenings. The rail is supported on double-shoulder canted tie-plates. Cut spikes are used to secure the tie-plates to the ties and to hold the rail in position. Rail anchors are used to prevent longitudinal movement of the rail ends. This track has been in service one summer and winter with no more than normal movement at the rail ends. However the temperature range at this location is not more than 100 deg. F.

Explanation of Performance under Temperature Variation

In these long stretches of welded rail there is no major movement of the rail ends because the expansion and

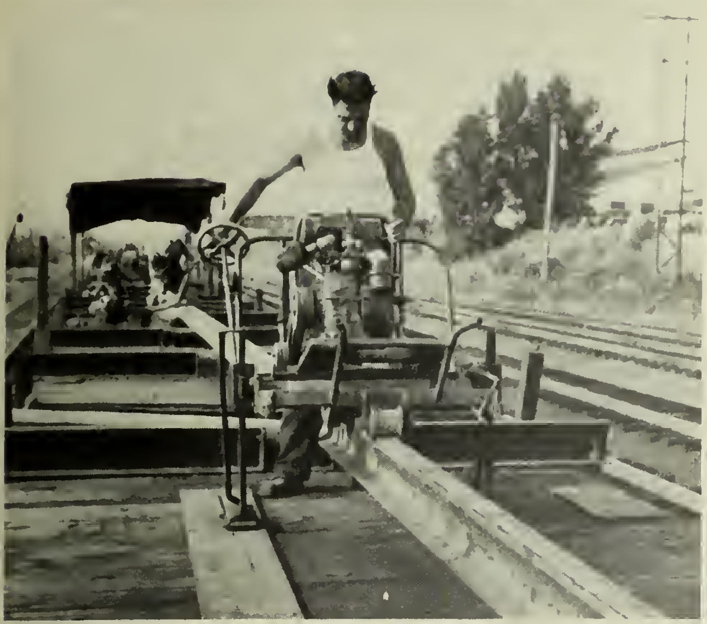

Fig. 4—Grinding Upset Metal off the Rail Head.

One of three grinding stations by which upset metal formed at the line of weld is contoured off; in the background a workman can be seen removing upset metal from the fillet of the rail.

contraction forces are equalled by the restraining forces. If a one mile length of rail is placed in track at 80 deg. F. and securely anchored against movement, there will be an average tension stress of 21,900 lb. per sq. in. in the rail when its temperature drops 100 deg., that is, to a minus 20 deg. F. If this mile of rail were free to move it would contract 46¼ in. due to the 100 deg. drop in temperature. This same mile of free rail would also stretch 46¼ inches if given a tension force at the ends of 21,900 lb. per sq. in. Actually with these two forces, contraction on the one hand and tension on the other, acting in opposition the rail remains in its original position. These forces of expansion and contraction in the long rails are not serious as the resulting stresses are far below the elastic limit of the steel.

Restraining Forces

Abnormal movement of continuous rail in track is prevented by five major restraining forces:

(1) The frictional resistance of the rail to movement due to weight on the tie-plates.

(2) Restraining effect of the insulated joints at the ends of the long rails.

(3) The positive grip fastenings with which the rail is held to every tie-plate.

(4) Rail anchors when used as on Central of Georgia Railroad.

(5) The ties well bedded in suitable ballast.

Development of Electric Flash Butt Weld

Continuous rail to be all that the name implies must be of uniform strength throughout its entire length. The welded joints must be comparable to the rail steel for hardness, tensile strength, impact value and resistance to fatigue.

In 1933, Sperry Products, Inc., in co-operation with the General Electric Company and the Delaware and Hudson Railroad, initiated a programme of research to develop the ideal weld for modern high carbon, large section, steel rail. Initial tests were conducted on every available type of welded rail joint to determine first, the state of the art and second, the type of weld best suited for continuous rail.

This early investigation, while including such physical tests as tension, impact and hardness determinations, was chiefly concerned with the resistance of the weld to fatigue. Railroad rails are subject to severe fatigue stresses due to the repeated application of wheel loads. In the year 1937, more than 20,000 transverse fissures were found in rails of the American railroads. These transverse fissures were fatigue failures produced by repeated wheel loads and had as their nucleus some minute shrinkage or shatter crack. It was feared that welded joints might contain some slag inclusion, oxide, or other discontinuity which would act as a nucleus for an internal transverse fatigue failure. The fatigue test, therefore, was of major importance and a rolling wheel load machine (Fig. 7) was immediately installed in the laboratory.

The rail is mounted in this machine as a cantilever beam with the weld line located 1½ in. from the support. The wheel is spring loaded to 65,000 lb. and the weld is passed back and forth under the wheel 120 passes per minute by means of a motor driven crank arm. This machine will produce failures in a rail containing incipient cracks in from one million to three million passes, while sound rail will stand up indefinitely under the load.

Drop of potential tests were made daily on the rolling load samples to detect incipient cracks and watch their growth. The rolling load test data for five different types of welded rail joints is given in Fig. 6. No flash welds are included in this tabulation. Failure started in all of these welds at less than one million passes of the 65,000 lb. wheel load. An internal transverse fatigue failure in a resistance butt weld is shown in Fig. 8. This fatigue crack was produced by 800,000 passes of the wheel load, and was growing at a rapid rate when removed from the machine.

The electric flash weld stood highest in all of the initial tests and had the added advantage of being rail steel throughout, whereas all other types of welds required the addition of foreign metal, or the use of special fluxes. Flash welding consists essentially of three operations, preheating, flashing and push-up. The rail ends are held by gripper dies, one fixed, one moveable, and are connected by heavy current clamps to the secondary of a low voltage transformer.

Fig. 5—Rail Alignment Gauge.

One of the tests to which each new weld is immediately subjected. Note upset metal at the line of the new weld; upset metal is ground off and the rail contoured to uniform smoothness.

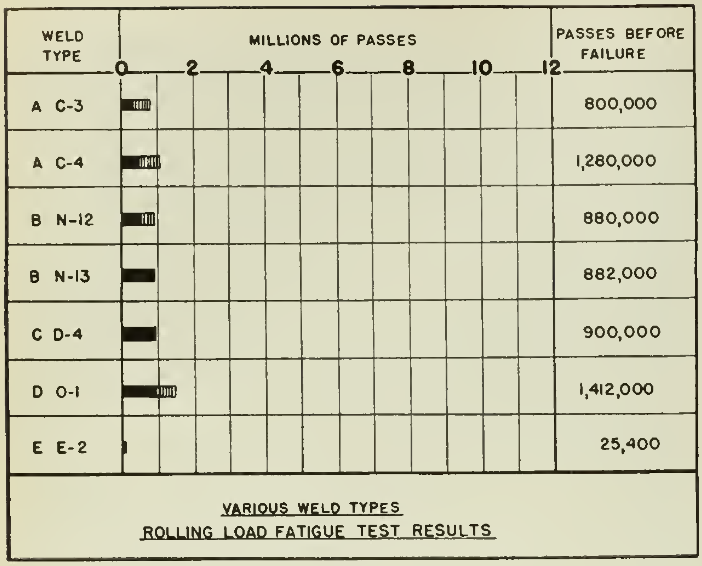

Fig. 6.

Preheating is accomplished by intermittently short-circuiting the rail ends for a definite period. Following this initial cycle, the rail ends are brought together at a predetermined velocity, resulting in repeated short-circuiting or flashing of the rail ends. When this flashing period has been completed, the rail ends are brought together under great pressure, thus squeezing out the molten metal and producing a sound homogeneous weld between the plastic faces of the rail ends.

In developing the correct welding technique it was necessary to determine the proper values for such variables as preheating time, flashing velocity, push-up pressure, voltage and current requirements and stress-relieving procedure. Flashing must be rapid and continuous, as it is the gas pressure due to flashing that excludes the atmosphere from the weld and thus prevents formation of oxides. The welding current must be sufficient to give rapid flashing. However, if the current density is too high it will result in tearing or flashing large chunks of metal from the faces of the rail ends. The push-up pressure must be sufficient to insure squeezing out of the liquid steel, but must not reach a value that will produce cold working of the metal.

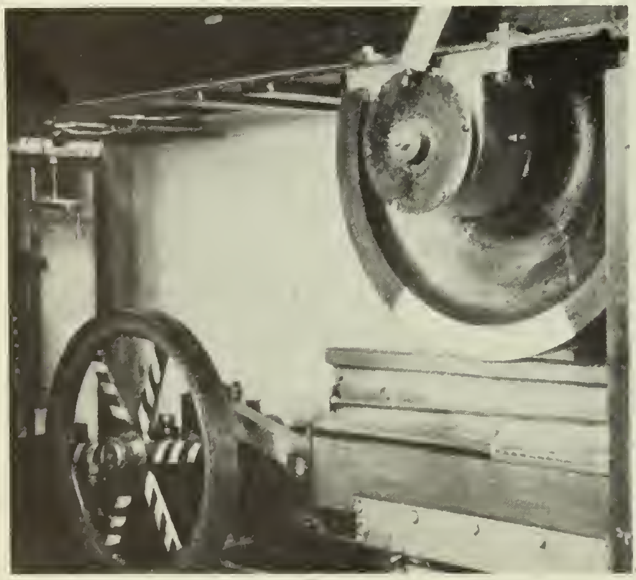

Fig. 7—Rolling Wheel Load Machine for Fatigue Tests.

The final welding cycle required 1¾ min. and with time for clamping and removal, a total of approximately 3½ min. With the production rate at 3½ min. per weld, it was necessary to develop a rapid yet effective stress-relieving cycle. The final procedure required three minutes heating in an oil fired furnace, followed by a 20 min. slow cooling by means of asbestos hoods.

Quality of Improved Flash Weld

Rolling load test data on flash welds, shown in Fig. 9, illustrate the improvement in weld quality which resulted from development of the proper welding technique. The final standard weld procedure resulted in welds which stood up under 12 million passes of the 65,000 lb. wheel load, 6 million with the rail mounted as a cantilever and 6 million with the rail mounted as a simple beam. These welds withstood one, two and three drops on a standard drop test, that is, a drop of the 2,000 lb. tup from a height of 22 ft. The physical properties, given in Fig. 10, show the remarkable strength of the weld. Etched samples of the weld disclose a sound homogeneous bond with no trace of cracks or slag inclusions.

Production Flash Welder

The equipment designed and constructed by Sperry Products, Inc., for production flash butt welding of rails consists of:

(*a*) A welding car, housing a specially constructed flash welding machine.

(*b*) A generator car, housing two turbo-generators for supplying current to the welding machine and to auxiliary equipment.

(*c*) A steam locomotive for supplying steam for the turbine driving the generators.

(*d*) A rail rack car, for lining up rail preparatory to movement into the welder car.

(*e*) A series of flat cars, on which are situated respectively:

1. An inspection station, where welds are inspected directly they come from welder car.
2. A stress-relieving oven.
3. A system of controlled cooling for complete removal of stresses set up in the rail during welding.
4. Three grinding stations.

The first grinder removes the upset metal from the sides of the rail head; the second grinder removes upset metal from the top of the rail and brings the point of weld to rail contour; the third grinder removes upset metal from the fillet (immediately beneath the rail head, on both sides) and from top of base of rail on both sides. All operations are simultaneous; that is, while a weld is being made in the machine, the weld previously made is being inspected, and so on.

Making the welds, inspecting, stress relieving, cooling and grinding may, therefore, be looked upon as a group of operations forming a complete cycle. Upon completion of this cycle, a weld is ready to meet the conditions of service in track. Upon completion of each particular operation, at the various stations, the rail is hauled one rail's length along the flat cars by means of a winch, thus permitting all operators to start afresh, on the next weld brought to them, without moving from their stations.

Welded rail is transported, conforming to curvature of track while on flat cars without the necessity of its being fastened in any way. In order to unload a long string of welded rail from the flat cars, the end of the rail is attached, with a cable, to an anchorage on the ground. The train of flat cars is then moved ahead, and the rail is hauled off at the rear of the train.

Out on track, "closure" welds are made between long strings of flash-welded rail. Thus in track is formed "continuous" rail, which can be installed in any lengths desirable, and limited only by the necessity for insulated joints for signal circuits, frogs and switches.

To insure uniform high quality production welds, the human element has been practically eliminated by making the welder operation automatic. As additional safeguards to weld quality, permanent records are made of the welding voltage, wattage, platen movement and the stress-relieving temperature for every weld fabricated. These records together with the inspector's report are permanent tangible evidence of weld quality.

Advantages of Welded Joint Continuous Rail

(1) *Joint Maintenance*

Welded rail eliminates joint maintenance items such as tightening bolts, oiling joints, building up battered rail ends, applying reformed bars and replacing damaged signal bonds.

(2) *Track Maintenance*

It is estimated that 45 per cent of the track labour is now consumed in keeping joints in proper line and surface. Vertical motion of the welded joint, due to axle oads, is no more than the motion of unwelded rail. Consequently, the amount of lining and surfacing to be done in the case of welded rail is extremely small.

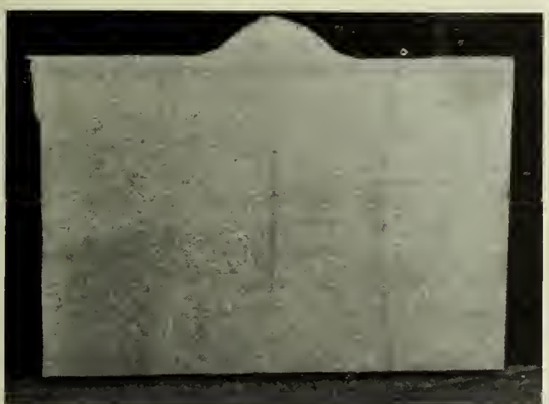

Fig. 8—Internal Transverse Fatigue Failure in a Resistance Butt Weld.

(3) *Rail Batter*

Rail end batter is responsible for a large percentage of the yearly rail renewals. Various methods have been developed for heat treating the rail ends to reduce the batter. Periodic building up of battered and chipped rail ends by welding has become common practice on a good many railroads. With welded joints there is no opportunity for batter.

(4) *Passenger Comfort*

Continuous rail gives the passenger a smooth, quiet, comfortable ride free from the noise and vibration caused by rail joints.

(5) *Rolling Stock Maintenance*

Rolling stock maintenance will be materially reduced when the impacts due to rail joints are eliminated.

(6) *Track Creepage*

There is no creepage with continuous rail, as uninterrupted wave motion of the track takes place with no longitudinal movement.

(7) *Tie Deterioration*

The rail joint plays a major part in tie deterioration. Installation of continuous rail results in a very definite increase in tie life.

(8) *Bonds*

Signal circuit bonds and power bonds are eliminated by the welded joint.

(9) *Safety*

Welded rail is safe rail. Rail rolled for welding is not drilled at the mill and, therefore, will have no failures

due to bolt hole fractures. Another important safety item is the fact that the entire rail and also the flash weld may be tested by the detector car, whereas it is impossible to test for defects that portion of an ordinary rail within angle bars.

Welding Two or More Rails

A survey of the benefits derived from welded rail reveals the fact that it is the elimination of the rail joints, rather than continuous rail *per se*, which accounts for most of the savings enumerated. Increasing the standard rail length from 33 ft. to 39 ft. resulted in a 15 per cent reduction in joints per mile. In recent years trial installations of 66 ft. rails have been made, thus cutting in half the number of joints per mile as compared with 33 ft. rail. One mile of 78 ft. rail has been installed on the Kansas City Southern Railroad and the subject of long rails is a live one today. In Europe the welding together of two or more lengths of rail has been practised for several years. In fact, the total number of welded joints in Europe today runs well over 400,000. The popularity of the 78 ft. or 99 ft. lengths of welded rail lies in the fact that substantial benefits are obtained from reduction of joints with no added cost for special track fastenings.

Continuous rail with its many advantages to the railroad and its assurance of added safety and comfort to the travelling public seems destined to take its place as the latest addition to the list of modern railway developments resulting from railway engineering research.

66-kv. Cable Operation in Montreal

Archie Benjamin, Jr.E.I.C.,

Montreal Light, Heat and Power Consolidated.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, November 11th, 1937.

SUMMARY—This paper is a sequel to one which was delivered several years ago to the Montreal Branch. It describes the additional power facilities that have been provided for Montreal in the downtown area. The oil pressure systems and the methods of making joints in the cable are well illustrated and described. Defects in materials have developed from time to time and the paper explains how they have been overcome.

Some years ago a paper* was read before this branch of The Institute describing the installation in 1927 by the Montreal Light, Heat and Power Consolidated of 66-kv. cables to feed the new Vallee substation. By means of these cables one of the two 66-kv. overhead rings around the Island was looped into the substation. The installation at that time consisted of six single conductor cables in a specially-built duct line extending approximately 4,000 ft. from the overhead lines at Commissioners Street and St. Lawrence Boulevard to Vallee substation, just south of St. Catherine Street and west of Benoit Street.

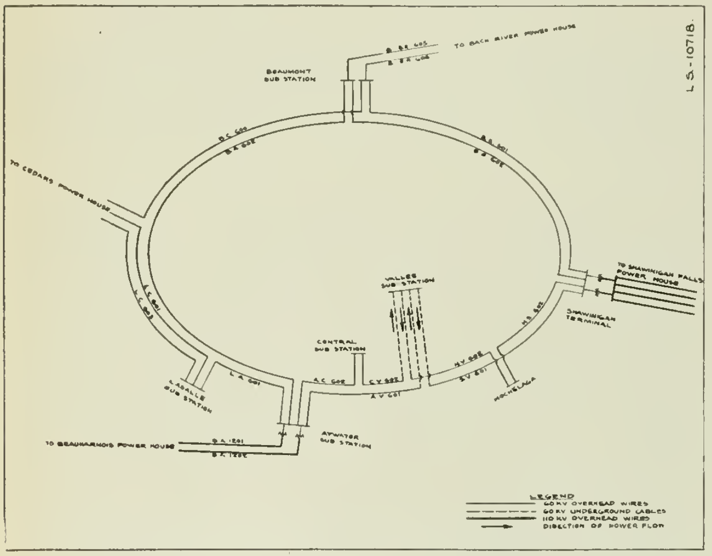

Fig. 1—Plan of Ring System at the Vallee Station.

In 1931 the capacity of Vallee substation was doubled and six additional single conductor cables were installed in another special duct line built along the same route and were connected to loop the other 66-kv. ring into the substation. A sketch of the ring system is shown in Fig. 1.

In 1937 one additional single-conductor cable was installed in the 1931 duct line to serve as a spare for any one of the other twelve cables. Figure 2 shows how the spare cable can be connected to any one of the twelve overhead wires by means of busses and jumpers at the Commissioners Street end of the line. A similar arrangement is provided at Vallee substation.

Thus there are now six cables in one duct line and seven cables in the other duct line, comprising four 3-phase circuits and one spare cable. The separation between the duct lines varies from 7 ft. to 45 ft. The general layout of the manholes and cables is shown in Fig. 3.

This paper will very briefly describe the duct lines, cables and accessories and outline the operating experience.

Duct Lines

Each duct line consists of ten fibre ducts 4½ in. inside diameter, 5 high, 2 wide encased in a concrete envelope. The distance between centre of ducts is from 7 to 8 in. The 1927 duct line has 12 manholes spaced from 235 to 430 ft. apart. The 1931 duct line has 10 manholes spaced from 220 to 495 ft. apart. The difference in elevation of the ducts between adjacent manholes varies from 1 ft. to 25 ft. The deepest manhole is about 16 ft. deep.

At the substation end of the duct lines the manholes are divided into 3 compartments. One of the manholes is approximately 40 ft. long, 12 ft. wide and 16 ft. deep, while the other is approximately 34 ft. long, 12 ft. wide and 13 ft. deep. The manholes at the Commissioners Street end are divided into 2 compartments and are approximately 38 ft. long, 10 ft. wide and 15 ft. deep. The other manholes are from 16 to 20 ft. long and 5 ft. wide at the centre.

Cables

The 1927 cables are 750,000 c.m. copper, 69 strands, hollow core, filled with a petrolatum base compound, 30/32 in. paper insulation, .003 in. metalized paper tape, and 9/64 in. lead sheath. The approximate outside diameter is 3.38 in. The end lengths of these cables have 10/64 in. lead sheath with ½ of 1 per cent. antimony. This reinforcement is to take care of the high static pressures due to the difference in elevation between the potheads and the manholes which is over 60 ft. at Vallee station and 75 ft. at the other end.

The 1931 and 1937 cables are 750,000 c.m. copper, 61 strands, solid core with a heavy oil base compound, 28/32 in. paper insulation; .003 in. metalized paper tape and 9/64 in. lead sheath. The approximate outside diameter is 3.1 in. The end lengths of these cables have .125 in. plain lead sheath, one layer of .008 in. paper, .005 in. phosphor-bronze tape, one layer of paper over that and .100 in. lead overall.

Since these cables are connected in series with the ring system, they are usually called on not only to feed Vallee substation but to transmit power east or west of

Fig. 2—Terminals at Commissioners Street.

*66-kv. Cables of Montreal Light, Heat and Power Consolidated, Humphreys Milliken, L. A. Kenyon, D. M. Simons. Engineering ournal, December 1928.

the substation. The ratings of the cables are: 350 amp. for the 1927 cables and 500 amp. for the other cables. The difference in these ratings is due to the fact that in the new cables sheath insulators prevent the flow of sheath currents.

Cable Terminals

The cable terminals are rated at 110 kv. The 1927 terminals have glass oil reservoirs mounted on them. The other terminals are fed by separate reservoirs. Figure 2 shows the terminals at Commissioners Street. The 1931 terminals at Vallee station are shown in Fig. 4.

in 1933 they were replaced by General Electric oil pressure bellows-type reservoirs. These reservoirs are mounted on the walls of the manholes and are connected by ⅜ in. outside diameter copper tubing to the joints—one reservoir for the three joints of each circuit. The rating of these reservoirs is a volume of 4 U.S. gal. with a corresponding pressure of 15 lb. The volume varies in a definite relationship with the pressure.

The reservoirs feeding the 1931 cables are Standard Underground type and are connected in the same manner as the others. These are also bellows-type and have the

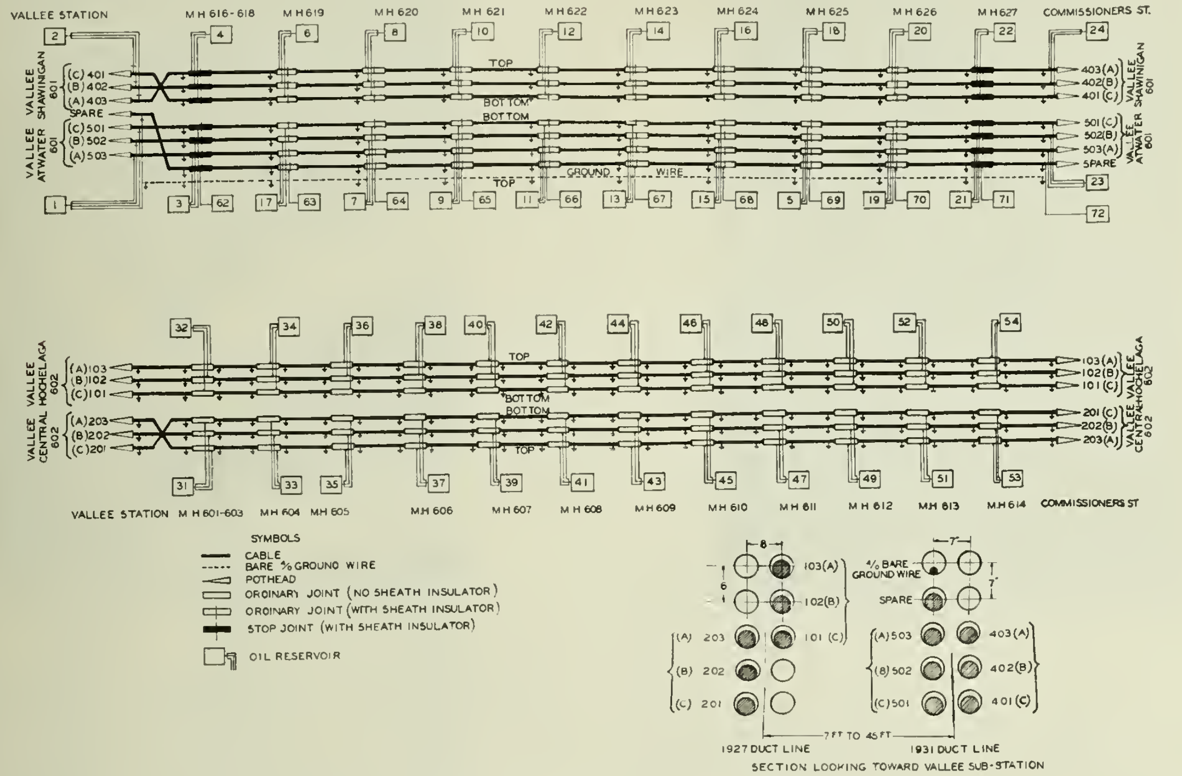

Fig. 3—General Layout of Manholes and Cables.

Joints

The joints on the 1927 cables are machine-wrapped as described in the previous paper. The replacement joints on these cables have been made by hand. There are two types of joints on the 1931 cables and the 1937 spare cable: ordinary and stop joints. The ordinary joints are all hand-wrapped with low loss black varnished cambric tape. The sleeves are equipped with sheath insulators and are grounded on one side of the joints only to prevent the flow of sheath currents.

In the manholes at each end of the duct line there are stop joints, connecting the reinforced riser cables with the ordinary cable. Figure 5 shows a stop joint being assembled. These joints are intended to prevent migration of the oil from the riser cables due to the head of oil. To prevent undue pressures from accumulating in the stop tubes of these joints the heavy oil in the riser cables had been bled by gravity until it was displaced by light oil. The normal pressures on these tubes are about 35 lb. to the sq. in., although over 45 lb. may be reached on the sudden application of the current. The joints are equipped with pressure gauges to indicate these pressures.

Reservoirs

The joints on the 1927 cables were originally equipped with sylphon tanks mounted directly on the joints. However, trouble was experienced with these sylphons and

same rating as the others. In addition to pressure gauge these reservoirs also have volume gauges. Thus a gas leak in the bellows of these reservoirs can be detected by a discrepancy between the relationship of volume and pressure from the normal. Figure 6 shows a Standard Underground pressure reservoir in one of the manholes.

The terminals on these 1931 cables are fed by feeder type reservoirs, mounted on the poles and on the wall of Vallee substation. The bellows of these reservoirs are exposed to the atmosphere and oil is fed into the terminals by gravity. One reservoir of 4 U.S. gal. capacity is connected to three terminals.

The 1937 spare cable has one General Electric pressure reservoir feeding each joint. These are of the same capacity as the others. The terminal on the pole is fed by a General Electric feeder type reservoir in which the active oil is contained in the bellows. The terminal at Vallee substation is connected to one of the existing reservoirs.

OPERATION

Oil Pressures

Thorough inspections of the cables and accessories are made every three months. The pressure gauges on the reservoirs are checked with a standard gauge. Reservoirs that are found with low pressures are pumped with oil until a pressure is reached that will be sufficient to ensure a positive oil pressure on the cable until the next

Fig. 4—1931 Terminals at Vallee Station.

Fig. 6—Standard Underground Pressure Reservoir in Manhole.

inspection. A pressure of 10 lb. usually is sufficient. Negative pressures in the reservoirs are undesirable due to the danger of the formation of voids in the cables and admitting air. However, in the spring care is taken that too much oil is not pumped so that the high summer temperatures will not cause excessive oil pressures. When high pressures are found they are reduced by draining oil from the reservoirs.

10-C transil oil is used in all the reservoirs and joints except at certain locations where migration of oil was experienced due to the difference in elevation of manholes—more than 20 ft. in one location. At these locations Sun XX heavy oil is used and our experience is that the migration is lessened.

All the oil used in the reservoirs is previously heated in an oven and tested for di-electric strength. The test required is over 30 kv. between 1 in. diameter discs spaced 1/10 in. apart.

In four years, from 1933 to 1936, a net amount of 182 U.S. gal. of oil was added to the 1927 cables and 135 gal. of oil to the 1931 cables. Assuming that the cables were well impregnated when installed, the possibility remains that the lead sheaths are stretched to make room for the extra oil. During the inspection of February of this year 108 U.S. gal. of 10-C oil and 25 gal. of heavy oil were pumped into the reservoirs to keep the pressures at 8 lb.

Fig. 5—Stop Joint Being Assembled.

Cable Defects

Some trouble has been experienced with the lead sheaths of the 1927 cables. Up to date there have been only two actual cables failures. However, the relay protection segregated the circuit from the system in each case without causing interruption of service.

The first failure was caused by accidentally driving a pick into a cable while excavating for a sewer connection. The second failure was apparently due to a break in the lead sheath as evidenced by oil emerging from the duct in the manhole some time before the failure. A few weeks later the cable broke down and it was difficult to ascertain the cause of the break.

In addition to the above failures there were eight stretches of the 1927 cable removed in anticipation of failure. In every case a break in the lead sheath was found. The first indications of these breaks were when oil was found emerging from the ducts into the manholes. This was usually accompanied by an abnormal decrease in pressure in the reservoir at the higher end of the suspected stretch.

Figure 7 shows a replacement cable being pulled up the pole at Commissioners Street. This cable is the hollow-core type with its regular sheath specially reinforced for this replacement by a bronze tape and outer lead sheath as on the 1931 cable end lengths. The wood block clamps holding the cable on the pole can be seen in the figure.

As this special cable is greater in diameter than the old cable, the grooves in the blocks on the pole had to be enlarged. As it was impossible to remove the inside halves of the blocks, a hot iron mandril was used on the pole to burn out the grooves to the proper diameter. Figure 8 shows a porcelain bushing being hoisted onto the pothead of a replacement cable at Commissioners Street.

Some of the breaks in the sheaths were apparently due to stretching of the lead. When the lead sheath was removed from this cable 4 in. on each side of the break, considerable oil was found between the paper insulation and the sheath. This piece of lead was cut into five equal strips and the thickness of lead measured around the circumference. These measurements indicated a stretching of the lead. The measured outside diameter of the cable at the break was 3.55 in. instead of the normal 3.38 in. All the defective stretches of cable on the 1927 system are now being replaced by solid core cable as installed in 1931.

The only defects experienced in connection with the 1931 cables were at the potheads on the pole. In two cases oil was found leaking from the duct in the manhole. Since these cables have their sheaths reinforced by phosphor-

Fig. 7—Replacement Cable Being Installed.

bronze tape and a second sheath it was thought improbable that both sheaths were broken. However, it was suspected that the wiped seal between the two lead sheaths inside the pothead might be broken and the oil from the pothead was allowed to pass between the two sheaths and out through a break in the thinner outside sheath. A wiped seal was therefore made between the two sheaths outside the potheads. This stopped the flow of oil from the duct and no further trouble was experienced.

Fig. 8—Porcelain Bushing Being Hoisted into Place.

Joint Defects

Leaks in the stop tubes of several stop-joints were found. This was remedied by replacing ⅛ in. thick vellumoid gaskets by 1/32 in. gaskets. These thinner gaskets have now been installed on all the stop joints and no further leaks found.

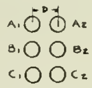

FIG 1
ARRANGEMENT OF CABLES

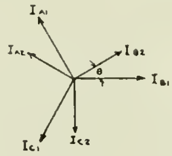

FIG 2.

INDUCED VOLTAGES ON CABLE SHEATHS – GROUNDED AT NOT MORE THAN ONE POINT.

CONSIDER SIX SINGLE PHASE CABLES ARRANGED AS SHOWN – (A_1, B_1, C_1) AND (A_2, B_2, C_2) ENERGIZED FROM TWO BALANCED THREE PHASE SYSTEMS WHICH MAY OR MAY NOT BE INTERCONNECTED. FIG 2 SHOWS THE VECTOR DIAGRAM OF THE TWO SYSTEMS. PHASE ROTATION IS ASSUMED TO BE A-B-C. PHASE B_1 IS TAKEN AS REFERENCE. θ IS THE PHASE ANGLE BETWEEN THE TWO SYSTEMS.

THE FOLLOWING RELATIONS HOLD:–

$$-je_{A1} = I_{A1}X_{A1A1} + I_{B1}X_{A1B1} + I_{C1}X_{A1C1} + I_{A2}X_{A1A2} + I_{B2}X_{A1B2} + I_{C2}X_{A1C2} \quad (1)$$

$$-je_{B1} = I_{A1}X_{B1A1} + I_{B1}X_{B1B1} + I_{C1}X_{B1C1} + I_{A2}X_{B1A2} + I_{B2}X_{B1B2} + I_{C2}X_{B1C2} \quad (2)$$

$$-je_{C1} = I_{A1}X_{C1A1} + I_{B1}X_{C1B1} + I_{C1}X_{C1C1} + I_{A2}X_{C1A2} + I_{B2}X_{C1B2} + I_{C2}X_{C1C2} \quad (3)$$

THREE SIMILAR EQUATIONS HOLD FOR e_{A2}, e_{B2}, AND e_{C2} RESPECTIVELY.

e_{A1} = INDUCED VOLTAGE TO GROUND ON CABLE SHEATH A_1.

X_{A1A1} = SELF-REACTANCE OF CABLE SHEATH A_1 = $K(\log P/R_m)$

X_{A1B1} = MUTUAL-REACTANCE BETWEEN CABLES A_1 AND B_1 = $K(\log P/D_{A1-B1})$

WHERE $K = 0.05292$ (FOR INDUCED VOLTS PER 1000 FEET)

R_m = MEAN RADIUS OF CABLE SHEATH.

$D_{A1\cdot B1}$ = SPACING BETWEEN CENTRES OF CABLES A_1 AND B_1.

P = DISTANCE FROM CENTRE OF CABLE TO A POINT AT INFINITY (IT CANCELS OUT IN THE FINAL RESULTS)

EQUATION (2) MAY BE WRITTEN AS FOLLOWS:–

$$-je_{B1} = I_{B1}\left(\epsilon^{j120}X_{B1A1} + \epsilon^{j0}X_{B1B1} + \epsilon^{j240}X_{B1C1}\right) + I_{B2}\left(\epsilon^{j(120+\theta)}X_{B1A2} + \epsilon^{j\theta}X_{B1B2} + \epsilon^{j(240+\theta)}X_{B1C2}\right)$$

IT IS EASY TO SHOW THAT

$$A\epsilon^{j120} + B\epsilon^{j0} + C\epsilon^{j240} = B - \tfrac{1}{2}(A+C) + j\tfrac{\sqrt{3}}{2}(A-C)$$

$$A\epsilon^{j(120+\theta)} + B\epsilon^{j\theta} + C\epsilon^{j(240+\theta)} = \left[B - \tfrac{1}{2}(A+C)\right]\cos\theta - \tfrac{\sqrt{3}}{2}(A-C)\sin\theta + j\left[\left\{B - \tfrac{1}{2}(A+C)\right\}\sin\theta + \tfrac{\sqrt{3}}{2}(A-C)\cos\theta\right]$$

USING THESE RELATIONS WE OBTAIN

$$-je_{B1} = I_{B1}\left[\left\{X_{B1B1} - \tfrac{1}{2}(X_{B1A1} + X_{B1C1})\right\} + j\tfrac{\sqrt{3}}{2}(X_{B1A1} - X_{B1C1})\right] + I_{B2}\left[\left\{X_{B1B2} - \tfrac{1}{2}(X_{B1B2} + X_{A1C2})\right\}\cos\theta - \tfrac{\sqrt{3}}{2}(X_{B1A1} - X_{B1C2})\sin\theta + j\left[\left\{X_{B1B2} - \tfrac{1}{2}(X_{B1A2} + X_{B1C2})\right\}\sin\theta + \tfrac{\sqrt{3}}{2}(X_{B1A2} - X_{B1C2})\cos\theta\right]\right]$$

FOR THE CONFIGURATION OF CABLES AS SHOWN ABOVE:–

$$-je_{B1} = 0.05292\left[I_{B1}\log\frac{D}{R_m} + I_{B2}(\cos\theta + j\sin\theta)\log\sqrt{2}\right] \text{ VOLTS PER 1000 FEET} \quad (2a)$$

$$-je_{A1} = 0.05292\left[-I_{B1}\left(\tfrac{1}{2}\log\frac{D}{2R_m} - j\tfrac{\sqrt{3}}{2}\log\frac{2D}{R_m}\right) + I_{B2}\left\{\left(\log\frac{\sqrt{5}}{\sqrt{2}}\cos\theta - \tfrac{\sqrt{3}}{2}\log\sqrt{5}\sin\theta\right) + j\left(\log\frac{\sqrt{5}}{\sqrt{2}}\sin\theta + \tfrac{\sqrt{3}}{2}\log\sqrt{5}\cos\theta\right)\right\}\right] \quad (1a)$$

$$-je_{C1} = 0.05292\left[-I_{B1}\left(\tfrac{1}{2}\log\frac{D}{2R_m} + j\tfrac{\sqrt{3}}{2}\log\frac{2D}{R_m}\right) + I_{B2}\left\{\left(\log\frac{\sqrt{5}}{\sqrt{2}}\cos\theta + \tfrac{\sqrt{3}}{2}\log\sqrt{5}\sin\theta\right) + j\left(\log\frac{\sqrt{5}}{\sqrt{2}}\sin\theta - \tfrac{\sqrt{3}}{2}\log\sqrt{5}\cos\theta\right)\right\}\right] \quad (3a)$$

EXPRESSIONS FOR THE INDUCED VOLTAGES ON THE OTHER CABLE SHEATHS MAY BE DERIVED IN A SIMILAR MANNER.

Fig. 9—Development of Formula Used in Configuration of Cables.

Induced Voltages on Sheaths of 66 kv. Cables

Test No.	Phase Amperes		Phase Angle between Current in Cables 401-2-3 and 501-2-3	Cable Tested	Phase	Length of Cable (Feet)	Induced Volts (Sheath to Ground)	
	Cables 401, 402, 403	Cables 501, 502, 503					Measured	Calculated
1	150	270	69 deg.	503	A	517	4.82	7.06
2	150	270	70 deg.	502	B	517	4.80	5.06
3	150	270	70 deg.	501	C	520	7.40	6.46
4	150	258	71 deg.	403	A	537	3.62	4.31
5	150	252	70 deg.	402	B	536	3.85	3.30
6	150	258	70 deg.	401	C	536	3.70	5.19

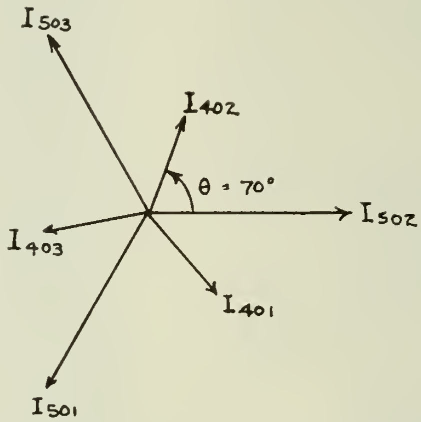

Fig. 10—Comparison Between Measured and Calculated Voltages.

Pothead Defects

Several oil leaks at the gaskets of the potheads were remedied by tightening the cap screws. Two porcelain bushings were cracked and had to be replaced.

Reservoir Defects

Trouble was experienced with the reservoirs on the 1931 cables. Leaks developed in the bellows of several reservoirs allowing gas to escape from them. These leaks were detected during the routine inspections and in most cases were repaired by soldering.

Induced Sheath Voltages

Some measurements were taken on all the insulated-sheath cables of the induced voltages built up between the ungrounded ends of the cable sheaths and ground. This was done with the twelve regular cables in service and the spare cable dead and grounded at both ends. Simultaneously a phase angle meter was used in Vallee substation to measure the angle between the currents in the insulated-sheath cables. The phase amperes were also noted. The configuration of the cables is shown in Fig. 3. Calculations have been made to check the voltage readings theoretically. Figure 9 shows the development of one of the formulae used. It is to be noted that the continuous-sheath cables in the other duct line have no appreciable effect on the induced voltages and they do not appear in the calculations. The reason for this is that because the distance between the cables in that duct line is very small compared to the distance between the two duct lines the mutual reactances are almost equal and their effects cancel each other.

Figure 10 shows a comparison between the measured voltages and the calculated voltages for the longest stretch of cables.

The induced voltages were also measured with the spare cable in service in place of cable 201 in the opposite duct line. The highest voltage measured was 8.50 volts in cable 501.

REQUEST FOR INFORMATION

To all members of The Engineering Institute of Canada

It is proposed to publish a membership list before the end of the year. In order that complete and up-to-date information may be available, will you kindly fill in this form and return it to Headquarters. The work is already under way; therefore a prompt response will be appreciated.

Preventing Condensation in Insulated Structures

By T. S. Rogers, Architectural Record, March 1938

Abstracted for Engineering Journal by Douglas S. Laidlaw, A.M.E.I.C.

A small, but growing, number of buildings have been observed in recent years in which dampness has developed in walls, roofs, or attic spaces. Most of these have been insulated houses, and a few have been winter air-conditioned. The erroneous impression has spread that insulation "draws" water into walls and roofs.

Among the several million houses containing insulation, only a very few develop chronic dampness conditions, and, of these, most show only a staining of plaster, though some show the formation of frost and ice in concealed spaces, or dry rot and fungus growths in wood members. Two investigations of the problem have recently been made, and are reported in (1) "Condensation in Walls and Attics," U.S. Forest Products Laboratory Report (1937) by L. V. Teesdale, senior engineer, Forest Products Laboratory, Madison, Wisconsin; (2) "Condensation Within Walls" by Pro essor F. B. Rowley, A. B. Algren, and C. E. Lund, of the Engineering Experiment Station, University of Minnesota, presented at a meeting of the American Society of Heating and Ventilating Engineers, in January 1938. This article and the Time Saver Standard sheets summarize their findings for the benefit of the architectural profession.

It was found by the investigators that water vapour has a tendency to migrate from an area of higher to one of lower relative humidity, and that, if this tendency be restrained by the interposition of a vapour-tight membrane between them, condensation on the surface of that membrane will result only when that surface is at a temperature below the dew-point temperature of the air on the high-humidity side. Under winter conditions, it is common to find a higher relative humidity inside a house than outside it, and this condition has been intensified by the introduction of winter air-conditioning apparatus. Common forms of construction, used for many years, have not proved vapour-tight, even where, as was not always the case, they were wind-tight. The intensified interest in insulation and wind-tightness has produced many new types of construction, of which a large number have proved vapour-tight. Where the vapour-tight membrane has been placed in the cold portion of the wall or roof, condensation has resulted.

Three general types of construction are, therefore, found to be unfavourable to condensation: 1. Construction that is not wind-tight, as exemplified by many old or poorly constructed buildings. In this the vapour moves through cracks in the wall or around windows or doors. The maintainance of a high relative humidity inside such a building is impossible. 2. Construction that, while wind-tight, is not vapour tight, so that the vapour may pass, unhindered, to the outside. Unpainted plaster, plaster-boards, some ply-woods and fibre boards, ordinary rock wool insulation, and ordinary wood sheathing with building paper and siding, are of this character. 3 Construction containing a single, or multiple, vapour-tight membrane, so placed that its surface temperature will be above the dew-point temperature of the air inside the house. For this purpose, two coats of aluminium paint, reflective foil insulation, and heavy, built-up, waterproof building papers, when applied in effectively continuous layers, have been found to be very effective.

Condensation found in existing construction can be eliminated either by increasing the vapour-tightness of the inner portions of the wall or roof or by decreasing the vapour-tightness of the outer portions. The first method would usually be effected by the installation of a vapour-tight membrane on the inner surface, the second by ventilation of the concealed spaces to the outer air.

It has been found that it is not necessary to reverse the position of the vapour barrier in the walls or roofs of buildings equipped for summer air-conditioning, because the temperature of the air within the building only rarely falls below the dew-point temperature of the outer air, and such condensation as then occurs is readily dissipated.

The article is accompanied by simple diagrams explaining the principles involved, illustrations of the test equipment used, and diagrams showing methods of construction.

THE ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

VOLUME XXI SEPTEMBER, 1938 No. 9

War and the Engineer

War has become so much a matter of engineering that it is doubtful if any group of citizens is more interested or concerned about the present apparent trend of events, than the engineers. So much is written in newspapers and periodicals, so much discussion is taking place, that it is not possible to avoid the subject. It is true that we are told by visitors to England that in the press there, there is little war talk, and that the Canadian and American papers by their over emphasis seem to make war much more probable than it actually is. Nevertheless we cannot dismiss with a shrug the undisputed fact that all Europe is arming, and that England is well on in a programme to spend not less than seven and a half billion dollars as part of a programme to defend herself. Surely we cannot be accused of pessimism for thinking of these things under such conditions, and for wondering just what our part will be as individuals and as a nation.

With war only a possibility the only action that can take place is that of preparation. But preparation is a very broad term and involves much more than the recruiting and training of armies. Today a whole nation goes into battle—not just the soldiers. Therefore preparation concerns every citizen, and victory will probably go to that nation which has done this work the best.

We see the Mother Country making preparation on a scale that is staggering. Authoritative accounts of the plans and policies of the British government are a revelation of cool calculation, and firm determination. The whole fighting force is having its face "lifted" in no uncertain manner. Industry is in step with governmental plans, and the way this has been worked out is beyond the comprehension of other nations. Yet it all sounds so reasonable in England.

Canada's share in any Empire war is a subject upon which there is no unanimity of opinion, but whether we like it or not, Canada is making some preparation, and the nature and extent of that preparation should be interesting. Hence, we propose publishing from time to time as the information becomes available, short articles on the subject. The material already in hand deals with "industrial preparedness," and has particular significance for the engineer. It will appear in the October Journal.

Progress is Reported

The work of repairing and redecorating the Headquarters building is well under way. In fact by the time this report is read the staff should be back in possession of their quarters. For weeks possession seems to have been abandoned to the contractor and his hordes, and at times it looked as though it might never be regained. However, the dust has settled somewhat, scaffolding has been removed, tarpaulins have been lifted, and we have been allowed to gain a little of the lost territory.

Someone has said "You can't make an omelet without breaking eggs," from which it would appear that we must have a very large omelet under way. Work of this nature always brings a lot of confusion even in small doses, but when the entire building, both inside and out, is in process it becomes "confusion worse confounded." However, good progress is being made, and before long the objectionable features of such work will be removed and forgotten, and only the pleasant after effects will remain.

Members are urged to visit the "new" Headquarters, and see for themselves what has been taking place. It is expected that not only will the appearances be improved but the facilities also. You will be very welcome.

Presidential Visit to Western Branches

At the Council meeting on August 19th, President Challies outlined the tentative arrangements for his western trip. The itinerary is definitely decided upon but as each branch is in charge of its own arrangements and there has not yet been time to complete a programme, final details were still lacking. It was, however, announced that the visit to Regina would coincide with the annual open meeting of the Association of Professional Engineers of Saskatchewan, and that arrangements had been made that the two organizations would hold certain of their functions jointly.

At Vancouver, in addition to the branch activities, the party would participate in the Annual Western Meeting of the Canadian Institute of Mining and Metallurgy. The final programme of meetings and functions will be published just as soon as all details are determined, but in the meantime here is the itinerary.

Hon. C. D. Howe Guest of Joint Meeting

Winnipeg engineers, to the number of two hundred, gathered at the Fort Garry hotel on Wednesday, August 3rd, to hear the Hon. C. D. Howe, Hon.M.E.I.C., speak on the Trans-Canada Air Lines. The occasion was a joint meeting of the Association of Professional Engineers of Manitoba and the Winnipeg Branch of The Engineering Institute of Canada.

Mr. Howe spoke very optimistically about the future of the Air Lines. He stated that the project would be a profitable aviation operation, and a great asset to the Post Office Department. He set October 1st as the probable date of inauguration of regular services. His confidence and enthusiasm were based partly on the very advantageous situation of the line, where the physical factors were favourable to successful operations. He referred particularly to the narrowness of the Rocky Mountains at the Crow's Nest Pass, and the absence of fog over the prairies and Northern Ontario.

He spoke of the advantages that an engineer has in dealing with such work as came into his department. He thought that such a post lent itself particularly to the qualifications of an engineer, and hoped and believed that for the future, engineers would continue to be placed in such positions.

The chairman of the meeting was E. P. Fetherstonhaugh, M.E.I.C., Dean of Engineering and Arthitecture at the University of Manitoba. P. Burke-Gaffney, President of the Association of Professional Engineers of Manitoba, introduced the guest of honour, and W. D. Hurst, A.M.E.I.C., chairman of the Winnipeg Branch of the E.I.C., offered the thanks of the meeting.

Changes in Service Involve Engineers

The recently announced promotions in the three branches of the Department of National Defence, affect several members of The Institute.

Air Commodore G. M. Croil, A.M.E.I.C., who is Senior Air Officer, becomes Air Vice-Marshal. A similar promotion goes to J. Lindsay Gordon, A.M.E.I.C., District Officer commanding Military District No. 10.

Group Captain E. W. Stedman, M.E.I.C., has been advanced to the rank of Air Commodore, and Wing Commander W. R. Kenny, A.M.E.I.C., has been made Group Captain.

It is also indicated that Major-General T. V. Anderson, A.M.E.I.C., is slated to succeed to the office of Chief of the General Staff.

Members of The Institute will be interested in these promotions, and will be pleased to know of the recognition that has come to their fellow members.

Fall Meeting of A.S.C.E.

Special invitations have been received by the President and Councillors and the General Secretary to attend the Fall Meeting of the American Society of Civil Engineers which is being held at Rochester, N.Y., on October 12th to 14th. Mr. Challies has already accepted the invitation, and will attend accompanied by Past-President J. M. R. Fairbairn, chairman of the Institute's Committee on International Relations, and the General Secretary. It is expected that several councillors will also be present. The meetings of the A.S.C.E. are always interesting and profitable, in addition to which visitors from Canada are made very welcome.

Erratum

We regret that in the August Journal on page 403, Dr. W. E. Cullen, was not given his correct title as President of the Institution of Chemical Engineers.

Joint Meeting at Sarnia

The London and Border Cities Branches are still busy on their plans for the big day on Saturday, September 24th. Considerable encouragement has come in the form of promised attendance from prominent members of many branches. Toronto, Hamilton, Niagara Peninsula, and the "Soo" will all be represented, along with a delegation from Headquarters.

In the morning there will be a trip of inspection of the Imperial Oil Refinery, and at one o'clock lunch at the golf club with an official of the Oil Company as speaker-guest. The afternoon starts out with an inspection of the new International Bridge, which in itself is an item of considerable interest. As you would expect, the day closes with a dinner. R. M. Smith, A.M.E.I.C., Deputy Minister of Highways, Province of Ontario, and President Challies will be the speakers, which seems to indicate that it will be a real occasion. Members from all branches will be very welcome.

OBITUARIES

John G. Sullivan, M.E.I.C.

With the death of John G. Sullivan in Winnipeg on August 7th, came to a close the career of one of the outstanding engineers of international reputation. Mr. Sullivan was born in the United States at Bushnell's Basin, N.Y., on January 11th, 1863, but lived in Canada almost continuously since 1893. In all that time he had been in the forefront of engineering progress and active in many projects having to do with the welfare of his community. He lived a full life and leaves behind him a country that is much better for his having been a citizen of it.

Shortly after graduating from Cornell University with the degree of C.E. in June 1888 he commenced railway work with the Great Northern Railway as rodman. He went to Washington Territory in the spring of 1889 and was engaged as instrumentman and assistant engineer, for the Spokane Falls and Northern Railway, until the fall of 1890 when he went to Seattle and was assistant engineer on the Pacific Extension of the Great Northern Railway.

He first came to Canada as assistant engineer on the Alberta Railway and Coal Company in July 1893. In 1894, all construction work having been stopped on account of a strike, he took a position as section foreman on the Northern Pacific Railway at Butte, Montana, which position he held for two or three months, after which he was engaged as locating engineer on the Butte Anaconda and Pacific Railway. In the spring of 1895 he began work as principal assistant engineer, on the Kaslo and Slocan Railway. The following year he became reconnaissance engineer for the Columbia and Western Railway, which subsequently became the property of the Canadian Pacific Railway.

From 1898 to 1900 he acted as principal assistant engineer on the construction of the Columbia and Western Railway and from 1900 to 1905 was division engineer of construction on the Canadian Pacific Railway; during this time he had entire charge of all surveys and construction on new lines built by the Canadian Pacific Railway, west of Fort William.

From 1905 to 1907 he was assistant chief engineer of the Panama Canal; his principal assignment being the excavation and disposition of waste from the Culebra Cut; but for three months while Mr. Stevens was in Washington, Mr. Sullivan was acting chief engineer in charge of all works. In the course of his duties on the Panama Canal, Mr. Sullivan designed details for the Lidgerwood Side Plow, which made the plow workable when operating flat cars with one solid side. As originally designed the plow would not work on a solid-side car in rock or boulders. His improvements increased the capacity of flat cars to 25 or 30 cubic yards, so that by reason of the long hauls involved, it was much more economical to use the plow and flat cars, than to use dump cars. The successful working of the improved plow and cars saved millions of dollars in the cost of canal excavation.

In 1907 Mr. Sullivan became manager of construction for the Eastern Lines of the Canadian Pacific Railway, and a year later was promoted to the position of assistant chief engineer for the Eastern Lines, with offices at Montreal. There being no chief engineer, he was in charge of the Engineering Department.

He was transferred in 1911 to the Western Lines of the Canadian Pacific Railway, as assistant chief engineer, with offices at Winnipeg. A few months later he was made chief engineer of the Western Lines, which position he held until 1915 when he was made chief engineer of the Canadian Pacific Railway. Although he resigned this appointment in 1918, he was retained as consulting engineer until 1927.

Beginning with the year 1911, there was a rapid growth of railways in the west; and during some of the years of Mr. Sullivan's tenure of office, as much as fifty million dollars per annum was spent for betterments and new lines under his direction. In the construction of the Connaught Tunnel, the plan of driving a centre heading was adopted. This was devised by Mr. Sullivan. With reference to this feature, the *Engineering News* of January 11th, 1917, made the following editorial comment:

> "A few months back, the completion of the Rogers Pass (Connaught) Tunnel, a sound-rock tunnel, signalized the brilliant success of a radically novel method of attack in rock. The system of blasting in rings from a central pilot tunnel, a bold innovation, was the key to success. Though centuries of prior art in rock tunnelling were available, sound engineering in this case lay, in abandonment of precedent."

In 1916 the Canadian Pacific Railway Company permitted him to act as a member of the special board of consulting engineers reporting on the design of the aqueduct for the Greater Winnipeg Water District. After retiring from the Canadian Pacific Railway he engaged in consulting work in Winnipeg, alone and later in partnership. For some years he was president of the firm of Sullivan, Kipp and Chace in that city.

Since 1918 he had varied experience, acting as arbitrator in labour disputes, as arbitrator between railways, and in an advisory capacity on engineering projects. Notes on some of this work are quoted below.

From 1919 to 1922 he was chairman of the Manitoba Drainage Commission, whose report was finally adopted by a committee of the local legislature, although not all of its recommendations were adopted by the government. In 1919 he reported to the Minister of Public Works of Manitoba on the economics of the proposed government electric power distribution system. During 1920 and 1921 he was retained by the Dominion Government as consulting engineer in the arbitration between the Government and the Grand Trunk Railway Company.

In 1922 he reported to the Premier of British Columbia on the physical and economic features of the Pacific Great Eastern Railway. In the following year he was a member of the commission appointed by the Government of Manitoba to study and report as to the policy the Government should adopt with regard to the Provincial Hydro System.

In 1924 he reported to the Southern Railway Company on the economics and revision of that company's line between Cincinnati and Chattanooga. The result of this report was a radical change of the policy of the Southern Railway in connection with the proposed plans for this line.

In the same year he reported to Price Brothers Company on the method to be adopted in protecting their paper mill plant at Kenogami from slides which threatened the plant. The protection works suggested by Mr. Sullivan were carried out.

He was appointed in 1925 as a member of a Board of Engineers to make a joint report to the Presidents of the Canadian Pacific and Canadian National Railways, on the railway situation in the Peace River country. The result of this report has undoubtedly saved the expenditure of several millions of dollars before the development of the country would justify such expenditure. In the same year he was retained by a firm of consulting engineers in London, England, who had charge of a private bill proposing a vehicular tunnel between Liverpool and Birkenhead, under the Mersey river, to give testimony before a Parliamentary Committee. The applicants were successful and the tunnel has been constructed.

In 1926 he was retained by the Denver and Salt Lake Railway Company to report and advise on the practicability of ventilating the Moffat Tunnel, to permit of the operation of steam locomotives. The tunnel having been ventilated in accordance with the plans proposed by Mr. Sullivan, steam locomotives are now being successfully operated through it.

He joined The Institute, then the Canadian Society of Civil Engineers, as a Member in 1900. He served on Council in 1910 and 1918, as Vice-President 1911-1913 and was President of The Institute in 1922. His interest in and services to the Winnipeg Branch were continuous. The Sir John Kennedy Medal for 1936 was presented to Mr. Sullivan. This gold medal established in commemoration of the great services rendered to the development of Canada, to engineering science and to the profession by the late Sir John Kennedy, Past-President of The Institute, is the highest honour which The Institute can bestow.

He is survived by two sons, Paul L. of Montreal and John T. of Temagami, Ont., and two daughters, Mrs. K. L. Puestow, Madison, Wis., and Mrs. John R. Lindsay, Winnipeg.

Walter Atkyns Ervine-Grim, M.E.I.C.

Members will learn with regret of the death of Captain Walter Atkyns Ervine-Grim, M.E.I.C., in Tampico, Mexico, on July 8th. Captain Ervine-Grim was born at Stratford, Ont., November 11th, 1880. His first engineering experience was gained with the Grand Trunk Pacific Railway on construction. In 1906 he became resident engineer with this company, then in 1907 he was transferred to their Mountain Division. After two years in this position he was again transferred to the Prairie Division. In 1912 he moved to Vancouver, B.C., as assistant engineer with the Western Canada Power Company.

Captain Ervine-Grim was on active service overseas from 1914 to 1919, being attached to the 16th Battalion of the Canadian Scottish from 1914 to 1917 and to the Canadian Engineers from 1917 to 1919. He enlisted as a private, was commissioned lieutenant in 1915 and was made a captain in 1917 when he was transferred to the Canadian Engineers.

In 1920 he went to Los Mochis, Mexico, as engineer in charge of standard gauge railways and irrigation system for the United Sugar Companies. After acting for some time as secretary of the Rockefeller Foundation Commission at Colima, Col., he was later connected with the Pan American Petroleum and Transport Company, Tampico, Mexico, and then with the Huasteca Petroleum Company of the same place. In 1928 he went to Maracaibo, Venezuela, S.A., with the Lugo Petroleum Corporation. In 1931 he returned to Tampico and was engaged in private practice as a consulting engineer at the time of his death.

Captain Ervine-Grim joined The Institute as an Associate Member in 1909, becoming a Member in 1919.

PERSONALS

W. S. Lea, M.E.I.C., **T. J. Lafreniere**, M.E.I.C., and **Ernest Gohier**, M.E.I.C., have been appointed by the Executive Committee of the city of Montreal as a committee of three to look into the project of building a new water intake at Ville LaSalle. The committee is to study both the urgency of the need of a new intake and the best method of constructing it.

Dr. H. G. Acres, M.E.I.C., Niagara Falls, Ont., has been appointed chief engineer of the Grand River Conservation Commission.

W. G. Murrin, M.E.I.C., president of the British Columbia Electric Railway Company Limited, has been receiving congratulations on the occasion of the completion of twenty-five years of service with that company.

G. E. Elkington, A.M.E.I.C., has been appointed general manager and president of the East Kootenay Power Company. He was formerly operating engineer.

Sir Alexander Gibb, G.B.E., C.B., LL.D. (Edin.), F.R.S. and Hon.M.E.I.C., Past-President, Institution of Civil Engineers, has recently had the honorary degree of LL.D. conferred upon him by the University of Edinburgh.

Frederick E. Bronson, M.E.I.C., has been elected president of the Ottawa Light, Heat and Power Company, Limited; the Ottawa Electric Company and the Ottawa Gas Company at a meeting of the directors of the three companies. He succeeds the late Hon. Thomas Ahearn.

A. E. K. Bunnell, M.E.I.C., is now president and general manager of Canadian Ventilating Shades Limited, Toronto.

T. M. Moran, A.M.E.I.C., Factory Manager of the Dominion Rubber Company, Limited, Montreal, will be one of the accredited delegates of The Institute attending the Seventh International Management Congress at Washington, September 19th to 23rd. Mrs. Moran will accompany him.

E. M. L. Burns, M.E.I.C., Works Manager of the Welland Plant, Canada Foundries and Forgings Limited, will be one of The Institute members attending the Seventh International Management Congress at Washington, September 19th to 23rd. Mrs. Burns will accompany him.

Secretary Emeritus **R. J. Durley** is now sufficiently recovered that he has been able to take a trip to the Maritimes. He will spend some time at Guysboro, N.S., after which he plans to visit in Sydney. From there he goes to Cambridge, Mass., to represent the Institution of Civil Engineers at the Fifth International Congress for Applied Mechanics on September 12th to 16th.

T. R. Durley, A.M.E.I.C., has been transferred to Montreal by the Canada Cement Company from Belleville, Ont., where he has been since 1935 at the Company's Plant No. 5. Since Mr. Durley's graduation from McGill University in 1928 he has been connected with the Canada Cement Company except for a few years spent with the General Electric Company at Schenectady and Philadelphia, and with the Canadian General Electric Company at Peterborough, Ont.

J. A. MacKenzie, A.M.E.I.C., division engineer, Trenton Division, Canadian Pacific Railways, has been promoted to the position of assistant engineer maintenance-of-way for eastern lines. He will be located at Toronto, Ont.

D. R. Smith, A.M.E.I.C., has been made Director of Works for the City of Saint John.

S. C. Carver, A.M.E.I.C., has been made assistant engineer, Public Works Department, Basutoland, South Africa. He has been in South Africa since March 1938, having been stationed at Mbabane, Swaziland, prior to his appointment at Maseru, Basutoland. He graduated from the University of British Columbia in 1929 and went to Glasgow, Scotland, where he was assistant designing engineer with Fleming Brothers, structural engineers.

David Hutchison, A.M.E.I.C., has been appointed manager of Mackenzie River Transport, Hudson Bay Company, and will be located in Winnipeg, Man. Prior to accepting this position he was construction superintendent of the Power Corporation of Canada, Montreal.

E. J. Davies, A.M.E.I.C., has accepted the position of principal of the Port Arthur Technical and Commercial High School, Port Arthur, Ont. He has been Director of Industrial Arts, Cornwall Collegiate Vocational School, Cornwall, Ont., for the past year.

W. U. Shaw, A.M.E.I.C., is now with the engineering division of the National Steel Car Corporation Limited, Malton, Ont. He was formerly chief engineer, Fairchild Aircraft Company, Longueuil, Que. Mr. Shaw is a graduate of Toronto University of the class of 1925.

William E. Ross, A.M.E.I.C., has been made manager of the apparatus sales department of the Canadian General Electric Company with headquarters at Toronto, Ont. Mr. Ross was formerly manager of the contract service department.

A. B. Sanborn, general manager and president of East Kootenay Power Company, has been elected president of the Northwestern Public Service Company.

Leo Hunt has recently been appointed lighting specialist of the Calgary Power Company.

Visitors to Headquarters

Leslie Gordon Jost, M.E.I.C., interrupted a nine thousand mile motor jaunt to visit The Institute in Montreal. He was on his way from Los Angeles to his old home at Guysboro, N.S., which he has not seen for twenty years. He has been in the structural steel business in Los Angeles for a great many years. He is enjoying the experience of looking up old friends and renewing acquaintanceships that have been neglected for years. His next points of call were Shawinigan Falls and Quebec. Address—8342 Kirkwood Drive, Los Angeles, Cal.

Councillor **R. A. Spencer**, A.M.E.I.C., Professor of Civil Engineering at the University of Saskatchewan, was in Montreal for the week of August 15th. He had conferences with the President and several councillors throughout the week and attended the Council meeting of August 19th, where the Saskatchewan agreement and other western topics were up for discussion. Montreal marks the easterly limit of his motor trip upon which he has been accompanied by Mrs. Spencer and his three children.

B. E. Bayne, A.M.E.I.C., councillor for Moncton, was in Montreal for the August council meeting, and spent Saturday morning at Headquarters discussing the branch programme for the coming season. He has some excellent ideas on this subject, which should be very valuable to the branch.

K. S. LeBaron, A.M.E.I.C., Councillor for the St. Maurice Valley Branch, was in Montreal on August 19th for the Council meeting.

Norman Marr, M.E.I.C., Chief Hydraulic Engineer, Dominion Water and Power Bureau, Department of Mines and Resources, Ottawa, dropped in on June 28th to talk about Institute affairs.

Robert F. Legget, M.Eng., A.M.E.I.C., recently appointed Assistant Professor of Civil Engineering at Toronto, has been in several times during the week of July 17th to consult the library. He was the luncheon guest of Councillor Fred Newell at the Mount Stephen Club on the 21st.

P. G. Gauthier, M.E.I.C., has been with the Ontario Paper Company Ltd. at Baie Comeau for two and a half years as townsite engineer. He recently returned to Montreal for his vacation, but will be back on the job again within a few weeks time.

Sidney Hogg, A.M.E.I.C., past chairman of the Saint John Branch, spent part of his vacation in Montreal which gave him an opportunity to drop in a few times at 2050 Mansfield Street and discuss Institute affairs. He is with the Saint John Drydock and Shipbuilding Co. Ltd.

A. Leslie Denton, Jr.E.I.C., was in Montreal for a few days in July. He has been with the Lamaque Mining Company, Limited, for five years where he is now instrumentman. Address—c/o Company, Bourlamaque, Que.

W. E. Weatherbie, Jr.E.I.C., was here on August 1st during his vacation. He is with the Department of Highways, N.S., and lives at Truro.

Recent Graduates in Engineering Additional List

Congratulations are in order to the following Associate Members, Juniors and Students who have completed their course.

Royal Military College

Prizes and Honours

Brown, M. C. Sutherland, Victoria, B.C.—Diploma; The Tommy Smart Cup.

Drury, Chipman Hazen, Montreal, Que.—Diploma; Honours; Sword of Honour for Conduct and Discipline; His Excellency The Governor-General's Silver Medal; Toronto Branch Trophy; First-Class Prize in Chemical Engineering; His Royal Highness The Prince of Wales Cup, and the Large Bexhill Cup.

Hyman, Ernest Roy, Winnipeg, Man.—Diploma; Honours; His Excellency The Governor-General's Gold Medal; First-Class Prize in Civil Engineering (including Mining).

Diplomas

Hall, Gordon Hudson, Peterborough, Ont.
Joyce, William Anderson, Kingston, Ont.
Lantier, Joseph Antoine Jacques Dunn, Kingston, Ont.
Mackenzie, Robert Kenneth, Kingston, Ont.
McNaughton, Andrew Robert Leslie, Ottawa, Ont.
Magee, Edward Desmond Boyd, Toronto, Ont.
Roy, Joseph Albert Maurice, Quebec, Que.
Spencer, George Hylton, Kingston, Ont.
Stephenson, John Gay, Windsor, Ont.
Thompstone, Robert Edward, Kingston, Ont.

ELECTIONS AND TRANSFERS

At the meeting of Council held on August 19th, 1938, the following elections and transfers were effected:

Member

RAYMENT, Arthur Charles, (Armstrong College), associate engineer, R. A. Rankin and Associates, Montreal, Que.

Associate Member

CONROD, Gerald Rhodes, B.Sc., (Dalhousie Univ.), wire and cable sales engr., Northern Electric Co. Ltd., Toronto, Ont.

Juniors

BARRETT, Michael Joseph, B.Eng. (Mech.), (N.S. Tech. Coll.), engrg. dept., Sun Life Assurance Company of Canada, Montreal, Que.

HORN James Gordon, B.Sc. (Elec.), (Univ. of Man.), student ap'tice, A. Reyrolle & Co., Hebburn-on-Tyne, England.

MITCHELL, David Alexander, B.A.Sc. (Elec.), (Univ. of Toronto), 29 St. Joseph Street, Toronto, Ont.

ROBINSON, Gordon Milford, B.A.Sc. (Civil), (Univ. of Toronto), 28 Scott St., Brampton, Ont.

SHERWOOD, Marvin Lorne, B.A.Sc. (Mech.), (Univ. of Toronto), district plant engr., The Barrett Co. Ltd., Montreal, Que.

Transferred from the class of Affiliate to that of Member

HARDING, Charles Percy, 69a St. Germain Blvd., St. Laurent, Que.

Transferred from the class of Student to that of Associate Member

INNES, Edward Patrick Nelles, B.Eng., (McGill Univ.), i/c engrg. dept., Canadian Canners Ltd., Hamilton, Ont.

Transferred from the class of Student to that of Junior

ARCHER, Maurice G., B.Eng. (Civil), (McGill Univ.), consltg. engr., Archer & Dufresne, Quebec, Que.

HAMILTON, William Garrison, B.Eng. (Mining), (McGill Univ.), Avon Gold Mines Ltd., Oldham, N.S.

PRESTON, William Walford, B.Sc. (Civil), (Queen's Univ.), struct'l. steel detailer, Hamilton Bridge Company, Hamilton, Ont.

ST. JACQUES, Gustave Fernand, B.A.Sc., C.E., (Ecole Polytechnique), Quebec Public Service Commn., Quebec, Que.

Students Admitted

BRANNEN, Arthur Douglas, B.Eng. (Civil), (N.S. Tech. Coll.), office engr., Engineering Service Co. Ltd., Halifax, N.S.

CONKLIN, Maurice William Murch, B.Eng. (Mech.), (Univ. of Sask.), junior engr., Algoma Steel Corporation, Sault Ste Marie, Ont.

CORBETT, Horace Kenneth, B.Sc. (Civil), (Univ. of N.B.), senior plant inspr., Milton Hersey Company, Fredericton, N.B.

MACKINNON, Donald Lauchlan, (Univ. of N.B.), asphalt paving inspr., Milton Hersey Company, Fredericton, N.B.

POLISKIN, Jacob, B.Sc. (Chem.), (Queen's Univ.), 691 George St., Sydney, N.S.

ADDITIONS TO THE LIBRARY

Proceedings, Transactions, etc.

American Standards Association: Year Book 1938.
Institution of Civil Engineers: List of Members, July 1938.

Reports, etc.

Canada Bureau of Mines: Investigations in Ore Dressing and Metallurgy, January to June, 1937.

Canada Mines and Geology Branch: Milling Plants in Canada, Pt. 1 Operators of Concentrating Mills Treating Metallic Ores.

Edison Electric Institute Electrical Equipment Committee, Apparatus and Design Division: Design of Switchhouses for Generating Stations and Transmission Substations.

Electrochemical Society: Anodic Behavior in Cyanide Copper Plating Baths; The Electrochemistry of Corrosion; A Theory of Cathodic Protection; The Effect of Pressure on the Passivity of Various Metals; Ethylene Diamine as an Ionizing Solvent; The Electrodeposition of Silver from Solutions of Silver Nitrate in the Presence of Addition Agents. (Preprints 74-1 to 74-6.)

India Forest Research Institute: Ascu—A Wood Preservative (Indian Forest Records, vol. 1, No. 6).

Institution of Civil Engineers: Kelvin Medal 1938, Report of the Proceedings at the Presentation on May 3rd, 1938.

International Joint Commission: Champlain Waterway; Richelieu River Remedial Works.

Ontario Department of Mines: Forty-Sixth Annual Report, 1937.

Ontario Hydro Electric Power Commission: List of Electrical Equipment, 4th ed. 1938.

U.S. Department of Commerce: List of Publications.

U.S. Department of the Interior: Geology and Fuel Resources of the Southern Part of the Oklahoma Coal Field, Pt. 3 Quinton-Scipio District; Preliminary Report on the Alunite Deposits of the Marysvale Region, Utah; Spirit Leveling in Vermont 1896 to 1935; Geophysical Abstracts 10, July-September 1937; Structure and Gas Possibilities of the Oriskany Sandstone in Steuben, Yates, and Parts of the Adjacent Counties New York. (Geological Survey Bulletin 874-C, 886-D, 888, 895-C, 899-A.

Technical Books, etc.

U.S. Works Progress Administration. **Bibliography of Aeronautics,** Pt. 2 Meteorology; Pt. 8 Autogiros, Pt. 9 Helicopters, Pt. 10 Cyclogiros, Gyroplanes; Pt. 12 Landing Gears; Pt. 13 Refueling in Flight, Pt. Tailless Airplanes, Pt. 15 Airplane Catapults, Pt. 16 Airplane Carriers; Vibration and Flutter of Aircraft Wings and Control Surfaces.

The Cracking Art in 1937. By G. Egloff, M. M. Doty and J. F. Jordan. Chicago, Universal Oil Products Co., 1938. 397 pp. 9 x 6 in., paper.

Direct-Current Machinery. By Thomas C. McFarland. Scranton, International Textbook Company, 1938. 439 pp., illus., diagrs. 5½ x 8½ in., lea., $4.00.

This book is primarily designed for use in courses on direct-current machinery by students majoring in electrical engineering.

Electrical Engineering Practice, Vol. 1. By J. W. Meares and R. E. Neale. 5th ed. London, Chapman and Hall, 1938. 780 pp., illus., plates, tab. 9 x 5½ in., cloth, 25s.

A practical treatise for electrical, civil, and mechanical engineers, which is the first of the three volumes in this series.

The Elements of Ferrous Metallurgy. By J. L. Rosenholtz and J. F. Oesterle. 2nd ed. New York, Wiley, 1938. 258 pp., illus., diagrs. 9 x 6 in., cloth, $3.00.

Northern Trails. By S. C. Ells, 263 Adelaide St. W., Toronto, Industrial and Educational Publishing Co. Ltd., 1938. 250 pp., illus., $2.00 (post paid). Available in October 1938.

Reports Wanted

Any members wishing to dispose of the following publications at $5.00 a copy should get in touch with the General Secretary.

International Waterways Commission, Compiled Reports, 1905-1913.

International Waterways Commission, Report on the Regulation of Lake Erie, 1910.

The Principles of **Motor Fuel Preparation and Application**, Vol. 1. By Alfred W. Nash and Donald A. Howes. 2nd ed. New York, Wiley, 1938, 628 pp., illus., plates, diagrs., tab. 10 x 6 in., cloth, $9.50.

Structural Design. By Carlton T. Bishop. New York, Wiley, 1938. 254 pp., illus. 9 x 6 in., cloth, $3.50.

Transformer Engineering. By L. F. Blume, G. Camilli, A. Boyajian, V. M. Montsinger. N.Y. Wiley, 1938. 496 pp., diagrs., charts. 9 x 6 in., cloth, $5.00.

Welding Handbook, 1938. New York, American Welding Society, 1938. 1,200 pp., illus., diagrs., tab. 9¼ x 6 in., cloth, $5.00 (to members), $6.00 (to non-members in U.S.A.), $6.50 (to non-members elsewhere).

BOOK REVIEW

The Engineering Catalogue

The 1938 edition of The Engineering Catalogue (formerly issued as the E.I.C. Engineering Catalogue) is now being distributed, and copies are available as before to any members of The Institute whose work involves the specifying or purchasing of equipment and materials. Requests for copies may be sent to the publisher or to the General Secretary of The Institute.

It will be recalled that arrangements were made earlier this year whereby the publication of the Catalogue would be transferred to N. E. D. Sheppard, A.M.E.I.C., with the assistance of the same organization as was previously responsible for its production. In doing this, Council felt confident that the standard of production which had characterized the Catalogue in the past would be maintained, and this confidence seems to have been fully justified by the volume which has recently been completed. Not only is the product of the same excellent quality, but there is a marked improvement in the copy supplied by advertisers and in the variety of products illustrated and described.

For the past five years the Catalogue has provided a valuable service to engineers and others engaged in related work throughout Canada. The convenient arrangement of its contents and the dependability of its data have earned for it undisputed recognition as a reference book for information about equipment and materials in this country.

Trade Literature*

Earth Moving.—Actual job data and photographs make up this booklet just released on mining subjects by R. G. LeTourneau Inc., Peoria, Ill.

Laboratory Pulverizing Mill.—Combustion Engineering Corporation, Ltd. (Office: Dominion Square Building, Montreal) have issued a 4-page illustrated bulletin announcing the new "Raymond Laboratory Mill," which has been recently developed and placed on the market by their Raymond Pulverizer Division. The new mill is of extremely small capacity and is designed for the laboratory pulverizing of non-abrasive products.

Switchgear.—Bepco Canada Limited (Office: 1050 Mountain St., Montreal) have published a 6-page illustrated leaflet, No. f. 985, describing Crompton Tested Switchgear.

Industrial and Scientific Instruments.—Frederick C. Baker and Co. (Office: 229 Yonge St., Toronto) have issued an 8-page condensed catalogue illustrating and describing the industrial and scientific instruments sold by them.

Oil Seal.—The Garlock Packing Co. of Canada Ltd. (Office: 620 Cathcart St., Montreal) have available for distribution an attractively prepared 16-page booklet, "The Garlock Split-Klozure," describing this new patented Oil Seal. As indicated by its name, the Split-Klozure is split, or cut open. It is applied by placing it around the shaft in somewhat the same manner as an ordinary packing ring, instead of sliding it over the end of the shaft as is necessary with solid oil seals of the conventional type. The booklet deals with the design, usage, installation, and sizes, and contains several pages of drawings showing the application of the Split-Klozure.

Nickel Cast Iron Data.—New data sheets, designed to assist the engineer or designer in the preparation of specifications for Grey Cast Iron, have been issued by International Nickel Co. Ltd. (Office: 25 King St. W., Toronto), and provide an easy guide to the selection of the proper castings for a wide range of applications. A.S.T.M. tables are given with examples of their use.

In an introductory note, it is pointed out that while strength is essential and high strength can be secured by alloys, the wider combination of properties available through their use is of even greater value in many cases. Machinability, wearing properties, density or freedom from porosity may be more important than tensile strength.

Instruments for Remote Control.—In a new bulletin, No. 506, published recently by The Bristol Co. of Canada Ltd. (Office: 64 Princess St., Toronto), there is a brief description of Bristol's Metameter System for Telemetering and Remote Automatic Control. This system is illustrated by photographs and chart records which give a few of the interesting facts regarding an installation of these instruments for the Remote Automatic Control of Gas Distribution Pressure. The instruments used, automatically maintain the pressure in a gas distribution system at a constant value, regardless of load variation.

Large Induction Motors.—An interesting illustrated bulletin, No. 1750, is being distributed by the English Electric Co. of Canada Ltd. (Office: St. Catharines, Ont.), describing in detail the company's larger induction motors, ranging in sizes from 75 hp. to 1,000 hp. in three different types, open, protected, and large fabricated frames. Constructional details are clearly illustrated by close-up views and cross-sections and particular emphasis is given to large wound rotor motors for hoist service.

Practical Low-Cost Homes.—An 8-page booklet entitled "Practical Low-Cost Homes" has been issued by Gypsum, Lime and Alabastine, Canada, Ltd. (Office: 50 Maitland St., Toronto). In it are described and illustrated the design and construction of an inexpensive home built at Beachville, Ont. for the company's workmen. This actual record of construction cost and the low maintenance expense should prove of interest to many who have to deal with this problem.

Millivoltmeter Pyrometers.—A complete line of Millivoltmeter Pyrometers is described in a new bulletin, No. 486, recently published by the Bristol Co. of Canada (Office: 64 Princess St., Toronto). In this publication, 12 pages of useful information are given regarding the construction and operation of Bristol's Millivoltmeter Pyrometers in all models—a type of Pyrometer built by this instrument manufacturer for some 40 years. Data concerning the available ranges and drilling dimensions are also included. Several scales are reproduced in actual size. This line of Millivoltmeter Pyrometers includes: Indicator Controllers, with enclosed mercury contacts or solid metal-to-metal contacts; single point indicators and multiple-point indicators with rotary switch. These operate with standard thermocouples or Bristol's Ardometer Radioation Pyrometer Unit.

Steel Scaffold.—Concrete and Building Specialties, Ltd. (Office: 1101 Yonge St., Toronto) are distributing a 12-page illustrated booklet describing "Safeway Steel Scaffold."

Pipe.—A small but interesting 16-page booklet entitled "The Story of a Pipe" has been published by Doulton and Co., Ltd., Royal Doulton Potteries, Lambeth, London, S.E.I. The "story" outlines the many processes necessary before raw clay is converted into glazed stoneware pipes. Messrs Doulton and Co. are represented in Canada by C. Kirkland McLeod, Ltd., Keefer Bldg., Montreal.

Less Water Yet More Placeability.—The Master Builders Co. Ltd. (Office: Toronto) have recently issued a 24-page book dealing with "Pozzolith," which they state is "a combination of a ferric alumino silicate with early effective pozzolanic properties and a cement plasticizing agent," and which they announce is now available in dry form for the first time.

Salt.—"Salt Stabilization, Principles and Practice" is the title of a new publication of the Canadian Industries Ltd., Montreal. It consists of 24 pages and in a well illustrated text deals with the important place that salt-soil stabilization is now taking in modern highway construction programmes.

Preventing Weld Spatter from Adhering to Metals.—A new material (Glyptal No. 1294) has been announced by Canadian General Electric Co. Limited (Office: Beaver Hall Hill, Montreal) for the prevention of the adhesion of weld spatter to metals which are to be welded. This material, which can be used without harm on any metal surface, including polished stainless steel, will not produce carbon to make the weld hard or brittle, nor will it reduce ductility. Likewise, it will not give off smoke to fog up the atmosphere and it will not form gas pockets or cause the weld to be porous.

Calrod Heating Units.—A new high-speed, high-heat Calrod heating unit has been developed by General Electric engineers for industrial applications that require temperatures as high as 1,500 deg. F. Among the uses of the product are applications in high-temperature air heating, industrial ovens with air temperatures up to 1,000 deg. F., hotplates, and various metal surfaces. The units are manufactured at the Ward Street Works of Canadian General Electric.

*Copies of these publications may be obtained by writing to the companies mentioned.

Meetings

American Society of Civil Engineers—Fall Meeting, October 12th-14th, 1938, at Rochester, N.Y.

American Society of Mechanical Engineers—Fall Meeting, October 5th, 6th and 7th, at Provience, R.I.

Canadian Chamber of Commerce—1938 Convention, September 28th-30th and October 1st, at the Seigniory Club, Montebello, P.Q.

The Canadian Institute of Mining and Metallurgy—Annual Western Meeting, November 9th, 10th, 11th, at Vancouver. H. Mortimer Lamb, Vancouver Secretary, British Columbia Division.

Dix-Huitième Congrès de Chimie Industrielle — Nancy, France, September 22nd to October 2nd.

The Engineering Institute of Canada—Annual General and Professional Meeting, February 20th-22nd, 1939, at Ottawa.

Fifth International Congress for Applied Mechanics—September 12th-16th, Harvard University and the Massachusetts Institute of Technology, Cambridge, Mass.

The Seventh **International Management Conference**—September 19th-23rd, 1938, at Washington, D.C.

The Iron and Steel Institute, and The Institute of Metals (London, England), Autumn Meeting, September 22nd Quebec; 23rd Shawinigan Falls; 24th and 25th Montreal; 26th Ottawa; 28th and 29th Toronto. Canadian Institute of Mining and Metallurgy are acting as hosts for Canadian visit.

Additional information about any of these functions may be secured from the General Secretary.

BOOK NOTES

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet, the books are not in The Institute Library, but inquiries will be welcomed at Headquarters, or may be sent direct to the publishers:

Aircraft Year Book for 1938. Ed. by H. Mingos. 20 ed. New York, Aeronautical Chamber of Commerce of America, 1938. 518 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $5.00.

This annual provides a record of developments in aviation during the past year, both at home and abroad. The work of the army and navy, the activities of the various Federal agencies and commercial firms are reviewed. Chapters are devoted to notable flights, to air lines, private flying, airports, to novelties and other fields of interest. The book includes tables of aircraft specifications, descriptions of aircraft and engine designs, a chronology of events and records, an aeronautical directory and statistics of the industry.

Business Correspondence and Office Management. By E. A. Duddy, L. E. Frailey and R. V. Cradit. Chicago, American Technical Society, 1938. 234 pp., illus., charts, tables, 9 x 6 in., cloth, $1.75.

The business letter, its importance, analysis of problems, letter form, and the various kinds of letters constitute the first section of this book. The second is devoted to the modern scientific technique of office management, including organization principles, filing methods, business machines, and other miscellaneous office equipment.

Civil Engineering To-Day. By E. Cressy. London and New York, Oxford University Press, 1938. 158 pp., illus., diagrs., maps, 9 x 6 in., cloth, $1.50.

This small volume provides a popular account of some outstanding modern bridges, tunnels, waterways, harbors, dams, power plants, water supplies, irrigation projects, etc., with brief outlines of the history of progress in these works. Excellent photographs add to the attractiveness of the book.

Elementary Practical Mechanics. By J. M. Jameson and C. W. Banks. 4 ed., New York, John Wiley & Sons, 1938. 363 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $2.75.

In revising this work, the editor has made a number of changes designed to make the arrangement more convenient and to bring the text up to date. A new chapter on heat has been added and the chapters on motion and on work and energy have been expanded. Numerous additions and many new problems are included throughout. The book is designed primarily for elementary technical and manual training schools, and as an introductory course in engineering colleges.

Elementary Practical Physics. By N. H. Black and H. N. Davis. New York, Macmillan Co., 1938. 710 pp., illus., diagrs., charts, tables, 9 x 5 in., cloth, $2.00.

A textbook for high-school students by two authorities in the field of physics. The subject is presented thoroughly, in simple language, and the significance of each principle is illustrated by applying it to familiar applications. Numerous diagrams and examples are included, and a large supply of problems and questions.

The Evolution of Railways. By C. E. Lee. London, Railway Gazette, 1937. 64 pp., illus., diagrs., 9 x 6 in., cloth, 2s. 6d.

A history of permanent way from its earliest evidences in antiquity to the late 19th century, with particular reference to its development for the British mining and metallurgical industries.

Great Britain. Dept. of Scientific and Industrial Research. **Building Research Board Report** for the Year 1937. London, His Majesty's Stationery Office, 1938. 172 pp., illus., diagrs., charts, tables, 10 x 6 in., paper, 3s. 6d. [obtainable from British Library of Information, 270 Madison Ave., New York, $1.10].

This report includes a very complete summary of the investigations carried on during the year upon a wide variety of subjects connected with building. The topics discussed include Materials, the Structures and strength of materials, and the Efficiency of buildings from the point of view of the user. A list of the reports and papers emanating from the Board and its staff during the year is included.

Great Britain. Mines Dept. **Coal Mines Act, 1911. General Regulations** as to the **Installation and Use of Electricity** with Explanatory Notes. London, His Majesty's Stationery Office, 1938. 59 pp., diagrs., 10 x 6 in., paper, 1s. [obtainable from British Library of Information, 270 Madison Ave., New York, $0.35].

Complete instructions as to the kind, care and treatment, installation, and application of materials and equipment for electrical purposes, as set forth under the "Coal Mines Act." Various special contingencies are covered in appendices, and the style of type used indicates whether the particular regulation is applicable above or below ground or both.

Illustrierte Technische Wörterbucher, Deutsch-Englisch-Französisch-Italienisch-Spanisch-Russisch. Bd. 1: Maschinenelemente —Machine Elements—Éléments des Machines—Elementi di Macchine —Organos de Mequinas—Detali Mashin. Ed. by W. Eppner. 3 ed. rev. and enl., Berlin, VDI-Verlag, 1937. 438 pp., diagrs., 10 x 7 in., cloth, 36 rm. (27 rm. in U.S.A.).

This dictionary provides definitions of words and phrases relating to the elements of machines. About five thousand terms are included, with the synonyms in English, French, German, Spanish, Italian and Russian. Illustrations are used to clarify meanings. This edition has been entirely rewritten, is greatly enlarged and is improved in format. It is an invaluable addition to the series in which it is included.

An Introductory Course in **Physical Chemistry.** By W. H. Rodebush and E. K. Rodebush. 2 ed., New York, D. Van Nostrand Co., 1938. 468 pp., illus., diagrs., charts, tables, 9 x 5 in., cloth, $3.75.

This book provides a one-year course, intended for college students who have had the usual training in chemistry, a course in college physics and some practice in the use of the calculus. The text aims to present fundamental principles clearly and precisely, and at the same time to stimulate interest in the subject. This new edition has been thoroughly revised.

La **Maison Insonore.** By V. Gavronsky, T. Kahan and M. Blumenthal. Paris, Dunod, 1938. 119 pp., illus., diagrs., charts, tables, 9 x 6 in., paper, 38 frs.

This volume is a translation of "Das laermfreie Wohnhaus," issued by the Anti-Noise Technical Commission of the Society of German Engineers. The book affords a popular, yet accurate, description of the effect of noise upon human beings, of methods of measuring noise and of practical methods of insulating buildings, machines, etc.

Radio, a Study of First Principles for Schools, Evening Classes and Home Study. By E. E. Burns. 3 ed., New York, D. Van Nostrand Co., 1938. 293 pp., illus., diagrs., charts, tables, 8 x 6 in., cloth, $2.00.

This book is based upon material used in teaching boys of sixteen to eighteen years of age. It aims to present the fundamental principles of electricity as applied in radio as simply and clearly as possible, as a basis for further theoretical and practical study. The new edition has been thoroughly revised. Obsolete matter has been replaced by new developments, including a chapter on television.

Solvents. A Series of Monographs on Applied Chemistry, Vol. 4. By T. H. Durrans, ed. by E. H. Tripp. 4th rev. and enl. ed., New York, D. Van Nostrand Co., 1938. 238 pp., diagrs., tables, cloth, $5.00.

This monograph is concerned with the technical application of solvents, especially in connection with the cellulose-lacquer industry, and attempts to present clearly and concisely the great mass of information scattered through the literature. Part one deals broadly and simply with such fundamentals as solvent action and power, plasticizing solvents, solvent balance, viscosity, vapor pressure and inflammability. Part two deals comprehensively with individual solvents. A list of trade names is appended.

Strength of Materials. By N. C. Riggs and M. M. Frocht. New York, Ronald Press Co., 1938. 432 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $3.75.

This book is intended for use in a first course in the subject and is designed for students with a knowledge of the calculus and the fundamentals of statics. Unusual features are a brief treatment of the theory and application of photoelasticity to the study of stresses, and the inclusion of curves giving the factors of stress concentration. The authors have endeavored to produce a unified, teachable text which stresses fundamental principles and illustrates the applications of the theory by numerous practical problems.

Symposium on Plastics. Rochester Regional Meeting, March 9, 1938. Phila., Pa., American Society for Testing Materials. 51 pp., illus., diagrs., charts, tables, 9 x 6 in., paper, $0.75; to members, $0.50.

BRANCH NEWS

Sault Ste. Marie Branch

N. C. Cowie, Jr.E.I.C., Secretary-Treasurer.

The young engineer and his needs, and the status of the engineering profession in Canada were discussed by J. B. Challies, M.E.I.C., President of The Engineering Institute of Canada, while addressing the members of the Sault Ste. Marie Branch of The Engineering Institute at a dinner meeting held at the Sault Ste. Marie Country Club on Wednesday, July 20th, 1938.

That engineers and the engineering profession had not advanced as it should was an opinion that has been expressed by some, Mr. Challies said, but he believed that good progress was and is being made by the profession in Canada. To illustrate this the speaker said that at Confederation in 1867 there was no engineering college or no professional faculty at any school then in existence in Canada. Today, however, there are 11 recognized engineering faculties in Canada and 3,517 students studying engineering courses. There was no professional engineering association of any kind in Canada 53 years ago. This was, the speaker said, because there were few if any professional engineers in Canada at that time. Last year The Engineering Institute of Canada celebrated the Semicentennial of its founding as the Canadian Society of Civil Engineers and was now honoured by other engineering and associated bodies throughout the world. In 1903, when the speaker entered the civil service, engineers filled jobs such as clerks and many outstanding engineering positions were not held by qualified engineers but by men who had little or no recognized engineering standing. At that time, Mr. Challies said, the engineer was not recognized in the federal civil service.

The credit for changing this situation belonged to Sir Wilfrid Laurier, the speaker said. He created the Civil Service Commission and set up the principle that men were to be advanced on merit and in so doing recognition of merit was to be made, university men were to be recruited and that the wishes of the politicians were to be ignored. One of the first steps of the Civil Service Commission was to recognize engineering as a profession and today no person can obtain an engineering position under the government unless he is fully qualified to hold it.

Fifteen years ago there was no professional engineers' association, and the founding of these associations in the various provinces was instituted and nurtured to a great extent by The Engineering Institute of Canada. Today these associations are endeavouring to protect the public from the unqualified and the charlatan as are the Bar and Medical Societies, for those other professions.

To summarize his remarks Mr. Challies expressed the opinion that engineering as a profession has not lagged behind the needs of the Dominion.

Speaking of The Engineering Institute of Canada, Mr. Challies said that this body was never in a better financial position. It had experienced growing pains, he said, but that was in itself evidence that The Institute was very much alive and expanding as the needs of the profession required it.

One of the real problems now confronting the engineering profession in Canada, and one that The Engineering Institute of Canada now had under consideration, was the needs of the young engineers and the young undergraduate engineers. In the past there has been a tendency to neglect this phase of the work, Mr. Challies said, but happily that day is rapidly passing. It is the aim of The Institute now to contact the younger men and by the co-operation of the older engineers to give them the advice, counsel and aid in their work that would be of very great assistance to them during the years following the completion of their university studies.

In order to assist in this work it was his opinion, Mr. Challies said, that engineers should first associate themselves with the professional engineers association and later affiliate with The Engineering Institute of Canada as they progressed in their profession. Membership in the elder parent engineering societies of Great Britain, the speaker felt, would be of value to the older members of the profession.

Mr. Challies was introduced to the meeting by John L. Lang, M.E.I.C., Councillor of the Sault Branch. The appointment of Mr. Challies as President of The Engineering Institute of Canada was no departure from the precedent of selecting outstanding men in their fields to lead The Institute, Mr. Lang said. Mr. Challies has had a long and distinguished career, first in the government service and later with the Shawinigan Water and Power Company of Montreal. He has built for himself a record as an outstanding engineer not only in Canada but throughout the world. Mr. Lang also mentioned the fact that in recognition of his accomplishments the University of Toronto would, this fall, confer on Mr. Challies the degree of Doctor of Engineering.

J. S. Macleod, A.M.E.I.C., chairman of the Sault Ste. Marie Branch, presided at the meeting. It was at his request that Mr. Lang introduced the speaker, and following Mr. Challies' address, Mr. Macleod had the pleasure of extending to the speaker the thanks of the meeting as expressed on a motion of Wm. Seymour, M.E.I.C., seconded by F. Smallwood, M.E.I.C.

The general meeting concluded a memorable day for the Sault Ste. Marie Branch of The Institute. Mr. Challies entertained the executive of the Branch at luncheon at noon. At this gathering many problems now before The Institute were explained and described by Mr. Challies. The remainder of Mr. Challies' visit to Sault Ste. Marie was spent in renewing and making acquaintance among the members of the Branch.

Saguenay Branch

Charles Miller, A.M.E.I.C., Secretary-Treasurer.
J. W. Ward, A.M.E.I.C., Branch News Editor.

The regular monthly meeting of the Saguenay Branch was held at the main office of the Aluminum Company of Canada, on June 22nd, 1938. Approximately 40 members and guests were present.

Mr. R. H. White, Manager and Vice-President of the Canadian Abrasives Company, Ltd., addressed the meeting on "Manufacture of Electric Furnace Abrasives." He gave an interesting history of the industry and described the development of the modern furnace.

Mr. White described the plant at Arvida. After the meeting an interesting discussion took place. Mr. Whitaker moved a vote of thanks.

A meeting of the executive of the Saguenay Branch was held immediately after the general meeting on June 22nd. The following members were present: Messrs. M. G. Saunders, Vice-Chairman; J. S. Fisher, M.E.I.C.; R. Rimmer, A.M.E.I.C.; A. C. Johnston, A.M.E.I.C.; Charles Miller, Secretary-Treasurer.

The minutes of the last executive meeting were read by the Secretary. Mr. Johnston moved and Mr. Rimmer seconded the motion that the minutes be adopted as read.

Mr. Fisher, chairman of the Annual Meeting committee, reported that they advised that the annual meeting be held in Arvida. The tentative date set was July 13th. The programme suggested was:—

2.00 p.m. Tour through plants of Aluminum Company and Canadian Abrasive Company.
Golf tournament.
7.30 p.m. Dinner at Staff House.

In line with Mr. Lawton's suggestion about the centenary celebrations in the Saguenay district, it was decided to have some of the older engineers in the district give a talk on early engineering in the Saguenay. The names of Messrs. Pelletier, Lavoie, Grenon and LaMothe were suggested.

The annual meeting of the Saguenay Branch was held at Arvida during the afternoon and evening of July 13th, 1938.

After a short business meeting and a highly instructive tour of the extensive additions to the Aluminum Company of Canada Ltd. works and the new plant of the Abrasive Company of Canada, some thirty-five members adjourned to the Saguenay Country Club. Golf and appropriate refreshments were provided.

Some forty members sat down to a most enjoyable dinner, the Branch Chairman, F. L. Lawton, M.E.I.C., presiding. Guests at the head table included Messrs R. E. Powell and O. M. Montgomery, President and Vice-President respectively of the Aluminum Company of Canada, Ltd., R. H. White, Vice-President and General Manager of the Abrasive Company of Canada, McNeely DuBose, General Superintendent of the Saguenay Power Company, and Major Flynn, General Superintendent of Price Bros. Company, Kenogami.

The toast "Our Guests" was proposed by James Shanly in characteristic style, while Major Flynn proposed "The Engineering Profession" in his own inimitable way.

This being the one hundredth year after the first settlers arrived in Grande Baie, the Chairman sketched briefly the early engineering developments in the "Kingdom of the Saguenay." G. F. Layne, A.M.E.I.C., one of the first branch chairmen very ably portrayed the part played by the "House of Price" in developing the paper industry. S. J. Fisher, M.E.I.C., dealt with the engineering problems met with in designing the very efficient and economical newsprint mill of the Lake St. John Power and Paper Company at Dolbeau.

A. W. Whitaker Jr., M.E.I.C., after remarking aluminum was discovered about the same time as the Saguenay was opened to development by the arrival of the first settlers, proceeded to discuss the engineering aspects of the Arvida works and the recent additions. Mr. R. H. White referred to the great promise the Saguenay held forth for the future, and to the need for the United States and Canada to work for peace and security in the world. Mr. McNeely DuBose, in telling of the early developments in hydro-electric power in the Saguenay, noted the first electric power for domestic use became available about 1895.

After paying tribute to Sir William Price as the "Father of Industrial Development" in the Saguenay, Mr. R. E. Powell very ably drew attention to the struggle between totalitarian and democratic states, and the necessity for the engineering profession, especially the younger men, to take a more definite interest in foreign trade and the political problems of our country.

The scrutineers' report on the election of officers was then given: Chairman, M. G. Saunders, A.M.E.I.C.; Vice-Chairman, Adam Cunningham, A.M.E.I.C.; Sec.-Treasurer, F. T. Boutilier, A.M.E.I.C.; Executive Committee, F. L. Lawton, M.E.I.C.; R. H. Rimmer, A.M.E.I.C.; A. B. Sinclair, A.M.E.I.C.; G. F. Layne, A.M.E.I.C.; Ex-Officio, A. C. Johnston, A.M.E.I.C.

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted after a lapse of one month, upon request.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

Vacancies

ROYAL CANADIAN AIR FORCE

The following information has been sent to The Institute by the Department of National Defence "Air Force" which will be interesting to members who have any idea of following a career in the Royal Air Force or the Royal Canadian Air Force. A supply of pamphlets outlining the conditions of eligibility, method of selection, etc., together with application forms is at Headquarters for distribution to members.

There are a number of vacancies for appointments to Permanent General List Commissions in the Royal Canadian Air Force and one vacancy for appointment to a Permanent Commission in the General Duties Branch of the Royal Air Force.

The next Ab Initio Flying Training Course for candidates selected for Permanent General List Commissions in the Royal Canadian Air Force and in the General Duties Branch of the Royal Air Force will commence on November 1st, 1938, at R.C.A.F. Station, Trenton, Ont.

Candidates should be directed to submit their applications to the District Officer Commanding the Military District in which they are resident, prior to October 1st, 1938. Such applications should be accompanied by a Birth certificate, two certificates of moral character, and proof of graduation from the Royal Military College or University.

Situations Wanted

ENGINEER, A.M.E.I.C., Combustion specialist heat balance. Steam, Mechanical. Refrigeration. Office routine. Correspondence. Plant layout. Apply to Box No. 5-W.

ELECTRICAL ENGINEER, JR.E.I.C., B.SC.; age 31; at present employed, desires change in location. Experience includes; three summers experience in power conduit construction; two years in telephone engineering; four years experience in radio, both development engineering and production; two and one half years in a paper mill on electrical maintenance, with a short time in the cost accounting and draughting departments. Would be interested primarily in electrical maintenance. Apply to Box 12-W.

PAPER MILL ENGINEER: B.A., B.A.SC. Married. Age 34. A.M.E.I.C. Ten years experience in paper mill costs, maintenance, design and construction. Now employed as cost engineer in Southern States. Hard worker with excellent references. Available immediately. Apply to Box No. 150-W.

SALES ENGINEER REPRESENTATIVE. Mechanical graduate with fifteen years experience in Eastern Canada in sales and service of mechanical equipment; full details upon request to Box No. 161-W.

MECHANICAL ENGINEER, JR.E.I.C., with thorough training in England and wide experience for past eight and a half years in Canada, is seeking a permanent position as mechanical engineer in an industrial plant. Has had varied experience in mechanical engineering, heating, ventilating and power plant equipment. Excellent references. Apply to Box No. 270-W.

ENGINEER-DRAUGHTSMAN, experienced in design of machines for widely varied purposes and arrangement of motor drives. Accustomed to layout of small mill buildings, steel and timber. Good references. Present location Montreal. Apply to Box No. 329-W.

CIVIL ENGINEER, M.A.SC., A.M.E.I.C. eight years survey and municipal engineering experience, and three years draughting, detailing steel, concrete, and timber structures. Apply to Box No. 467-W.

PAPER MILL ENGINEER. If you are willing to pay around $5,000 per year for the services of an engineer, age 36, with twelve years experience in paper mill design, construction and operation, apply to Box No. 482-W.

CIVIL ENGINEER, B.SC. (McGill '20), A.M.E.I.C. Married. Twelve years experience in pulp and paper mill design, and six years general construction. Available immediately. Location immaterial. Apply to Box No. 547-W.

Situations Wanted

CIVIL ENGINEER, B.A.SC., A.M.E.I.C. Married. Experienced in engineering and architechtural design and in supervision, office management, etc., wants to round out experience in the contracting field. Ten years experience since graduation. Present location Toronto. Apply to Box No. 576-W.

ELECTRICAL ENGINEER, B.SC. E.E., Age 39. Married. Seven years experience in operation, maintenance and construction of hydro-electric plants, and sub-stations. Five years maintenance and installation of pulp and paper mill electric equipment. Reliable and sober, with ability to handle men. Best references. Any location, at once. Apply to Box No. 636-W.

ELECTRICAL AND CIVIL ENGINEER, B.SC. Elec. '29, B.SC. Civil '33. JR.E.I.C. Age 32. Experience includes four months with Can. Gen. Elec. Co., approximately three years in engineering office of large electrical manufacturing company in Montreal, the last six months of which were spent as commercial engineer, also experience in surveying and highway work. Year and a half employed in electrical repair. Best of references. Apply to Box No. 693-W.

CIVIL ENGINEER, B.A.SC. (Toronto '27), age 34, married. Five years railway and construction work as building inspector and instrumentman. Level engineer and on construction of a long timber flume for a pulp and paper mill. Field engineer for a sulphite company, in charge of the following mill buildings, acid, digester, blow pit, barker room, chip storage and acid towers. Available immediately. Apply to Box No. 714-W

ELECTRICAL ENGINEER, B.SC. '31 (U.N.B.), JR.E.I.C. Age 30 years. Single. Experience in electrical wiring, construction of concrete wharves, inspection of piling, rip rap, concrete reinforcing, forms, and dredging. Also junior engineer. Available at once. Apply to Box No. 722-W.

CIVIL ENGINEER, B.SC., M.SC., P.P.E.; Lieut. C.E., R.O. Sixteen years municipal, highway and construction. Five years overseas. Married. Read, write and talk French. Will go anywhere. Apply to Box No. 737-W.

MECHANICAL ENGINEER, JR.E.I.C. Technical Graduate. Bilingual. Married. Experience includes five years with firm of consulting engineers, design of steam boiler plants, mechanical equipment of buildings, heating, ventilating, air conditioning, plumbing, writing specifications, etc. Six years with large company on sales and design of power plant, steam specialties and heating equipment. Available on short notice. Apply to Box No. 850-W.

CONSTRUCTION ENGINEER, Grad. Toronto '07. Experience as resident engineer and superintendent on railroad, municipal, hydro-electric and industrial construction. Intimate with organizing, layout, survey, estimates and costs. Available immediately. Apply to Box No. 886-W.

CIVIL ENGINEER, B.SC. '29, JR.E.I.C., R.P.E.M. Age 31. Married. Experience includes railway and highway surveys and construction, land and mineral claim surveys, 4 years draughting, structural and hydraulic design, preparation of plans and estimates for hydro-electric development, sewage disposal project, water treatment plant, subway construction, buildings, etc. Experienced in reinforced concrete design including statically indeterminate frames. Also capable of preparing designs in steel and timber Desire permanent employment, preferably in structural design. Available immediately. Apply to Box No. 1023-W.

ELECTRICAL ENGINEER, B.SC. '29, age 30. Single. Eight and a half years experience on maintenance, on construction, floorman and operator on hydro-electric system. Desires construction, service, sales or research work. Any location. Excellent references. Apply to Box No. 1062-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 41. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experience in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

Situations Wanted

ELECTRICAL ENGINEER, B.SC. '28. Two years student apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660-W.

TECHNICALLY TRAINED EXECUTIVE. General experience administrative, organization and management in business and industrial fields, including; business, plant, property and estate management; plant maintenance, modernization, production and personnel; economic studies, company reorganizations and amalgamations, valuations; railroad, highway, hydro, pulp, newsprint, housing, industrial surveys, investigations and construction; B.Sc. degree in engineering, age 49, married, Canadian. Apply to Box No. 1175-W.

CHEMICAL ENGINEER, grad. McGill '34, experienced in meter repairs, control work; and also chemical laboratory experience. Apply to Box No. 1222-W.

CIVIL ENGINEER, B.A.SC. (Toronto '33), S.E.I.C., age 27. Married. Five years experience includes highway surveys, bituminous and concrete paving, steel and reinforced concrete building construction, instrument work, draughting, cost accounting and estimating and some experience as foreman. Available immediately. Apply to Box No. 1265-W.

FIELD ENGINEER AND DRAUGHTSMAN, A.M.E.I.C. Age 36. Married. Fifteen years experience in civil engineering, general draughting and instrument work. Experience covers office and layout work on construction of sewers, water mains, gas mains, (6" to 30" dia.) and transmission line structures; topographic and stadia surveys. Draughting covers general civil, reinforced concrete and steel design, mechanical detailing and arrangements, and mapping. Present location Montreal, but willing to locate anywhere. Available at once. Apply to Box No. 1326-W.

ENGINEER SUPERINTENDENT, A.M.E.I.C., R.P.E., Que. and Atla. Age 47. Twenty years experience as engineer and superintendent in charge of hydro-electric, industrial, railroad, and irrigation construction. Specialized in rock excavation and suction dredging. Intimate knowledge of costs, estimating and organizing. Available immediately. Apply to Box No. 1411-W.

CIVIL ENGINEER, graduate 1927, age 34 years, desires position as town engineer. Eight years municipal experience. Location immaterial. Apply to Box No. 1628-W.

CIVIL AND ELECTRICAL ENGINEER, JR.E.I.C. (Univ. of Man.). Married. Age 25. Good draughtsman. Four months draughting, one year instrumentman on highway location and construction, inspection and miscellaneous surveying and estimating. Six months as field engineer on pulp and paper mill construction. Prefer electrical or structural design. Available at once. Apply to Box No. 1633-W.

ELECTRICAL ENGINEER, B.SC. E.E. (Univ. of Man. '37). Age 24. Single. Experience in highway construction as inspector. Also experience in sales work and petroleum refining. Available on short notice. Apply to Box No. 1703-W.

CIVIL ENGINEER, B.SC. in C.E. '34. S.E.I.C. Age 27. Five years experience, including harbour construction, highway paving, one and a half years paper mill construction, instrument work, draughting, estimating, interested in design. Available on short notice. Apply to Box No. 1737-W.

CIVIL ENGINEER, B.A.SC. '33. O.L.S. Age 27. Married. One year and a half in charge of power plant construction. Four summers on land surveys and one summer on mine survey work. Also experience in draughting, electrical wiring, and highway engineering. Apply to Box No. 1757-W.

ELECTRICAL ENGINEER, B.E. in E.E., N.S. Tech. Coll. Single. Age 25. Experience in sales, electrical installation, and construction work. Available immediately. Will go anywhere. Apply to Box No. 1758-W.

CHEMICAL ENGINEER, graduate, Toronto '31. Seven years experience in paper mill, meter maintenance, control work and chemical laboratory. Speaking French and English. Location immaterial. Available at once. Apply to Box No. 1768-W.

CIVIL ENGINEER, B.A.SC., JR.E.I.C. (Toronto '35). Age 24. Experience in structural design, construction and surveying, including one year in South America. Details on request. Apply to Box No. 1784-W.

ELECTRICAL ENGINEER, JR.E.I.C. B.SC. Age 25. At present employed, but desiring change of location. Three years maintenance and test work, toll and automatic telephone equipment; two years sales engineering, telephone and electrical equipment. Prefer to remain in telephone field, but would be interested in any opportunities in electical engineering. Apply to Box No. 1817-W.

Preliminary Notice

of Applications for Admission and for Transfer

August 27th, 1938.

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in October 1938.

L. Austin Wright, General Secretary.

*The professional requirements are as follows:—

A **Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A **Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A **Student** shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BECKETT—RUSSELL MacDONALD, of 327 St. Mark St., Fort William, Ont., Born at Portage-du-Fort, Que., Feb. 26th, 1891; Educ., I.C.S.; With the H.E.P.C. of Ontario as follows: 1910-13, ap'tice, 1913-18, operation of power house, Cameron Falls, 1919-22, i/c elect'l. installns., Cameron Falls, and 1922-27, electrician; 1927-31, electrician, Mahon Electric Co., Fort William, Ont ; 1933-38, electrician, at Churchill, Man., for Dept. of Rlys. and Canals, and at present, electrician in charge at Port of Churchill, National Harbours Board.
References: K. A. Dunphy, S. E. Flook, J. N. Stanley, G. Kydd.

BURNETT—FRANCIS C.E., of 145 Percival Ave., Montreal West, Que., Born at Galashiels, Scotland, April 16th, 1878; Educ., Heriot Watt College, Edinburgh. Member, Inst. Elec. Engrs. (Great Britain); Three years in shops, Waverley Iron Works, Galashiels, and two years ap'tice, Waverley Electric Co. Ltd., Edinburgh; dftsman. and asst. to chief dftsman., Siemens Bros. & Co. Ltd., London (about 3 years); asst. engr., estimating, constrn., etc., Witting, Eborall & Co. Ltd., London; asst. engr., power and rly. work, Kincaid, Waller, Manville & Dawson, London, consltg. engrs.; 1907-10, asst. to chief engr., J. Kynoch, Can. Gen. Elec. Co. Ltd.; 1910-19, power engr. to Canada Cement Co. Ltd., i/c of all power, steam and electric, designed electric steel furnaces and other equipment for munitions work; 1920-29, in business on own behalf,iron foundry; 1929 to date, representing various British firms for engineering apparatus.

WING—ERNEST, of 118 Macaulay Ave., St. Lambert, Que., Born at Southampton, England, Aug. 21st, 1898; Educ., 1910-13, Ringsend Technical School. First Class British Board of Trade Cert.; 1913-16, ap'tice engr., Dublin Steam Trawling Co. Served with Army Service Corps, and completed ap'ticeship 1917-19, with Howden Engrg. Co., Glasgow; Marine engr., 1919-22, with Gow Harrison Co., Glasgow, and 1922-26, British Tanker Co., London, England; 1927-31, steam plant supt., St. Anne Paper Co., Beaupre, Que.; 1931-35, mech'l. supt., i/c of all mech. mtce. work, and 1935 to date, plant engr., i/c of design and installn. of all new equipment, also responsible for mtce. of all existing machinery, bldgs., etc., Canada and Dominion Sugar Co. Ltd., Montreal, Que.
References: R. A. Gurnham, R. H. Findlay, F. S. B. Heward, G. H. Midgley, W. G. Scott.

FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

WHITMAN—KARL EWART, of Upper Vaughan, N.S., Born at Advocate Harbour, N.S., Aug. 6th, 1887; Educ., B.Sc. (Civil), N.S. Tech. Coll., 1914; R.P.E. of N.S. 1914-15, i/c erection of struct'l. steel, Toronto Structural Steel Co. Ltd.; 1918-19, instructor in engrg. subjects., Dept. of Soldiers' Civil Re-Establishment; 1913 (summer), res. engr. on constrn., Western Union Cable Co. Ltd.; 1916, asst. supt. of plant engaged in mfture of munitions, Standard Steel Constrn. Co. Ltd.; 1920-21, detailer and checker, Manitoba Bridge & Iron Works Ltd.; 1922, Dryden Paper Co. Ltd., investigation and constrn. of hydro-electric development and paper mill extension; 1923, res. engr. on power development, Avon River Power Co. Ltd.; 1924-25, design and constrn. of power development, N.S. Power Commn.; 1925-26, asst. professor of civil engrg., N.S. Technical College; 1926-28 and 1932-37, in private practice on struct'l. design and hydro-electric power investigation; 1928-32, hydraulic engr., and 1937 to date, chief designing engr., hydraulic and civil, Nova Scotia Power Commission, Halifax, N.S. (*A.M. 1919.*)

U.S. Department of Commerce National Bureau of Standards: Report of Vehicle-Scale Testing Service, November 1936-May 1938.

Canada a Sound Field for Investment

Freedom from labour troubles and natural business recovery have strengthened Canada's attraction for investors. The bulletin of the National Industrial Conference Board of New York points out the following highlights of the situation: Economic trends and conditions in Canada compare favorably with those of the United States without comparable governmental measures. Canada has higher relative production and employment figures; fewer strikes in relation to population; lower per capita relief expenditures and living costs and proportionally higher dividend payments. Gross governmental debts have increased 36 per cent in Canada and 115 per cent in the United States since 1929.

Setting Poles in Loose Soil, One Operation With Dynamite

Difficulty is often experienced in digging post holes in soft soil, sand or swamp land flooded with water. Often caissons are required to keep water and soil from filling up the pole hole which has been dug before the pole can be set.

In such situations considerable success has followed the practice of blasting the pole hole and setting the pole in one operation, according to A. E. Dyment, Manager, Technical Department, Explosives Division, Canadian Industries Limited. A hollow drill of about 1½ in. pipe is driven into the ground to the depth desired for the bottom of the pole. The soil is forced out through the lower end of the drill with a ram. A sand point on the end of the drill will help where the soil is such that it clogs the pipe, making ramming difficult. The pipe can be withdrawn leaving the sand point in the hole.

The charge of dynamite, primed preferably with an electric blasting cap, is pushed down through the pipe to the bottom and the pipe withdrawn. The pole is then raised above the surface directly over the dynamite and held in place by pike poles or rigged four ways, and the dynamite is detonated.

The explosion will create a pear-shaped pocket into which the pole will settle as the gases rush upward. The ground and water pressures press the soil back around the pole.

Some difficulty may be experienced in getting the pole to drop straight. It may be necessary to pull up the pole and blast another hole if the pole leans. The secret of settling the pole straight is in holding it straight above the ground by means of the pike poles or rigging. Care should be taken to see that the pole is exactly upright before the blast.

If the charge does not sink the pole far enough, the drill may be driven down along the pole and a second charge fired.

The amount of dynamite needed varies with the soil conditions encountered, but the following are suggested by experienced blasters who have done this work. In each case 40 per cent Polar dynamite is recommended: a 6 ft. to 7 ft. depth hole in swamp with muck underlying—2½ cartridges; a 5 ft. to 7 ft. hole in swamp with muck and rock underlying—3 cartridges; a 7 ft. to 7½ ft. hole in sand and water —3 cartridges; a 6 ft. to 7 ft. hole in coral rock—4 to 5 cartridges.

School Lighting

The American Standards Association has announced the completion of the new American Recommended Practice of School Lighting prepared under the leadership of the Illuminating Engineering Society and the American Institute of Architects.

The primary purpose of this "Recommended Practice" is to set forth standards of good illumination for the guidance of architects, engineers, school officials, and others interested in the conservation of children's eyes.

Scientific research by ophthalmologists, physicists, physiologists, and other experts has added materially to our knowledge of the relation between light and seeing. In line with these developments the new "Recommended Practice" suggests the minimum intensity for the general illumination of classrooms, studies, and offices at 15 foot-candles, a considerable increase over the minimum recommended in the code of 1932, which the present "Recommendations" supersede. However, in view of the fact that many school systems are today using much higher intensities with advantage, this estimate is conservative.

The new "Recommended Practice" is the work of a representative committee including eyesight specialists, physicians, research workers, public health officials, architects, and engineers. In its work the committee made use of actual tests and studies on lighting conditions. One such test involving two rooms of pupils of approximately equal age and intelligence proved that over a period of time children in the more adequately lighted room did better work than those in the other.

For sewing rooms, drafting rooms, art rooms and other rooms where fine detail work is to be done, intensities as high as 25 foot-candles on the work are recommended by the standard, while for locker rooms, corridors, and stairs, intensities as low as 4 foot-candles were deemed to be sufficient.

Not only the question of how much light, but what kind of light is taken up in the new "Recommended Practice." Such important factors to eye comfort as colour quality of light, light reflection from ceilings and walls, diffusion, distribution, and direction of lighting are considered. A section of particular interest to architects, engineers, and those responsible for the maintenance of school buildings discusses the wiring of school buildings and the capacity provisions which should be made in view of the trend toward higher illuminations.

Snow Surveys

A New Medium for Forecasting Run-off

*By R. C. Farrow, M.E.I.C.,**

District Engineer, in charge of Power Investigation Division, Water Rights Branch, Victoria, B.C.

Introduction

Over large portions of the temperate zones snow is the largest contributor to stream run-off. This is particularly true of mountainous and forested regions, such as the western portion of this continent. In the semi-arid southwestern states of the U.S.A. it is estimated that over 90 per cent of the run-off originates as snow in the Rockies and High Sierras. In British Columbia it has been found that 200 typical streams average 85 per cent of their run-off in the seven months March to September; moreover none of the 200 individually depart very far from this average. On many watersheds this 85 per cent is almost exclusively due to melting snows. Commencing in March or April, according to locality, the winter snows, melting in response to advancing spring, swell the streams till they reach their peaks some time in June and July, and then gradually recede.

Where storage is possible this great volume of snow-water is held over in reservoirs and lakes for power purposes, irrigation and domestic supply, as a reserve against the months of low flow.

Fig. 1—An Ideal Type of Forest Cover for Conserving Snow.

Snow itself is a variable element; it is elastic, and its density varies greatly. In its newly-fallen condition it has a range of density, so far as is known, of from 5 per cent to 18 per cent, whereas the meteorological services assume 10 per cent in reducing it to terms of water. At the end of winter the snow mantle has a far greater range of density, depending on altitude, exposure, depth, temperature, wind velocities, etc. In a single season the density of the snow on British Columbia Courses varied from 19.4 per cent to 71.1 per cent.

It is obvious, therefore, that only under favourable circumstances can meteorological records of snowfall serve as a criterion for estimating run-off, while depth alone as indicated by the snow stake is of little value. A scientific knowledge of the evolution of the snow-cover and its water content when melting begins is, therefore, of prime importance. Snow surveying, a young but healthy offspring of the science of hydrology, relates snow-cover to stream-flow, and thus makes it possible to forecast the latter from a knowledge of the former.

*Member, Committee on Hydrology of Snow, American Geophysical Union,

History

Snow surveying had its genesis in Europe, but it was many years afterwards before its practical application was developed in the High Sierras of Nevada and California. On the 10,800-ft. summit of Mt. Rose Dr. J. E. Church, meteorologist of the Nevada Agricultural Experiment Station, established an observatory in 1904. In so doing he became the father of snow surveying, and remains its Dean today.

At Mt. Rose observatory every phase of the evolution of the snow pack and its melting were scientifically studied, and from this research certain fundamental relationships were isolated, studied, and finally put to practical use; the Nevada or percentage method of snow surveying was thus evolved.

As in most pioneering efforts recognition came slowly and grudgingly; but gradually one organization after another tried this new idea and found it worth while. These agencies were many and diverse; power companies, irrigation companies, cities, State Departments of water resources, etc. A fairly comprehensive, contiguous network now extends throughout the States of California, Oregon, Washington, Idaho, Montana, Wyoming, Colorado, Utah, Nevada and New Mexico, and portions of British Columbia and Alberta. There are also systems in Newfoundland, Quebec, and New York State, while in far-away Australia snow surveys are being tried out in the southern mountains of the Continent.

The earliest attempt at formal co-operation and standardization was through the medium of a Western Interstate Snow Survey Conference. This still functions and Mr. O. H. Hoover, Engineer-in-Charge, Dominion Water and Power Bureau, Calgary, and the writer were elected to its Executive Committee this year.

About 1934 the U.S. Department of Agriculture entered the picture as a more formal and authoritative coordinating agency, and the Bureau of Agricultural Engineering was entrusted with the work. They now receive and assemble all data, issue and supervise the distribution of new snow sampling equipment and provide for the systematic expansion of the various systems.

Scientific research into snow survey problems was early undertaken by the American Geophysical Union, through a Committee on the Hydrology of Snow, one of the standing committees of the Section of Hydrology. Of late years a meeting of the Snow Survey Conference is always included in the agenda of its Annual General Meeting and its Western Regional Meetings.

In 1934 snow surveys were initiated in B.C., by Major J. C. MacDonald, M.E.I.C., Comptroller of Water Rights, the writer being entrusted with their development.

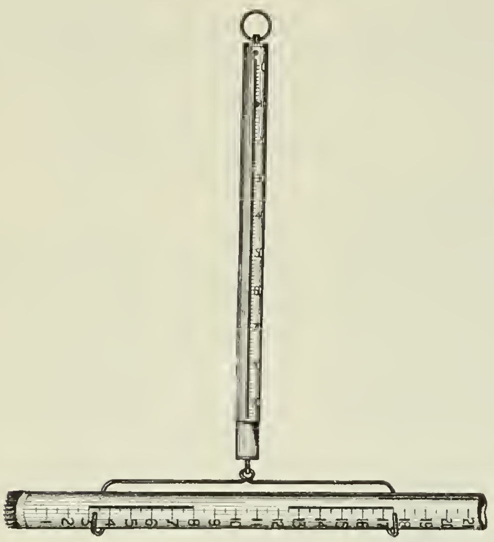

Fig. 2—Scales and Snow Sampler in Position for Weighing.

Fundamental Relationships

The fundamental facts upon which the Nevada, or percentage method of snow surveying are based are as follows*:

First: That over a given basin the relative snow cover was the same wherever measured, provided neither drifting nor melting had taken place. In other words, if the water content at some point was found to be, say, 75 per cent of normal, it would also be 75 per cent of normal at other points in the same basin within a very small margin of error, regardless of the depth of snow at either point.

Second: That the percentage of normal of the water content of the snow pack at the end of the snow-fall season agreed closely with the percentage of normal streamflow to be expected during the ensuing run-off months.

Distorting Factors

Certain factors may cause divergence between the snow water content and ensuing run-off. Those of sufficient magnitude to seriously affect the accuracy of forecasts are as follows:

(*a*) A normal relationship between snow and run-off is in some regions dependent on normal rainfall during the run-off period. If this rainfall is above normal the run-off is increased; if below normal run-off is decreased.

The magnitude of its effect is in general influenced by the ratio of early summer rains to snowfall. Where the ratio is large this factor will ordinarily produce a maximum effect.

It is the writer's opinion, however, that the possibilities of the distorting influence of this factor has been considerably over-rated. For instance, in the Canadian Columbia Basin, which includes parts of the Rocky and Selkirk mountain ranges, it had been supposed by experts that precipitation during run-off would be a seriously distorting factor. But in research studies† on the snowfall-run-off relationship over the period of record of 21 years, its effect was either entirely absent or quite negligible, nor has it shown any effect on the first three years of tentative forecasts.

Its lack of effect in this region is probably due to three causes:—

First: That most of the precipitation stations on which the supposition was based are located at valley points where the proportion of summer rains to winter snows happens to be much greater than in the surrounding higher elevations which produce the major portion of the run-off.

Second: That the summer rains while locally intense are much more spotted in occurrence than the major winter storms which produce the snowfall.

Third: That as summer temperatures throughout the region are high, and relative humidity low, the summer rains falling on increasingly large areas of snow-free ground as the season advances are almost entirely taken up by evaporation, soil absorption, plant use and transpiration.

Where precipitation during run-off is found to be a distorting factor, forecasts have to be corrected at the end of each month in light of the precipitation data received since the previous forecast.

(*b*) If the soil is deficient in moisture when melting begins, it is obvious that a certain proportion of the melting snow will be needed for re-priming before run-off can take place, and this represents a loss to run-off. The writer has termed this the "Soil Priming Factor," and the magnitude of its effect on run-off depends on the topography and geology of the region, and the yearly variation in autumn rains.

In the arid regions of Utah and Nevada where the snow falls on a dry soil in most years, it has been found that as much as 50 per cent of the snow cover is absorbed in re-priming the soil before any run-off occurs.

In the main Canadian Columbia and Kootenay basins this factor is apparently either negligible or relatively constant from year to year, thus exerting no distorting influence on the snow run-off ratio. This is probably partly due to the steep and rugged topography and the average shallowness of the earth mantle, and partly to autumn rains of sufficient intensity even in minimum years to prime the soil before the snow falls.

In the Okanagan Basin, on the other hand, a semi-arid region of more gentle contours and with deep deposits of glacial detritus and alluvials, the soil priming factor often exerts a marked influence on the snow run-off ratio.

In the Utah snow surveys, under the direction of Dean Clyde of Utah State Agricultural College, whose contributions to snow surveying are second only to those of Dr. Church, tests of soil moisture content are made at the time of snow sampling, and the average snow-water content weighted accordingly. This is probably the ideal method of approach.

Before undertaking this method for the Okanagan, however, with its additional expense for equipment and field work, the writer made a study of the relationship between autumn precipitation and the apparent effect of the Soil Priming Factor, as indicated by the frequent discordance between recorded snowfall and run-off. With fourteen years of precipitation data at three different stations to work with, a correction curve was developed; from this a coefficient is obtained which is applied to the snow-water content. Using this curve snowfall and run-off were brought into reasonable agreement for the fourteen years of record (11 years' precipitation data and 3 years' snow surveys were used).

Accuracy

Forecasts within an accuracy of even 10 per cent are usually of considerable value, but in most established

*Snow Surveys for the Purpose of Forecasting Streamflow by R. C. Farrow, Forestry Chronical, Vol. XIII, No. 1, February 1937.

†Snowfall and Run-off in the Canadian Columbia Basin: a Study to Determine the Ideal Location for Snow Survey Stations by R. C. Farrow, American Geophysical Union Transactions, 1937, pp. 632-644.

systems accuracies within 2 to 5 per cent are becoming more and more common.

The following gives the accuracy obtained in a group of 63 comparatively new courses in the U.S.A.:—

Accuracy within following percentages; based on normal run-off	No. of Forecasts
0 to 5 per cent	27
5 to 10 "	14
10 to 15 "	7
15 to 20 "	6
20 to 25 "	5

The accuracies so far obtained on British Columbia snow surveys are shown in the tabulation at the end of this article.

Snow Losses and Conservation

The higher altitudes of our mountain ranges, well above timber line, despite the heavy snowfall which they usually receive, appear to yield very little water to run-off; most of it is dissipated through evaporation both in winter and summer.

In winter the high winds which blow almost constantly about the bare peaks induce a high rate of evaporation even at low freezing temperatures.

The extent of this loss was examined at Mt. Rose Observatory. The acceleration in the rate of evaporation appeared to be roughly proportional to the increase in wind velocity. It was found that on the leeward slope, under an average wind velocity of 10.8 m.p.h. evaporation amounted to 7.17 in. (water content) per month, while on the windward slope under an average wind velocity of 30.6 m.p.h. evaporation reached 24.21 in. per month. At the higher velocities erosion began to take place forming cornices and sweeping the snow into crevasses and ravines.*

In summer the sun allies itself to the wind and further increases the rate of evaporation.

The writer's observations while engaged on work above timber line in the spring and summer led to the belief that very little run-off accrued from these high snowfields. Vast areas of snow even on the hottest days showed but meagre trickles from their fringes. Their yearly dissipation, therefore, appeared to be largely due to evaporation. Certain solar rays become very intense in the clear air at high altitudes, and the solar radiation itself is greatly magnified at the snow surface. The relative humidity is usually low and the ever prevalent winds keep the air in motion, so that conditions for a high evaporation rate are ideal.

Fig. 4—High Bare Slopes Which Appear to Yield Little to Run Off.

Last year Mr. F. E. Nathes of the U.S. Geological Survey made an exhaustive examination into the problem of how much of the high snow accrued as run-off. In a comprehensive paper† he laid his findings before the Western Regional Meeting of the American Geophysical Union in California in January 1938. His considered opinion, supported by a mass of data and photographs, was that very little water found its way to the streams from this source, and that the yearly dissipation of this high snow was due largely to evaporation.

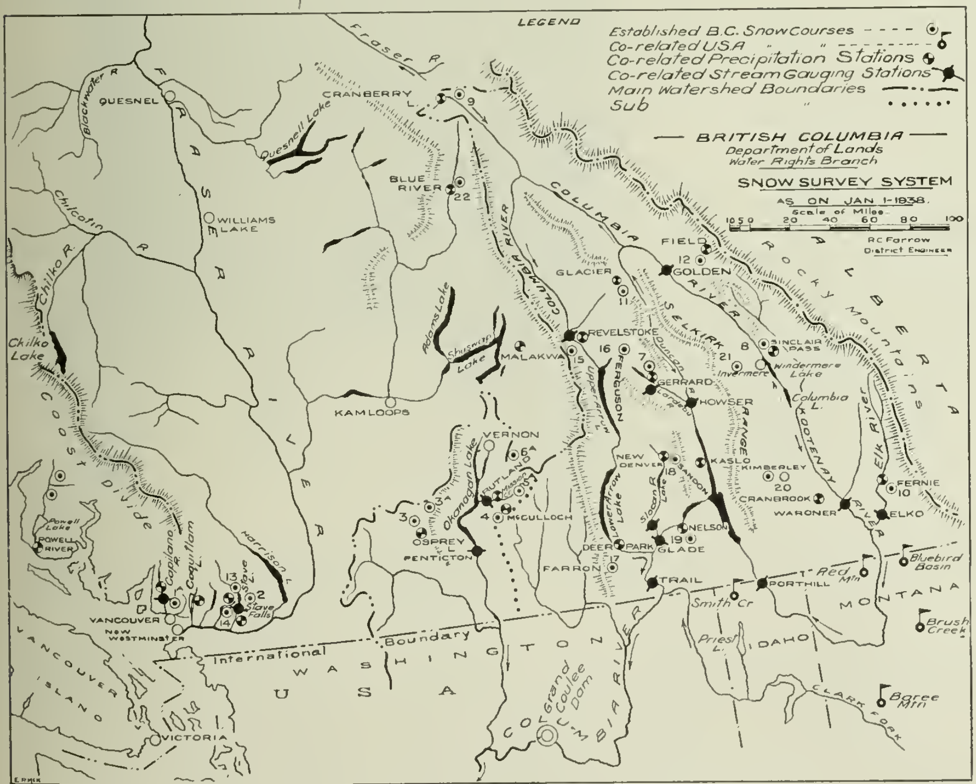

Fig. 3

On the other hand research has shown beyond refutation that forests are great conservers of snow; their effectiveness in gathering and retaining it is most marked as compared to bare open slopes. As an illustration, Dr. Church's studies on Mt. Rose disclosed the following conditions at the end of the snowfall season, the whole area under consideration having received the same snowfall. Depth of snow is in inches; water content in inches in brackets:

> "Unforested talus slopes 40.8 (18.4), distributed thus: cornice below Observatory 52.5 (25.1); windswept slope 8.1 (2.6); protected slope 78.1 (35.1); forested slope 88.6 (41.1)"

The conserving effect of forests undoubtedly far outweighs the losses in interception, plant use and transpiration.

*See Geographical Review, Dr. J. E. Church, Vol. XXIII, No. 4, October 1933.

†(Will be published in the "Transactions" 1938.)

Table I

Final Comparison for 20 Years 1915-1935, Run-off Columbia River at Revelstoke in Per Cent Departure from Snowfall at Glacier, Cranberry Lake, Revelstoke, and Malakwa, and Averages of Various Combinations

[Indications for averaged stations are: H_c = Glacier and Cranberry Lake; I_c = Glacier, Cranberry Lake, and Revelstoke; J = Glacier and Revelstoke; K_c = Glacier, Cranberry Lake, Revelstoke, and Malakwa; L = Glacier, Revelstoke, and Malakwa; M = Revelstoke and Malakwa; N = Glacier and Malakwa]

Precipitation-station or average	Per cent departure						No. of years in which per cent lies between					Total years
	Aggregate	Maximum	Minimum	Mean	Modal group	Median	0-10	10-15	15-20	20-25	25+	
Glacier	248.9	45.4	0.3	12.44	4 to 10 for 9	9.3	12	2	0	5	1	20

N	235.8	26.2	1.1	11.79	1 to 5 for 7	8.5	10	2	6	1	1	20

Note:—Suffix "c" (as in H_c) indicates that combination includes Cranberry Lake.

Inaugurating a Snow Survey System

As with many problems, while snow surveying is fundamentally simple, many complex problems arise in actual practice. Before attempting to lay out a system and locate snow courses, the climatology, topography, geology and hydrometric data of a basin should be studied. In particular, a complete study and analysis of the entire precipitation data for the region will often yield valuable information.

This was done by the writer for the Canadian Columbia Basin, with the result that a relationship was established between combinations of certain key precipitation stations and run-off at co-related gauging stations.*

While the relationship was not close enough to encourage the use of precipitation data alone for forecasting, except in the case of a few stations, it furnished a valuable guide in evaluating the probable effect of distorting factors, and served as a criterion for the location of snow courses. These were laid out adjacent to the precipitation stations but at higher elevations.

The type of final analysis used and the close agreement between the snowfall at certain precipitation stations and run-off are shown above (Table I).†

This method of approach assures a minimum number of courses to cover a given area. In the case of the Canadian Columbia Basin we have only 15 courses to represent 40,000 sq. mi. of watershed, and it is unlikely that many more will be necessary even in light of later experience.

In contrast, most of the U.S.A. systems were laid out by placing courses broadcast wherever they could conceivably be useful, very little attention being given to prior studies of precipitation; efforts were being concentrated on perfecting the technique of snow surveying itself. Many of the systems were laid out more or less under emergency conditions in order to obtain quick results and far more money was available for the work than we could ever hope to obtain.

It is now admitted that in many areas from 25 to 50 per cent of the courses could be dropped without affecting the accuracy of forecasts.

Snow Courses

A snow course is a permanently established line over which measurements of depth and water content are made at fixed observation points each year.

*Snowfall and Run-off in the Canadian Columbia Basin, American Geophysical Union Transactions 1937, pp. 632-644.

†Snowfall and Run-off in the Canadian Columbia Basin by R. C. Farrow, American Geophysical Union Transactions, 1937, p. 638.

In the earlier days of snow surveying it was thought necessary to have long courses with as many as 60 observation points, preferably 100 ft. apart. It soon became evident, however, that shorter courses were just as reliable, and as the records accumulated and were studied it appeared that 10 to 15 observation points, preferably about 100 ft. apart, were quite ample. The course should be high enough to be safe from premature melting, protected from drifting, and shaded to some extent from the sun's direct rays.

Fig. 5—Snow Sampling in the Southern Rockies, Kootenay River Drainage.

Snow Sampling

This is the operation of determining the depth and water content of the snow. Monthly samplings throughout the winter are useful for studying the evolution of the snowpack, and in some cases for preliminary forecasts where very close regulation of reservoirs is necessary. The important samplings for the main forecasts, however, are usually made about the end of March. The actual time is governed by the local conditions of snowfall and run-off.

The snow-surveying equipment now in general use, and standard with the U.S. Bureau of Agricultural Engineering (see Fig. 2), consists of jointed aluminum alloy tubes, slightly over 1½ inches in diameter; they are slotted in order that the rise of the snow-core can be noted, and are graduated in inches for measuring the depth. The bottom section is equipped with a steel saw-toothed cutter, for boring through ice and crusts. There is a spring balance and cradle for weighing the tube and snow-core. The throat diameter of the cutter is such that an ounce in weight is equivalent to one inch of water-content. A wrench is provided to assist in forcing the tube down, in deep and dense snow.

In sampling, the tube is forced down through the snow at each observation point on the course, and on being withdrawn retains a core of snow. Depth of snow is noted; and the difference in weight between the empty tube, and tube with snow-core represents the water content in inches. The average for all observation points is the water content for the course.

Forecasting

A preliminary normal of water content can be established in the following ways:

(*a*) By using the computed normal of run-off at the correlated stream gauging station.

(*b*) By using the normal of snowfall as recorded at a precipitation station, when close to the snow course, and when its data have been found to be reasonably well related to run-off.

(*c*) When neither run-off nor precipitation data are available, a number of years must elapse before an independent normal of water content can be built up.

Where several courses are to be related to a single stream gauging station, each course may be assigned a certain zone, or partial area of the whole tributary watershed; and an average water content for the whole, computed by weighting the water content of each individual course according to the percentage of the whole which it represents. This method is used with our Okanagan courses.

Where each course represents a large area, and such courses have been scientifically located on the basis of precipitation run-off studies, the average of the percentages of normal of these courses can usually be used for forecasting. This method is used in the Canadian Columbia Basin.

Correction for the Soil Priming Factor may be necessary; and in areas where precipitation during run-off can be a distorting factor, forecasts may have to be revised each month if this factor departs from normal. A systematic method of receiving, tabulating and analysing the snow-sampling data as soon as received has to be worked out.

Fig. 6—A Snow Course Site in the Selkirk Range, Columbia River Drainage.

Forecasts for major streams with established gauging stations are made in acre-feet; small streams having meagre or no stream-flow records at all are of necessity more general in nature and are usually expressed in per cent of normal or per cent of the previous year's run-off, if known.

B.C. Snow Survey Systems

The snow surveys inaugurated by the Water Rights Branch fall under three groups (see Map, Fig. II).

(1) Coastal, in the vicinity of Vancouver; with four courses. (In addition, the Powell River Co.—the largest pulp and paper concern in B.C.—have started their own system, with at present 2 courses.)

(2) Okanagan, with 6 courses.

(3) Columbia-Kootenay, with 15 courses, one being common with the Okanagan. In addition, 5 U.S.A. courses are used for the section of the Kootenay which flows through the States of Montana and Idaho.

This makes a total of 30 courses used in our forecasts.

As our snow surveys only date from 1934 and the systems outlined above were only rounded out last year, it will probably be several years before general public forecasts are ventured; but in the meantime the snow survey data are available to organizations having a technical staff capable of appreciating its short record limitations.

They are also transmitted to the U.S. Bureau of Agricultural Engineering, and U.S. Weather Bureau, and used in conjunction with their own data in their spring forecasts.

The results of our last year's tentative forecasts are as follows:—

Table II—British Columbia Snow Surveys Forecasts 1937

River		Snow Course Nos.	Per cent of Normal	R.O. in Ac. Ft.		Error in Per cent of Actual	Per Cent Error in 1936 Forecast

Industrial Preparedness in Canada for War

(Contributed)

Modern war demands a huge expenditure in money and material. The fighting forces must not only take the field equipped with every up to date device for making war, but in addition a continuous stream of equipment and munitions must be poured into the theatre of operations to replace expenditure in battle and wastage caused by enemy action. The great powers of the world to-day, therefore, base their war plans, not so much on the number of men that they can raise, as on the number which can be adequately equipped and maintained in the field. In other words, all are agreed that industry is one of the most decisive factors in modern war.

As the mechanical contrivances used in normal peace time pursuits are subject to improvement in design with mechanical progress, so too are the weapons of war. To depend on huge reserves built up in peace time is to invite obsolescence of equipment when an emergency arises. No country can afford to maintain in peace time sufficient manufacturing establishments to cope with the wastage of modern war. The mass production which is required must be undertaken by the whole industrial structure. Reserves built up in peace time can only hope to cover the interval between the rising of an emergency and the time when national industry can produce requirements on the scale required. The sooner industry can achieve this purpose after emergency, the smaller need be the size of reserves built up in peace, with a consequent saving in the financial burden placed on a country for defence purposes in normal times. This can only be achieved by industrial preparedness.

In their efforts to achieve industrial preparedness, nations have adopted methods which differ considerably depending on the extent to which the country is industrialized and the extent to which their industries are centrally controlled. Nevertheless similar general principles have been adopted on the basis that the essentials for a complete plan for mobilization of industry are as follows:

Firstly—Determination of material requirements.

Secondly—Plans for obtaining such requirements.

Thirdly—Determination of measures to be employed to ensure the proper co-ordination and use of the nation's resources.

Fourthly—Plans for the organization of administrative machinery to execute these control measures.

In any plan of industrial preparedness one cannot neglect the needs of the civilian population. These needs must necessarily be curtailed to some extent, but an underfed, under-privileged population at home will lose the will to continue the struggle resulting in collapse of the industrial machine so necessary to maintain the fighting machine.

It may be of interest to note at this point that the United States has given the question of industrial mobilization a very intensive study over the last fifteen years. As a result, a very elaborate and nation-wide system of industrial preparation for war has been built up under the direction of the Secretary of War. So much stress is laid on this phase of defensive preparation, that an Army Industrial College was established at Washington twelve years ago for the purpose of training certain selected Army and Naval officers in "planning procurement" and industrial mobilization. In addition further officers are trained for the purpose in the Harvard Business School of Administration. Great Britain has been intensively studying the question of supply in war since 1924, and very recently a new department under the Minister for Co-ordination of Defence has been established as its designation implies, for the purpose, of ensuring the co-ordination of the nation's industrial efforts and resources, in the development of the present extensive defence programme.

The Canadian Situation

In the autumn of 1936, the Minister of National Defence, the Honourable Ian MacKenzie, caused a joint Navy, Army and Air Supply Committee to be set up within his Department for the purpose of investigating emergency supply. This committee immediately commenced a survey of commercial undertakings in Canada with a view to ascertaining what facilities existed in the country for the production of war stores in an emergency. To date 800 plants have been surveyed, and individual records completed, setting forth the existing facilities possessed by each for the production of war stores. In its work of investigation, the committee has received valuable assistance from other government departments—the National Research Council, the Department of Mines and Resources, the Dominion Bureau of Statistics, the Department of Transport, and that of Trade and Commerce. Perhaps one of the most outstanding features of the whole investigation has been the loyal spirit of co-operation which industrialists and manufacturers have shown the committee during its investigations. Trade information of a confidential nature has in many cases been given which under other circumstances would not have been divulged. But for the interest shown by the private manufacturer, the committee would not to-day be in the position of having such complete records on individual plants.

As soon as the present survey is completed, and it is very much in the nature of a preliminary survey, there will be information at the disposal of the Department of National Defence which will permit a fairly accurate gauge of the existing facilities possessed by Canadian industry for the production of war stores. From the information available, a preliminary allocation can be made which will permit more detailed investigation of plants selected for the production of specific war stores best suited to the facilities which they possess. Finally, a plan can be drawn up which will allocate production to industry in an emergency based on probable requirements. Such a plan will go far toward cutting down the time that manufacturers will be given an opportunity to consider and study production methods of the store which they will be called on to produce in an emergency.

The production of war stores by Canadian industry may be broadly classified as:

Firstly—Those which are of ordinary commercial pattern or an adaptation of such to military use.

Secondly—Those which have no commercial equivalent and are of special design and methods of manufacture.

To obtain military stores falling under the first category presents little difficulty in peace or war. Those under the second may, however, prove difficult since this classification includes most of the lethal armament—guns, bombs, torpedoes, shells, service aircraft, tracked vehicles, etc. To date, the preliminary survey has divulged that there is little reason to doubt that Canadian industry would be capable of supplying the bulk of our armament requirements. We must realize that the demand created by the peace time needs of the defence forces of Canada would hardly warrant entering production of certain items of special manufacture unless we are prepared to accept very high production costs, or unless a demand develops from other markets.

Amongst other factors in the preparation of a plan of industrial preparedness are those appertaining to raw material supply and labour. The former may well prove a bottleneck in emergency production, thus all available sources of supply must be explored. Where a possibility of shortage of raw material may occur, arrangements must be made to build up reserve stocks. In some cases the difficulty may be overcome by changes in specification which will permit substitution of a material more readily available. The labour problem cannot be over-emphasized. Shortage of skilled mechanics may be a retarding factor in reaching emergency output. The solution of this problem appears to be one which the industrialist and labour unions must solve in co-operation with each other. The enlistment of skilled mechanics into the defence forces during an emergency will have to be carefully scrutinized.

The role which our national industry will play in an emergency needs no further emphasis. The ability of Canadian industry to produce the requirements of the defence forces will measure the success of any defensive precautions of a naval, military or air force nature which may be devised. Finally, it must be borne in mind that other nations have been engaged in planning for "Industrial Mobilization" over a period of twenty years. Owing to constantly changing circumstances, their plans can never be wholly complete but must be subject to periodic revision. We should bear in mind then, that such planning takes time and much careful investigation. It is not a matter which can be rushed at boldly and completed over night, but one which takes form gradually.

The Relation of Cost to the Speed of Rail Transport

Herbert Ashton, C.E., Ph.D.,
Transportation Consultant, Swarthmore, Pa.

NOTE.—The author has specialized on the economics of railroad operation. From the date of his graduation at Cornell, where he majored in transportation, up to the present time he has worked with the railroads of the States and South America, lectured in the universities, sat on commissions and research boards, and generally investigated and studied transportation problems, until to-day he is recognized as one of the experts on this subject in the United States.

In view of the importance which is attached to-day to the speed of transport, and which is evidenced by the insistance of shippers on reducing the time consumed in transit of goods, the following analysis of the relation between the cost and the speed attained in the movement of tonnage freight by railroad may be of some interest. It must be pointed out in the beginning, however, that the analysis presented here deals only with the movement of commodities over the road, and does not include consideration of the costs of terminal handling, or those incident to collection and delivery service where that is provided by the railroads. Such terminal costs are independent of the speed of actual movement, and represent constants to be added to the cost of the run.

An analysis of the sort contemplated here must be based on certain assumptions in order to simplify the problem as well as to help bring out more clearly the effect of the particular factor being studied, in this case the speed of movement. Accordingly, it is assumed that the locomotive is operating under full load; that the cars in the train are loaded to capacity; and, in developing the characteristics of the locomotive tractive effort for different speeds, the movement takes place over straight, level track. These assumptions represent the ideal, rather than the normal situation, perhaps; but conform to standard practice in this type of analysis, whereby any deviation from these assumed conditions would constitute a particular situation for which allowance could be made more readily. The analysis must also be based on a particular stage of technological development. Further technological advance may modify the data presented here so as to change the result numerically. This is almost certain to be the case. But the underlying relationships involved in the present study are well established.

Movement of Commodities

In developing a cost curve of speed the element of size, or carrying capacity, in this case the train load, will not be held strictly constant, but will be allowed to vary with variations in the speed as it does in actual operation. The elements of cost include wages, fuel and locomotive supplies, maintenance, and other customary charges. A preponderating proportion of these cost factors are independent of the speed of movement. Wages and fuel are the principal variables. But wages are in part on an hourly basis, with mileage allowances added. Moreover, on the assumption made here, namely, that the locomotive is working to capacity at all speeds, there would be practically no variation in the rate of fuel consumption. It is possible, therefore, to take a cost per train-hour on the road which is constant for all practical purposes. Then, by relating variations in locomotive tractive effort and train resistances for different speeds, an allowable weight of train can be developed for any given speed.* The corresponding cost per ton-mile of transportation produced is computed from this data. From this relationship developed between cost and speed, it is possible to discover the speed for which the unit cost is a minimum. The rate of movement so determined represents the most economical speed, where the agency of transport alone is considered. These computations have been made for three types of steam locomotives now in use, hauling trains of 50-ton capacity cars.† If the capacity of the cars were increased the tendency would be to reduce the train resistances and thus to increase the "economic" speed.‡

The results of these computations have been plotted on the chart (Fig. 1) for the three locomotives, the cost per ton-mile being plotted against speed. Certain facts which are revealed by this chart deserve some attention. In the first place, there is a clearly defined point of minimum cost per ton-mile for each of these locomotives. Secondly, it is seen that not only does the cost increase rapidly as the speed is increased beyond the optimum (the minimum points of the respective curves), but also that the cost increases equally rapidly as the speed is reduced below this point. Data are not available for the higher ranges of speed, but the curves, as plotted suggest symmetry about the minimum points, and have the general appearance of parabolas. This indicates that the cost does not vary directly with the speed, but with some higher power. This is in line with the relationship which obtains in marine transport. The curve, M-M_2, giving the speed-cost relationships for a mountain type locomotive, rep-

---

* The train resistances at different speeds used in the present analysis are derived from the findings of the Engineering Department of the University of Illinois, Bulletin No. 39, Vol. VI, pp. 31-33, as modified by findings more recently of one of the large railway supply companies.

Variations in locomotive tractive effort have been taken directly from drawbar-pull curves developed through tests conducted by one of the large railway systems.

† For detailed computations, see Appendix.

‡ This effect would also be produced at the higher speeds by streamlining.

resenting the most recent development in steam locomotive design, indicates a substantial increase in the range of speeds for which operating costs are reasonably low. This is of considerable importance from the economic standpoint, as will be shown shortly. It should be noted that the points of minimum cost obtained here are at speeds considerably in excess of that formerly claimed by writers on this subject as the most efficient speed for tonnage freight trains.* In view of this fact it may be well to examine the effect of variations in speed on the volume of transportation produced over some measurable period of time.

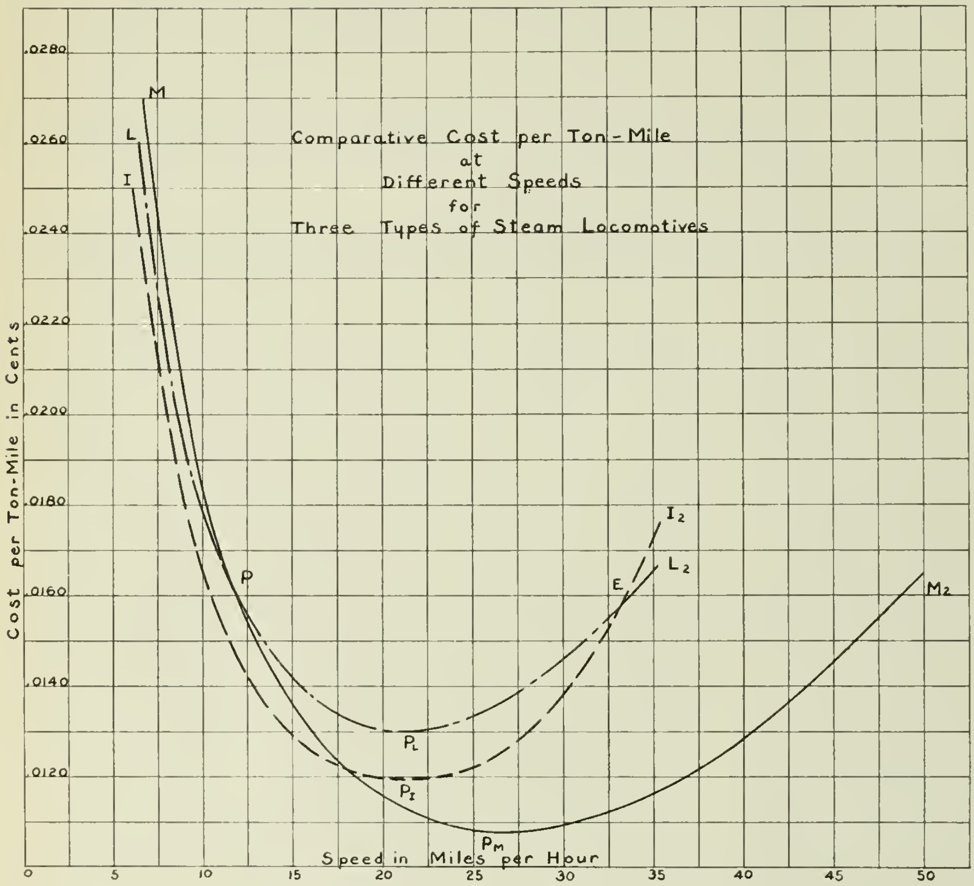

Fig. 1.

It is possible to approach closely actual conditions by taking the figures for allowable weight of train at different speeds for one or more of the locomotives studied, using the actual variations in tractive effort and train resistances developed by test. The locomotive which is most efficient at a speed of approximately 25 mi. per hr. is capable of hauling a train of 6,000 tons at that speed, and will produce 150,000 ton-miles per hour. In an eight-hour day this would mean a production of 1,200,000 ton-miles. The same locomotive can haul a train of approximately 8,300 tons at a speed of 12.5 mi. per hr.; but the ton-miles produced per hour will be only 104,000; and in an eight-hour day, would be only 832,000 ton-miles, or a decrease of over 40 per cent in ton-miles produced per hour and per day. Moreover, the cost has increased proportionately. The cost per ton-mile at a speed of 12.5 mi. per hr. is 143 per cent of the cost at a speed of 25 mi. per hr. The argument advanced on practical grounds for the former low rate of movement has been based on the contention that divisional operation required yarding of trains at the end of a 100-mile haul, on the average, for change of crews. This has been about the average length of a division, and could be covered in eight hours at a speed of 12.5 mi. per hr. Any higher speed, which would reduce the time consumed in completing this run, it has been contended, would not effect any savings in wages, since eight hours represents the minimum day's pay, and the increased speed would call for a lighter train load, and so reduce the ton-miles produced per eight-hour day, and, therefore, per man-hour. The answer to this argument has been that, even if crews are changed at the division termini, the trains do not have to be yarded at these intermediate points, but may be run through to ultimate destination intact in many cases

The result has been the development of inter-divisional runs, which have materially improved the over-all speed of freight movement. The distance limits imposed by former operating methods have thus been done away with, as well as a considerable amount of unnecessary yarding of trains. Crews may be changed at division points (though this is not always done), but the locomotive and train are moved straight through for distances up to 500, and even 1,000 miles, or more, without yarding.† It can now be fairly said that managements have definitely broken away from the former policy of moving the greatest possible tonnage per train at what might almost be termed the slowest possible speed, to a policy of getting freight over the road at much faster rates. For the consummation of this achievement they (and the shipping public) have largely to thank the competition of the motor trucks.

But, as the cost of moving commodities increases as the speed is reduced below the economic or most efficient level, so also does it increase if the attempt is made to improve the rate of movement without due consideration being given to volume; that is, if the attempt is made to produce miles per hour without regard to tons. Thus, if the speed of the locomotive we have been considering is increased from 25 mi. per hr. to 35 mi. per hr., the locomotive-miles, or train-miles produced in eight hours will increase from 200 to 280, or by 40 per cent. But, at this speed the locomotive can haul only about 4,000 tons, as opposed to 6,000 tons at a speed of 25 mi. per hr. Therefore, although the train-miles have been increased by 40 per cent, the ton-miles, i.e. the actual transportation of goods, has been reduced from 150,000 to 140,000 ton-miles per hour, or a reduction of about 7 per cent; and the unit cost has increased by a similar proportion.

There is, thus, apparent validity to the theory of an optimum, or economic speed for tonnage freight at any given stage of technological development. An examination of the cost curves developed for the three types of locomotives studied here indicates, moreover, that with tech-

* Byers, M. L., Economics of Railway Operation, 1907, pp. 499-505.
Haines, H. S., Efficient Railway Operation, 1919, p. 361.
Droege, J. A., Freight Terminals and Trains, 1912, pp. 168-171.

† Freight trains are run through to-day from Denver, Colorado, to Ogden, Utah, on the Union Pacific, a distance of 577 miles; from Saint Paul, Minnesota, to Minot, North Dakota, on the Great Northern, a run of 526 miles; and from Los Angeles, California, to El Paso, Texas, on the Southern Pacific, a distance of 815 miles, without yarding.

nological advance the slope of the positive section of the cost curve tends to be reduced. The slope of the curve, P_m-M_2, is less than that of either curve, P_1-L, or P_I-I. This has considerable significance, for it indicates that with continued improvement in motive power the decrease in tractive effort as the speed is increased tends to be less rapid for a given locomotive. This, in turn, permits a greater allowable weight of train for the higher speeds, thus reducing the cost per ton-mile. It may, therefore, be possible to increase the speed of movement via rail by further considerable increments without materially increasing unit costs.

It should be noted also that, in the case of the latest type of locomotive tested by the above analysis (curve M-M_2), not only is the most efficient speed considerably greater than for the other two types, but, in addition, the unit cost at the "economic" or optimum speed is considerably lower. This latest type can be operated at 40 mi. per hr. with the same unit cost (per ton-mile) as that obtained for the other types at their respective optimum speeds of 20-21 mi. per hr.

If these curves are considered in the light of cost curves, then, down to the minimum points on the respective curves speed is supplied on the basis of increasing returns. If, however, rates are stabilized on the basis of costs determined from operation at some lower speed, such as that represented by the common point, P, an inducement will be presented to the carriers to offer faster schedules to shippers without any increase in rates. In fact, a substantial increase in speed can be effected with the same motive power (the difference between 12 and 32 mi. per hr. or 20 mi. per hr.) before unit costs will again come up to the same figure as for a speed of 12 mi. per hr. And, at the higher speed the optimum operation of the more efficient locomotive has been only slightly exceeded. With this locomotive trains could be run at any speed between 12 mi. per hr. and approximately 45 mi. per hr. at a net gain to the carrier. This is a steam locomotive with a characteristic diminishing tractive effort as the speed is increased. While accurate information concerning the characteristics of the tractive effort of electric locomotives is at present rather meagre, it can definitely be stated that there is a lower rate of decrease in tractive effort as the speed is increased than for steam locomotives, i.e., the tractive effort of electric locomotives remains more nearly constant for a higher range of speeds. The effect of this would be, obviously, to make possible very substantial further increases in the speed of trains without any appreciable increase in operating costs, except as wages are affected; for, the allowable weight of trains being greater, the cost per ton-mile would tend to be lower. Maintenance charges would tend to increase with higher speeds, though not in the same proportion. Another factor is the possible legal limit to the length of trains. If the length, and therefore the weight, of trains were restricted, unit operating costs would be affected, although the speed of operation itself were not.

The value of high speed to the users of transportation may be sufficiently great to warrant a speed considerably higher than the optimum operation developed by the above method, at a correspondingly higher cost. The true "equilibrium" speed in the economic sense is reached when any further increase can be secured only at a cost beyond that which the traffic will bear. What this true equilibrium speed will be at any time will depend in part upon the type of industrial organization which has been developed to most effectively meet current trade customs. These trade customs will determine the standards of service demanded. The speed of transport is a vital factor in securing whatever distributive service is obtained.

APPENDIX

Computations Involved in the Development of an Economic, or Optimum Speed for Rail Freight Transport

A basic cost per train-hour of $14.50 was taken for the Mikado locomotive (curve L), which is composed of direct operating expenses only, and includes the wages of a full crew, locomotive expenses, including the cost of fuel, oil, supplies, maintenance charges, etc.; but does not include overhead, fixed capital charges, and the like. The cost per train-hour for the other two locomotives (curves I and M on the chart) is proportioned to their respective capital costs relative to that of the Mikado type locomotive.

The relative capital costs, using the Mikado as base (100 per cent), are 104.4 per cent for the Decapod, type I, and 109.2 per cent for the Mountain type, M. These figures are derived from the actual prices paid for the locomotives used in this analysis. The respective costs per train-hour are:

Cost per train-hour, type L engine—100.0 per cent—$14.50
" " " " I " —104.4 " — 15.14
" " " " M " —109.2 " — 15.83

To vary the cost per train-hour according to the capital costs of the respective locomotives seemed justified, partly by the lack of detailed operating cost data for each locomotive, and partly by the fact that wages could not properly be held strictly constant because of the custom of paying the engine crew higher rates on larger locomotives than on smaller, though this practice varies somewhat among the different railroads because of differences in design.

In the following tabulations the computations involved are: Column 4 equals column 2 divided by column 3; column 6 equals column 1 multiplied by column 5; column 7 is based on the assumed costs per train-hour given above for the three types of locomotives respectively. All unit costs are given in cents, except as indicated.

The Concrete Gang

P. B. Motley, M.E.I.C.

This little sketch was inspired by the operation of "the gang" laying new road and sidewalk in front of the author's home. It gives a somewhat different view of the labourer and artisan than that usually held by the engineer. It just shows you what perspective will do.

These men are counterfeiting nature. The work of centuries is being done in a day for the service and convenience of man! There are not many of them—probably twenty-five in all—and they are like a ship's crew, of all ages and nationalities.

Here is a man with a battered Borsalino, that he has riddled with holes. His mates say, "he's air conditioned!" Then there's Fatty, who's not yet thirty, and weighs two hundred and fifty pounds! His job is to hang onto a rock drill because, they say, he doesn't feel the vibration. There's also Mike, the big Ukrainian with a chest like a grizzly bear, and a hand as big as a Virginia ham! In the dinner hour, he amuses himself and the boys, by carrying one of his pals around on one arm.

"Come on now ye little troglodites," shouts the foreman, a restless man, who always seems to be going somewhere or wigwagging his arms to a truckdriver over there! He carries a plan in his hand, but he does more than that. He's the "Headman" and a thinker; he lays out the work according to the engineer's plans, sees the mix is right and the materials correct as to quality and quantity—and he's a financier; he makes out the payrolls at the end of the day! Important man this!

Now they're off, and at it. This is a rush job and several hundred feet must be poured by night so that it may have Sunday to harden. "Come on now you —." It is rumoured that if he did not speak in these affectionate terms, the boys would think he was getting swelled head or "high hat," or was losing interest in them. "Hurry up there you'se barrow men. Where's the guy with the 'blasted' hose?"

The mixer, which looks for all the world like a simple dairy churn, with much clatter, spues out the sludge from its insides, and all the Joes and Mikes and Fattys and Rodrigues fall upon it with shovels and big spreading rakes, and wheelbarrows, transporting it by much push and pull and vocal effort to the farthest corners of the work, as happy as mudlarks—which they actually are, in their long boots, verily wading in the wet concrete, like boys in spring puddles; with this difference—it's stone they are making!

There are some men ahead working on the wooden forms which give the proper curves to the curbs and walks. One of them has his mouth full of nails. He is an artist in his way. He has a hammer in his hand, sometimes a foot rule, that simplest of engineering instruments of precision, that critic and criterion of the work, which he silently uses from time to time—as a sculptor does in his studio.

"Come on now boys" again shouts the foreman who is afraid of the weather and wants to get this run finished before rain or nightfall. He knows the value of time and team work—and so do these big bespattered grey men. They have their officers and obey them, just as on shipboard on the main yard on a pitch dark night, or in front line trenches in the face of the enemy. No man tries to fool his fellows—while he may at times try to fool the boss.

At last, with continuous din from the machinery and shouting from the men, at seventeen minutes after quitting time, the work is finished. It's done. The long boots are washed at the water pipe as are faces and hands, for these soiled bronzed Adonises, when off the job, are quite fastidious about their appearance, and they are proud of their work—it's permanent!

Consider those other fellows, who expose themselves to a course of technical instruction for a period of years, at the end of which they get a piece of sheepskin which lets them into *their* little union whereupon they become "specialists"! These men too are specialists—union and all. Hats off to the men of the "Concrete Gang."

Recent Developments of the Gas Industry in Canada

John Keillor,
Gas Engineer, British Columbia Electric Railway Company, Vancouver, B.C.

Presented at the International Engineering Congress, Glasgow, June 21st-24th, 1938.

SUMMARY.—This paper was written in compliance with a specific request which The Institute received from the London Executive Committee of the International Engineering Congress in Glasgow. It deals with the sales of gas, existing and recommended standards, new methods of manufacture, gas burning appliances, and in particular the fields in Alberta. It describes the largest underground storage holder in the British Empire situated in Southern Alberta and a unique method of transporting gas across a three hundred foot lift bridge.

The Decline in Gas Sales in Canada

Perhaps the most outstanding fact about the gas industry in Canada is that the combined sales of manufactured and natural gas in 1937 were less by over 3 billion cu. ft. than in 1930. The decline in manufactured gas sales being greater in proportion than that of natural gas.

The gas industry in Canada is taking cognizance of its position following a period of recession—six consecutive years (1930-1936) of decline in gas output due to new and intensive forms of competition—low priced fuel oil, Diesel oil, electricity and sawdust. The remarkable improvement in the design of appliances for using the various grades of oil, electricity, sawdust, etc., has enabled the new competition to successfully invade homes and industrial plants throughout the Dominion, making serious inroads into domestic, commercial and industrial gas sales. An amazing increase has taken place in recent years in the use of these cheap competitive fuels to the exclusion of gas.

Gas sales began to decline and the need for new construction fell off. Only two new coal gas plants have been built in Canada since 1930, a chamber oven plant in Vancouver, B.C., and a continuous vertical retort plant in Guelph, Ontario.

Following are the changes in million cu. ft. sales of manufactured and natural gas in Canada in recent years:

Manufactured Gas	M. cu. ft.	Therms
Year 1930-31 to March 31st	18,266,000	89,503,400
" 1936-37 "	16,577,000	81,227,300

Average calorific value of manufactured gas 490 B.t.u.'s per cu. ft.

Natural Gas	M. cu. ft.	Therms
Year 1929-30 to March 31st	31,881,000	369,819,600
" 1936-37 "	30,291,000	351,375,600

Average calorific value of natural gas 1,160 B.t.u.'s per cu. ft.

	Therms
Combined sales of the two gases, year 1936-37	432,602,900

Total manufactured gas sales are down 9½ per cent from 1930-31
Total natural gas sales are down 5 per cent from 1929-30

The losses are principally due to cheap fuel and Diesel oil and electrical competition in the domestic and industrial markets. These forms of intensive competition are common to most cities in both Canada and the United States.

It is interesting to note that while sales of both manufactured and natural gas in the United States declined in about the same ratio as they did in Canada between 1930-1933, combined losses in the United States have since been more than recovered, while manufactured gas sales in Canada are still down 9½ per cent and natural gas down 5 per cent as compared with 1930. The writer is hopeful this unsatisfactory situation may soon be remedied in Canada.

Four year's figures taken from American Gas Association returns illustrate the remarkable recovery and trend of the business in the United States.

Percentages of Increase in M. cu. ft. Sales, 1937 over 1933

	House Heating	Industrial	Domestic	Total
Manufactured Gas				
Change in M. cu. ft. output	+127.8%	+65.2%	−12.8%	+13.5%
Natural Gas				
Change in M. cu. ft. output	—	+73.0%	*+21.6%	+55.1%

*Include house heating.

There are no similar figures available in Canada to show plus or minus sales in the three main branches of the business, but it is well known that the recovery in United States total sales is due to the rapid increase in sales for "space heating" and "industrial" purposes.

Only a few of the companies in Canada are as yet actively promoting the sale of gas for "space heating." Those who do are recording increases in total cubic feet sales. Those who don't show gas sales are languishing or further declining.

Gas Standards

Canada has a "uniform" or minimum 450 B.t.u. standard governing the quality of manufactured gas sold throughout the Dominion.

Throughout Canada gas is still made to the same "uniform" standard regardless of the varying qualities of coal or oil available for gas and coke making, geographical location, vulnerability of companies to competition of foreign fuels or manufacturing economies.

A committee of the Canadian Gas Association realizing that Canada's regulations are now out of date recently brought the matter to the attention of the Association and that body is now studying more recent British, American and Australian regulations with a view to modernization of the regulations in this country.

There are as yet no gas companies in Canada selling gas on a "therm" or other heat unit basis. No companies making gas under the "Declared" C.V. System.

There are no companies manufacturing gas of lower than 460 B.t.u.'s but opinion is gaining favour that it would be well for the industry and the gas consuming public if the "uniform" standard were abandoned in the Dominion as it was in Great Britain and the British system of requiring each gas company to "declare" the quality of gas it is best equipped to make and sell from available raw materials adopted. The gas to be sold on a "therm" or other heat unit basis. The writer believes that the

Fig. 1—Hydro Electrolytic Gas Plant, Top View of Battery of Cells.

"Declared" C.V. System is the fairest and most scientific formula for manufactured gas company operations yet devised and if adopted in Canada will give gas companies freedom to make the kind or composition of gas that will enable them in most districts to give consumers a better product than they get now—at the burner point a high flame temperature gas at a lower price. This should be the aim of every gas company in these days of keen competition among fuels.

More attention is being given to constancy of specific gravity, combustion characteristics, flame temperature, the composition of gases, etc. It is becoming recognized in Canada as elsewhere that calorific value alone is an indeterminate measure of value of gas. If the industry in Canada would increase the efficiency of manufacture, reduce manufacturing costs, attain greater efficiency in the use of gas and make progress in the future the writer believes that one of the first steps toward the accomplishment of these objectives should be the revision of the Canadian gas regulations. In the meantime present Government regulations prevent gas companies adopting more efficient methods of manufacture and sale, made possible in other countries by more flexible regulations.

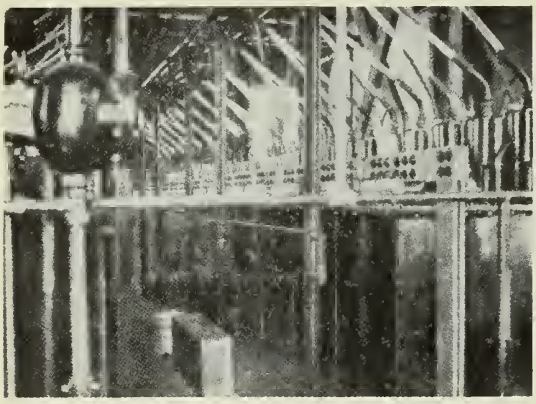

Fig. 2—View Between Battery of Cells.

Recent Gas Engineering Developments

Several new and interesting engineering developments have taken place in Canada in recent years. These the writer will endeavour to describe briefly, quoting from papers written on the respective developments.

Mixing Gas Electrically—Complete Gasification of Coal with Oxygen

A recent Toronto experiment conducted by A. T. Stuart, Director, Gas Department, Hydro-Electric Power Commission of Ontario, shows how complete gasification of coal or coke, etc., can be accomplished in the generator designed by Mr. Stuart in collaboration with American engineers, using oxygen produced from water by electrolysis.

Excerpts from description of the process by Mr. Stuart follow:—

"For many years it has been known and realized by experts in all parts of the world that the solution of the problem of the economical and complete conversion of coal into gas will depend upon large supplies of cheap oxygen.

When we consider the manufacture of domestic gas, it becomes apparent that air may not be the logical source for oxygen. If we use air oxygen we produce a gas abnormally high in carbon monoxide and higher in gravity than the gas now in city mains. If however we use water instead of air as the source of oxygen we restore the balance and can produce gas almost identical with the gas now in city mains.

The Hydro-Electric Power Commission of Ontario may therefore claim to be among the first to demonstrate on a commercial scale how coal can be completely gasified by means of electricity for the manufacture of gas similar in composition, heat value and gravity to that now being distributed in city mains.

This plant is capable of producing some 2,000 cu. ft. of oxygen and 4,000 cu. ft. of hydrogen per hour. (Figures 1, 2, and 3.) A standard type of gas producer having stationary grates was installed for operation with oxygen and steam.

Although it is a simple matter to carburet these gases to present standards, and although costs would still be less than competitive methods, the lowest possible costs would be reached if 333 B.t.u. gas could be sold on a therm basis."

The Three Stage or "Triple" Process of Manufacturing—Coal Gas, Blue Gas and Carburetted Water Gas Simultaneously

There has recently been developed in the gas works of the British Columbia Electric Power and Gas Company, Vancouver, B.C., a process for the manufacture in intermittent chamber ovens of coal gas, blue gas and carburetted water gas simultaneously. This process has certain economic advantages compared with manufacturing coal gas and blue gas in intermittent chambers or continuous vertical retorts, and carburetted water gas in a separate water gas plant.

The three stage process makes possible control of coke production, reduces the cost of making mixed gases and increases the gas production capacity of the ovens in Vancouver, 25 per cent. It is described in a paper read by Mr. J. Kirkhope, Vancouver, B.C., before the Canadian Gas Association, July 1936, excerpts from which follow:—

"In the ordinary two stage process of making gas by the carbonization of coal in the intermittent ovens it is well known practice to admit steam to the bottom of the ovens when the carbonizing period is complete, this practice serving the purpose of utilizing some of the coke for making blue gas and thus increasing the total make of gas per ton of coal carbonized.

At the completion of coal gas and blue gas manufacture in the ovens, i.e., at the end of the second stage, there is, of course, still left in the resultant coke a large amount of available sensible heat which, however, cannot be employed for further blue gas production without lowering the calorific value of the mixed gas.

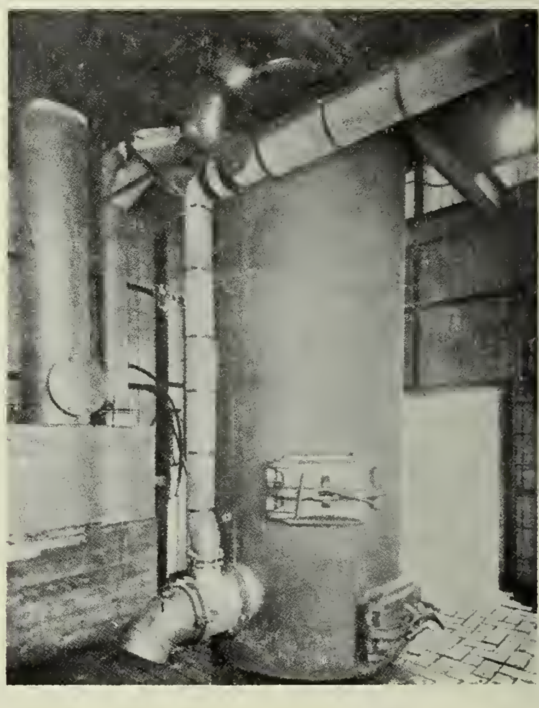

Fig. 3—Gas Producer Installation.

If, however mixed gas of the same calorific value is required, enrichment of the surplus blue gas is necessary. This enrichment was accomplished at Vancouver by the admission of liquid hydrocarbons to the ovens at the top simultaneously with the admission of steam at the bottom. The liquid hydrocarbons sprayed on top of the hot coke in the chambers at regulated temperatures causes cracking of the hydrocarbons to take place, with consequent formation of a permanent gas of high calorific value, which gas mixes with the water gas resulting from the prolonged reaction of the steam with the hot coke. The resultant mixture of water gas and cracked gas can, within certain limits, be made to any desired calorific value between that of either constituent, by adjustment of the proportions of steam and hydrocarbon liquid admitted to the chamber.

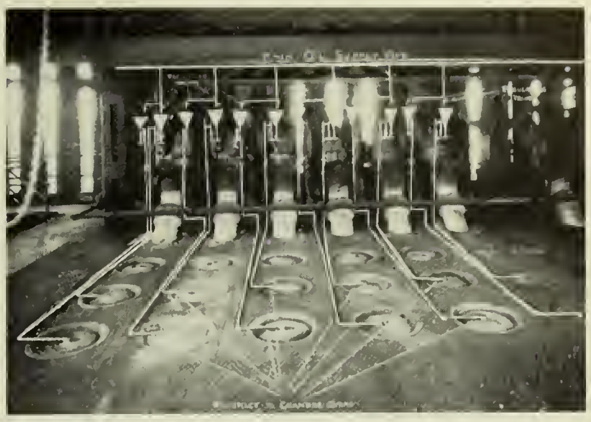

Fig. 5—Equipment for Oiling Oven Charges, Vancouver Plant.

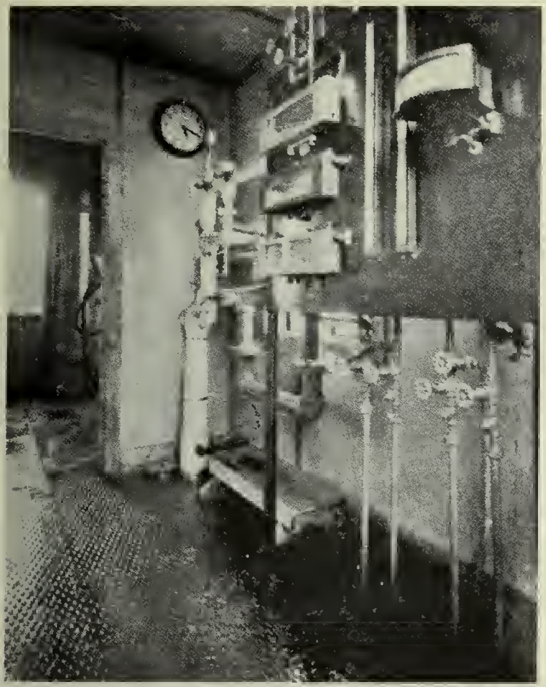

Fig. 4—Recording Instrument Rooms.

Each of the thirty-six ovens in Vancouver is equipped with two funnels and U-sealed delivery lines and the oil discharges into the ovens through nipples in two of the three charging port lids. Either one or both can be used to suit the proportions of oil gas wanted in the mixture. (Fig. 5.)

In a modern gas producing plant of the intermittent oven type the "Triple Process" of making coal gas, water gas and carburetted water gas can thus be carried on simultaneously, thereby controlling the coke output in a manner hitherto not attempted. The coke residue is still of good marketable quality.

In the case of the results obtained without oiling, i.e., making coal and blue gas only, the points lie fairly close to the curve "*A*." When the "Triple Process" is in use, the results obtained when using twenty to twenty-five gallons of oil per ton of coal carbonized are shown plotted, and fall on, or close to, curve "*B*" (different curves are obtained for different oil consumptions).

When using the "Triple Process," the make of coal gas, blue gas and carburetted water gas usually averages 25,000 cu. ft. (117.5 therms) per ton of coal and oil used and on occasion 30,000 cu. ft. (141 therms) has been exceeded. Thus the third step in the process-making carburetted water gas increases the yield of gas per ton of coal and oil used, so that coke production can be controlled at will and without utilizing the auxiliary water gas plant, except when the output exceeds the capacity of the chamber oven plant."

A Unique Natural Gas Engineering Development— Production of Natural Gas in Turner Valley and Recharging a Depleted Natural Gas Field at Bow Island, Alberta

The largest gas producing plant in the Empire is the Turner Valley Natural Gas Wells, Alberta. They are producing more therms annually (880,000,000) than all the gas companies in London, Glasgow, Edinburgh, Manchester, Liverpool, Birmingham, put together. And no gigantic coal gas, water gas or complete gasification plants on ground level are required to produce this enormous therm output. The natural gas has a C.V. of 1,160 B.t.u.'s per cu. ft. after it has been stripped of its gasoline content.

At the present rate of proration approximately 208 million cu. ft. of natural gas (2,412,800 therms) is being produced daily in the Turner Valley field. Of this amount 9 million cu. ft. (104,400 therms) is being used in field boilers and for heating purposes in the field proper while between 30 and 50 million cu. ft. daily is being consumed through the pipe line system of the Canadian Western Natural Gas, Light, Heat and Power Company, Ltd., Calgary, depending on weather conditions. The balance, an average of 160 million cu. ft. (1,856,000 therms) is blown to the atmosphere and wasted daily after the wet gas has been treated in separators and stripped of its gasoline content.

Storage of Natural Gas in the Bow Island Field

Southern Alberta also possesses the largest underground gas storage holder in the Empire. There is now stored in the Bow Island field 10 billion cu. ft. of natural gas which has all been pumped from the Turner Valley field into the near depleted wells at Bow Island (160 miles distant) there to be conserved. Pumped underground against outlet pressures on compressors from 297 lb. to 566 lb., the filling of of this great underground holder has been going on for 7 years.

Repressuring near depleted wells and storing quantities of natural gas underground at increasing pressures is a remarkable piece of natural gas engineering. It is a successful attempt to conserve at least a small part of the enormous surplus gas now going to waste in the Turner Valley.

The writer is indebted to Mr. P. D. Mellon, General Superintendent and Chief Engineer of the Calgary Company, for this up to date information re Turner Valley operations and for the following details of the operation.

Report on Storage of Turner Valley Gas in Bow Island Field, form Commencement of Operations August 4th, 1930 to July 31st, 1937

Automatic High Pressure Valves on a 300-ft. Lift Bridge—The Only Installation Extant

An interesting development in Gas Distribution Engineering was described in a paper read before the Pacific Coast Gas Association, Seattle, Washington, August 1937 by Mr. F. E. Reed, British Columbia Electric Power and Gas Company, Vancouver, B.C., the designer of the automatic valves. A short time ago the company extended its distribution system to the north shore of the harbour in Vancouver and it became necessary to either lay a high pressure submarine main under heavy tidal water or devise a means of getting the gas across a lift bridge. How this was done is described in the paper referred to, excerpts from which follow:—

Fig. 6—Second Narrows Bridge, Vancouver, B.C., Carrying Gas Mains.

"At the point where the bridge (Fig. 6) is built there is a tidal current which runs at times as fast as 10 knots according to the variation of the tides.

At first the possibility of laying an under-water gas main at a location a short distance from the bridge where the City Water Department has several cast iron water mains was considered. These water mains are 1½ in. thick, 18 in. in dia. and weighing over 450 lb. per ft. and on information obtained we were advised that the effect of the silt and sand deposited from the creeks, passing back and forth with the tidal current over these pipes, had been known to wear sections of them through within a very short period, also some of them had been broken by vessels dragging their anchors, etc.

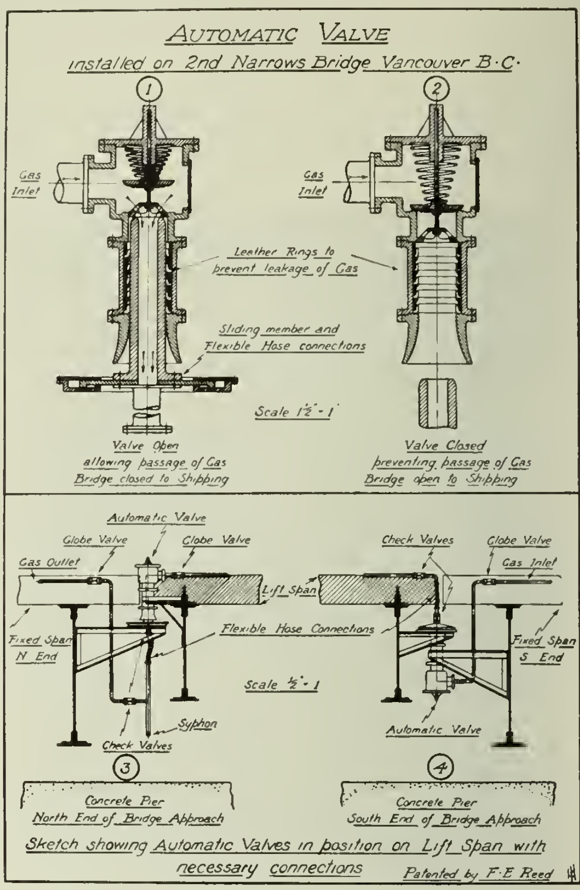

Fig. 7—Operation of Automatic Valves on Second Narrows Bridge, Vancouver, B.C.

Finally after very careful consideration and in view of the physical difficulties and high capital and depreciation costs of a submerged gas main it was decided to install on the bridge and lifting span section two automatic joints and valves.

This is the first and only installation of its kind in the world to be used by a gas company in the transmission of its product. On each end of the 300 ft. lift span was installed an automatic joint. When the bridge span lifts for the passage of a vessel the joints come apart and the gas supply to North Vancouver is automatically cut off. This does not affect the supply to the consumer for the demand is taken care of by storage of gas in a Hortonsphere holder on the North Vancouver side. When the lift span is brought down to the traffic level the joints automatically couple themselves, opening valves and permitting gas to flow from the city plant to the North Vancouver shore. The valves were placed in operation in 1934 and to date they have worked without giving the slightest trouble and requiring very little attention.

Figure 7 explains the operation of these valves. This drawing has been divided into four sections, 1, 2, 3 and 4 and by referring to Fig. 7 (1) you will see how the two halves of the joint are joined together when the bridge is in position and the gas is passing through our main."

Certification and Approval of Gas Burning Appliances

The writer is indebted to Mr. George Allen, Secretary, Canadian Gas Association, Toronto, for the following information:—

The gas industry in Canada has for twelve years been keenly interested in the certification and approval of gas burning appliances, so that users of gas service may be supplied with equipment that is at once safe, efficient and durable. The Canadian Gas Association has taken keen interest in the activities of the Testing Laboratories of the American Gas Association and has adopted the standards of gas appliance manufacture laid down by the Approval Requirements Committee of that organization. Most of the gas appliance manufacturers of Canada have fallen in line with this excellent movement, and are doing all they can to bring up the quality of their products to a standard that promises well for the gas industry in this country.

The certifying and approving of gas appliances, especially those that fit into domestic service, has done much to increase the efficiency in use of both manufactured and natural gas and improve customer satisfaction. The central testing laboratory located at Cleveland, Ohio, and the branch located in Los Angeles, California, has tested and approved nearly 6,000 individual gas appliances made by manufacturers in Canada and the United States. In addition, about 23,000 other appliances have also been approved by visual inspection only based on their similarity to those previously tested. At the present time the laboratories are certifying equipment for nearly 300 manufacturers located throughout the United States and Canada. The value of the property and physical equipment of the laboratories amounts to about $250,000.

The Seal of Approval of the Canadian or the American Gas Association shown on a gas appliance, appurtenance, device or accessory, is a guarantee to the public of compliance with basic national requirements for safety, and any such equipment that cannot meet these requirements is not fit to be used, and all practical means should be employed to prevent its sale and use.

Monel Metal Tanks

Of the many new types of appliances approved, special mention might be made of the recent use in Canada of monel metal tanks in automatic gas water heaters, increasing numbers of which are being sold. Where they have been in use for three years or more it is found that customers get a supply of hot water absolutely free of rust or discoloration. This confirms the belief that monel metal tanks will outlast other makes of tanks so far as internal corrosive action of the water is concerned, but it is not known yet what effect the products of combustion of various gases are going to have on the exterior of the tanks. This will take some years to find out.

Aviation Radio

A. K. Bayley,

Assistant Radio Electrical Engineer, Department of Transport, Aviation Radio Branch, Ottawa, Ont.

Presented before the Lethbridge Branch of The Engineering Institute of Canada on January 22nd, 1938.

SUMMARY.—The value of communication in transportation cannot be overestimated. In the field of aviation this value is greatly enhanced, but the means of establishing the communication is much more complicated than in other forms of travel. The author describes the different systems and equipment that are now in use in Canada.

There are many angles from which a subject so complex as aviation radio might be approached. Indeed, within the prescribed limitations, it is possible to cover only a small portion of the subject. In preparing this material an endeavour has been made to deal with the features that would have the most interest of a general nature.

The history of transportation shows the development of its dependence upon communications from the early days of slow motion travel to this day of speed. This dependence has steadily grown until to-day it is evident that our transportation systems could not operate without it. Trains, boats, busses, and air lines would be at a standstill if they did not have efficient methods of maintaining contacts with other moving vehicles and with the stationary points on land. Hence we see that the first work of a communication system is to establish safety in transportation. With that most modern of all conveyances the aeroplane, it is more than ever important, and it is the object of this paper to outline the needs of this form of rapid transportation and to describe the equipment and the methods that apply to this modern method of communication.

This field divides into two parts:

1. The facilities for rapid inter-communication between ground stations and between these ground stations and the planes.

2. The facilities for guiding planes in their flights between the various terminus points and for assisting them in landing when the visibility is poor.

1. In dealing with the first requirement, it has become standard practice to include a teletype circuit which connects all stations along the airway. Weather reports are normally sent along these circuits in order to render the radio facilities available for plant to ground communication at all times. It is obvious therefore, that as far as the dispatching of weather reports from one ground station to another, the radio is only used as a standby in the event of trouble on the teletype lines.

The radio communication system is, however, used for service or routine messages between the terminus points of the system. These messages include such things as the times of arrival and departure of planes and in fact all the normal routine details of concern to a transportation system. This radio set is also used for the purpose of assisting in the landing of planes when visibility is poor. Even under good conditions the station contacts the plane immediately before it lands, giving last minute reports on details that might affect the landing.

This ground equipment serves another important service. The operator of the ground station keeps constant watch on the communication frequency. The plane is required to report at fixed times each hour. In the event of a plane failing to report on one of these allotted times, immediate investigation is made as to its location. Therefore a continued check is maintained from the time the plane leaves one terminus until it arrives at the next.

To fulfil the requirements imposed on the terminus ground station these stations must be equipped with:

a. A transmitter of sufficient power to ensure an uninterrupted communication service between any three adjacent ground stations and constant communication with planes flying between any two adjacent ground stations.

b. A receiver capable of receiving the messages directed to the ground stations from either adjacent ground stations or planes.

The planes must be equipped with:

a. A transmitter of sufficient power to ensure reliable communication with the two terminus ground stations between which it is flying.

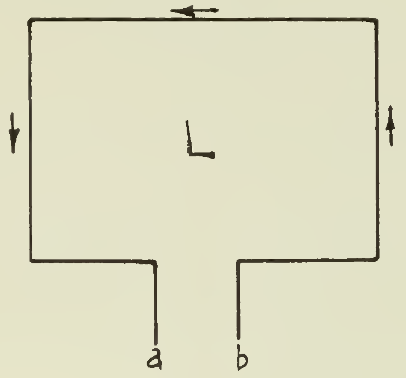

Fig. 1.

b. A receiver capable of receiving signals from the adjacent ground stations between which the plane is flying.

Due to the present popularity of multiband broadcast receivers, nearly everyone has at one time or another heard the type of message that is directed both from the aviation ground stations and the planes themselves, thus this section is concluded with a brief outline of the factors which determine the type of equipment used in this branch of the Aviation Radio Service.

Obviously the power required for the ground transmitters is determined by the distance between the terminus points where these stations are located, but what about the plane transmitters? Every pound of weight added to the equipment carried by the plane means one pound less "pay load." It is a well known fact that the more power required, the larger and heavier is the equipment necessary to deliver that power to the transmitter for its operation. The problem of seelcting the plane transmitter then resolves itself into selecting the transmitter of the least

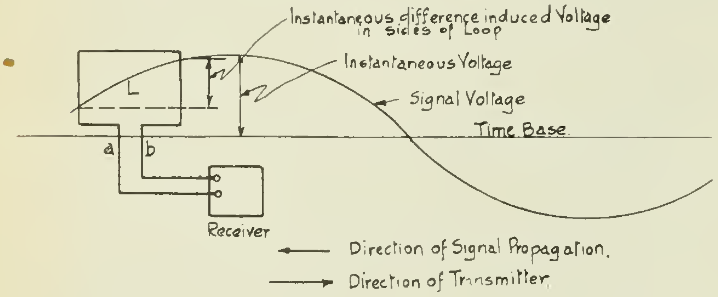

Fig-2

bulk, requiring the least power to operate it, which will still fulfil the communication requirements. The answer to the problem is apparent, namely short wave transmitters. The bulk of this transmitter and the power required to operate it are appreciably less than those transmitting long waves for the distances over which communication between ground and plane must be maintained. Obviously the answer to the plane transmitter problem dictates the type of transmitting equipment to be used on the ground since it is not economical to install separate equipment for each of the two services required of the ground station.

Since the selection of receivers is tied with the solution of the transmitter problem it will suffice to say that short wave receivers are less bulky than those for long wave operation.

2. The discussion of the radio equipment necessary to guide planes from one point to another, logically falls into two subsections: in other words, there are two methods which may be used to guide planes by radio signals.

a. The first method involves the installation of a direction finding receiver, in each plane. By the reception of signals from ordinary broadcast stations or stations specially constructed for this service, the operator in the plane can determine his position by triangulation. The ground station transmitters for this service do not have to be specially adapted for the service. By using direction finding equipment, the pilot may tune his direction finder on a station located near his destination airport and fly directly towards it. This system is used extensively in Europe and also for trans-oceanic flying where it is not possible to install transmitters of a better type. On this continent this system has so far been used only to supplement that which is described later.

Numerous commercial direction finders for this type of service are available but all of them are based upon a property peculiar to loop type antennae. Since a review of all the various types available would be a discourse of

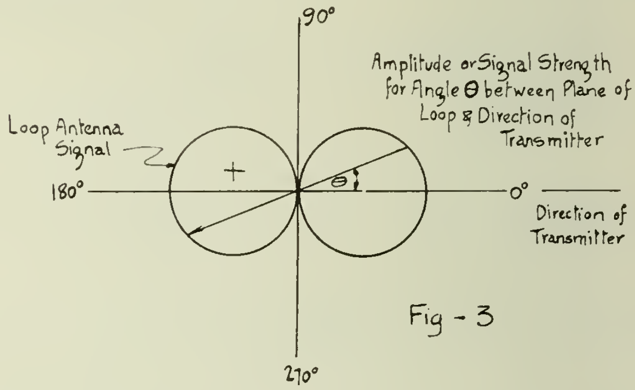

Fig - 3

great length in itself, the writer will deal only with this common property.

Before the efficient household broadcast receiver deteriorated into a piece of furniture, loop type aerials were mounted on the receiver so that its directional properties could be used to help us select the station we wished to listen to. This deterioration along with interference difficulties involved in the use of such an aerial have caused it to vanish from the household field. Let us observe this directional property peculiar to this type of antenna in a general way in order to establish a basis for the discussion of the system described later.

Let us represent the loop aerial diagramatically as L (see Fig. 1). If this loop were connected to a battery with its positive terminal connected to b and its negative to a, the current around the loop would conventionally be in the direction of the arrows. In other words, the current would flow upwards in one vertical side of the loop, and downwards on the other. If an alternating voltage were connected to a and b the current would continually change its direction, but at any given instant the currents in the two vertical sides of the loop would still be in opposite directions. These currents are said to be 180 deg. out of phase. Let us now disconnect the battery from the loop and connect a and b to the input terminals of a receiver (see Fig. 2). The radio signal received is in itself an alternating voltage travelling through space as shown in the diagram. The dimensions of the loop are chosen so that they are small compared with the wave length of the signal. Therefore, with the loop placed in the position shown, there will be a difference in the voltages induced in the two vertical sides of the loop which will send a current around the loop. The currents in the two vertical

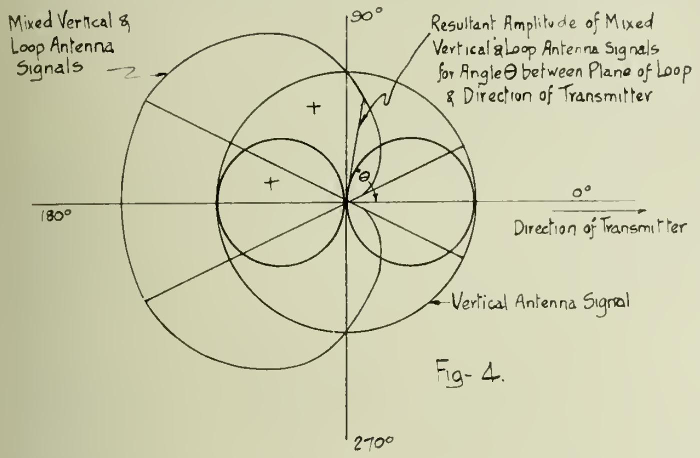

Fig- 4.

sides will still be 180 deg. out of phase at all times. We might add that this voltage appears at the terminals of the loop *a* and *b*, and is fed to the reciever input.

Let us now rotate the loop so that its plane makes an angle of 90 deg. with the direction of the transmitter. Here we see that no difference of voltage is set up in the vertical sides of the loop and hence, no voltage appears at *a* and *b*. Therefore, if we plotted the polar diagram of the signals received at any instant as we rotated the loop through 360 deg. we would get a diagram known as the "figure of eight" (see Fig. 3). In this and following figures the representation of the loops of the figure of eight diagrams as circles is not strictly correct, but for the purposes of this discussion the figures illustrate the general theory involved. In other words, we get a maximum signal from the transmitter with the loop at 0 and 180 deg. but a zero signal at 90 and 270 deg. It is obvious from the shape of the curve that the minimum signal is more distinct than the maximum, so that it is used to give the directional indication. It should be noted from Fig. 3 that at any instant the signals for the loop in any two positions 180 deg. apart (other than 90 and 270 deg.) will be 180 deg. out of phase. To remove the ambiguity of the directions, a vertical antenna signal is introduced which cancels out one side of our figure eight pattern. The signal received in the vertical antenna is in phase or 180 deg. out of phase with the loop signal at any instant depending on the angular position of the loop. The proper relationship of vertical and loop antenna signals is determined by the adjustments made during calibration of the direction finder. It is obvious, however, that the amplitude of the signal from the vertical antenna must equal the maximum amplitude received by the loop (i.e. in its 0 and 180 deg. positions). See Fig. 4. This latter adjustment is called the determination of "sense." The actual direction in degrees is found by the former adjustment as difficulties involved in the adjustment for sense make absolute accuracy very difficult to obtain. In other words the sense adjustment is only used to determine which of two bearings 180 deg. apart is the correct bearing or direction of the transmitter.

Hence we see that if a plane were to have a loop mounted rigidly at right angles to its length, it would be possible for the pilot to fly towards the station in question by flying in the direction necessary to maintain minimum signal in his receiver. The disadvantage of such a system is of course the fact that the plane may fly a curved path due to wind drift, taking if off the straight line course between two points.

b. The other alternative method of guiding planes by radio is to use equipment popularly called a radio beacon, more accurately named radio range. In the original set-up the directional property of loop antenna was again used to produce a group of four directional signals which combine to yield four distinguishable courses which can be recognized by the pilots of the planes utilizing an ordinary receiver without automatic volume control. Two loop aerials were erected at right angles to each other and fed with signals from a goniometer unit. By use of a keying mechanism the signal was alternately fed to each of the loops producing first one figure of eight pattern then another at right angles to the first (Fig. 5). The field or signal pattern of the tramsitted signal is exactly similar when the loop is used as a transmitting antenna to the case in Fig. 3, when the loop is used as a transmitting antenna. It is obvious from the diagram that planes flying along the directions at 45 deg. to the two loops will receive signals of equal strength from both figure of eight patterns. In order to distinguish one signal from the other the 0-180 deg. loop was keyed with the letter A (· – in code), and the other loop with the letter N (– · in code.) The signals are so interlocked that when the plane flies on course, a steady signal is heard in the receiver. That is, the dot of the A fills up the space between the dash and the dot of the N and the dash of the A fills up the space between the N's and vice-versa. If the plane flies to either side of the course either an A or an N is heard in the receiver.

It is obvious that the courses that are required may not be 45 deg. to the loop directions. Let us rotate the goniometer primary into the 45 deg. position and find where the courses will lie. It is evident that when the keyer is in the A position, the output of the transmitter is divided equally between the two loops. Similarly, the

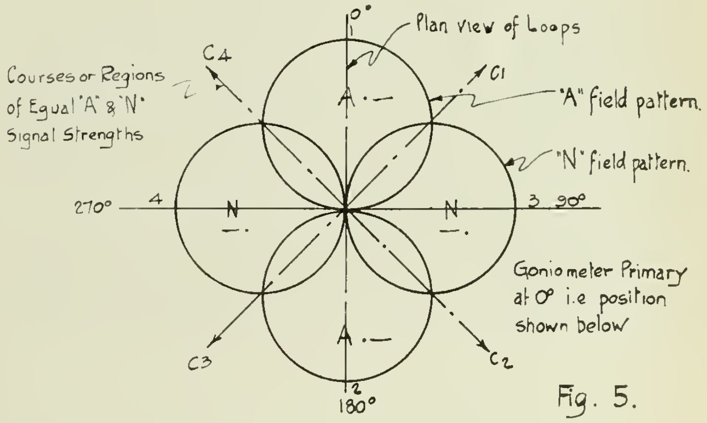

Fig. 5.

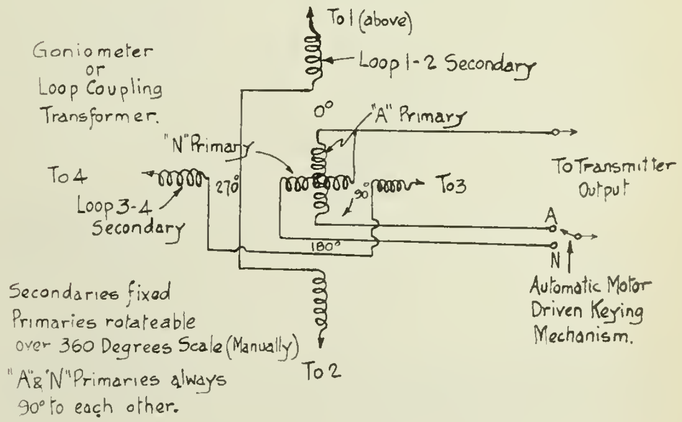

power in the N position is divided equally between the two loops. This produces two figure of eight patterns as shown, and we see that our courses are now 0-180 deg. and 90-270 deg. See Fig. 6. Thus by rotating the goniometer primary from 0 to 45 deg. the courses have also swung around through 45 deg. If we continued to turn the

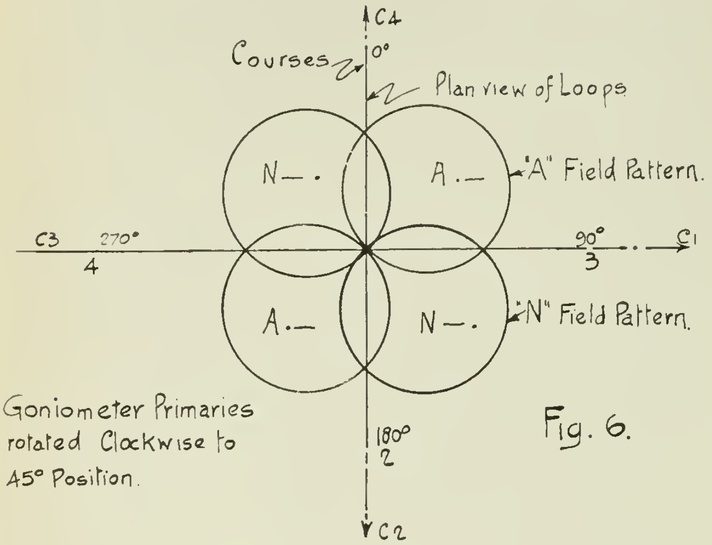

Fig. 6.

goniometer through the entire 360 deg. we would see that the courses rotated 45 deg. ahead of the goniometer setting. It must be noted that the four courses still remain 90 deg. apart.

Again it is obvious that the required courses from a given range station may not be all disposed 90 deg. apart. Let us leave the goniometer at 45 deg. and introduce a resistance in series with the N side of the keying system. A voltage drop occurs accross this resistance, hence the voltage which is delivered to the N primary will be less than that delivered to the A primary of the goniometer. This means that the N figure of eight pattern will be reduced in size. See Fig. 7. Here we see that our courses have been moved from their 90 deg. relationship, but reciprocal or opposite courses still remain 180 deg. apart. This process is called course squeezing. Even this adjustment may not fill the requirements, so some means must be used to bend the reciprocal courses away from their 180 deg. relationship.

With the loop beacon this can be done by introducing a vertical aerial into the centre of the system and distorting the figure of eight patterns in the same manner that sense

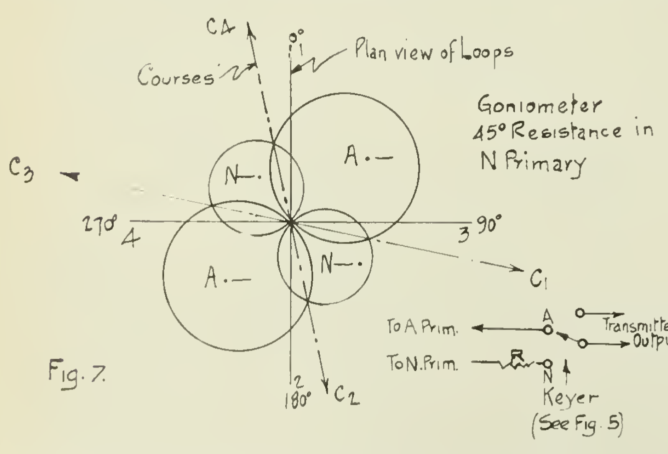

Fig. 7.

was obtained for direction finding, not carrying the process far enough to completely cancel out one loop of each diagram. The resulting field patterns will take on the approximate shape shown in Fig. 8, with the goniometer at 45 deg. Here we see that we have changed the angle between the east and west courses from 90 deg.

As this adjustment is very difficult, as was the case of our sense adjustment, for direction finding, the designers of such installations concentrated their attention on modifying the system to make course bending easier to achieve.

Also the loop aerial system is subject to errors due to a condition known as "night effect." The ability to obtain accurate and stable courses depends entirely upon the reception of what is known as the horizontal ground wave which is sent out by the vertical sides of the loops. The signal transmitted by the horizontal sides of the loop is called the vertical signal or wave. This vertical wave is reflected by the hypothetical Heaviside layer and when it comes back to the earth, it has usually been bent in both horizontal and vertical planes. If this vertical signal is strong at the receiving station then it will mix with the horizontal signal and produce errors. This effect is most noticeable between the hours of 8.00 p.m. and 8.00 a.m. and is therefore given the name "night effect."

As this effect was also apparent in direction finding, a designer by the name of Adcock decided to eliminate the horizontal sides of the loops. At the time Adcock designed his new system, receivers were not developed to a state of high sensitivity and since the new system of aerials was less efficient in picking up signals, it was discarded temporarily. However, with the advent of supersensitive

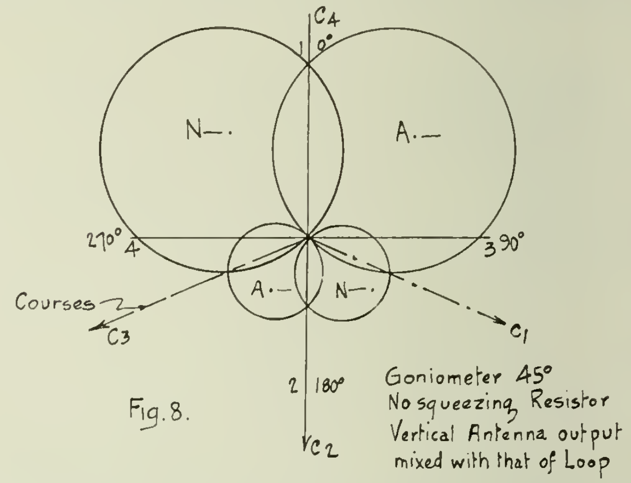

Fig. 8.

receivers, the Adcock aerial system again came to the fore and is now being used in aviation direction finding work from the ground for the purpose of locating planes in flight. This same aerial system has been applied to radio ranges to eliminate the undesirable night effect and coincidentally affords a more readily controllable method of course bending.

In this system, four vertical antennae or towers are erected which represent the four vertical sides of two loop aerials (Fig. 9). They are connected in the initial set up so that the currents in each of the opposite pairs are 180 deg. apart. We have seen that this was the condition in the loop aerial. The towers, therefore, are connected so that they are, in effect, exactly similar to two loop aerials placed at right angles. As the vertical signal radiated from such a system has been reduced almost to zero, the undesirable night effect is reduced from a possible ±45 deg. error to perhaps a ±10 deg. error.

Rotation of all the courses together is obtained by rotating the goniometer as before. Course squeezing is also obtained as before by inserting resistance in either the A or the N primary circuit. Coincidentally however, with the reduction of night effect we now have an easier method of controlling and adjusting the course bends.

In the loop system the currents in the vertical sides of the loops were always 180 deg. out of phase, now that towers are used we may chnage this condition. Changing the phase relationship between opposite towers has a similar effect to the introduction of a signal from a vertical aerial in the case of the loops.

This phase adjustment is obtained by the introduction of an artificial transmission line as well as the physical line to each of the towers. By adjusting the electrical length of this line we can change the phase relationship between the currents fed to the diagonally opposite towers. As it is possible to calculate the phase adjustment necessary between the opposite towers to give the desired bends in the courses, the system lends itself more readily to the efficient alignment of courses. Admittedly, the calculations from theory only give the engineer a place to start, having then to juggle the courses to compensate for the difference between theory and practice, but this is better than having to start off the adjustment by trial and error, as is the case with loop type installations.

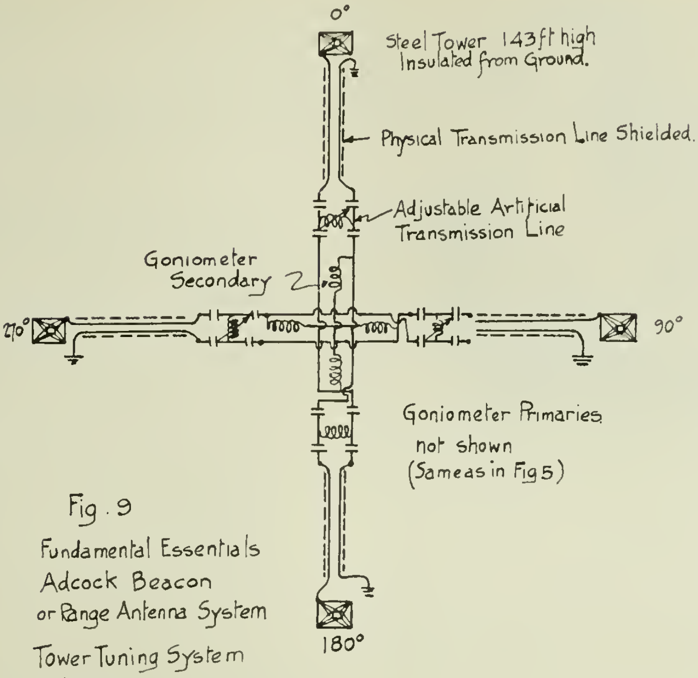

Fig. 9
Fundamental Essentials
Adcock Beacon
or Range Antenna System
Tower Tuning System
not shown.

It is interesting to follow the method by which a pilot may locate himself when after being lost with no range signal for a period he suddenly picks up a range signal. The identification signal which is given over each pair of loops in turn every 30 seconds tells him the station he is listening to. Looking on his chart he determines the line bisecting the angle enclosed between the courses bordering the A or N quadrant, whichever he happens to be in. He then adjusts the receiver to minimum volume and flies the bearing of this bisector. If he is flying towards the station the signal becomes louder. If he is flying away from the station the signal fades out. He therefore knows the direction that he must fly to pick up one of the courses.

A few words as to how the range may be used as an assistance to landing might also be in order. Directly above the station there occurs what is known as the cone of silence. This is a conically shaped region directly above the centre of the range station inside whose bounds the signal is reduced almost to zero. The pilot flying over the cone then locates himself even though it is impossible to see the ground. The range is usually located three miles from the airport with one of its courses lined up with the emergency runway of the field. He then knows that he is three miles from the field, his altimeter tells him his altitude and he has a course to guide him to the runway. Therefore, when he comes down out of the overcast, the runway is right in front of him.

There are two incorrect but popular conceptions regarding the operation of range stations, namely:—

1. That a radio beam similar to that emitted by a searchlight exists in the direction of each course. As indicated in Fig. 5, the courses are marked by regions of equal signal strength from two distinct field patterns set up alternatively around the range station.

2. That each course may be adjusted independently to its correct location. A study of Figs. 6, 7, and 8 indicate that each adjustment affects at least two courses, and when the goniometer is in other positions than 45 deg., all courses are affected by every adjustment. Hence the process of course alignment is one requiring considerable patience and time in order to obtain a set of specified courses.

Many other radio aids to airway navigation at present being developed are rapidly nearing perfection. Among these are: radio markers, to yield additional position checks along the airway routes; radio blind landing systems, to make landing under zero ceiling conditions entirely safe; and ultra-high frequency radio equipment to cope with the ever-present interference problem. Indeed, the complete removal of all skepticism as to the safety of air transportation, depends to a large extent on these new developments.

The National Housing Act 1938

by Horace L. Seymour, M.E.I.C.

SUMMARY.—The recently passed National Housing Act is of importance to all parts of Canada. The working of it is rather complicated, but the author explains it in such a way that it can be understood. He also points out the difficulties that will attend the operation of it, and suggests considerations that will facilitate its usefulness.

Early this year the writer received a letter from the Secretary of The Engineering Institute of Canada asking him to represent The Institute at a meeting which was being called in Ottawa by the National Housing and Planning Association for the purpose of urging the Dominion Government to extend existing federal legislation so that it would more adequately provide for low-rent housing projects.

At the meeting (held May 11th) were many business men, engineers, architects and members of parliament. Among those taking part in the speeches and discussions were Dr. S. H. Prince of the Nova Scotia Housing Commission, Professor at Dalhousie University, Halifax; P. E. Nobbs, chairman of the Housing Committee of the Civic Improvement League, and Professor of Architecture at McGill University, de Gaspe Beaubien, M.E.I.C., of the Montreal Housing Committee, and George S. Mooney, of the Montreal Metropolitan Commission, Secretary of the National Housing and Planning Association, all from Montreal; Captain G. H. Rochester, First Vice-President of the Ontario Command of the Canadian Legion, Dr. T. H. Leggett, President, and Horace L. Seymour, M.E.I.C., Secretary, of the Ottawa Housing and Planning Association, all of Ottawa. Members of parliament were from all parties, and all took an active part in the meeting. Twenty-four national organizations sponsored the gathering, and three others, including The Engineering Institute of Canada, had official observers.

The main resolution of the meeting was presented to the Hon. C. A. Dunning, Minister of Finance, on the morning of May 12th, by a committee of twelve representatives of national organizations, who resided in Ottawa or remained there for this purpose. The Minister of Finance pointed out the need for co-operation by provinces as well as by municipalities if national housing legislation were to be successful. In spite of difficulties he indicated the possibility of legislation along the lines requested and the impression gained was that such legislation was already in draft form.

On June 28th, 1938, the National Housing Act was passed, the preamble reading:

WHEREAS *The Dominion Housing Act, 1935*, has encouraged the building of houses by persons with moderate incomes but the facilities of the Act have not been largely used by persons with small incomes or by persons living in small or remote communities; and Whereas, it is desirable to stimulate the construction of houses to be owned by persons with small incomes and by persons living in remote or small communities; and Whereas, as a result of the low level of building activity during the recent depression, the employability and efficiency of the urban population may be adversely affected by reason of congestion in potential slum areas and of overcrowding in housing accommodation which falls short of minimum standards of health and amenity; and Whereas, such decline of employability and efficiency may retard the full employment of the working population living under such conditions; and Whereas, the task of providing adequate housing accommodation at rentals within the capacity of low income groups to pay is, in its aspects of public health, morals and minimum living conditions, primarily a responsibility of the provinces and municipalities; and Whereas, nevertheless, it is in the national interest that a limited experiment in low-rental housing should be undertaken now, creating needed employment and directing public attention to the importance of housing problems generally, and providing a basis of experience on which the provinces and municipalities may follow sound and proven policies in the future; and Whereas, high real estate taxes have been a factor retarding the construction of new houses and it is therefore desirable to encourage prospective home owners to construct houses for their own occupation by paying a proportion of the municipal taxes on such houses for a limited period.

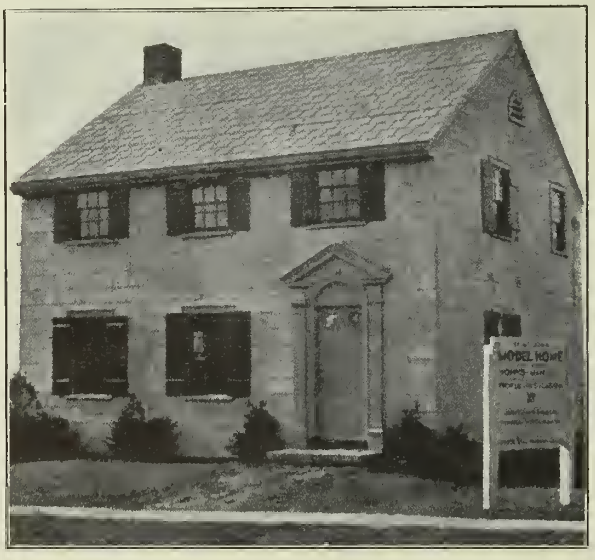

Fig. 1—First House Built in Saint John, N.B., under Dominion Housing Act.

General satisfaction has been expressed that the Act provides the machinery for a more active home building programme. It is felt that for real success co-operation and active interest are required not only by those interested in the building trades and industries, but also by provinces, municipalities, lending institutions, housing authorities, and corporations and individuals.

The Act provides, essentially, cheap money. It follows modern European housing policy and practice, a study of which indicates that the actual building of houses by national governments has been generally discontinued and that subsidies to stimulate house production have been generally abandoned. Now the most widely adopted form of assistance is the extension of government credit through loans or guarantees.

The National Housing Act—Part I

The new Act is divided into three parts.

Part I is an extension of the provisions of the Dominion Housing Act 1935, under which up to May 31st, 1938, the financing of 4,249 family housing units had involved aggregate loans of $17,350,000. This represents an average loan of $4,083 or an average cost for each home, including house, land and other incidental expenses of over $5,000, although the number of smaller loans is increasing.

The National Housing Act provides for a total federal expenditure of $20,000,000 under this part of the Act but of this amount about $4,500,000 has already been spent as the Dominion's share of the $17,350,000, the balance being provided by approved lending institutions—Insurance and Trust Companies.

Under Part I of the Act the Federal Government plans, therefore, to spend a further $15,500,000 as its part of loans for individual home ownership. This represents a possible expenditure of $75,000,000 in home construction in the next few years.

Under the Dominion Housing Act, not only has it been impossible to obtain loans in "small or remote" communities, but certain sections of the Dominion have been served only with apparent reluctance on the part of the lending institutions, which naturally were not anxious to set up new offices where a large volume of business was not expected or where the areas in which homes were to be built were not adequately planned or where there were no zoning regulations to protect the investments during the life of the housing loans. For example, in the City of Saint John and vicinity no loans were made for many months and it required considerable negotiation and the assurance of a Zoning By-law (as prepared by the Saint John Town Planning Commission and now passed for the City and district) to encourage the granting of loans.

Figure 1 shows the first house built in Saint John, N.B., under the provisions of the Dominion Housing Act 1935. It cost well over $5,000 and cannot be considered in the low-cost class. Part I of the new Act encourages lending institutions to finance homes costing $4,000 or under even if to be built in small or remote communities, but the intending owner is still required to make a 20 per cent down payment.

The ten winning designs in the Minimum Cost House Competition, conducted by the Federal Housing Administration, were made public in February 1938. Figure 2 shows one of the designs with a modernistic touch. It was submitted by Mr. A. H. Tremblay, M.I.R.A.C., of Quebec City. It was hoped that these houses, exclusive of land or other charges, were to cost not more than $3,000. Working

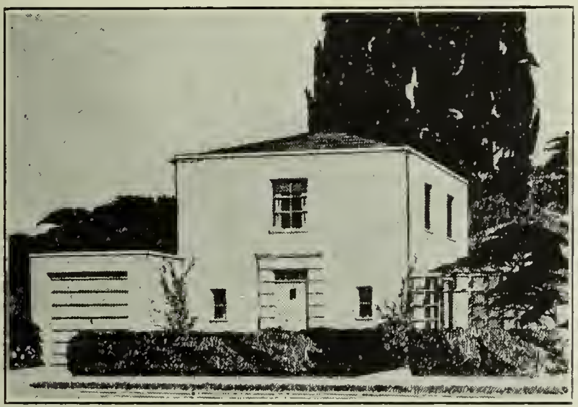

Fig. 2—One of the Prize-winning Designs in the Minimum Cost House Competition.

drawings of the ten designs have been purchased by the Federal Government from the architects, and for any one design four sets of blue prints together with four Dominion Housing Memorandum Specifications (to be filled in by the owner and builder) may be purchased from the Housing Administration, Department of Finance, Ottawa, for the sum of $10. With this information the individual can secure an estimate or preferably a tender from a reliable builder.

Three bedrooms on the top storey are provided in the home illustrated in Fig. 2. The dimensions of the house are 20 ft. by 24 ft. with a height from cellar floor to roof of 26 ft. This gives a volume of 12,480 ft. To build this house for $3,000 would mean a cost of only about 24 cents per cubic foot. This is only approximate but your architect or builder will no doubt tell you how difficult it is to build up to the Housing Administration standards at, or near, this figure—even if building materials are now to be exempt from the 8 per cent sales tax.

Fig. 3—Another Prize-winning Design—Architects Greensides and Langley, Toronto.

In the preamble to the National Housing Act it is stated that "it is desirable to stimulate the construction of houses to be owned by persons with small incomes." And it is provided in the Act that if a home can be built for $2,500 or under, then the down payment can be reduced from 20 per cent to 10 per cent. The terms in all cases are for a maximum 20 year repayment with equal monthly installments requiring both loan and interest at 5 per cent at the end of that period. (The portion of the loan granted by the Federal Government is at 3 per cent interest and by the lending institution at about 5½ per cent interest.)

It is claimed that one of the obstacles to the full application of the Dominion Housing Act has been the down payment of 20 per cent of the total cost of the property; that only a very few have that 20 per cent and that the depression of recent years has depleted the savings of many prudent and thrifty families, though such families are still good "risks."

But who can build the $2,500 home and pay only 10 per cent instead of the 20 per cent down payment required for homes of greater cost? The possibility of a farmer with his own labour constructing the $2,500 home is admitted but doubt is expressed of the possibility of building the low-cost home at that figure in urban or suburban areas in any province in Canada with the possible exception of British Columbia. It is felt that in any event only by the building of a great many homes standardized in nearly all particulars and on a well planned site can the necessary benefits of mass production and reduced cost of utilities be obtained to keep costs of home building at the $2,500 level. Prefabrication of standardized parts or even prefabricated rooms may help. While in the United States costs of prefabricated houses have generally exceeded those of ordinary construction, there still seems a reasonable hope of help from this source.

The National Housing Act—Part II

Part II of the National Housing Act involves new principles for federal relationship to low-cost, low-rental homes. The Government is prepared to grant loans up to $30,000,000, pro rata, to urban population, for low-rental housing projects in urban communities. This should represent over $35,000,000 in developments which on account of the low costs involved will probably be of the apartment or multiple dwelling type rather than single family homes.

Under the provisions of the National Housing Act low-rental projects may be undertaken by the municipality or by a limited-dividend housing corporation A municipality can obtain a 90 per cent loan from the Federal Government but must also obtain a provincial guarantee for such loan. For this and other reasons it seems likely that the limited-dividend corporation (composed of public spirited citizens) must be depended on for effective action. While it can obtain only an 80 per cent loan from the Federal Government yet a provincial guarantee is not required.

According to the provisions of the Act, a family ordinarily eligible for a low-rental home must not have a total *family income* of over five times the economic rental, which is approximately 12 per cent of the cost of a housing unit (to average not more than $3,000). Therefore the family income must ordinarily not exceed $1,800 per annum. The maximum rental must ordinarily not exceed one-fifth the total family income or $30 per month (*for the maximum income*). There will be but few maximum incomes, it is believed. Interest centres in minimum rentals, which must be sufficient for all carrying charges, and which, including allowances for management and repairs, maintenance and vacancies, might still amount to but $14 to $15 per month for a $2,400 apartment (which it is maintained can be built). The rental provides for a 5 per cent return on capital invested by the limited-dividend corporation and in case any higher rents were charged the difference only increases the semi-annual payment to the Federal Government.

A Federal Housing Development New York City, United States.

Co-operative Apartments in Stockholm Sweden.

A Housing Scheme in Folkestone, England.
Fig. 4—Group and Low-cost Housing in other Countries.

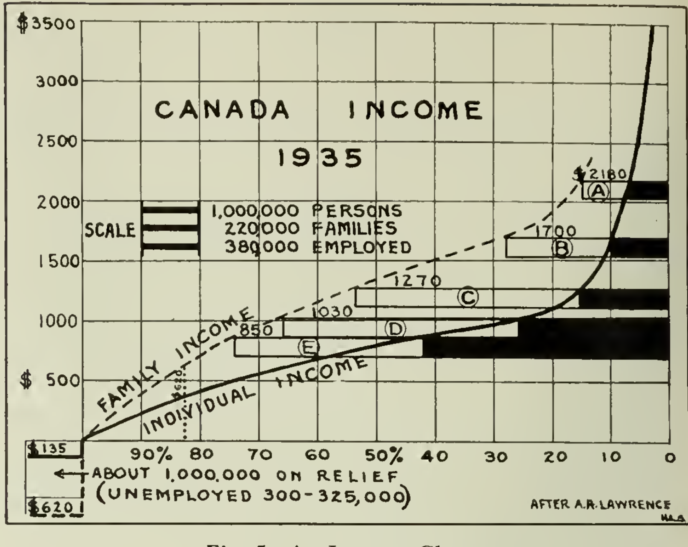

Fig. 5—An Income Chart.

It might be explained that the low rental is made possible by the low interest rate (1¾ per cent per annum payable half yearly in the case of a limited-dividend corporation), charged by the Federal Government to be repaid over 35 years, and to the low taxes (generally involving the consent of the province as well) which the municipality must agree shall not exceed 1 per cent of the cost of construction and to the exemption of the limited-dividend corporation from income tax by the municipality.

The area in which a housing project is being developed must be adequately planned and the zoning regulations must be sufficient to secure the investment and the loan during its life. Adequate municipal services must be available or be supplied forthwith.

THE NATIONAL HOUSING ACT—PART III

Part III of the National Act deals in tax assistance for homes costing $4,000 or under when built before the end of 1940 by the owner for his own occupation in any municipality that agrees, if it owns lots suitable for residential purpose, to offer to sell a reasonable number at not more than $50 per lot (or at the lowest amount it may be otherwise authorized to dispose of such lots). Under such conditions, taxes due to the building of the house only will be paid by the Federal Government as follows: 100 per cent the first year taxes are levied, 50 per cent the second year and 25 per cent the third and final year for such tax assistance.

The Minister of Finance, admitting the impossibility of accurate prediction, makes the assumption that in the next three years $100,000,000 of new houses may be eligible for this tax subsidy. Assuming the average tax levy to be 2½ per cent of the cost, the Federal Government would then spend nearly $5,000,000 in tax assistance in the next three years. Many of the houses built with tax assistance will no doubt also be constructed under the provisions of Part I of the Act and they should not be counted twice in making an estimate of the amount of building that may be expected under the provisions of the new National Housing Act.

With the full co-operation of all concerned, homes built under the provisions of Part I of the Act, that are not eligible for tax assistance, are estimated at 1,000 per year; low-rental housing units are estimated at 3,000 per year as built under the provisions of Part II of the Act, and some 10,000 family units per year under the tax assistance provided by Part III of the Act. If this be considered a generous estimate it is still only about half the accommodation required for the 30,000 families that, it is estimated, are added each year to our population. Can unassisted building take care of the balance and also relieve present housing shortage that is apparent in the "doubling-up" of families and the many obsolescent homes that should be extensively repaired or demolished?

In exploring the ways in which the National Housing Act can be most effective it seems of advantage to relate housing costs to incomes. A generous allowance for monthly commitments in the case of purchase or for monthly rental in the case of lease is from 30 per cent of monthly income in the higher income brackets reducing to 20 per cent in the lower incomes. In the case of purchase the monthly payments include interest and principal reduction over 20 years, taxes, insurance, maintenance, water and local improvements and generally amount to 11 per cent to 12 per cent of the total cost of the home or about 1 per cent a month.

Figure 5 shows a chart that has been prepared to indicate the relation between income and the cost of a home it can afford. Group A (representing 7 per cent of the individuals in Canada gainfully employed) are those of the income group that, it was estimated, might build with the interest rates and other conditions that prevailed before the passage of the Dominion Housing Act 1935. For homes costing $4,000 to $5,000 and requiring monthly payments of $40 or so, Group B takes in the gainfully employed that receive a yearly income of $1,700 or more. This group takes in only 10 per cent of individuals gainfully employed (including those in group A) but is the group that might be counted on to have saved the necessary 20 per cent down payment as required by the Act. Group C with individuals receiving at least $1,270 per year, includes those who might finance the $3,000 home if they had the necessary 20 per cent for a down payment, either in land, in cash or partly of both. But it would appear that very few receiving less than $1,700 per year have managed to keep or to save that necessary 20 per cent.

Group D includes all individuals who might afford to build the $2,500 home, on which only a 10 per cent down payment need be made. Even if the $2,500 home can be built, it should be noted that Group D includes less than 30 per cent of all individuals gainfully employed. If family incomes could be considered, Group D would be greatly increased but for purchase over a long period it is considered wise to depend on individual incomes.

Family incomes may be considered in the case of rentals and are specifically referred to in the National Housing Act. Allowing 20 per cent of the family income for rent, it takes an income of $850 per year to provide a rental of $14 per month, just the very minimum rental that seems possible for a family of any size under the provisions of Part II of the Act. It would seem that families of lower income could not be accommodated by the low-rent provisions of the Act unless a voluntary rent-reduction fund, as mentioned in the Act, is subscribed to by the province and/or municipality. Of the gainfully employed in Canada more than 55 per cent receive less than $850 per year. Family incomes increase this percentage to a great degree but there are still, it is estimated, at least 25 per cent of our Canadian families (some 2,500,000 persons) with an income below $850 per year. And then there was that 1,000,000 on relief (fortunately now a diminishing number) or some 200,000 or more families receiving as much as $14,000,000 from government sources in one year for rent accommodation, and as a rule the very poorest accommodation.

Without large direct subsidies, it would appear impossible to help the lowest income groups. But if without further subsidy, those of higher income groups can be induced to build then the employment provided, both

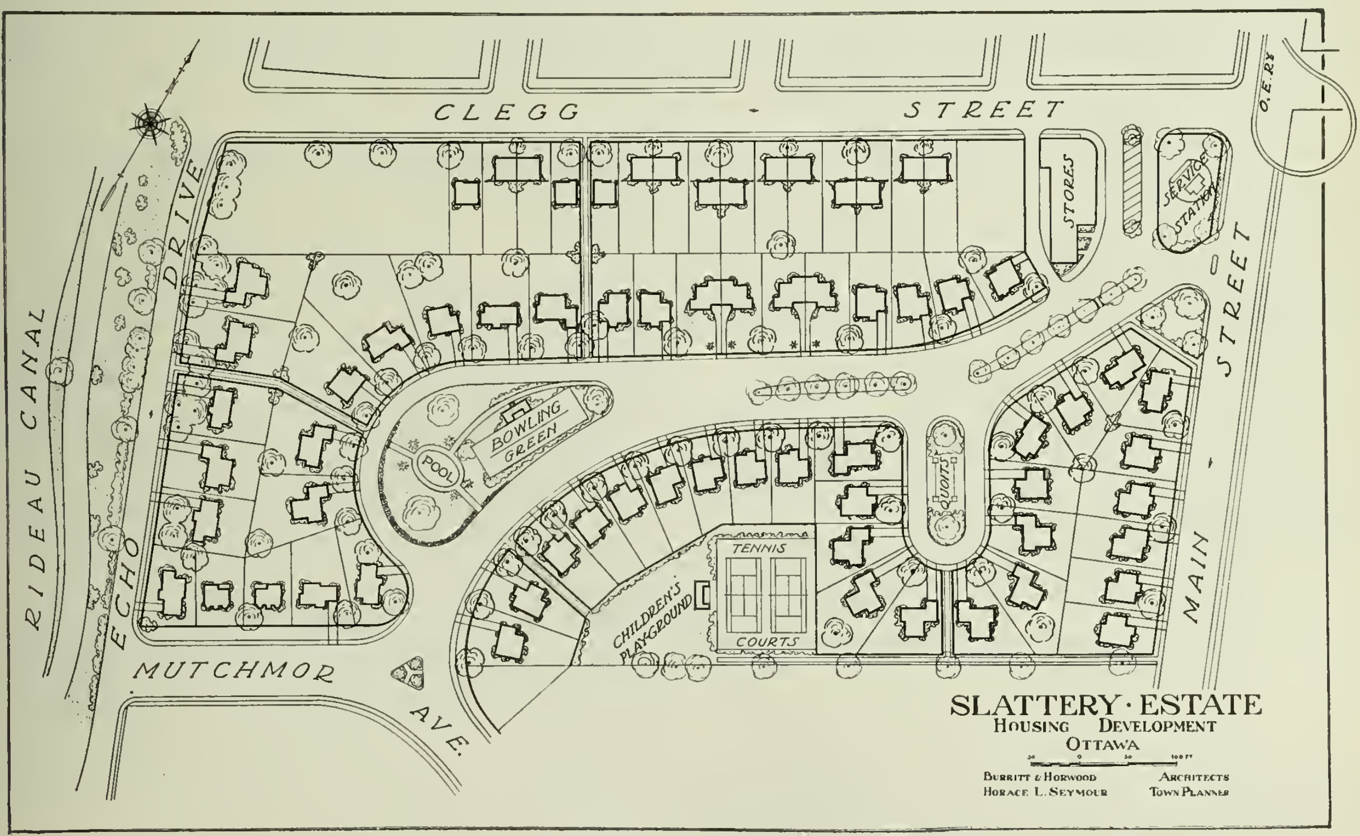

Fig. 6—A Proposed Subdivision Illustrating Modern Design.

Fig. 6 illustrates some features of modern subdivision design; the long block for this motor age but with footpaths for pedestrians; the cul-de-sac or one-way street for greater safety and privacy; the small interior block playground; wider lots or a double building line for narrow lots; the provision of community services; and a greater consideration for the amenities and the appearance of the subdivision as a whole.

directly and indirectly, should help those in the lowest income groups. It would seem that it is for the homes costing between $2,500 and $4,000 that assistance might be given to provide the intending owner with at least half of the 20 per cent down payment which he is required to make but for the lack of which he cannot build. The experience of other countries indicates how this might be accomplished without subsidy.

The Building Societies of Great Britain, the Building and Loan Associations of the United States and the Housing Co-operatives of other countries, it is believed, are the kind of organizations necessary to further the housing programme now begun by the Federal Government. In Great Britain the building society idea started over 100 years ago in the smallest way. Now building societies there have tremendous assets. Over half the mortgages in England and Wales are held by them and it is estimated by informed observers that from 80 per cent to 90 per cent of all new mortgage money comes from these societies engaged in a co-operative form of private enterprise. There are some 3,500,000 members in Great Britain. In the United States there are 7,000,000 members of building and loan associations which take a prominent part in the building programme of their country.

For reasons that cannot be detailed in this article, federal and most provincial legislation and practice in Canada is not particularly favourable to the building society or the housing co-operative form of home building assistance. This should be and is being remedied. Small housing co-operatives are now operating in the province of Nova Scotia. The Minister of Finance has urged the assistance of localized institutions. He has stated, for example, that a Credit Union having sufficient assets, being empowered to do this kind of thing by the legislation creating it, and having the ability to do the job, might be considered as a lending institution.

In the Dominion Housing Act of 1935 and the regulations thereunder, and in the National Housing Act of 1938, that amends and amplifies the earlier legislation, the need and advantage of houses thoughtfully planned are fully recognized. Of equal importance is the emphasis placed in the new Act and in statements of Federal Housing Administration authorities on the adequate planning of areas where individual homes or low-rental housing projects are to be built, and for zoning regulations and building codes that will protect the communities (where the housing units are constructed) against the intrusion of undesirable structures or a type of development that might destroy property values of the individual.

In conclusion, let it be emphasized that the National Housing Act 1938 is merely permissive; it does not provide, as has been done in some other countries, for actual construction of low-cost housing or for slum clearance by a national or central authority. The initiative must come from individuals and all others interested.

When the National Housing Act was introduced in the House of Commons, the Minister of Finance pointed out that prior to May 31st of this year only 4,249 family housing units had been financed under the Dominion Housing Act of 1935. The average loan was $4,083 per family unit (80 per cent or less of the total cost). This is too few homes at too great a cost.

An endeavour has been made to provide under the National Housing for income groups that, up to the present, have not been able to build or rent reasonable accommodation. As explained in this article, low-interest long-term money is made available under certain conditions and other inducements offered, but active leadership must come from the provinces, municipalities, the trades and the labour unions, public spirited groups and individuals.

The National Housing and Planning Association and its affiliating branches are endeavouring to assist through educational means. Included in the membership of such groups are members of The Engineering Institute. Many more may welcome the opportunity to take an active part in the programme of education which should precede actual construction if we are to have successful operation and maintenance of low housing projects.

Seventh International Management Congress

T. M. Moran, A.M.E.I.C.,

Chairman, Industrial Management Section, Montreal Branch and Institute Delegate to this Congress.

The Seventh International Management Congress took place in the building of the United States Chamber of Commerce in Washington, D.C., U.S.A., from September 19th to 23rd, 1938.

Sponsoring Organizations

The Congress was held under the auspices of the International Committee of Scientific Management, an organization which represents seventeen countries, and which in the past twelve years has held congresses in a number of European capitals.

The President of the International Committee is:—

The Rt. Hon. Viscount Leverhulme
(Governor of Lever Bros. and Unilever, Ltd.)

The incoming President of the International Committee is:—

William L. Batt,
President, S. K. F. Industries, Inc.

The Congress was organized by the National Management Council of the United States in collaboration with other scientific, professional and industrial associations. Through its membership of the International Committee of Scientific Management, the National Management Council represents internationally those societies in the United States which are concerned with various aspects of management.

Ministerial Support

While it is not the practice of the Government of the United States officially to sponsor any undertaking of the type of the present Congress, the Cabinet Heads and the Government Departments in the spheres of public interest touched upon by the Congress were good enough to indicate their hearty approval of the Congress and its objectives and their willingness to do everything within their power to make its session successful.

To this end Secretary Cordell Hull of the Department of State and Secretary Roper of the Department of Commerce officiated respectively at the opening and closing sessions of the Congress.

Co-operation of the United States Chamber of Commerce

The Congress was fortunate in securing the cordial and hearty co-operation of the United States Chamber of Commerce, which placed its handsome and dignified building in Washington, and its office staff, at the disposal of the Congress for the duration of its sessions. All sessions, accordingly, were held in the Chamber of Commerce building, which was admirably adapted for this purpose.

Objectives and Programme

A free, open and factual discussion, from a world-wide point of view, of the problems and achievements of management in agriculture, industry and the home, is the primary and general objective of the Congress. To this end it set out:—

1. To provide a forum for the interchange of management experience in order to increase the efficiency of production and consumption of all forms of goods and services.
2. To appraise the present situation and probable future course of management in its broader social and economic aspects.
3. To provide an authoritative and public reminder, to management itself and to the world it serves, of the fact that the only type of management worthy of the name is that which contributes to the welfare of mankind.

The Congress falls into two main divisions:—

General Sessions

The General or Plenary sessions were devoted to the theme: "Social and Economic Aspects of Management," and were addressed by distinguished leaders of thought and action from both sides of the Atlantic, chosen as being best qualified to speak with authority upon the vexed questions of management's responsibilities to society as a whole—for example the influence of technological progress; the problems of incentive and security, and of free enterprise versus social control; the interrelations of worker and owner, and of both with the public, and the responsibilities of management to all three.

Technical Sessions

At these sessions the theme "Recent Developments in Management" were discussed on the basis of over 250 papers, which were submitted from some twenty countries. These papers cover a very wide range of topics, the conditions governing the contribution of papers being such as to permit of the treatment of any technical aspect of management provided that the problem dealt with represents a "recent development in management" in the author's country, which for the purposes of the Congress has been taken to mean a development which has either manifested itself or has made definite progress since the international management congress held in London in 1935.

Administration:

Fundamentals of a Public Relations Programme for Business—Arthur W. Page (U.S.A.).

Financial World Criteria for Business Enterprises—Sidney J. Weinberg (U.S.A.).

The Constituents and Functions of the Administrative Group—Henry P. Kendall (U.S.A.).

Developments and Trends in Administrative Management—Dr. H. Pasdermadjian (France).

Essential Information for Effective Business Administration—Harry A. Bullis (U.S.A.).

Statistics and Graphical Control as an Aid to Commercial Management—L. C. Vervooren (Holland).

Control of Business Through an Integrated Corporate Budget—Henry C. Perry (U.S.A.).

Der Aufbau Wirtschaftlicher Funktionen Als Organisations-Grundsatz — Ein Gemeinschaft-licher-Beitrag (Deutschland).

Decentralizing The Operating Organization—Edgar W. Smith (U.S.A.).

Facilitating Co-ordination in Business Establishments—Walter D. Fuller (U.S.A.).

Relationship Between Headquarters' Departments and the Operating Groups of Imperial Chemical Industries, Ltd.—H. J. Mitchell (Great Britain).

Note sur la Technique du Travail en Commission—Jean Coutrot (France).

Opportunities for Executive Development and Advancement—Robert R. West (U.S.A.).

A Modern Executive Training Programme at the Top—Lawrence A. Appley (U.S.A.).

L'Ecole Superieure des Messageries Hachette—Paul Hemmerdinger (France).

Executive Compensation and Incentives in the Business World—Morris E. Leeds (U.S.A.).

The Control of Office Work—Gordon A. Hardwick (U.S.A.).

Maintaining A Responsive Office Staff—I. J. Berni (U.S.A.).

Il Macchinismo Nel Lavoro Di Ufficio Di Fronte Ai Postulati Ed Alla Disciplina Del Corporativismo Fascista—Giuseppe Landi (Italia).

Adapting Office Procedures and Facilities to Administrative Requirements—Harry L. Wylie (U.S.A.).

Organization and Recording of Remittance and Payment Transactions in a Banking Institution—Francizek Jazwinski (Poland).

Organization Scientifique du Travail de Bureau dans les Grands Ateliers des Chemins de fer du P.O.—Midi—les Chemins de Fer du P.O.—Midi (France).

Office Management: Recent Developments in Office Technique—H. Keegstra (Holland).

How to Study Office Machines—R. W. Starreveld (Holland).

Criteri di Classificazione Della Materia Inerente L'Organizzazione Scientifica Del Lavoro—Ente Nazionale Italiano per l'Organizzazione Scientifica del Lavoro (Italia).

Administrative and Financial Controls for Public Bodies—Edwin O. Griffenhagen (U.S.A.).

Public Personnel Administration—Leonard D. White (U.S.A.).

A Few Measures of Rationalization Introduced at the Royal Hungarian Post Office—Akos Tersztyanszky de Nadas (Hungary).

Assessment of Qualifications for Promotion in the British Civil Service—A. L. N. D. Houghton (Great Britain).

A Government Department Adopts a Commercial Viewpoint—Harold Whitehead (Great Britain).

These papers will be available to members of The Engineering Institute. Please send your requests direct to Mr. L. Austin Wright, General Secretary.

The writer would like to take advantage of this occasion to advise the Members of The Engineering Institute of Canada of a dinner that was given by Washington engineers to our General Secretary. Forty prominent engineers of various groups attended. This expression of good will is a real reminder of our status in the Engineering Profession and of our splendid relationship with our American neighbours.

THE ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

VOLUME XXI OCTOBER, 1938 No. 10

The New Era

Saskatchewan Shows the Way

One of the most significant events in the annals of the engineering profession in Canada will be the signing of the co-operative agreement between The Engineering Institute and the Association of Professional Engineers of Saskatchewan, which is to take place in the capital city of Saskatchewan on Saturday evening, October 29th. It is fitting that Council should arrange that the President and the General-Secretary, with the chairman of the Council's Committee on Professional Interests, should journey from Headquarters to Regina to complete the historic document. The popularity of the movement, both within and without The Institute, for a closer working arrangement with the Associations is manifest everywhere. At the recent joint dinner of the London and Border Cities branches in Sarnia, there was a notably enthusiastic response from the entire company to the gracefully worded wish of the engineer-mayor of Sarnia for an early and satisfactory conclusion to the negotiations for an entente cordiale between The Institute and the Associations.

It is both a happy circumstance and a good omen that the first agreement has been approved of so wholeheartedly. It is doubtful if a more decisive vote has ever been recorded on any issue in The Institute. From coast to coast the councillors voted unanimously in favour of the agreement, and in Saskatchewan the corporate membership did not record a single negative ballot. The Association membership gave similar approval, and all but two members voted in favour of the progressive movement. Under such preponderantly favourable support the signing ceremonies at Regina at the end of October take on an added importance.

The committees of both organizations are to be congratulated. After the long period of negotiations, it must bring them much satisfaction to see their efforts crowned with achievement. Engineers everywhere owe them a debt of gratitude for their courage, perseverance and acumen in bringing to consummation the much talked of ideal of co-operation.

To Saskatchewan goes the honour of blazing the trail that leads to the goal desired by the great majority of professional engineers—COMMON MEMBERSHIP between The Engineering Institute of Canada and the Provincial Professional Associations.

"Paul Sise and Company"

It was interesting news to all Canadians to read of the appointment of a group of men to take charge of the construction in Canada of bombing planes for the British Air Ministry, but it was particularly interesting to members of The Institute because the man who heads up that group is an engineer and a Member of this organization. The project is a combination of engineering, industry and finance and it seems only right that an engineer should be at the head of it.

General satisfaction has been expressed at the personnel of the group. The "Montreal Gazette" aptly refers to it as "Paul Sise and Company," and speaks in no uncertain terms of praise for the group and for the individuals that constitute it. We quote. "This is not the official title of the new Canadian organization, but it stands for what is, perhaps, individually and collectively the ablest group of industrialists and financiers ever associated in any one undertaking in the long history of Canadian business. The British authorities who are sponsoring the enterprise have been exceedingly fortunate in enlisting the services of Mr. Paul F. Sise and in having him supported by a Board composed of men who are without exception leaders in industry and finance, whose reputations are of the highest and whose business experience has been comprehensive and successful."

There is no one who will be pleased that it has become desirable or necessary to start Canadian industry on the production of war materials or equipment, but we can all be thankful that this unhappy business is in the hands of such competent citizens as Mr. Sise and those who are serving with him.

Journal Cover Design Competition

The Publication Committee reports that it has been very gratified with the result of the competition for a design for a new cover for The Engineering Journal, and has decided to award the prize of $25.00 for the best design to John G. Hall, M.E.I.C., Montreal.

There was an excellent response to the competition, 29 different designs, obviously the result of much thought and study, were submitted by the following 20 members:—

H. W. Buzzell, A.M.E.I.C.	Lachine
John G. Hall, M.E.I.C.	Montreal
James Dick, A.M.E.I.C.	Ottawa
R. H. Vaughan, A.M.E.I.C.	Victoria Island, B.C.
Adam Hay, M.E.I.C.	Toronto
M. Wolff, A.M.E.I.C.	Westmount
F. E. Palmer, Jr.E.I.C.	Montreal
W. G. Mitchell, M.E.I.C.	Montreal
E. L. Miles, M.E.I.C.	Charlottetown
M. D. McFarlane, A.M.E.I.C.	Hollywood, Cal.
Robert W. Allen, M.E.I.C.	Regina
Gordon R. MacLeod, S.E.I.C.	Montreal
A. S. Wootton, M.E.I.C.	Vancouver
J. P. Svarich, Jr.E.I.C.	Edmonton
K. G. Cameron, A.M.E.I.C.	Hampstead
M. H. Marshall, M.E.I.C.	Regina
M. I. Bubbis, S.E.I.C.	Winnipeg
J. M. Cameron, S.E.I.C.	Niagara Falls
J. Stuart Neil, A.M.E.I.C.	Calgary
R. H. Cratchley, A.M.E.I.C.	Ottawa

The Committee has decided that it will not recommend the adoption of any one of the designs submitted, but rather that the principal features of the present cover design should be adhered to. There were so many good features in the designs submitted, that it may be found possible to use some of them without losing the advantages of the present design and colour scheme, which have done such good service for so many years.

Industrial Management Under the Microscope

When fifteen hundred well established business executives get their heads together to discuss their management problems and their findings, and when this number includes psychologists, engineers, scientists, financiers, accountants and statisticians, you can expect that there will be some substantial contributions made to the field of industrial management. This is exactly what has been happening at the Seventh Industrial Management Congress at Washington, D.C., during the week of September nineteenth. Over three hundred of these executives came from countries other than the United States. Twenty-three different nations were represented, and the phases of the subject discussed seemed almost as many as the number of delegates.

The Institute's interest in this subject comes through its Industrial Management Group. Today so many engineers are progressing right through the engineering phases of industry to managerial positions that it has seemed appropriate to many that some time and study should be given by engineering organizations to management problems. This development is already well established to the south of us and it appears that the beginning which has been made by The Institute may be enlarged to interest many more members and many more branches.

Industrial management, industrial administration, scientific management—call it what you will—is of vital importance to engineers. It is inconceivable that an engineer can go very far in his profession without meeting management problems of administration, of production, of distribution, and of personnel, and these problems are not best solved by cut and try methods. The best brains of business have been working on them for years, and working largely in a scientific manner, and although all problems are far from a permanent solution, great progress has been made.

It was the aim of The Institute's representatives at the Congress to discuss with similar English and American organizations which have already made gigantic strides in this study, the possibility of closer affiliation. Canadians are just beginners in this field of learning and from the point of view of organization have almost nothing to offer. It appears that The Institute is well qualified to give substantial leadership, and to render a real service to engineers. It is encouraging to know that the advances which were made to these other bodies were well received and that tentative proposals for co-operation have already been made. Beyond a doubt a sound basis for future progress has been laid by the negotiations which took place at the Congress.

Kingston Plans to Honour Dr. Malcolm

Negotiations have just been completed whereby Dr. W. L. Malcolm, M.E.I.C., formerly Professor of Municipal Engineering at Queen's University, and now Dean of the School of Engineering at Cornell University, will be feted by the Kingston Branch on Saturday, October 22nd. The occasion is to mark the branch's appreciation of Dr. Malcolm's new appointment, and to give the officers, councillors and other members an opportunity to join with them in doing honour to him.

Details of the arrangements have not been completed at the time of going to press, but Councillor Grant of Kingston states that officers and members from Headquarters and from branches will be very welcome. President Challies has already accepted the invitation, and it is expected that many councillors from the Montreal district and from Ontario will also be present.

Dean McKiel, of Sackville, has wired to say that he expects to be able to join in the well deserved tribute to Dr. Malcolm.

Saskatchewan Agreement

Ballot of Corporate Members Resident in Saskatchewan

In accordance with our acceptance as scrutineers of the ballot recently taken under Section 76 of our By-laws, on the vote by the Saskatchewan Branch, the undersigned two scrutineers are pleased to submit their report.

We have received sixty-one ballots from the secretary of the Saskatchewan Branch covering the vote by the members of the Branch, returnable Saturday noon, September 24th. From an examination of the ballots in question we find as follows:

Total ballots received	61
Number of ballots marked "yes" favourable to proposed agreement	60
Number of ballots marked "no" opposed to proposed agreement	nil
Number of ballots spoiled	1

Yours truly,
H. S. Carpenter, M.E.I.C.
D. A. R. McCannell, M.E.I.C.
Scrutineers.

Hamilton Prepares for President's Visit

Arrangements are well underway at Hamilton for the celebration on Friday, October 14th, at which time President Challies is the guest of the Branch. The principal event is the reception and dinner at the Connaught hotel at six o'clock at which function the President will speak on Institute activities, and on the general situation in Canada in the engineering profession. Mr. W. J. McCulloch, editor of the "Hamilton Spectator," will also speak, and his subject will be "World Affairs." The General Secretary, L. Austin Wright, will accompany President Challies.

Other events for earlier in the day include the following:

During the afternoon the following Industrial Plants will be visited:—

The Steel Company of Canada Limited; New Blooming Mill, operated by a 7,000 h.p. motor.

Dominion Foundries and Steel Limited; New Tin Mill and the only Plate Mill in Canada.

The Canadian Westinghouse Co. Ltd. will be open for those interested in the manufacture of electrical apparatus.

Those who wish to visit any of these plants will proceed to the main offices of the plant desired at *2 o'clock p.m.*

The Branch is putting forth a real effort to make this an interesting occasion. They expect representation from sister organizations, visitors from other branches, and a large turnout of Hamilton members. On the notice that was received at Journal headquarters we notice that "tickets may be obtained from the Chairman of the Branch, and the Secretary-Treasurer, or members of the executive. An early application for tickets will be greatly appreciated."

The Blue Water International Bridge Connecting Port Huron, Mich., with Point Edward, Ont.

Joint Meeting is a Great Success

Border Cities and London Provide Interesting Day

Saturday, September 24th, in Sarnia, was surely a big day in the affairs of The Engineering Institute. From ten thirty in the morning until ten thirty at night it was just one thing after another, culminating in a bang-up dinner at the Vendome hotel. There were approximately one hundred and twenty-five who shared in the pleasures and the privileges of the programme, and not one but voted the whole affair a great success.

It is hard to tell who deserves the most credit for the arrangements, but it was evident that many capable people co-operated to produce the result. A. O. Wolff, of London, was master of ceremonies for the day, and a fine job he made of it. Councillors Vance and Chambers, Harry F. Bennett, E. M. Krebser, J. F. Bridge and D. S. Scrymgeour were conspicuous throughout the day, carrying on the staff work. Even "Scoop" MacLean, the photographer, excelled himself, and gave many examples of the dangers to which newspaper camera men are exposed!

The first item on the programme was a tour through the Imperial Oil Refinery, which is the largest and most complete of its kind in Canada. C. E. Carson, superintendent of the plant, opened the proceedings with a description of the layout and the operation of the refinery. He gave a very complete picture of the five hundred acre development in a very short time, and started the various parties out on the tour under the care of nine excellent guides.

We were permitted to look into the sanctums of the research department, and the testing department, to see the rows of test tubes and retorts and bottles and ovens, and queer shaped pipes. Outside we gazed on high at the tops of the huge vertical cylinders, row on row, and wondered how the oil could find its way through such a labyrinth of pipes and passages from one cylinder to the other, as the guide assured us it did. And yet they called it "crude." Occasionally we could peep through a small glass and see a white fluid bubbling merrily out of one pipe and into another. "Gasoline," the guide said, and we gazed in awe at such quantities of the precious fluid. Strange how difficult it is to keep the old flivver's tank full when there are such copious quantities running around like that. We dealt in such terms as fractions, cracking, viscosity, flash point, volatility, and so on, and really had a good time. We proved that you don't have to be a chemist to be interested in the breaking down of plain crude oil into the myriad of useful products that help to make life more pleasant and more luxurious. On the other hand, the oil company proved that the manufacture of these products for our convenience is far from simple—that not only brains and ingenuity are required, but enormous quantities of capital as well.

The programme for the afternoon was an inspection of the brand new Blue Water International Bridge across the St. Clair River of which Messrs Monsarrat and Pratley were the designing engineers for the Ontario Government on the Ontario approach and were associate engineers with Messrs Modjeski and Masters who in turn are the designing engineers for the Michigan State Bridge Commission. Forty cars made up the caravan, and led by Lieut.-Col. C. K. S. Macdonnell, A.M.E.I.C., resident engineer, Department of Highways of Ontario, first drove down on the Canadian shore under the bridge, to have a look from the ground up. Then the line was reformed and the procession returned to the Canadian approach and drove over the deck to the centre span, where an inspection was made from the top down. The international boundary line is nicely indicated by two bronze plates on the guard rails. A new material for marking the lanes on the roadway has been used, and it is expected will give unusual satisfaction, both from the point of view of utility and of maintenance.

At the invitation of the Sarnia Bridge Company the entire company continued to Port Huron and reassembled in the quarters of that city's leading hotel, where a brief talk was given by John R. Giese, resident engineer for Modjeski and Masters, consulting engineers, on the design and construction of the new structure. Refreshments were served by our hosts, and were much appreciated by the entire "entourage." When you stop to think of it, this bridge inspection privilege was something very unusual. Somebody deserves a lot of credit for getting it through. When you realize that the bridge is not yet open to the public, and remember the complications that usually develop when crossing the border, you begin to appreciate that somebody must have done a powerful lot of arranging in order that we could be granted access to the new highway and permitted to pass back and forth almost as though there were no border line. Incidentally, it was a wonderful gesture of hospitality and cordiality on the part of the U.S. officials.

The festivities were concluded by a dinner presided over by A. O. Wolff, chairman of the London Branch, and graced by the presence of President Challies, R. M. Smith, Deputy Minister of Highways for Ontario, Fred Pelling, Mayor of Sarnia, Mr. Stinson, Secretary of the Michigan State Bridge Commission, George Guthrie, M.L.A., John R. Giese, of Modjeski and Masters. There were visitors from other branches such as Toronto and Niagara Falls, but the two whose visit was most appreciated were John L. Lang and John S. Macleod, councillor and chairman respectively of the Soo branch. They made the trip by motor especially to attend the meeting. There were also present E. V. Buchanan, of London, vice-president of The Institute for Ontario, E. M. Krebser, chairman, and W. C. Miller, past-chairman of the Border Cities Branch, Councillor W. E. Bonn, and General Secretary L. Austin Wright.

The principal speakers were Mr. Smith and Mr. Challies. Mr. Smith gave a very interesting account of his trip to Europe to examine the new highways, and showed some excellent lantern slides of roads over there as well as in Ontario. The Ontario ones did not seem to suffer by the comparison. Mr. Smith made his talk very interesting, and his contribution was more appreciated because it is seldom that The Institute gets such talks on roads from such authoritative persons. It would be nice if we could have more talks and papers on this highway situation.

Mr. Challies dwelt on the values of such structures as the new bridge, as factors in maintaining peace between nations. He stated "It is a noteworthy fact that from the Atlantic to the Pacific, most of the strategic points from a military standpoint are marked only by important works such as bridges, tunnels, hydro-electric developments, navigation dams, canals, locks, etc. The genius of the engineering profession of neither country has been used to conceive and construct works of defence or offence along their common boundary."

He pointed out the fine work which was being done by the International Joint Commission in promoting concord and co-operation respecting boundary waters between the United States and Canada, and commented on the fact that all this had been done by them without any "fanfare of publicity." In describing the character of the Commission he said "There is nothing else quite like it; nor has there been in the past. Three Americans and three Canadians sit, not as national sections more or less competitive, but as one judicial body determined to give the best possible judgment with the utmost impartiality to the settlement of boundary water questions that arise sometimes on one side of the boundary and sometimes on the other. It is significant of the sympathtic attitude of Canadians and Americans toward each other and toward their common problems that in every case dealt with by the Commission since its organization, the decision has been unanimous. This is because each of the six commissioners realizes that while he is a citizen of but one nation, he is constituted a judge for both."

The gathering broke up about ten thirty with many handshakes and promises of getting together more frequently in the future, which is not a bad idea. Meetings such as this are not only pleasant but they are profitable, and the success of this one would seem to offer sufficient encouragement to other branches that they would be tempted to follow suit.

On the International Boundary Line

Left to right: J. M. May, superintendent of plaza construction at Point Edward; L. B. Henderson, engineer Michigan Highways Dept.; B. L. Irwin, engineer Dept. of Highways for Ontario; John Giese, resident engineer in charge of bridge construction; W. C. Stinson, manager of bridge; J. B. Challies, M.E.I.C., Montreal; E. V. Buchanan, M.E.I.C., London, Ont.; James Vance, A.M.E.I.C., Woodstock, Ont.; John A. Baird, M.E.I.C., Ont. Dept. of Highways resident engineer; Col. C. K. S. MacDonell, A.M.E.I.C., district engineer, Dept. of Highways of Ontario; William A. Guthrie, M.P.P., West Lambton; A. O. Wolff, M.E.I.C., London.

Washington Engineers Honour E.I.C.

An indication of the high regard in which The Engineering Institute is held in the United States and of the friendly relationships which exist between all engineering bodies was given on Wednesday, September 21st, when forty of the leading engineers of Washington gathered at the Cosmos Club, with the General Secretary, Austin Wright, as their honoured guest. The occasion was a luncheon in the private dining room of the club. The chairman was Col. D. H. Sawyer, Director of Space Control, Procurement Division, and the prime mover was John C. Hoyt, Consulting Engineer, U.S. Geological Survey, who is well known in the capital of Canada for his advice and assistance to members of the Canadian Government Service who were responsible for instituting the Hydrometric Survey of Canada.

The chairman made most kindly references to Canadians and to Canadian institutions, with special reference to The Engineering Institute, and emphasized the fact that the Secretary was a most welcome visitor to the capital. He asked that the compliments of the gathering, which represented many branches of engineering, be presented to the Council of The Institute at the first opportunity, and charged the Secretary with delivering the message.

The Secretary spoke on the excellent international relationships that exist between engineers and engineering organizations, and thanked the Washingtonians for this luncheon which was just another indication of this helpful friendliness. In response to an inquiry he also spoke at length on the relationship between The Institute and the various provincial professional associations. The situation in the States is much more complicated than in Canada, and the meeting was very much interested in knowing the progress which The Institute was making in the solution of it.

List of Nominees for Officers

The report of the Nominating Committee was presented to and accepted by Council at the meeting held on September 9th, 1938. It is published herewith for the information of all corporate members as provided by Sections 68 and 74 of the By-laws.

List of Nominees for Officers for 1939 as Proposed by the Nominating Committee

President:	H. W. McKiel, M.E.I.C.	Sackville, N.B.
Vice-Presidents:		
*Zone "A" (Western Provinces)	A. L. Carruthers, M.E.I.C.	Victoria
	H. N. Macpherson, M.E.I.C.	Vancouver
	P. M. Sauder, M.E.I.C.	Lethbridge
*Zone "C" (Province of Quebec)	W. G. Mitchell, M.E.I.C.	Montreal
	F. Newell, M.E.I.C.	Montreal
Councillors:		
†Halifax Branch	J. R. Kaye, A.M.E.I.C.	Halifax
	Ira P. MacNab, M.E.I.C.	Halifax
†Saint John Branch	S. Hogg, A.M.E.I.C.	Saint John
†Saguenay Branch	A. C. Johnston, A.M.E.I.C.	Arvida
†St. Maurice Valley Branch	E. B. Wardle, M.E.I.C.	Grand Mere
‡Montreal Branch	E. Gohier, M.E.I.C.	Montreal
	H. Massue, M.E.I.C.	Montreal
	B. R. Perry, M.E.I.C.	Montreal
†Ottawa Branch	W. F. M. Bryce, A.M.E.I.C.	Ottawa
†Kingston Branch	L. F. Grant, M.E.I.C.	Kingston
†Toronto Branch	A. U. Sanderson, A.M.E.I.C.	Toronto
†London Branch	J. A. Vance, A.M.E.I.C.	Woodstock
†Border Cities Branch	T. H. Jenkins, A.M.E.I.C.	Windsor
†Lakehead Branch	P. E. Doncaster, M.E.I.C.	Fort William
†Saskatchewan Branch	A. P. Linton, M.E.I.C.	Regina
†Edmonton Branch	W. R. Mount, M.E.I.C.	Edmonton
†Vancouver Branch	J. Robertson, M.E.I.C.	Vancouver

*One Vice-President to be elected for two years.
†One councillor to be elected for two years.
‡Two councillors to be elected for three years each.

Additional Nominations

Section 68 provides also that "Additional nominations for the list of nominees for officers signed by ten or more corporate members and accompanied by written acceptances of those nominated, if received by the General Secretary on or before the first day of December, shall be accepted by the Council and shall be placed on the officers' ballot."

English Engineer Visits E.I.C.

Dr. A. P. M. Fleming, C.B.E., M.Sc., is the President Designate of the Institution of Electrical Engineers (London, England), and it was in that capacity that he visited The Engineering Institute of Canada in Montreal on September 1st. The Institute received him at an informal luncheon in the University Club, with President Challies presiding, and with twenty-two past-presidents, officers and councillors in attendance. Dr. Fleming is Director of Metropolitan-Vickers Electrical Company Limited, and is in charge of their departments of research and education

In a world that is all "cockeyed," said Dr. Fleming, it would be a great help if the logical thinking of engineers could replace the irrational ideas and actions of the great majority of people who hold public office. Engineers are specially trained and experienced for such work, and their participation in it would result in a reduction of to-day's hysteria and irrationalism in world affairs. He urged that the profession give serious thought to the idea of taking on added responsibilities of this type.

As one would expect, Dr. Fleming touched on research work. He said he thought that one of the chief factors in keeping England "in the running" in world competition was the tremendous development which had taken place in research. New materials, new methods and new uses had been found that made possible tremendous advancement in industry. He also stated that the new practices in selecting and training personnel had contributed to the success of industrial England to an extent that exceeded their expectations.

Dr. Fleming has visited frequently in Russia, Germany, and Italy. He had had plenty of opportunity to observe the effects of the new forms of government, and deplored the great loss of freedom of thought and action. He spoke of the "ruthless efficiency" of these countries "that was bought at too high a price," and by comparison referred to his own country where they were enjoying the results of voluntary co-operation and "freedom for action."

Many questions were asked on the European situation, and the speaker gave very illuminating responses. It was interesting to hear him say that he thought the Russian policy in theory was very sound and dead right. In spite of the restrictions placed on the citizenry they enjoyed a much more liberal administration. He also spoke at length on the development of munition manufacture in England and described the government's policy of encouraging established industries to become experienced in these new lines so that tremendous facilities and experienced personnel would be available in the event of war. The government frequently supplied the machinery and let the contract on a percentage basis through the experimental period. The manufacturers had responded in a remarkable manner.

In conclusion he referred to the bonds that held The Engineering Institute of Canada close to the English Engineering Institutions—the common ground of education and vocation, a common nationality and language, sympathy, understanding and wholesome friendliness. From the Institution of Electrical Engineers be brought warm greetings, and for The Engineering Institute of Canada he wished "abiding prosperity."

Ecole Polytechnique Makes Appointment

With the appointment of Maurice Danloux-Dusmesnils, a graduate of the Ecole des Mines de Paris, as professor of geology and mineralogy to replace the late Prof. Adhemar Mailhiot, the Ecole Polytechnique intends to turn out a greater number of competent mining engineers.

Armand Circe, director of the Ecole Polytechnique, pointed out that Professor Danloux-Dumesnils is one of the world's leading authorities on mining. He is a graduate of the Ecole des Mines de Paris and has been engaged as mining expert in a number of countries where expert opinion was imperative.

Mr. Circe referred to the possibility of the establishment of a sixth year at the institution which would enable the school to prepare students fully for the mining industry and possibly award them diplomas.

Headquarter's Renovation Now Complete

Since The Institute moved into the present quarters twenty-five years ago, the building has never been redecorated and only sufficient maintenance has been expended to keep it in the minimum of good repair, with the result that appearances had become shabby and repairs were badly needed. This spring it was decided that something would have to be done about it, and arrangements were made by the House Committee to let the whole undertaking to one contractor, and to accomplish as much as could be done within the financial limitations that had to apply.

The work has been under way for a month and a half, but at long last is complete. The money has been carefully spent, and while a larger sum could have been required to do a complete job, the present expenditure seems to have brought about a complete transformation.

The chief items of renovation are:

A new roof surface over the front portion of the building. Redecorating of the lecture hall, including new curtains at the rear of the platform, and drapes for the windows and new light control. Redecorating the reading room, hallways, council room, secretary's office and the general office. The latter has been re-arranged to give a more convenient and efficient layout. The secretary's office has been greatly improved by the addition of new drapes and lighting fixtures and a badly needed carpet.

Larger and more efficient radiators have been installed in the secretary's office, council room, reading room, and the lower hallway. Metal weather stripping has been placed around all windows, and the frames have been caulked with mastic.

All outside woodwork and ironwork has been repainted.

In general, the interior of the building has been greatly improved and it is felt that it is more in keeping with the handsome war memorial that it houses. The exterior not only looks better but is again in condition to resist the rigour of the weather.

Members are invited to visit the Headquarters. It is hoped they will make full use of the building and avail themselves of the facilities offered. Out of town members will be particularly welcome, and are urged to make this their headquarters while in Montreal.

J. B. D'Aeth, M.E.I.C.,
Chairman House Committee

Institute Delegates Report on International Engineering Congress, Glasgow

Engineering Institute of Canada,
2050 Mansfield Street,
Montreal, Que.

Gentlemen:

You will no doubt be interested to hear that having had the honour to be appointed an official delegate of The Engineering Institute of Canada, I attended the International Engineering Congress at the Empire Exhibition, Glasgow, from June 21st to 24th inclusive.

On the morning of the 21st, I met my compatriot, Mr. E. V. Buchanan (Vice-President, E.I.C.), at the Exhibition and together we attended several of the Technical Sessions Meetings on June 21st and 22nd. We also were guests at Lord and Lady Weir's dinner to the official delegates and later at the civic reception given to the Congress by the Rt. Hon. the Lord Provost and Corporation of Glasgow.

The last two days of the Congress were devoted to most enjoyable road, rail and sailing trips and visits to Scottish works. The Congress concluded on the evening of June 24th with a very pleasant reception and conversazione in the Palace of Art of the Empire Exhibition given by the President and Council of the Institution of Engineers and Shipbuilders in Scotland.

Very cordial welcomes and excellent addresses were given to the delegates and members of the Congress by Lords Weir and Elgin and by Rt. Hon. John Colville, M.P., Secretary of State for Scotland.

The technical papers submitted to the Congress were all by distinguished authors and were of a very high order throughout. To me they were most interesting and instructive.

The Empire Exhibition is a very fine one, well planned and on a magnificent scale. A conspicuous and worthy feature is the fine Canadian Pavilion on Dominions Avenue with its numerous and very interesting exhibits. It was pleasing to note that the men of the R.C.M.P. on duty there were so popular with the throngs of visitors.

I am glad to take this opportunity to express to you my high appreciation of the Congress in general and of the cordiality of the welcome and the splendid hospitality extended to the delegates and also for the honour and privilege of having been able to attend the Congress as one of your two delegates.

Yours faithfully,
James McGregor, M.E.I.C.

Gleniffer,
Thorn Road,
Bearsden, Glasgow, Scotland.

Engineering Institute of Canada,
2050 Mansfield Street,
Montreal, Que.

Gentlemen:

At the Council meeting of The Institute held in London in January of this year the writer was appointed The Institute's delegate to the International Engineering Congress in Glasgow in June and also to the International Electrotechnical Commission Plenary meeting held in Torquay and London from June 22 to July 1. The other Institute delegate to the Glasgow Congress was Major J. McGregor, D.S.O., A.M.E.I.C., who is now resident in Glasgow. The other Canadian delegates to the Electrotechnical Commission meeting were Alexander J. Grant, A.M.E.I.C., representing the National Research Council, Ottawa, and H. Lebouteux of the Aluminum Company, resident in London.

The International Engineering Congress at Glasgow was managed by the staff of the Institution of Engineers and Shipbuilders in Scotland and was very well organized. The headquarters for the technical sessions were in the Concert Hall at the Empire Exhibition grounds. The Rt. Hon. Viscount Weir, P.C., G.C.B. was the President of the Congress. I was shown every courtesy on my arrival and was immediately invited, along with my wife, to lunch with Viscount and Viscountess Weir, together with one of the German and one of the American delegates and their wives. Viscount Weir opened the Congress in an address of welcome in which he deplored the preparations for war and that the engineers' knowledge was being made use of for purposes of destruction, when so much more good could be brought to humanity by the efforts of the engineers in peace purposes.

I attended the following technical sessions:

"The Building of Ships—A British Survey," by Sir James Lithgow, Bt., M.C., D.L.

"Municipal and Industrial Planning,"—by A. Lilienberg, Esq. (Sweden).

"Technical and Economic Developments in Electrical Engineering," by S. B. Donkin, Esq.

"International Air Transport,"—by the Rt. Hon. Lord Sempill, A.F.C.

"Recent Developments of the Gas Industry in Canada," by J. Keillor, Esq. (Canada).

The last paper was the only Canadian paper, and in Mr. Keillor's absence, was presented by his nephew, who is an engineer in the gas industry in Greenock. A great many visits to works were arranged from which the delegates could make their choice. I visited the works of John Brown and Company at Clyde Bank where the "Queen Elizabeth" is being built, and Bruce, Peebles and Company, Limited, electrical manufacturers in Edinburgh. An excellent dinner was given to all delegates and their ladies by the President, the Rt. Hon. Viscount Weir and Viscountess Weir. The interesting feature of this banquet was that there were no speeches, except a vote of thanks proposed by the President of the Société des Ingenieurs Civils de France, and replied to briefly by the President. Beautiful souvenirs were presented to the ladies by Viscountess Weir. The delegates were also the guests of the Corporation of the City of Glasgow at the municipal buildings and were received by the Rt. Hon. The Lord Provost, Sir John A. Stewart.

No doubt the International Engineering Congress was organized with the aid of Engineering Institutions of Great Britain to attract engineers from all parts of the world to the Empire Exhibition in Glasgow. This report would not be complete without some reference to the Exhibition itself. Having had the privilege of visiting the British Empire Exhibition at Wembley in 1925 and the North East Coast Exhibition at Newcastle in 1929, I feel that the Glasgow show far surpasses both of these in every way.

It is natural, in an exhibition held in Glasgow that the Engineering Pavilion should be the most extensive. One of the delegates remarked that an Empire exhibition should feature engineering, as the real builders of Empire were the engineers. In this building there is literally everything in engineering, an epitome of the world of engineering.

Things of interest to engineers are not confined to the Engineering Pavilion. In the United Kingdom Pavilion, for instance, there are a working model of a coal mine, a blast furnace, a fully equipped bridge of a battleship and a mechanical man.

The predominating feature of the Exhibition for miles around is the modernistic observation tower, rising 300 feet above the crest of the hill in the centre of the grounds. For the structural engineer, this tower is undoubtedly of much interest. I was told that the maximum downward pressure on any one leg is 700 tons, while the overturning pull due to wind pressure and the unbalanced balconies that could be developed in any one leg is 400 tons.

The fountains and water displays are of great magnitude, novelty and variety. The use of special nozzles to aerate the water, giving it a sparkling white appearance, is an entirely novel device. The grading of the height of the jets, the carefully planned parabolas, and the skilful use of floodlighting all contribute to marvellous effects.

The Canadian Pavilion is the largest in Dominions Avenue and is a strikingly designed building. The engineering feats for which successive generations of Canadian engineers have been responsible are represented in pictures and dioramas from the Welland Canal to the construction of bridges like that at Quebec. The murals depicting Canadian life in ultra-modernistic, or almost sur-realist type are a mistake. It should have been evident to the designers that the vast majority of exhibition visitors are realists and take everything literally. These murals constantly created much mirth.

Following the International Congress in Glasgow, I proceeded to Torquay and arrived at the International Electrotechnical Commission meeting two days late, as the two conferences overlapped.

The meetings in Torquay were of an entirely different nature from those in Glasgow. The Glasgow Congress consisted of the delivery of papers of a very general nature and without discussion. At Torquay, on the other hand, the delegates were assigned to advisory committees and engaged in long discussions of a technical nature.

The International Electrotechnical Commission was the outcome of the St. Louis Electrical Congress held in the United States thirty-two years ago. A paper at that Congress on the Rating of Electrical Machinery given by Colonel Crompton led directly to the formation of this commission. It appeared that there were considerable discrepancies between the laws relating to electric units or their interpretation in various countries and that there was a great need of securing practical uniformity. Other questions bearing on nomenclature and the determination of units and standards were also raised on which it seemed desirable to have international agreement. After two years of study, Government delegates and those from various national engineering societies organized the I.E.C. in England in 1906.

All nations, large and small, have equal voice and freedom in the work of the I.E.C. Twenty-seven countries are now affiliated with the I.E.C. and in each of these countries, either through the leading electrical association or through the Government, where there is no such institution, there is found an electrotechnical committee representative of all the electrical interests of the country.

I attended the meetings of the committees on switchgear, transformers and overhead lines. The divergent practices in the rating of transformers in different countries was a problem which engaged the attention of the committee and some progress was made to reach uniformity.

One or two of the discussions at the conference have been simply indicated above, as it would be out of place here to attempt to report on the work of the numerous committees. One of the impressions gained by me at this conference was the loss of time due to the difficulties of language. Every remark made by a delegate had to be translated from English to French or vice versa. There were also unnecessary delays caused by apparently stubborn opinions based chiefly, I fear, on national pride. These differences, of course, are natural but, it would appear to me that more preparation should be done prior to these Plenary sessions by committees of action and thus speed up the work of the Plenary meetings.

Approximately 350 delegates in addition to about 100 ladies, representing twenty-two countries were present. The programme included a great many social functions which my wife and I enjoyed greatly. We are now in a position to instruct the members of The Engineering Institute and their ladies in the latest English dances, namely, the Lambeth Walk and the Palais Glide. The high spot, however, in entertainment was the banquet in London arranged by the British Standards Institution in the Guild Hall, where the delegates had for the guest of honour His Royal Highness the Duke of Kent, and were received by the Lord Mayor and his Sheriffs. It was a thrill which will be long remembered to dine in this old building, which has been the centre of the Corporation's social life since the year 1191. I had the pleasure of sitting opposite Sir Charles Bressey, Chief Engineer of the Department of Transport, who has just completed a 40,000 word report on the traffic problem in the City of London. His almost fantastic proposals, such as elevated and sunken main thoroughfares, three storey parking spaces on Trafalgar Square, etc. are most interesting.

While in London, I made an official visit to the headquarters of the Institution of Electrical Engineers, the Institution of Civil Engineers and the Institution of Mechanical Engineers, to pay the respects of our Institute. I also had the pleasure of attending the Dominion Day reception at Canada House and paid the respects of the President of The Engineering Institute to Mr. Vincent Massey, our High Commissioner in London. Along with my family, I had the great privilege of attending a garden party at Buckingham Palace and having tea in the Palace with His Majesty the King and Queen Mary, Queen Elizabeth being absent on account of the recent death of her mother.

There are many impressions which one could give on a trip of this kind, but space will not permit extending this report further.

Yours very truly,

E. V. Buchanan, M.E.I.C.

London, Ont.

Meetings of Council

A meeting of Council was held in Montreal on August 19th, 1938, at eight o'clock p.m., with President J. B. Challies in the chair, and eleven other members of Council present.

A resolution was passed recording the regret of Council at the death of Past-President J. G. Sullivan.

On behalf of the Publication Committee, Mr. Busfield reported that twenty-nine designs had been submitted for The Journal cover competition, and also that twenty-five members of The Institute had agreed to become Advisory Members of the Publication Committee to act in a technical advisory capacity to the editor of The Journal.

The President referred to the report on membership classification which had been prepared by Professor Spencer's committee. It was agreed that the report, with the memorandum and a questionnaire from Council, be sent to all branch executive committees for an expression of opinion.

There was a long discussion on the relationship of The Institute to the engineering students. It was felt that there should be some further service rendered to this basic group. In view of the Secretary's pending visit to Washington to gather information on this subject, further discussion was postponed until the next meeting.

Councillor Newell reported on the Saskatchewan agreement, and asked Council to authorize the submission of the agreement to councillors and corporate members resident in Saskatchewan in accordance with By-law 76. This was agreed to, the following scrutineers being appointed: Vice-President H. S. Carpenter, M.E.I.C., Councillor R. A. Spencer, A.M.E.I.C., and Past-Councillor D. A. R. McCannel, M.E.I.C.

At the request of the Association of Professional Engineers of Nova Scotia consideration was given to the passing of an amendment to By-law 76 that would facilitate the consummation of a co-operative agreement between the Nova Scotia Association and The Institute. This was agreed to.

The President's visit to the western branches was described and the itinerary submitted. The party will consist of President and Mrs. Challies, Councillor and Mrs. Newell, and the General Secretary. From Winnipeg to Calgary they will be accompanied by Mr. Gaherty, chairman of the Committee on Western Water Problems. In Regina the visit will coincide with the Semi-Annual Meeting of the Association of Professional Engineers of Saskatchewan, and in Vancouver with the Western Fall Meeting of the Canadian Institute of Mining and Metallurgy.

The President reported on the progress which had been made with the arrangements for the Annual Meeting which takes place in Ottawa on Monday, Tuesday and Wednesday, February 20th, 21st and 22nd, 1939. A number of distinguished guests have been invited.

An invitation had been received from the American Society of Civil Engineers to join with them in a meeting which is being arranged in New York in September 1939 with the Institution of Civil Engineers. The suggestion was accepted and a committee consisting of the President, Past-President Fairbairn and the General Secretary was appointed to discuss arrangements with the officers of the American Society of Civil Engineers.

After a long discussion and a report from the Treasurer, Mr. deGaspe Beaubien, it was decided to accept the invitation of L'Institut Scientifique d'Etudes des Communications et des Transports to appoint two members of the executive to their Committee of Honour. The President and Mr. Beaubien were made appointees.

A number of applications were considered, and the following elections and transfers were effected:

Elections		*Transfers*	
Member	1	Student to Associate Member	1
Associate Member	1	Student to Junior	4
Juniors	5	Affiliate to Member	1
Students admitted	4		

The Council rose at eleven fifteen p.m.

* * *

A meeting of Council was held at Headquarters on September 9th, 1938, at eight o'clock p.m., with President Challies in the chair, and nine other members of Council present.

The President commented on the presence of Vice-President R. L. Dunsmore, of Halifax, and thanked him for representing The Institute at the meeting of the Mining Society of Nova Scotia in Sydney, and presenting the Leonard Medal to T. L. McCall, M.E.I.C., on that occasion.

Past-Councillor R. E. Smythe, Director and Secretary of the Technical Service Council, was present by invitation. He had come to Montreal for the purpose of discussing with the General Secretary and other councillors who were particularly interested, the possibility of improving the employment services of The Institute and the Council by closer co-operation.

Consideration was given to a letter from the Secretary of the American Society of Mechanical Engineers dealing with the joint meeting of that body and the Institution of Mechanical Engineers in New York in September 1939. It was suggested by the A.S.M.E. that The Institute might co-operate with them at a joint meeting in Niagara Falls or Toronto during the tour which followed the meeting in New York. The President pointed out the difficulty of co-operating satisfactorily with both the A.S.C.E., which had previously invited The Institute to co-operate with them, and with the A.S.M.E., and it was left with the committee previously appointed to discuss this with the officers of both societies so that arrangements could be worked out to the best advantage.

The ballot of Council on the Saskatchewan agreement was reported upon, and it was noted that out of thirty-six ballots received not one negative vote was recorded.

Mr. D'Aeth reported for the Library and House Committee that the work on the Headquarters building was practically completed, and he wished to invite members of Council and members of The Institute in general to visit the building and see the changes for themselves.

The report of the Nominating Committee, under the chairmanship of Harry F. Bennett, M.E.I.C., for the officers for 1939, was received and accepted.

A recommendation from E. P. Muntz, M.E.I.C., Council's representative on the National Construction Council of Canada, that the proposed amendment to the by-laws of the Construction Council be supported, was agreed to, and the Secretary was directed to inform Mr. Muntz that Council approved of his recommendation.

As replies had not been received from all the branches on the proposed re-organization of Council, which was submitted to them in June, it was decided to extend the period for replies until October 1st.

Four resignations were accepted; two Life Memberships were granted; the names of two members were removed from the list, and two special cases were considered, and decisions reached in accordance with their merits.

On the recommendation of the Finance Committee, Council decided to recommend an amendment to By-law 35 so that the fee charged to new members for fractional portions of the year would be based on the actual number of months contained in the unexpired portion of the year. It was also decided to propose and sponsor an amendment to By-law 32 fixing the entrance fees as $10.00 for Members, Associate Members, and Affiliates, and $5.00 for Juniors. This rate was established by a resolution of Council on December 17th, 1937, and confirmed at the last Annual Meeting, and the amendment is proposed for the simple purpose of recording the resolution in the by-laws.

The President drew Council's attention to the proposal of the Kingston Branch to have a special gathering in Kingston to honour Dr. W. L. Malcolm, M.E.I.C., who had been appointed recently Dean of the School of Engineering at Cornell University. As the President wished to be present at such a function, and as many councillors also wished to attend, the Secretary was instructed to submit two dates to Councillor Grant in the hope that either one would be acceptable to Dr. Malcolm and the branch. It was hoped that a date could be agreed upon that would be suitable for a Council meeting. (The second date, namely, October 22nd, has since been agreed upon, which makes it impossible to hold the proposed Council meeting in Kingston).

It was reported that the secretary of the Peterborough Branch had invited the President and the General Secretary to be their guests on the occasion of their Annual Dinner. Councillor Bonn stated that as this was always an important gathering, it would be well if a date could be found that would permit many councillors, as well as the President and Secretary to attend. The Secretary was instructed to recommend Saturday, November 26th, as a suitable date, and to express the hope that this would be satisfactory to the Peterborough Branch. It was also proposed that Council hold its November meeting in Peterborough at the same time, subject, of course, to the approval of the branch executive.

The American Society of Heating and Ventilating Engineers had invited The Institute to participate with them in a special meeting which they were holding on October 6th in Montreal. At this meeting it was expected that all the officers of the Society would be present. Council expressed its appreciation of the invitation and approved of it. As the co-operation would have to come principally from the Montreal Branch the matter was referred to them, with the request that they co-operate if it could be arranged.

A number of applications were considered, and the following elections and transfers were effected:

Elections		*Transfers*	
Member	1	Associate Member to Member	4
Associate Members	4	Junior to Associate Member	2
Junior	1	Student to Associate Member	1
Student admitted	1	Student to Junior	5

It was decided that the next regular meeting of Council would be held in Montreal on Friday, October 7th, 1938.

The Council rose at eleven o'clock p.m.

E.I.C. Transactions Wanted

The Library needs the following number of The Institute Transactions:

Canadian Society of Civil Engineers, Vol. 25, pt. 1, 1911.

It would be appreciated if any member wishing to dispose of this number would communicate with the General Secretary. Single copies are worth $1.50.

Reports Wanted

Any members wishing to dispose of the following publications at $5.00 a copy should get in touch with the General Secretary.

International Waterways Commission, Compiled Reports, 1905-1913.

International Waterways Commission, Report on the Regulation of Lake Erie, 1910.

OBITUARIES

Marshall Willard Hopkins, M.E.I.C.

Word has recently been received of the death of Marshall Willard Hopkins, a Life Member of The Institute, at his home in St. Paul, Alta. Mr. Hopkins was born at Stoney Creek, Ont. on May 24th, 1861. He was graduated from McGill University in Civil Engineering with honours in 1888. Prior to his graduation and for a year after he was assistant engineer of the Montreal Sanitary Association. His first railway experience was obtained as early as 1890 when he was given charge of a twelve mile section of railway construction on the Charleston, Cincinnati and Chicago Railway, South Carolina. The next year he was associated with Stewart Noble on the reconnaissance of the Danville and East Tennessee Railway. In 1892 he returned to Canada and took up private practice as consulting engineer in Hamilton, Ont. He became consulting engineer for the municipalities of Hamilton, Barton, Saltfleet, North Grimsby, South Grimsby and Grimsby. He then became connected with the Hamilton, Grimsby and Beamsville Electric Railway and later with the Niagara Central Railway for which he made a preliminary survey from Hamilton to St. Catharines and Thorold. As well as engaging in railway work Mr. Hopkins made reports on the water supply of Hamilton and nearby towns, drew up surveys and plans of streets for the Hamilton Street Railway Company, located the Radial Electric Railway across Burlington Beach, Hamilton, and made surveys as chief engineer for the location of the International Radial Railway Company from Hamilton to Guelph.

In 1897 he moved to Rat Portage, Ont., where he practised mining engineering and land surveying for a considerable time. In 1904 he went to St. Paul, Alta. After surveying a great tract of the Peace River country for the Dominion Lands Department he did considerable surveying for the municipal districts. In 1923 after his retirement from the government service he wrote a mathematical book "Chance and Error." This book has been used in several universities.

Mr. Hopkins joined The Institute in 1887 as a Student, becoming an Associate Member in 1891 and a full Member in 1901. In 1925 he was made a Life Member.

Stewart Robertson McDougall, A.M.E.I.C.

Members will learn with regret of the death of Stewart Robertson McDougall, A.M.E.I.C., in Montreal, September 3rd. He was born at New Westminster, B.C., on April 10th, 1900. In 1922 he received the degree of B.A.Sc. in chemical engineering from the University of British Columbia and in the following year the degree of M.A.Sc. from the same University. During the year 1922-23 he was instructor in advanced analytical chemistry. He continued his studies at the University the following year, 1923-24, having obtained a Dominion Research Council Bursary. He came to Montreal in 1924 to attend McGill on a Dominion Research Council Studentship. The next year he entered the employ of the Northern Electric Company as chemical engineer and for ten years held various positions as development engineer. Since 1935 he had been acting in an advisory capacity in the Operating Department of the Cable Division of the company.

Mr. McDougall joined The Institute as a Student in 1920, becoming an Associate Member in 1927.

Charles Cathmer Ross, M.E.I.C.

Members of The Institute will regret to learn of the sudden death of Charles Cathmer Ross, M.E.I.C., in Vancouver, B.C., on September 12th. Mr. Ross, formerly Minister of Lands and Mines in the Alberta Government, was spending a holiday in Vancouver with Mrs. Ross. He was born at Ottawa, Ont., on June 14th, 1884. He attended Lisgar Collegiate there prior to entering McGill

University. In 1909 he graduated from the University with the degree of B.Sc. (civil) and following graduation was with the International Boundary Survey and subsequently with the Hydrographic Survey.

From 1911 until 1913 Mr. Ross was in private practice, contracting. In 1916 he went to Calgary, where he made his home until his death. As senior mining inspector and later as supervisory engineer for the Department of the Interior, he accomplished noteworthy results in the evolution and harmonious operation of the regulations for the development of the mineral resources of the prairie provinces. In 1928 he was chosen to organize the administrative machinery necessary to perfect a similar satisfactory service in northern Manitoba and northern Saskatchewan and in the Northwest Territories. In 1931 he left the Government service and engaged in the development of oil and gas and mining as a consultant. In 1935 he was appointed Minister of Lands and Mines in the Alberta Government, a position which he held until 1937.

Mr. Ross joined The Institute as a Member in 1925 and was always active in Calgary Branch affairs.

Edward James Turley, A.M.E.I.C.

We regret to have to record the death of Edward James Turley, A.M.E.I.C., on August 23rd in Montreal. He was born at Frankfort, Ont., on March 15th, 1884, and attended Trenton High School prior to entering McGill University. He graduated from the University in 1906 with the degree of B.Sc. in mechanical engineering. After graduation he entered the Montreal Locomotive Works where he remained for two years. He was then appointed factory engineer of the Northern Electric and Manufacturing Company. In 1910 he became associated with the Montreal Light Heat and Power Company as mechanical superintendent. After three years in the company he was made superintendent of general shops, the position which he held until his death.

Mr. Turley joined The Institute as a Student in 1906, becoming an Associate Member in 1913.

PERSONALS

Dr. T. H. Hogg, M.E.I.C., has completed twenty-five years of service to the Hydro-Electric Power Commission of Ontario. To mark the occasion and to acknowledge his attainment to the chairmanship, the staff of the Commission, on September 16th, 1938, paid tribute by the presentation of an illuminated address expressing the warm feeling and good wishes of the staff throughout the Province. The address recalled the fact that Dr. Hogg was associated with the first hydraulic plant constructed by the Commission, and expressed confidence in the administration of the Chairman in the future.

As a more tangible evidence of the staff's good wishes, Dr. Hogg was presented with four covered serving dishes of fine old English sterling, made by Paul Storr in 1822.

Because of the large numbers in attendance it was necessary to make the presentation from the steps of the west door of the Commission's head office building. The presentation was made by Mr. C. F. Publow, President of the Ontario Hydro-Electric Club.

Edgar T. J. Brandon, A.M.E.I.C., chief electrical engineer of the Hydro-Electric Power Commission of Ontario, has retired from active duties. On April 25th, 1938, Mr. Brandon completed thirty years of service with the Commission and it is a matter of regret that, owing to ill-health, he finds himself unable to carry out his active executive duties. However, as he will be retained upon a consulting basis, his services will continue to be available to the Commission. Mr. Brandon will be succeeded by Mr. Arthur H. Hull who has been appointed acting electrical engineer.

Archie B. Crealock, M.E.I.C., is now in the hospital suffering from pneumonia. The last report before going to press was that the doctor was well satisfied with his progress and expected he would be able to leave hospital in about two weeks time.

P. L. Pratley, M.E.I.C., of Monserrat and Pratley, is in hospital in Montreal for observation and treatment, but expects to be back in his office within a few days.

J. Hoogstraten, A.M.E.I.C., lecturer in civil engineering at the University of Manitoba, Winnipeg, Man., attended the University of Michigan this summer, taking graduate work in rigid frames and advanced fluid mechanics in preparation for a M.Sc. degree.

Harold G. Mosley, Jr.E.I.C., is now chief surveyor of the Cumberland Railway and Coal Company (a subsidiary of the Dominion Coal Company), at Springhill, N.S. He held the same position with the Dominion Coal Company at Glace Bay prior to his being transferred to Springhill.

A. B. Dove, A.M.E.I.C., is now in Montreal in the engineering department of the Steel Company of Canada. Mr. Dove is a graduate of Queen's University of the class of 1932 in chemical engineering. After graduation he entered the Steel Company of Canada, Hamilton, Ont., as chemical engineer. He later become assistant superintendent as well and held these positions until his transfer to Montreal. While in Hamilton he was active in Branch affairs, serving on the executive in 1937.

J. B. Hamilton, A.M.E.I.C., has been appointed manager of Western Securities Limited, 200 Lancaster Building, Calgary. This company is interested in the McCanachie Air Transport Limited and in the development of 104,000 acres of Pouce oil lands and generally in royalties in the Turner Valley oil fields. Prior to accepting this position he was sales manager of the International Bitumen Company Limited.

Charles D. Woolward, A.M.E.I.C., has accepted a position with Anglin-Norcross Limited, Montreal. He was formerly steel designer with the Canadian Industries Limited, Montreal.

Louis Trudel, S.E.I.C., has been appointed production engineer with the Marine Industries Limited in Sorel, Que. He has previously been with the Southern Canada Power Company Limited and with the Provincial Electricity Board. He will be greatly missed from his executive position as Vice-Chairman of the Junior Section of the Montreal Branch.

Douglas S. Laidlaw, A.M.E.I.C., is now associated with Chapman and Oxley, architects, Toronto. For the past four years he has been in the firm of Catto and Catto, architects, Toronto. Previous to going to Toronto, Mr. Laidlaw was located in Montreal for two years. He obtained his degree of B.A.Sc. from Toronto University in 1928.

Ralph G. Johnstone, A.M.E.I.C., has been promoted to the position of production manager of the E. B. Eddy Company, Hull, Que. He has been with the company since 1931 and for a year has been assistant production manager.

W. Sidney Kidd, A.M.E.I.C., is now managing director of the E. B. Eddy Company, Hull, Que. He has been connected with the company since 1926 and has held the positions of assistant chief engineer, mechanical superintendent and production manager.

W. A. Dawson, A.M.E.I.C., has been appointed plant manager of the E. Long Limited, Engineering Works, Orillia, Ont. He was graduated from Queen's University, after which he was associated with the Ford Motor Co. of Canada for eleven years, first as mechanical draftsman and later as chief in charge of machine and tool design. In 1935 and 1936 he was connected with the Algoma Steel Corporation, Sault Ste. Marie, Ont. as assistant superintendent of shops and foundry. Last September he returned to Windsor as plant engineer of the new motor plant of the Chrysler Corporation of Canada.

W. W. Preston, Jr.E.I.C., has accepted a position on the staff of the University of Alberta. He is a graduate of Queen's University 1935, and prior to his present appointment has been in Hamilton with the Hamilton Bridge Works Company Limited. He has been assistant secretary and branch news editor of the Hamilton Branch.

R. DeL. French, M.E.I.C., has started on a series of weekly radio broadcasts dealing with his favourite hobby, postage stamps, Friday nights, 7 p.m., station CFCF, Montreal.

D. H. McDonald, A.M.E.I.C., has been transferred to London, Ont., as senior assistant engineer in the Department of Public Works there. He has been lately in Ottawa with the Department as chief, Engineers Branch.

Visitors to Headquarters

H. F. Bennett, M.E.I.C., visited Headquarters September 29th on his way through Montreal to Saint John, N.B., to attend the funeral of his father.

Norman Hall, M.E.I.C., professor of mechanical engineering of the University of Manitoba, was at Headquarters September 22nd when in Montreal to visit his brother John Hall, M.E.I.C., assistant to the vice-president of Combustion Engineering Corporation.

Dean Mackenzie, of Saskatoon, visited Headquarters on August 27th, when he had an opportunity of discussing Institute developments with President Challies and Councillor Newell.

G. B. Moxon. A.M.E.I.C., of the Aluminum Company of Canada at Arvida, paid a visit to Headquarters recently.

C.P.R. Appointments

Recently changes have been announced by the Canadian Pacific Railway that affect several members of The Institute. They are as follows: **Lieut.-Col. Blair Ripley,** M.E.I.C., district engineer, Toronto, Ont., was appointed engineer, maintenance of way, eastern lines, Toronto; **J. H. Forbes,** A.M.E.I.C., assistant district engineer, Montreal became assistant right-of-way agent, Montreal; **W. C. E. Robinson,** A.M.E.I.C., division engineer, Laurentian division, Montreal, is now division engineer, London, Ont.; **James Edward Beatty,** M.E.I.C., engineer maintenance of way, eastern lines, Toronto, retired; **T. B. Ballantyne,** A.M.E.I.C., assistant district engineer, Toronto, was made district engineer; **A. O. Wolff,** M.E.I.C., division engineer, London, Ont. is now assistant district engineer, Toronto, and **L. M. Duclos,** A.M.E.I.C., assistant engineer, North Bay, became division engineer, Sudbury, Ont.

Cotton in Roads

Cotton fabric woven with a coarse mesh is being used at Burnley (Lancashire), Eng. as a road-building material. Concrete is laid in the usual way to a depth of five inches. The cotton, looking like a fish net, is then placed on top, separating the foundation layer from the concrete surface, which is three inches thick. In consequence, when re-surfacing is necessary, it is a simple matter to remove only the top layer, leaving the bottom layer undisturbed. The cost of the material, which is manufactured at a Burnley mill, is about twopence a yard.

MEETINGS

American Society of Civil Engineers—Fall Meeting, October 12th-14th, 1938, at Rochester, N.Y.

American Society of Heating and Ventilating Engineers—Annual Meeting, January 23rd to 26th, 1939, William Penn Hotel, Pittsburgh, Pa.

Canadian Construction Association—January 10th-12th, at Winnipeg, Man.

The Canadian Institute of Mining and Metallurgy—Annual Western Meeting, November 9th, 10th, 11th, at Vancouver. H. Mortimer Lamb, Vancouver Secretary, British Columbia Division.

Canadian Institute on Sewage and Sanitation—October 20th-21st, at the Royal York Hotel, Toronto. Secretary, Dr. A. E. Berry, M.E.I.C., Ontario Department of Health, Parliament Buildings, Toronto, Ont.

The Engineering Institute of Canada—Annual General and Professional Meeting, February 20th-22nd, 1939, at Ottawa.

E.I.C. Kingston Branch—Complimentary Dinner to Dr. Malcolm, October 22nd, 1938.

E.I.C. Peterborough Branch—Annual Banquet in the evening and Special Meeting of Council in the afternoon, November 26th.

Thirteenth Exposition of Power and Mechanical Engineering—December 5th to 10th, 1938, Grand Central Palace, New York.

Twelfth National Asphalt Conference—February 20th to 24th, 1939, Biltmore Hotel, Los Angeles, Calif.

Additional information about any of these functions may be secured from the General Secretary.

ADDITIONS TO THE LIBRARY

Proceedings, Transactions, etc.

Institution of Mechanical Engineers: Proceedings, Vol. 138, January-April 1938.

Institution of Mining and Metallurgy: Transactions, Vol. 46, 1936-37.

North East Coast Institution of Engineers and Shipbuilders: List of Members, July 31st, 1938.

Reports, etc.

British Columbia Dept. of Lands: Water Powers, Fraser River. 1938.

Canada Bureau of Mines: Comparative Pulverized Fuel Boiler Tests on British Columbia and Alberta Coals and on Ontario Lignite by C. E. Baltzer and E. S. Mallock.

Connecticut Society of Civil Engineers: Annual Report 1938.

Edison Electric Institute: Transmission and Distribution Committee, Transmission Group: Lightning Proof Transmission Lines. July 1938.

International Boundary Commission: Joint Report upon the Survey and Demarcation of the Boundary between the United States and Canada from the Gulf of Georgia to the Northwesternmost Point of Lake of the Woods. 1937.

Manitoba Economic Survey Board: Mineral Resources of Manitoba. 1938.

Ohio State University: Soil Mechanics Applied to Highway Engineering in Ohio. (Engineering Experiment Station Bulletin No. 99.)

U.S. Bureau of Mines: Minerals Yearbook, 1938, Review of 1937; Copper Mining in North America (Bulletin 405); Methods for the Detection and Determination of Carbon Monoxide, Flotation for Recovery of Scheelite from Slimed Material, Notes on the Sampling and Analysis of Coal (Technical Papers 582, 585, 586).

U.S. Geological Survey: Geology and Ore Deposits of the Southwestern Arkansas Quicksilver District, Metalliferous Mineral Deposits of the Cascade Range in Oregon, Subsurface Geology and Oil and Gas Resources of Osage County, Oklahoma (Bulletin 886-C, 893, 900-A); Species and Genera of Tertiary Noetinae, Pliocene Diatoms from the Kettleman Hills, California, Lower Pliocene Mollusks and Echinoids from the Los Angeles Basin, California (Professional Paper 189-A, 189-C, 190); Geology and Ground-Water Resources of the Valley of Gila River and San Simon Creek, Arizona, Surface Water Supply of the United States 1936 Pt. 10 the Great Basin, Drought of 1936 with Discussion on the Significance of Drought in Relation to Climate (Water-Supply Paper 796-F, 810, 820).

U.S. Public Health Service: Planning the Organization and Conduct of Stream Pollution Surveys.

University of Illinois: The Friction of Railway Brake Shoes at High Speed and High Pressure, Fatigue Tests of Riveted Joints, Solutions for Certain Rectangular Slabs Continuous Over Flexible Supports, A Distribution Procedure for the Analysis of Slabs Continuous Over Flexible Beams, Fourth Progress Report of the Joint Investigation of Fissures in Railroad Rails (Bulletin Vol. 35, Nos. 72, 79, 81, 84, 93).

Technical Books, etc.

American Men of Science. Ed. by J. McKeen Cattell and Jaques Catell. 6th ed. New York, Science Press, 1938. 1608 pp. 10¼ x 7½ in., cloth, $8.00.

Engineering Mechanics. By Seibert Fiarman and Chester S. Cutshall. New York, Wiley, 1938. 267 pp., diagrs., 9¼ x 6 in., cloth, $2.75.

Estimates and Costs of Construction. By Frank W. Stubbs. New York, Wiley, 1938. 234 pp., front., illus., plates, diagrs., charts, 9¼ x 6 in., cloth, $3.00.

(*Continued from page 479*)

Among those present were Major R. S. Buck, M.E.I.C., of Niagara Bridge fame; Major William Bowie, formerly Chief, Division of Geodesy, U.S. Coast Surveys; John F. Coleman, Reconstruction Finance Corporation, Past-President of the Engineering Council and of Am.Soc.C.E., and Honorary Member, Am.Soc.C.E.; Roy W. Crum, Director, Highway Research, National Research Council; Com. C. L. Garner, Chief, Division of Geodesy, U.S. Coast and Geodetic Survey; J. L. Harrington, Consulting Engineer, Kansas City, formerly President, Am.Soc.M.E.; W. W. Horner, Professor of Municipal and Sanitary Engineering, Washington University, Past-Director, Am.Soc. C.E.; E. W. James, Chief, Division of Highway Transportation, Bureau of Public Roads; Gen. R. C. Marshall, Consulting Engineer, formerly head of Construction Division, during World War; William McClellan, President, Potomac Electric Power Company, President, Engineering Council; O. C. Merrill, Director, World Power Conference; T. W. Norcross, Chief Engineer, U.S. Forest Service; Gov. Thomas Riggs, U.S. Commissioner, Alaska Boundary Commission, formerly Governor of Alaska; O. G. Taylor, Chief Engineer, U.S. Park Service; Gen. M. C. Tyler, Assistant to Chief of Engineers in charge of civilian activities; E. F. Wendt, Consulting Engineer, Past-President, Institute of Consulting Engineers, formerly Interstate Commerce Commission, and Capt. Paul C. Whitney, Chief, Division of Tides and Currents, U.S. Coast and Geodetic Survey.

BOOK NOTES

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet, the books are not in The Institute Library, but inquiries will be welcomed at Headquarters, or may be sent direct to the publishers:

British Non-Ferrous Metals Research Association, Research Reports, Association Series, No. 472, May, 1938. **Nickel Silver:** a Survey of Published Information by T. F. Pearson, London, The Association, Regnart Bldgs., Euston St., London, N.W.1. 36 pp., tables, 10 x 6 in., paper, 3s.

This survey presents a very compact account of the available information. After a short introductory section, the specifications for nickel-silver alloys issued in various countries are discussed. Following sections discuss the mechanical and physical properties of the alloys, the technique of melting and casting them, sands and sand mouldings, the effect of impurities, methods of working the alloys and the effect of annealing. There is a select bibliography.

Concentration des Minérals par Flotation, Exposé Théorique et Pratique. By H. Havre. Paris and Liége, Librairie Polytechnique Ch. Béranger, 1938. 461 pp., illus., diagrs., charts, tables, 10 x 6 in., cloth, 190 frs.

The concentration of minerals by flotation is covered in detail. The opening chapters discuss the various important methods with or without agitation or agents. Following this come descriptions of machinery and equipment used, then practical information concerning the treatment of sulphides, oxides, native metals and non-metallic minerals, concluding with process control and cost and equipment estimating.

Demonstration Experiments in Physics, ed. by R. M. Sutton, prepared under the auspices of the American Association of Physics Teachers. New York and London, McGraw-Hill Book Co., 1938. 545 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.50.

This is a collection of nearly twelve hundred lecture experiments for the use of high school and college teachers of physics and general science. The book was prepared under the auspices of the American Association of Physics Teachers, and includes contributions from two hundred physicists. The descriptions of experiments are direct and emphasis has been placed upon simplicity of apparatus and procedure.

Group Purchase of Medical Care by Industrial Employees. By L. Brown. Princeton, N.J., Princeton University, 1938. 10 x 7 in., paper, $1.00.

The problem of medical care is presented and the developments in this line within industry are discussed. A limited number of representative group purchase plans are analyzed and summarized, including the attitude of organized medicine toward such plans. A selected bibliography is appended.

REQUEST FOR INFORMATION

To all members of The Engineering Institute of Canada

It is proposed to publish a membership list before the end of the year. In order that complete and up-to-date information may be available, will you kindly fill in this form and return it to Headquarters. The work is already under way; therefore a prompt response will be appreciated.

BRANCH NEWS

Niagara Peninsula Branch

G. E. Griffiths, A.M.E.I.C., Secretary-Treasurer.
J. G. Welsh, A.M.E.I.C., Branch News Editor.

EXECUTIVE 1938-1939

Chairman—C. G. Moon, A.M.E.I.C., 66 Yates Street, St. Catharines, Ontario.
Vice-Chairman—A. W. F. McQueen, A.M.E.I.C., H. G. Acres and Company, Ferry Street, Niagara Falls, Ont.
Secretary-Treasurer—G. E. Griffiths, A.M.E.I.C., Box 385, Thorold, Ontario.
Branch News Editor—J. G. Welsh, A.M.E.I.C., 83 Niagara Street, Fort Erie, Ontario.

ELECTED EXECUTIVE

District No. 1—St. Catharines—
C. G. Moon, A.M.E.I.C., 66 Yates Street, St. Catharines, Ontario.
A. L. McPhail, A.M.E.I.C., 52 York Street, St. Catharines, Ontario.
M. H. Jones, A.M.E.I.C., Ontario Paper Company, Thorold, Ontario.
District No. 2—Niagara Falls—
A. W. F. McQueen, A.M.E.I.C., H. G. Acres and Company, Ferry Street, Niagara Falls, Ont.
C. G. Cline, A.M.E.I.C., Ontario Power Plant, Box 237, Niagara Falls, Ontario.
D. W. Bracken, A.M.E.I.C., 1975 Drummond Road, Niagara Falls, Ontario.
District No. 3—Thorold, Port Colborne, Welland and Fort Erie—
C. H. Burns, M.E.I.C., 105 Dorothy St., Welland, Ontario.
P. E. Buss, A.M.E.I.C., Spun Rock Wool, Box 40, Thorold, Ontario.
E. C. Little A.M.E.I.C., Welland Ship Canal Office, Humberstone.

COMMITTEES

Programme—C. G. Moon, A. W. F. McQueen, G. E. Griffiths.
By-Laws—W. Jackson, M.E.I.C.
Publicity—J. G. Welsh.
Visitors and Social—Chairman, M. B. Atkinson, M.E.I.C. with H. M. King, M.E.I.C., and C. H. Burns.

DISTRICT REPRESENTATIVES

Port Colborne—G. N. Geale, A.M.E.I.C., Welland Ship Canal, Humberstone, Ontario.
Welland—V. S. Dyson, 229 Maple Ave., Welland, Ontario.
Fort Erie—L. J. Russell, JR.E.I.C., c/o Horton Steel, Box 471, Fort Erie, N. Ontario.
Thorold—P. E. Buss, A.M.E.I.C., Spun Rock Wool, Box 40, Thorold, Ontario.
St. Catharines—D. D. Hall, A.M.E.I.C., c/o Dominion National Gas Company, Ltd., St. Catharines, Ontario.
Niagara Falls—M. F. Ker, A.M.E.I.C., 2057 Drummond Road, Niagara Falls, Ontario.

Saguenay Branch

F. T. Boutilier, A.M.E.I.C., Secretary-Treasurer.
J. W. Ward, A.M.E.I.C., Branch News Editor.

SECRETARY'S REPORT FOR YEAR ENDING JUNE 30TH, 1938

Mr. Chairman and Gentlemen:

I take pleasure in bringing to your attention the activities of this branch of The Institute during the past year. This was very active during the last season, having held eight general meetings.

Our last annual meeting was held at Dolbeau, on July 30th. After luncheon at the Dolbeau Inn, the members made an inspection tour of Lake St. John Power and Paper Co.'s papermill and the Trappist Brothers' limestone quarry.

On October 15th, Mr. McNeely DuBose, General Superintendent of the Saguenay Power Co. Ltd., delivered a very interesting address on the "Costs of Power." The costs involved in building hydro-electric plants were described in detail as well as the various methods of setting rates.

On February 11th, T. M. Moran, A.M.E.I.C., Chairman of the Industrial Management Section of the Montreal Branch, gave an instructive paper on the "Technical Men in Industry."

On February 25th, Mr. Frank Calder of the Aluminum Co. of Canada, Limited addressed the Saguenay Branch on "Paper Unloading Facilities at Port Alfred." This paper proved to be very interesting and was well illustrated by slides.

On March 25th, N. D. Paine, A.M.E.I.C., General Electrical Superintendent of Price Brothers & Company, Ltd., gave an illustrated address on "Operating Experience with Wood Pole Transmission Lines in the Saguenay District." F. L. Lawton, M.E.I.C., Chief Engineer of the Saguenay Power Co. Ltd., gave a similar address "Operating Experience with Steel Tower Transmission Lines in the Saguenay District." His address, illustrated with a number of slides, covered general features and insulation levels of three double circuit steel-tower lines in the Saguenay district.

On May 4th, G. E. LaMothe, A.M.E.I.C., Logging Division Engineer of Price Bros. & Co. Ltd., gave a timely address on "Wood Preservation," before a well attended meeting. After the meeting two talkies were shown, "Structural Shapes" and "Golden Gate Bridge."

On May 13th, Mr. A. Leuthold, Engineer of the Brown Boveri Company, Switzerland, delivered a very interesting illustrated paper on "Latest Application of Grid Controlled Mutators" just after the installation of the mercury arc rectifier station at the Aluminum Company's platt.

Mr. R. H. White, Manager and Vice-President of the Canadian Abrasives Company, Ltd., addressed the meeting on "Manufacture of Electric Furnace Abrasives." He gave an interesting history of the industry and described the development of the modern furnace.

During the past year the membership increased from 53 to 60, which is a result of the excellent work of the Membership Committee. The membership now stands at four members, 35 associate members, 7 junior members, 12 student members and 2 affiliate members.

CHARLES MILLER, A.M.E.I.C.,
Secretary-Treasurer.

Vancouver Branch

T. V. Berry, A.M.E.I.C., Secretary-Treasurer.
J. B. Barclay, A.M.E.I.C., Branch News Editor.

A joint dinner under the auspices of the Engineering Bureau, Vancouver Board of Trade, and The Engineering Institute of Canada, Vancouver Branch, was held in the Georgia hotel on September 13th, 1938, with A. S. Wootton, M.E.I.C., chairman of the Engineering Bureau, in the chair. Fifty members of these two organizations sat down to dinner.

The guest speaker was P. L. Pratley, M.E.I.C., who delivered a paper on "The Collapse of the Niagara Arch Bridge."

In an interesting address illustrated by lantern slides and film, Mr. Pratley described the unusual meteorlogical conditions over Lake Erie in the two or three days previous to the collapse of the bridge, which served to force unusual quantities of ice over Niagara Falls, the enormous lateral pressure of which on the lower chord members of the arch brought about its final demolition on January 28th, 1938.

A vote of thanks to the speaker was proposed by C. E. Webb, M.E.I.C., vice-chairman of the Vancouver Branch, Engineering Institute of Canada.

Electrodynamic Ammeter as Standard of Current at High Frequencies

A jewel-bearing oscillating-ring electrodynamic ammeter was described recently to the members of the New York section of the Institute of Radio Engineering in a paper presented by Harry R. Meahl of General Electric's General Engineering Laboratory. The author explained his method for calibrating this instrument, and showed it to be a standard of currents above one ampere, at high frequencies.

Past investigators of high-frequency phenomena have wondered why some practical standard of current at high frequencies was not found long ago. The reason is that many efforts were made to use the heating effect of the current, and only a few to use the energy in the magnetic field. Even on direct current, an instrument using the heating effect of the current is not a standard, because of the difficulty of accurately calculating its characteristics. The performance of the electrodynamic ammeter can be accurately calculated from measurements of length, mass and time, giving a standard of current at high frequency. This instrument is used with currents from 3 to 6 amperes over the 5 to 42 megacycle frequency range with an accuracy of plus or minus one per cent.

Atom Faces Disintegration

The mighty atom is going to have things happen to it, judging by reports emanating from Harvard University. It appears that a number of eminent professors have concentrated their united efforts upon the construction of a cyclotron atom-smasher, one of the largest machines of its kind in the world. This machine is expected to generate atom-smashing projectiles of 8,000,000-volt energy and above, permitting the most precise measurements ever made of the forces released by atomic disintegration. The third such machine for which General Electric has furnished parts, it is expected to be in operation this summer. Two years ago, it is recalled, two coils were made for a unit at the University of Rochester and an oscillator was made for another cyclotron at Princeton University. The pole cores of the Harvard cyclotron, it has been learned, are two times greater in diameter than those of the machine at Rochester, and will give four times as much magnetic flux. One interesting and possibly very valuable application of the cyclotron is the production of radio-active material having some advantages which radium does not possess. Such material has been produced by bombarding common salt, or metallic sodium, by the high speed ions, and has been successfully used in treating cancer in rats. By producing a substitute for that rare and exceedingly costly metal, radium, the cyclotron may provide another means for combating cancer, supplementing the powerful weapon now used, the X-ray tube.

Preliminary Notice

of Applications for Admission and for Transfer

September 25th, 1938.

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in November 1938.

L. Austin Wright, General Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and sball have been engaged in some branch of engineering for at least twelve years which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council. be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible cbarge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, whicb period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. Tbe occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the hranch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate bas beld a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he bas attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in tbe profession, in which case be shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant tbe extension of this age limit.

An Affiliate shall be one wbo is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact tbat candidates give tbe names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

CARSON—CECIL EDWARD, of 315 London Road, Sarnia, Ont., Born at Westmount, Que., Dec. 17th, 1900; Educ., B.Sc. (Chem.), McGill Univ., 1922; With the Imperial Oil Limited as follows: 1923-29, asst. chemist, and 1929-33, technical asst. to refinery supt., Montreal East; 1933-34, refinery supt., Regina, and 1934 to date, gen. supt., Sarnia, Ont.

References: T. Montgomery, F. C. Mechin, R. L. Dunsmore, E. R. Smallhorn, V. A. McKillop.

CAWLEY—HUGH ROSE, of Melville, Sask., Born at Glasgow, Scotland, Feb. 20th, 1909; Educ., B.Sc. (Mech.), Univ. of Sask., 1938; With the C.N.R. as follows: 1926-28, general shopwork, 1928-34, machinist ap'tice, 1934-38 (summers), machinist; June 1938 to date, asst. locomotive foreman, Melville, Sask.

References: C. J. Mackenzie, I. M. Fraser, R. A. Spencer, A. M. Macgillivray, J. J. White.

DOBSON—FRANKLIN ALVER, of 223 S. Archibald St., Fort William, Ont., Born at Stanstead, Que., Dec. 29th, 1908; Educ., B.Sc., Queen's Univ., 1932. Two years post-graduate study in aeronautics, Goettingen, Germany; 1935-36, dftsman., Fleet Aircraft of Canada, Fort Erie, Ont.; 1936-37, dftsman., Fairchild Aircraft of Canada, Longueuil, Que.; 1937, stress analyst, Waco Aircraft Co., Troy, N.Y.; 1937-38, project engr., and at present, re earch engr., Canadian Car and Foundry Co., Fort William, Ont.

References: D. Boyd, G. R. Duncan, P. E. Doncaster, H. Os, L. T. Rutledge, D. S. Ellis, A. Jackson, D. M. Jemmett.

DuBOSE—McNEELY, of Arvida, Que., Born at Ashville, N.C., Jan. 9th, 1892; Educ., B.E. and E.E., North Carolina State College, 1912. R.P.E. of Que.; 1912-18, with the following companies: Appalachian Power Company, Isthmian Canal Commission, Riegos y fuerza Ebro (Spain), Catawba Valley Co., Tallassee Power Company, U.S.A. Engineers; 1919-25, supt., Tallassee Power Company; 1925-26, supt., Aluminum Co. of Canada Ltd.; 1926-38, gen. supt., Saguenay Power Co. Ltd., also vice-president and director, Saguenay Electric Co., Saguenay Transmission Co. Ltd., Alma & Jonquiere Ry. Co. (Member, A.I.E.E.).

References: J. B. Challies, P. S. Gregory, J. Morse, J. W. McCammon, O. O. Lefebvre, J. A. McCrory.

HAMILTON—HAROLD PERCY, of Island Falls, Sask., Born at Regina, Sask., June 6th, 1912; Educ., B.A.Sc., Univ. of Toronto, 1934; 1932 (summer), electrn's and mechanic's helper; 1935-36, rodman and dftsman., Prairie Farm Rehabilitation, Swift Current, Sask.; 1936-37, operator, and 1937 to date, acting as dftsman and asst. engr. on design of structures for a storage reservoir, Churchill River Power Company.

References: J. B. D'Aeth, J. J. White, P. C. Perry, B. Russell, C. J. McGavin, D. A. R. McCannel, R. W. Jickling.

LORIMER—WILLIAM CLARENCE, of Kerrobert, Sask., Born at Manor, Sask., Dec. 27th, 1907; Educ., B.Sc. (Mech.), Univ. of Sask., 1929; 1929, dftsman., City of Regina; With Canadian Utilities Limited as follows: 1929-30, dftsman., instrument work, inspection, 1930-31, field inspr., 1931-32, res. engr., 1937 to date, plant operator and part time lineman.

References: C. J. Mackenzie, R. W. Allen, J. W. D. Farrell, J. J. White, W. E. Lovell.

SPENCE—HOWARD CLEMENT, of Ste 11A, Guelph Apts., Winnipeg, Man., Born at Winnipeg, April 13th, 1909; Educ., B.Sc. (Civil), Univ. of Man., 1934; 1926-27 (intermittent), constrn. and location surveys for C.P.R. and C.N.R.; 1928-35, 1 year, foreman and surveyor, 3 years, asst. field mgr., 2 years, acting field mgr., 2 years, field mgr., Winnipeg Anti-Mosquito Campaign. Full time employment during vacations with part time duties during academic years, incl. estimating, directing and reporting of all control measures (larvicides, drainage, etc.); 1935 to date, in Highway Traffic and Taxicab Office, Municipal and Public Utility Board, Province of Manitoba, 1½ years, inspr., 2 years, secretary. Work involves licensing and regulation of trucks, buses and taxicabs, incl. investigations relative to awarding of certs. of "public convenience and necessity," arrangement of bus and truck schedules, provisions for safety, use of downtown streets in urban districts by trucks and buses from country points, supervision of stations and terminals, tariff for passengers, freight and express traffic, etc.

TAYLOR—FRANK BUTLER, of 4384 Draper Ave., Montreal, Que., Born at Liverpool, England, March 18th, 1903; Educ., 1919-24, Liverpool Technical School. 1919-24, five years ap'ticeship, Marine Engrg., steam and Diesel, Cammell, Laird & Co., Birkenhead, England. British Board of Trade Chief Engr's Cert. for steam and motor vessels; 1924-28, engr. officer on British steamships; Since 1928 has specialized solely in study of high powered Diesel engines as applied to marine propulsion; With the Imperial Oil Shipping Company as follows: 1928, second engr. of motor tankers of 4,000 h.p., since 1932, chief engr. of motorships of over 6,000 h.p., several months during 1936 and 1937, and at present, marine supt., at Montreal.

References: F. C. Mechin, G. Agar, R. C. Flitton, P. F. Stokes, R. C. Simon.

WILLIAMS—CHARLES GUNNING, of 417 Rosemary Road, Toronto, Ont., Born at London, Ont., March 16th, 1882; Educ., B.A.Sc., Univ. of Toronto, 1905; 1913-28, with Hollinger Consolidated Gold Mines, 12 years as gen. supt.; 1929, private consltg. practice; 1934, general secretary, Canadian Metal Mining Association; 1936, general consltg. practice; at present, professor of mining engineering, University of Toronto, Toronto, Ont.

References: C. H. Mitchell, R. W. Angus, C. R. Young, H. E. T. Haultain, W. S. Wilson.

FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

MacKENZIE—GORDON LESLIE, of 2230 Elphinstone St., Regina, Sask.; Educ., B.Sc. (Civil), Queen's Univ., 1919; D.L.S., S.L.S., R.P.E. of Sask.; 1913-19, Dom. Govt. surveys with the Dept. of Indian Affairs; 1920-34, with Underwood & McLellan, consltg. engrs., Saskatoon, in responsible charge of surveys for, design of, and constrn. of municipal engrg. works in Saskatchewan; 1934-37, Dominion Public Works, on Outlook Bridge, Prince Albert, retaining wall and other misc. works; 1937 to date, office and designing engr., water development, Prairie Farm Rehabilitation, Dominion Dept. of Agriculture, 1937 i/c design and constrn. water conservation projects in Manitoba, 1938, office design and specifications on large projects. (*St. 1919, Jr. 1922, A.M. 1922.*)

References: F. G. Goodspeed, A. M. Kirkpatrick, A. J. Taunton, B. Russell, J. J. White, C. J. McGavin.

WATSON—McCLELLAND BARRY, of Toronto, Ont., Born at Toronto, Jan. 22nd, 1889; Educ., B.A.Sc., C.E., M.E., Univ. of Toronto, 1910; R.P.E. of Ont.; 1911-12, res. engr., waterworks and sewage systems, design and supervision of installns., Chipman and Power; 1912-13, chief asst. to mech'l. engr., Toronto Power Company; 1913-14, chief dftsman., Ontario Dept. of Highways; 1919-27, director, dept. of engineering, Central Technical Scbool, Toronto; 1927-31, partner, Angus &

Watson, consltg. mech'l. engrs.; July 1931 to date, private consltg. practice, also Director, Dept. of Military Studies, University of Toronto. (*Jr. 1914, A.M. 1919.*)
References: C. H. Mitchell, R. W. Angus, J. R. Cockburn, W. E. P. Duncan, W. S. Wilson, C. R. Young, T. R. Loudon, E. G. T. Taylor.

FOR TRANSFER FROM THE CLASS OF JUNIOR

RICE—WALTER LESLIE, of Toronto, Ont., Born at Hinckley, Leicestershire, England, March 6th, 1904; Educ., Toronto Technical Schools and private study. Passed E.I.C. exams. for admission as Junior, Nov. 1933. Passed E.I.C. exams. under Schedule "C" for admission as Associate Member, Nov. 1936; With the City of Toronto as follows: 1926-28, rodman, chainman and acting instr'man. on gen. sewer constrn.; 1928-30, dfting. and assisting with design of sewer constrn.; 1930, instr'man., St. Clair Reservoir constrn.; 1930-31, instr'man., and acting res. engr., filtered water tunnel; 1931 to date, dftsman., work includes dfting and assisting with the design of steel and concrete water mains, chambers, etc., specializing in reinforced concrete design; checking contractor's drawings; misc. surveying, dfting and field work covering Toronto waterworks extension projects and present water supply system. (*Jr. 1933.*)
References: G. G. Powell, A. U. Sanderson, G. Phelps, J. M. Walker, W. L. Shelden, H. J. Ross.

VINCENT—PAUL EMILE ALBERT, of Quebec, Que., Born at Montreal, Dec. 8th, 1906; Educ., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1934; 1927 (summer), asst. junior engr., Wayagamack Pulp and Paper Co. Ltd.; 1929-31, with Heroux & Robert Ltd., general contractors, May 1930 to Sept. 1931, asst. engr. i/c constrn.; Session 1934-35, asst. professor, elect'l. laboratory, Ecole Polytechnique; 1935 (summer), asst. on constrn., Aluminum Co. of Canada Ltd.; 1935-37, asst., water levels investigation, Marine Dept., Ottawa; 1937 (Apr.-June), i/c field party, Quebec Roads Dept.; June 1937 to date, district engr., roads and bridges divn., Colonization Dept., Quebec, Que. (*St. 1934, Jr. 1935.*)
References: A. I. Cunningham, C. G. Cline, A. Frigon, A. Gratton, A. B. Normandin, A. O. Dufresne.

FOR TRANSFER FROM THE CLASS OF STUDENT

BEIQUE—HENRI F., of 9 Belvedere, Quebec, Que., Born at Montreal, May 5th, 1911; Educ., B.Eng. (Elec.), McGill Univ., 1936; 1932, 1934, 1935 (summers), Quebec Streams Commission and Shawinigan Water and Power Co.; 1936-37, Shawinigan Water and Power Co., and 1937 to date, engr., Quebec Power Company, Quebec, Que. (*St. 1936.*)
References: O. O. Lefebvre, P. A. Beique, G. R. Hale.

COUSINEAU—LOUIS PHILIPPE, of Sorel, Que., Born at Montreal, May 9th, 1909; Educ., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1936. 1936-37, Ecole Supérieure de Soudure Autogène, Paris, France, welding engr.; 1929-35 (summers), surveying, Quebec Streams Commn.; 1937 (summer), Société L'Air Liquide, Paris; 1936 (summer), constrn. work, Chantiers Manseau; 1936-38, Chantiers Manseau and Marine Industries Ltd.; at present, welding supt., Marine Industries Limited, Sorel, Que. (*St. 1934*)
References: O. O. Lefebvre, A. Frigon, A. Cousineau, C. E. Frost, L. Trudel.

STEVENSON—CHARLES LESTER, of Arvida, Que., Born at Waltham, Mass., June 5th, 1911; Educ., B.Sc. (Civil), Univ. of N.B., 1934; 1930-31 (5 mos.), dftsman., etc., N.B. Highways Dept.; 1931 (5 mos.), instrument man, Northern Construction Co., Montreal; 1933 (4 mos.), materials checker, E. G. M. Cape Co., Montreal; 1934 (4 mos.), 1935-36 (10 mos.), asst. to res. engr., City of Saint John, N.B.; 1936 (9 mos.), instrumentman, Ontario Paper Company, Baie Comeau, Que.; 1937, constrn. engr., A. F. Byers & Co., Montreal, and Can. Engrg. and Contracting Co., Hamilton, Ont.; 1938 (9 mos.), plant engr., i/c of installn. of plant equipment, further constrn. on plant, and constrn. of houses, for the Abrasive Company of Canada, Arvida, Que. (*St. 1934.*)

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted after a lapse of one month, upon request.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Situations Wanted

ENGINEER, A.M.E.I.C., Combustion specialist heat balance. Steam, Mechanical. Refrigeration. Office routine. Correspondence. Plant layout. Apply to Box No. 5-W.

ELECTRICAL ENGINEER, JR.E.I.C., B.SC.; age 31; at present employed, desires change in location. Experience includes; three summers experience in power conduit construction; two years in telephone engineering; four years experience in radio, both development engineering and production; two and one half years in a paper mill on electrical maintenance, with a short time in the cost accounting and draughting departments. Would be interested primarily in electrical maintenance. Apply to Box 12-W.

PAPER MILL ENGINEER: B.A., B.A.SC. Married. Age 34. A.M.E.I.C. Ten years experience in paper mill costs, maintenance, design and construction. Now employed as cost engineer in Southern States. Hard worker with excellent references. Available immediately. Apply to Box No. 150-W.

SALES ENGINEER REPRESENTATIVE. Mechanical graduate with fifteen years experience in Eastern Canada in sales and service of mechanical equipment; full details upon request to Box No. 161-W.

ENGINEER-DRAUGHTSMAN, experienced in design of machines for widely varied purposes and arrangement of motor drives. Accustomed to layout of small mill buildings, steel and timber. Good references. Present location Montreal. Apply to Box No. 329-W.

CIVIL ENGINEER, M.A.SC., A.M.E.I.C. eight years survey and municipal engineering experience, and three years draughting, detailing steel, concrete, and timber structures. Apply to Box No. 467-W.

CIVIL ENGINEER, B.SC. (McGill '20), A.M.E.I.C. Married. Twelve years experience in pulp and paper mill design, and six years general construction. Available immediately. Location immaterial. Apply to Box No. 547-W.

ELECTRICAL ENGINEER, B.SC. E.E., Age 39. Married. Seven years experience in operation, maintenance and construction of hydro-electric plants, and sub-stations. Five years maintenance and installation of pulp and paper mill electric equipment. Reliable and sober, with ability to handle men. Best references. Any location, at once. Apply to Box No. 636-W.

Situations Wanted

ELECTRICAL ENGINEER, B.SC. '28. Two years student apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660-W.

CIVIL ENGINEER, B.A.SC. (Toronto '27), age 34, married. Five years railway and construction work as building inspector and instrumentman. Level engineer and on construction of a long timber flume for a pulp and paper mill. Field engineer for a sulphite company, in charge of the following mill buildings, acid, digester, blow pit, barker room, chip storage and acid towers. Available immediately. Apply to Box No. 714-W

ELECTRICAL ENGINEER, B.SC. '31 (U.N.B.), JR.E.I.C. Age 30 years. Single. Experience in electrical wiring, construction of concrete wharves, inspection of piling, rip rap, concrete reinforcing, forms, and dredging. Also junior engineer. Available at once. Apply to Box No. 722-W

CIVIL ENGINEER, B.SC., M.SC., P.P.E.; Lieut. C.E., R.O. Sixteen years municipal, highway and construction. Five years overseas. Married. Read, write and talk French. Will go anywhere. Apply to Box No. 737-W.

CIVIL ENGINEER, B.SC. '29, JR.E.I.C., R.P.E.M. Age 31. Married. Experience includes railway and highway surveys and construction, land and mineral claim surveys, 4 years draughting, structural and hydraulic design, preparation of plans and estimates for hydro-electric development, sewage disposal project, water treatment plant, subway construction, buildings, etc. Experienced in reinforced concrete design including statically indeterminate frames. Also capable of preparing designs in steel and timber Desire permanent employment, preferably in structural design. Available immediately. Apply to Box No. 1023-W.

ELECTRICAL ENGINEER, B.SC. '29, age 30. Single. Eight and a half years experience on maintenance, on construction, floorman and operator on hydro-electric system. Desires construction, service, sales or research work. Any location. Excellent references. Apply to Box No. 1062-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 41. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experience in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

Situations Wanted

TECHNICALLY TRAINED EXECUTIVE. General experience administrative, organization and management in business and industrial fields, including; business, plant, property and estate management; plant maintenance, modernization, production and personnel; economic studies, company reorganizations and amalgamations, valuations; railroad, highway, hydro, pulp, newsprint, housing, industrial surveys, investigations and construction; B.Sc. degree in engineering, age 49, married, Canadian. Apply to Box No. 1175-W.

CHEMICAL ENGINEER, grad. McGill '34, experienced in meter repairs, control work; and also chemical laboratory experience. Apply to Box No. 1222-W.

ELECTRICAL ENGINEER, B.SC. '31. Age 35. Experience in oil field work and railways construction survey. Two years on installation and maintenance of mine equipment, and two years industrial plant engineering on design and layout of equipment. Available immediately. Will go anywhere. Apply to Box No. 1249-W.

FIELD ENGINEER AND DRAUGHTSMAN, A.M.E.I.C. Age 36. Married. Fifteen years experience in civil engineering, general draughting and instrument work. Experience covers office and layout work on construction of sewers, water mains, gas mains, (6″ to 30″ dia.) and transmission line structures; topographic and stadia surveys. Draughting covers general civil, reinforced concrete and steel design, mechanical detailing and arrangements, and mapping. Present location Montreal, but willing to locate anywhere. Available at once. Apply to Box No. 1326-W.

CIVIL AND ELECTRICAL ENGINEER, JR.E.I.C. (Univ. of Man.). Married. Age 25. Good draughtsman. Four months draughting, one year instrumentman on highway location and construction, inspection and miscellaneous surveying and estimating. Six months as field engineer on pulp and paper mill construction. Prefer electrical or structural design. Available at once. Apply to Box No. 1633-W.

CIVIL ENGINEER, B.SC. in C.E. '34. S.E.I.C. Age 27. Five years experience, including harbour construction, highway paving, one and a half years paper mill construction, instrument work, draughting, estimating, interested in design. Available on short notice. Apply to Box No. 1737-W.

CHEMICAL ENGINEER, graduate, Toronto '31. Seven years experience in paper mill, meter maintenance, control work and chemical laboratory. Speaking French and English. Location immaterial. Available at once. Apply to Box No. 1768-W.

CIVIL ENGINEER, B.A.SC., JR.E.I.C. (Toronto '35). Age 24. Experience in structural design, construction and surveying, including one year in South America. Details on request. Apply to Box No. 1784-W.

ELECTRICAL ENGINEER, JR.E.I.C. B.SC. Age 25. At present employed, but desiring change of location. Three years maintenance and test work, toll and automatic telephone equipment; two years sales engineering, telephone and electrical equipment. Prefer to remain in telephone field, but would be interested in any opportunities in electical engineering. Apply to Box No. 1817-W.

CIVIL ENGINEER, B.E., JR.E.I.C., 28 years of age. Married. Desires position with reliable construction firm. Intends to make construction life work. Over five years experience on permanent highway construction, inspection, estimates and instrument work. Available on short notice. Apply to Box No. 1820-W.

THE ENGINEERING JOURNAL

VOLUME XXI, No. 11 NOVEMBER, 1938

Advanced Practices in the Use of Automatic Oxy-Acetylene Cutting Machines

W. A. Duncan,

Manager, Process Service, Dominion Oxygen Company Limited, Toronto, Ont.

Paper presented before the Hamilton Branch of The Engineering Institute of Canada, December 14th, 1937.

SUMMARY.—Flame cutting, particularly with the aid of automatic machines, has now become a most valuable workshop process. The paper gives guidance as to its limitations and possibilities, and information as to the technique needed for successful operation.

Oxy-acetylene cutting of ferrous metals is a process of preheating the material to be cut to its kindling or ignition temperature and rapidly oxidizing it by means of a closely regulated jet or stream of oxygen issued from a special tool called a cutting blowpipe or cutting torch.

In the case of plain carbon steel, the metal is preheated to a bright red colour in daylight, reached between 1,400 and 1,600 deg. F., approximately. Only the metal within the direct path of the oxygen jet is acted upon, to form a narrow cut or kerf, as it is usually called, having uniformly smooth and parallel walls. Under skilled workmanship, such as produced by mechanically-guided blowpipes, the tolerances of cutting as to squareness and longitudinal alignment of the cut surface may range from a few thousandths of an inch for the thin materials, 2 in. and under, with proportional tolerances for the thicker materials ranging to 26 in. in thickness under present practices. Thus, a very accurate and economical means of shaping steel products is provided.

The faces or walls of the cut, in the commonly used steels, are not injured by the cutting operation. On the contrary, their strength and toughness, if of plain low carbon steel, are slightly improved. The heat effect upon the metal induced by normal cutting operations penetrates about 1/10 in. below the cut surface. Oxy-acetylene preheating flames are used to heat the metal to kindling temperature. These usually surround the cutting jet of oxygen and vary in number and size with the composition and thickness of the metal and the condition of its surface.

Oxy-acetylene cutting is primarily a chemical process based on the remarkable chemical affinity of oxygen for ferrous metals when at and above kindling temperatures. When commercially pure oxygen is brought into contact with most steels or iron, at kindling point, a very active chemical reaction between them results. The commercial process, viz. controlled linear cutting, is obtained through close regulation of the gases supplied and the rate of progression of the cutting.

In addition to the chemical reaction, there is a noticeable and very helpful mechanical eroding effect produced by the kinetic energy of the cutting oxygen stream which washes away some of the metal in unconsumed or metallic form.

Chemistry of Oxy-Acetylene Cutting

Oxidation of Ferrous Metals—The iron oxide formed in oxy-acetylene cutting is black or magnetic iron oxide, identical in composition with hammer scale or magnetite ore. Its chemical formula is Fe_3O_4. It contains a smaller proportion of oxygen than rust or red iron oxide, Fe_2O_3. The complete chemical equation for the oxidation reaction in gas cutting is:

3 Fe	+ 2 O_2	=	Fe_3O_4
3 Mols*	+ 2 Mols	=	1 Mol + 26,691 calories.
Iron	Oxygen		Black Iron Oxide

From these data it can readily be determined that theoretically one cu. ft. oxygen will oxidize 0.217 lb. or 0.761 cu. in. of pure iron. However, as already mentioned, the iron removed from the kerf in actual gas cutting is not entirely consumed by the oxygen. Due to the eroding effect of the cutting oxygen stream, about 30 to 40 per cent of the metal is washed out of the cut as unconsumed or metallic iron.

In practice, therefore, one cu. ft. oxygen may actually remove one cu. in. of iron or more.

Assuming 65 per cent of the iron to be oxidized to magnetite (Fe_3O_4) the heat generated by the reaction in the cut will be 1,865 B.t.u. per lb., or 531.7 B.t.u. per cu. in. of metal removed from the kerf. This is at least twice as much heat as is supplied by the preheating flames of the oxy-acetylene blowpipe in ordinary light cutting, and the ratio increases rapidly with the thickness.

Theoretically again, the heat thus generated by the oxidation of the iron is more than ample to maintain the metal being cut at a kindling temperature. This is actually the case for certain classes of work. However, for machine cutting on commercial plate, the heat lost in the oxides and metal blown out of the kerf, by conductance into the adjacent metal, and by radiation, is such a large proportion of the total generated that preheating flames are essential in maintaining the cut as well as in starting it.

The function of acetylene in oxy-acetylene cutting is, of course, that of the fuel gas required to supply sufficient heat on combustion to bring the steel to its ignition point and to maintain sufficient heat to allow the cutting operation to be carried on continuously. Acetylene is unquestionably the most satisfactory fuel gas. Acetylene with oxygen gives the highest flame temperature, by a wide margin, of any known fuel gas. It requires a minimum of oxygen for complete combustion and its heating efficiency remains high at elevated temperatures.

Nozzle Design

Oxy-acetylene blowpipes utilize the Bunsen principle of premixing gases prior to combustion. This principle in

*A 'Mol' is a mass equal to the molecular weight in grams.

itself produces a much better and shorter flame than when fuel gases are simply allowed to flow out into the air and burn without premixing.

The cutting blowpipe nozzles of various manufacture show considerable variation depending on the type of service for which each is designed. Even for automatic machine cutting a varied selection of nozzles is available. The variations are essentially in the size, shape, number and grouping of the preheating orifices, as shown in Fig. 1.

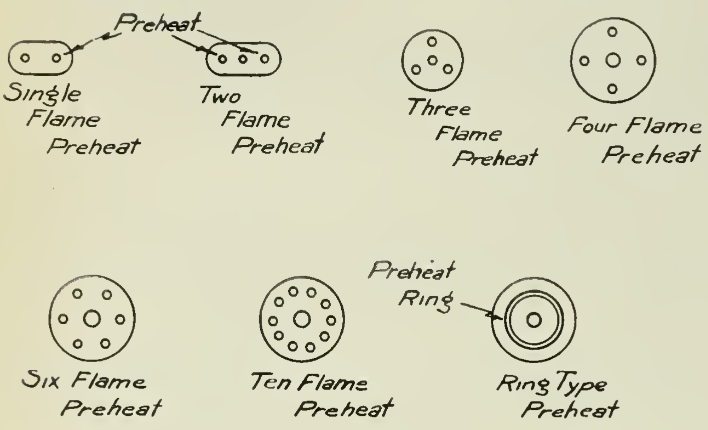

Fig. 1—Typical Grouping of Preheating Flames for Cutting Nozzles.

The simplest type of cutting nozzle has a single preheating flame ahead of the cutting oxygen orifice. This may be satisfactory for cutting thin material in one direction only. Other nozzles provide two preheating flames for two-directional cutting. The most common nozzle used in this country has four preheating flames equally spaced about the centre cutting orifice.

For intricate shape machine cutting, a cutting nozzle having a minimum of six preheating flames should be provided to give approximate uniform preheating in front of the cutting jet of oxygen no matter in which direction the blowpipe is travelling.

Effect of Flame Cutting on Steel

For some reason or other the flame-cut edge has at times been regarded with suspicion where certain further operations are to follow, such as mechanical caulking, holes in which tubes are to be rolled or rivets driven and where fusion welding is to be applied. It is doubtful whether there is any real reason for this suspicion which is believed to be due to an unfortunate use of terms wherein this process has been referred to as a "burning" operation. This may, perhaps, have led to the inference that the highly heated oxidation process has had some injurious effect upon the edges of the kerf, such as cracking, or that the structure of the steel adjacent to the kerf has been damaged.

It is well known that certain of the mechanical methods of severing metals have injurious effects upon the condition of the severed edges. Examples are shearing and friction sawing. Also, machining can, under conditions of heavy cuts and high cutting speeds, create effects that are akin to shearing. In such cases it has been customary to require that the damaged surface be removed by machining, chipping or grinding before supplementary operations are applied thereto, and it is undoubtedly this practice that has been carried over bodily into codes and specifications to apply to flame-cut surfaces.

There are, however, no data to show that a clean smooth flame-cut is detrimental for any of the above uses, as long as the steel contains less than 0.35 per cent of carbon and is of the non-alloy variety.

Comparison of Flame Cutting with Mechanical Methods

Numerous investigations have been made to determine the effect of the cutting flame on the physical properties of flame-cut surfaces of plain low carbon steel and sufficient data are on record to show that the effect is negligible. Neither tension tests of specimens with flame-cut edges nor bend test specimens with the flame-cut edge on the outer or stretched surface show materially different results from those having machined edges. In the case of the bend test specimen, the increased force necessary to bend and elongate the flame-cut surface indicates that the flame cutting has introduced a tough layer adjacent to the surface.

As compared to sheared surfaces or those resulting from friction sawing, the flame-cut edge has much to recommend it. Both the shear and friction saw inflict a certain amount of punishment on the surface of the metal. The shear tears the metal adjacent to the edge and causes more or less flow in the direction of the path of shear, and often results in the formation of incipient cracks. The friction saw causes a high degree of localized heating and always considerable flow of metal at the edge. The resulting hardening and deformation may be damaging to the surface for subsequent operations.

Recent tests of flame-cut edges of plain low carbon structural steel with regard to hardness, microstructure, resistance to impact and ductility, have shown that there need be little hesitation in using flame-cut surfaces for almost any type or character of mechanical treatment or service. With properly controlled technique the disturbance of the hardness and structure of plain low carbon structural steel plate is less severe in flame cutting than in either shearing or friction sawing and ductility, as determined by the cold-bend test, is less seriously affected by flame cutting than by either shearing or friction sawing.

This statement is based on recent investigations of this subject, particularly those of J. H. Zimmerman, of the Massachusetts Institute of Technology.* The appearance of the surfaces resulting from the various processes examined by Mr. Zimmerman is shown in Fig. 2, taken from one of his papers.

Preheating and Post Annealing

When higher carbon steels or alloy steels are flame-cut, troostite or even martensite may be produced. Steels having these structures may not be ductile enough to withstand the stresses set up. As the steel is heated, it expands, but it is restrained by the adjoining cold metal

Fig. 2—Appearance of Cut Surfaces Resulting from the Five Cutting Procedures Under Test (from Top to Bottom: Machined, Sheared, Friction Sawed, Hand-Torch Cut, and Machine-Flame Cut).

*See Mechanical Engineering July 1935, pp. 423-427, and June 1936, pp. 363-368.

and the action called "upsetting" results. Then when cooling down occurs, contraction of the upset metal may produce severe stresses, and in some cases the ductility near the cut edge will not be sufficient to prevent cracking. But it has been found by experience that, in general, if the high carbon or alloy steels are preheated to a temperature of the order of 500 to 600 deg. F., the cracking will not occur. The reason, of course, is that first the difference in expansion between the metal heated during cutting and the adjoining metal is less, with resulting great reduction in the stresses set up during the subsequent cooling, and second, since the difference in temperatures is less, the cooling goes on more slowly and the formation of the undesirable troostite and martensite is prevented.

These precautions in cutting apply to some of the newer structural steels such as the so-called structural silicon steels which have come into prominence in recent years. The several grades have a tendency toward air-hardening under the action of ordinary flame cutting practices and call for consideration of the recommendations given above.

Flame Softening

Due to the increasing general use of high strength structural steels just mentioned, the necessity arose for a rapid method of satisfactorily cutting with the oxy-acetylene process and at the same time maintaining the desirable physical properties at the cut edge. To this end a procedure called "flame softening" has recently been developed. Certain aspects of these processes of flame softening are covered by patents and patents pending; however, the processes are to be made available to the fabricating industry through reasonable licensing agreements.

Flame softening is a localized heat-treatment carried out after or simultaneously with the cutting operation. For certain types of work it is accomplished by mounting a bank of oxy-acetylene flames on the cutting machine either to precede or follow the cutting blowpipe.

A chart showing the effect of "flame softening" in connection with oxy-acetylene cutting of a number of different steels is given in Fig. 3, by permission of the Linde Air Products Co.

Warping

Whenever metal is heated it expands, the amount having a direct relation to the increase in temperature. If uniformly heated, the forces set up by the expansion are

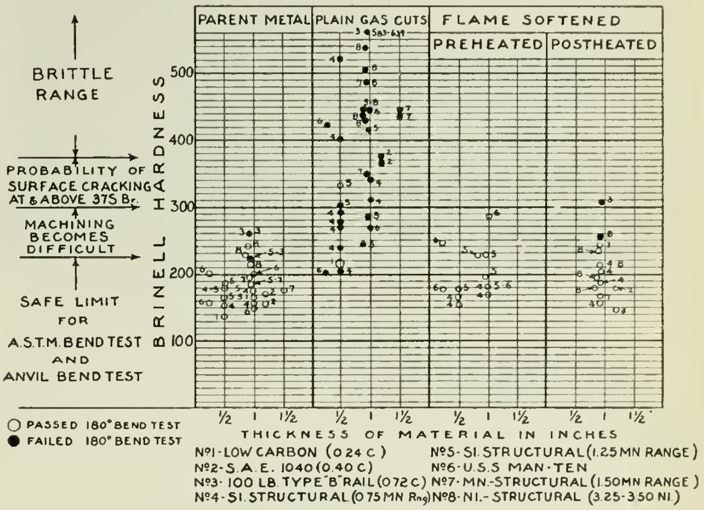

Fig. 3—Chart Showing Effect or "Flame Softening" in Flame Cutting Various Steels.

likewise uniform throughout the part, which, if lying flat or fully supported and free to expand or contract, will, after uniform cooling, resume its original state as to dimensions and alignment. If, however, a part is locally heated, there is likelihood of warpage of the part unless:

1. Its cross-sectional engineering properties are sufficient to resist the forces which such local heat sets up, or

*As the pressure of acetylene for the preheating flames is more a function of blowpipe or torch design than of the thickness of the part being cut, the pressure data, therefore, have been omitted from this table. For acetylene pressure data, see cutting apparatus manufacturers' charts.

†Lowest speeds and highest gas consumptions per linear foot are for inexperienced operators, short cuts, dirty or poor material. Highest speeds and lowest gas consumptions per linear foot are for experienced operators, long cuts and clean and good material.

‡The apparent inconsistencies which will be noted in some of the columns in the table are due to the fact that there does not exist a straight-line relationship between the elements of pressure, speed and orifice sizes for the range of apparatus data from which this table was devised.

2. The part is fixed in position by clamps or weights during the cutting operation and the subsequent cooling of the part to room temperature, or
3. The cutting is performed simultaneously or in rapid succession about the neutral axis of the part, thus equalizing the forces about said axis, in turn, reducing their effect (physically) on the part to zero.

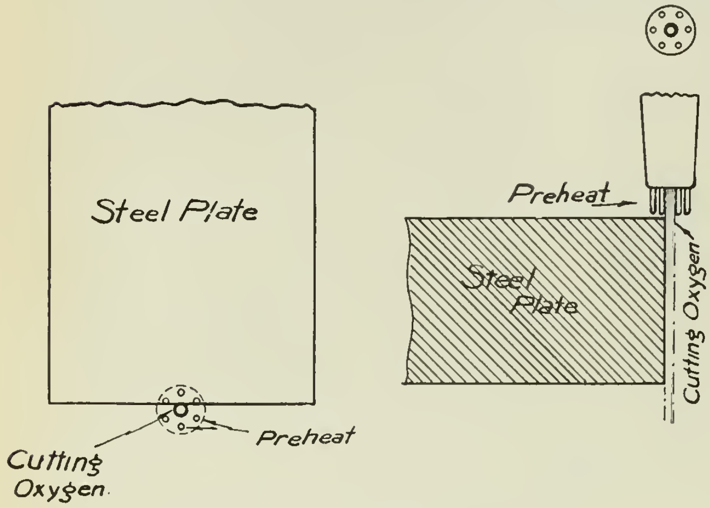

Fig. 4—Correct Starting Procedure.

Experience has shown that at and above ½ in. thickness there is little tendency for a part to warp if not unduly narrow. Many simple operations, such as cutting off rods or bars, structural shapes, rail, piping and similar lengthy materials, do not involve the matter of warpage.

In splitting narrow materials, such as flat bar stock and structural I-beams and channels, the practice of so-called "skip-cutting" has proved to be satisfactory to prevent warpage. In this method, the cut is made to skip at intervals depending upon the narrowness of the material, leaving a series of uncut sections along the line of cut, each about ½ in. to 1 in. long. These uncut ligaments hold the material in line until cooled, whereupon they are cut through to separate the parts.

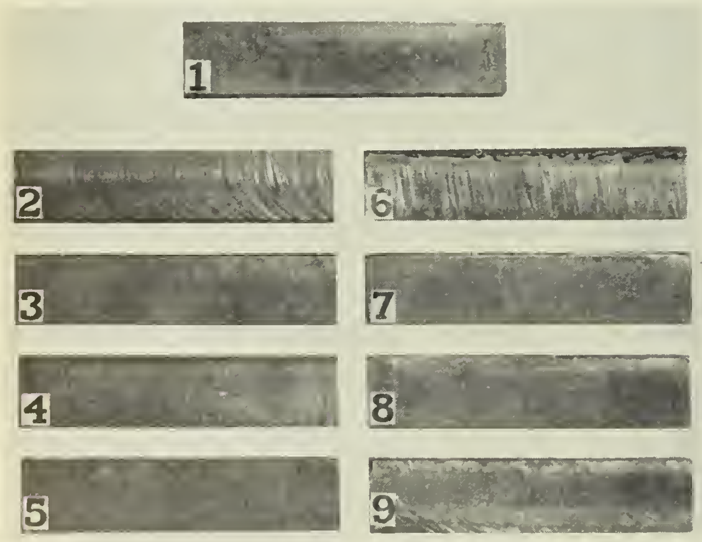

Fig. 5 Cut Surfaces Resulting from Correct and Incorrect Technique.

1. Effect of correct cutting technique. 2. Blowpipe advanced along line of cut too quickly. 3. Blowpipe advanced along line of cut too slowly. 4. Cutting oxygen pressure too high. 5. Cutting oxygen pressure too low. 6. Excessive preheat flames used. 7. Blowpipe nozzle adjusted too close to surface of plate. 8. Blowpipe nozzle adjusted too far from surface of plate. 9. Shows the effect of a dirty blowpipe nozzle cutting oxygen orifice.

In cases where great accuracy is demanded in the overall dimensions of the cut parts, account must be taken of the dimensional changes which are produced by the heat of cutting. The intense heat along the line of cut develops expansion immediately ahead and astern of the point of cutting (more particularly astern) and upon cooling to room temperature the surface will have shrunk slightly which will affect the overall dimensions unless a correction factor has been applied in making the cutting layout.

Cutting Technique

In automatic oxy-acetylene machine cutting the human element and other variable factors are greatly reduced as compared with cutting with a hand-operated blowpipe. However, the proper cutting speed, oxygen pressure, and nozzle size must be selected in accordance with the plate thickness being cut. For this purpose the equipment manufacturer's charts should be consulted. A typical example of such a pressure speed chart is shown on page 495, taken from a booklet "Oxy-Acetylene Cutting," published by the International Acetylene Association. Such charts give the proper cutting nozzle, gas pressures and cutting speeds for a given thickness of material. The gas consumption per hour or per linear foot of cutting is often included. The only remaining factors affecting the quality of the cut obtained are the mechanical condition of the cutting equipment, the adjustment of the preheating flames, and the technique used to start the cut. This latter item is quite important. The correct starting procedure is shown in Fig. 4.

The quality and accuracy of the work is largely dependent on correct adjustment of pressures and speeds, and on the proper technique as regards the preheating flame or flames. This is illustrated in Fig. 5, showing the cut surfaces resulting from various incorrect practices (samples 2 to 9) as compared with the result of correct technique (in sample 1).

Oxy-Acetylene Cutting Machines

From crude beginnings, oxy-acetylene cutting machines have been improved to the point where they are now comparable with machine tools. These machines are capable of making flame cuts with a flexibility equivalent to woodworking with a jig saw and of such high quality and accuracy that for usual purposes little or no finishing is required. Oxy-acetylene cutting machines now available include manual or motor-driven, partly or almost fully automatic, portable or stationary, having various capacities suitable for practically all classes of work of almost any size or thickness.

Some machines are equipped with two, or as many as six cutting blowpipes, centrally controlled and guided, and will flame-cut a like number of identical shapes simultaneously, thereby effecting marked economies where high production rates are essential. Still other types of machines crawl around pipes, making one or two square or bevelled cuts as desired. Nearly every conceivable requirement is covered by the wide assortment of machines now manufactured.

Special Machine Flame Cutting

In addition to the types of machine flame cutting already discussed, there exists quite a wide field of special applications for the process. This field includes cutting of pieces which are not flat, cutting in different planes or at different levels and angles on the same piece, cutting sections of variable thickness and similar work. For example, digester shell plates are dished and formed like orange peelings, although of uniform thickness. They may be machine flame-cut or trimmed to size, with bevelled edges for caulking where desired, very satisfactorily and economically. Severing of I-beams and other structural shapes or rails requires positioning of the blowpipe to cut at different heights and angles.

Stack Flame Cutting

In addition to cuts made through single thickness of material, flame cutting is utilized in some cases for cutting through several thicknesses simultaneously. This operation is known as "stack flame cutting." While this is a relatively new development and therefore not widely applied as yet, it may be utilized with success and economy under certain conditions of material, thickness, quality of cut, tolerances and cost of setting up the work. The plates in the stack should be clean and flat, with edges in alignment where the cut is started. Their number should vary with thickness of individual plates, to keep stack thickness constant. They should be clamped together as nearly as possible along the line of cut. In stack flame cutting very thin plates, a "waster plate" having sufficient rigidity to lie flat while the cut is being made, is usually clamped on to prevent the top thin plate from buckling. It serves also to maintain ignition in the cut by its own combustion, thereby facilitating the speed of cutting in this kind of work.

Precision Machine Cutting

The degree of precision attained in modern precision machine flame cutting practices is within several thousandths of an inch in material up to 2 in. thickness; that is, the cut surfaces are true as to cross-sectional squareness to

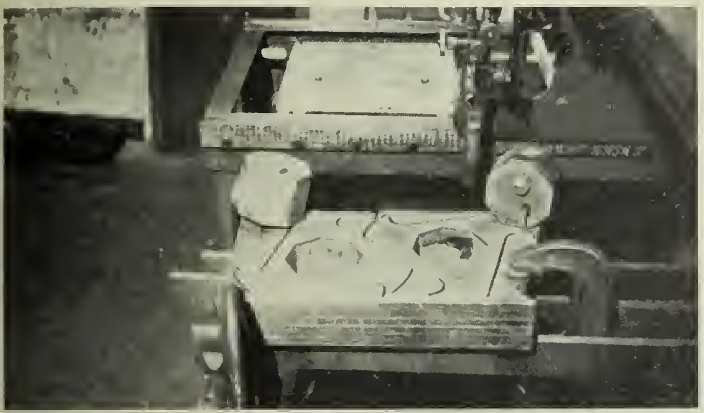

Fig. 6—Close-up Showing Templet and Stack of Plate with two Sets of Parts Completely Cut.

within this amount. Longitudinally, the degree of precision depends upon the trueness of the guide rails of the cutting machine, the clearance of operating mechanism and the regularity of the propelling unit, similarly as with machine tools. The more recent straight line and shape cutting machines are constructed so as to maintain very close traverse alignment; however, much depends upon the sensitivity of the tracing mechanism, which, if not carefully adjusted as to grip and speed, will defeat the precision of the cutting machines beyond this point. With regular forward movement of the torch and with proper preheating, there may be obtained precision tolerances in plain carbon steel ranging from 3/1000 of an inch for material 1 in. thick to 3/100 for material 6 in. thick. Such close tolerances however are not always commercially obtainable.

Applications of Automatic Cutting

The automatic oxy-acetylene cutting process is extensively used in steel mills and steel jobbing warehouses for

Fig. 7—Completed Stack of Circles Showing High Quality of Cut, on Strip Material.

the cutting of steel plate and structural shapes to size. In numerous industries it is used for the fabrication of machine bases and frames from assemblies of flame-cut steel plates and shapes.

This process of fabrication is also particularly suitable for all manner of jigs and fixtures. The construction time is reduced and the materials may be used repeatedly where alterations or completely new fixtures replace old ones.

In other industries the process is used for the rapid fabrication of innumerable small tool parts such as cams, lever arms, sprockets, etc. In this field parts may be cut in three different planes, eliminating or reducing machining to a minimum.

Stripper, trimmer, moulding and backing-up dies are cut on automatic machines in a fraction of the time formerly required to shape by ordinary machining methods.

Some typical examples of finished work, showing what can be accomplished by machine flame cutting, are given in Figs. 6 and 7. It would be impossible to list all the many and varied applications of automatic cutting, since they embrace almost every industry. Wherever plain carbon and low alloy steels are to be cut accurately to size, automatic oxy-acetylene cutting may well be considered for it combines accuracy, speed and economy, probably the three essentials in modern industry.

The Measurement of Canada's Water Resources

J. T. Johnston, M.E.I.C.,

Controller, Dominion Water and Power Bureau, Surveys and Engineering Branch, Department of Mines and Resources, Ottawa.

It is safe to say that to most people water, as a provision of nature, is as commonly taken for granted as the air they breathe. They fail to appreciate that, unlike air which is universal, *water is a resource* which is available in ever varying quantities. Actually, it is the most vital of all natural resources. Without water there is desert and life is impossible.

The primary source of the water supply is precipitation occurring in the form of rain and snow. Its benefit to any country depends upon its volume and upon its seasonal and territorial distribution. This all-governing precipitation is not subject to any human control. Nevertheless man has to act interminably in order that he may on the one hand enjoy this natural resource and on the other prevent it from doing harm.

Rain is partly dissipated by evaporation, is absorbed and used to promote plant growth, is absorbed in the ground to maintain groundwater supplies which may later be made use of from springs or wells, or flows off to enter the creeks and rivers and maintain what is known as surface run-off.

It is this surface run-off which is available for measurement, regulation, control, and conservation, in order that, as a resource, it may be harnessed for effective service to mankind to provide navigation, power, irrigation, and water supply generally, and in order that its capacity for doing damage may be minimized by the construction of culverts, bridges, flood protection works, and drainage projects.

As already stated water as a resource has largely been taken for granted. It is only when there is a deficiency, as in recent years in the drought areas of Canada and the United States, that the complete dependence of mankind upon its water supply is widely appreciated; or when there is an excess as instanced by disastrous floods such as occurred in 1937 on the Mississippi and Ohio rivers in the United States, that the almost immeasurable possibilities of destruction by water, arising from uncontrolled stream flow, are nationally realized.

Canada has been particularly blessed by Providence in her water resources. Consider only the power phase. *Power* is the basic tool of modern industry. *Low-cost* power is the key to industrial supremacy. *Water-power* is Canada's basic power tool. A few startling facts may be mentioned. Ninety-eight per cent of all the power developed for sale in Canada is hydro power and it represents a capital investment of $1,600,000,000 in its development and distribution—the largest single industry of the Dominion.

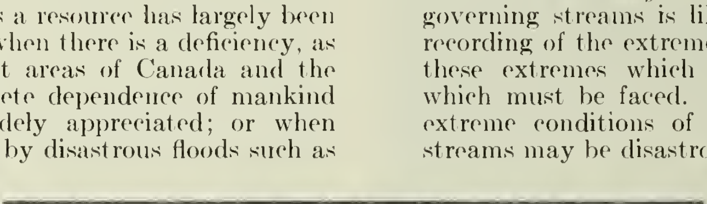

Fig. 1—Birchbank Cable Station, June 25, 1937. Water Elevation 1370.33.

Much has been written and spoken of Canada's lakes and rivers, of her navigable waterways, and of her immense water-power resources. Few have considered what lies behind the regulation, the control and the conservation of this resource to ensure its effective utilization in the service of the public.

The natural resources of land, forest, and mine are carefully measured, appraised and recorded in our national balance sheet. Our water resources are similarly measured by stream flow and water level records. Unfortunately the flow of streams is as variable as the precipitation which produces it. It varies from day to day, from month to month, from season to season, from year to year, and from cycle to cycle. In Canada, also, the winter accumulations of snow and ice interject further complications in the records. There are, furthermore, changing natural conditions of flow resultant from drainage of surface and subsurface waters, from deforestation and from agricultural development. A dependable record and knowledge of our water resources therefore necessarily involves much more than intermittent or casual measurement. Basic principles govern:—

Records of flow *over a long period* of time are essential to a thoroughly reliable appraisement of our surface water supply and of all that is dependent thereon. Data covering one or two years are useful but entirely inconclusive. If the period is one of twenty years or upwards the data are of proportionately greater value and, by allowing reasonable factors of safety, works can be constructed with the expectation that they will be adequate for the purposes for which they are designed. Longer term records are of the utmost value and lead to economy in that the factors of safety required can be more closely approximated.

The *continuity* of records in representative or governing streams is likewise essential to ensure the recording of the extremes of high and low flow as it is these extremes which constitute critical conditions which must be faced. Failure to secure a record of extreme conditions of high or of low flow in such streams may be disastrous.

A further basic factor underlying the analysis and appraisement of our water resources is the necessity of planning the measurements and studies upon *watershed* bases. Surface run-off is essentially a watershed resource, governed by the topographical conditions prescribed by nature rather than by artificial geographical boundaries. The interrelationship of the main stream and the tributaries, and the relationship of the natural and artificial reservoir sites to hydro power, navigation, or irrigation possibilities, or to possible locations of regulation or control, all enter into the planning of the measurement stations.

In a country of the wide extent of Canada *co-operation* among many interests and jurisdictions to ensure the maximum availability, conservation, and utilization of this resource is essential.

In Canada, the systematic measurement of stream flow was only commenced about thirty years ago. The Dominion Government's activities in hydrometric work were first undertaken in areas where deficient rainfall rendered irrigation necessary and where, in the interests of administration, it became essential to determine the amount of water in these areas available for this purpose. A short time later the question of water available for the production of hydro-electric power became active and hydrometric

Fig. 2—Birchbank Gauge House, Looking Upstream, June 25, 1937.

work was extended. In due course the value of systematic, reliable and uniform stream flow data became apparent to all administrators both Federal and Provincial with the result that a Hydrometric Service, Dominion wide in its scope, was established and is still maintained under the Department of Mines and Resources of the Federal Government. This service is maintained in close co-operation with the Provinces and with many municipal and corporate bodies concerned with water utilization. Six district offices are located in the major drainages of the Dominion, measurements are made of the various rivers and continuous water level records secured. These are assembled, compiled and published biennially, on a watershed basis, and are thus readily available to all interested in water questions.

At the present time there are about 570 gauging stations in Canada established upon rivers and lakes of importance in connection with international, navigation, water-power and water-supply or water-control problems generally. There are other stations (about 1,800 in number) at which records have been secured for a certain length of time but which have been discontinued. A considerable number of these were on small irrigation streams or irrigation ditches where the information secured was sufficient for the purpose required. In addition to these, a large number of miscellaneous measurements have been secured on remote streams which are visited by engineers for the purpose of investigation but where observations could not be maintained due to the absence of suitable observers.

Co-operative agreements with the Provinces ensure the entire absence of duplication of effort or expenditure as between the Dominion and the Provinces.

They provide for:—

(*a*) The complete standardization from coast to coast—
of methods of measurements;
of computation and analysis of water resource records;
of methods of water and water power study; and
of publication of run-off records and of water power resources data—all upon a uniform, dependable, watershed basis.

(*b*) The making of these data available—
to Dominion, Provincial and Municipal administrative officers; and
to all public and private bodies who are interested in water administration or utilization for purposes of the development of power, navigation, drainage, irrigation and for water supply projects and undertakings generally.

It is of interest to note that the National Resources Committee of the United States published a report in September 1936, prepared by a special Committee dealing with hydrological data and the deficiencies therein. This report contains many arresting statements which cannot be extensively quoted herein. A number of instances are given of losses in the United States running into many millions of dollars which would have been avoided if adequate stream-flow data had been available, and, in urging a programme for the correction of glaring deficiencies in knowledge of water resources, the report states:—"There is every reason to suppose that these small expenditures, systematically and scientifically made, would save the country many millions of dollars and perhaps many human lives during the coming generation."

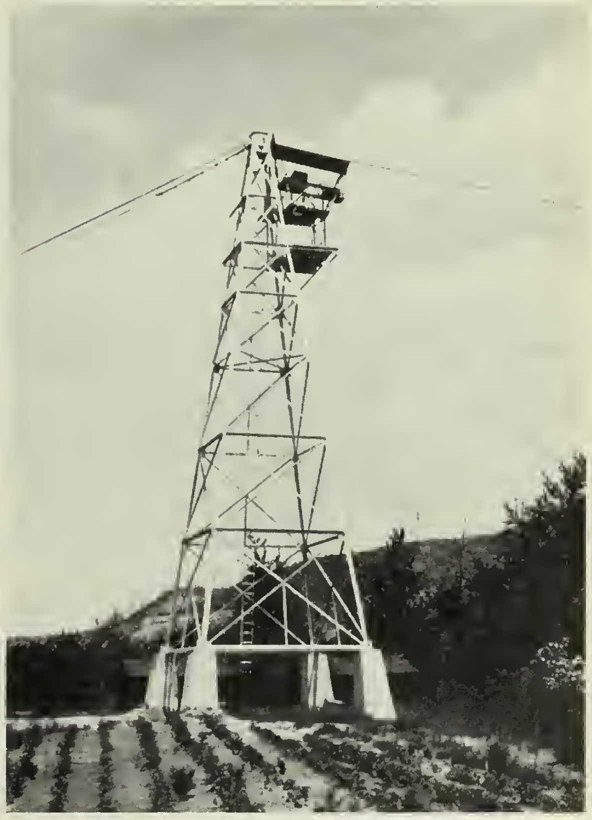

Fig. 3—Birchbank Tower, Right Bank, June 25, 1937.

Canada's water supply constitutes one of her greatest natural resources, in some respects her greatest. It is only with definite knowledge as to its volume, distribution, availability and usability that a full measure of regulation and control can be exercised, and its full weight applied to the development of her resources of land, mine, and forest, and the full value of these resources realized.

Safety in Industry

With Particular Reference to Ontario

R. B. Morley,

General Manager, Industrial Accident Prevention Association.

Paper presented before the Niagara Peninsula Branch of The Engineering Institute of Canada, at Niagara Falls, November 9th, 1937.

Accident prevention is like everything else, effort must be put forth if reasonable results are to be obtained. It has been said that the Safety movement is tied up in "the three E's"—Engineering, Education and Enforcement. Rules and regulations are of no use unless there is enforcement; for example, much of the problem of traffic control is tied up with that word "enforcement." If you have a community where the police force is not supported by public opinion, there is little encouragement for its members to carry out arrests or to endeavour to bring offenders to book. Enforcement is vital.

Safety education is a broad general term that may include instruction in safe work methods, it may include all that goes under the term "supervision"; it may take in good plant housekeeping, provision for first aid and so on. The basic idea of the middle of these three E's is good, it is necessary and it will produce worthwhile results.

Before dealing with the first of the three E's, Engineering, it is desirable to note the way in which the matter of Workmen's Compensation has been handled in Ontario.

Ontario's Law

The late Sir William Ralph Meredith, Chief Justice of Ontario, was appointed by the Government to make a report on the laws relating to the liability of employers. His report resulted in the Workmen's Compensation Act of the province, which became effective on the first of January, 1915, and has served as a model for all compensation laws in Canada. Such acts are now in effect in all provinces except Prince Edward Island. They have relieved industry of litigation in dealing with accidents to employees and have made for promptness and certainty of payment to injured workers without unduly burdening the employer.

Compensation Benefits

Under the Ontario Act compensation is paid for accidents and specified industrial diseases arising out of, and in the course of, employment, except only when the disability lasts less than seven days or where the accident is attributable solely to the serious and wilful misconduct of the worker; even this latter circumstance is not considered when the accident results in death or serious disablement. In death cases the widow, if any, receives a payment of $40 a month for life or until re-marriage, and there is an allowance of $10 per month for each child under sixteen; the total paid, however, not to exceed two-thirds of the average earnings of the worker. In non-fatal cases the injured worker is entitled under the Act to two-thirds of his average earnings up to $2,000 per annum. If the injury is a permanent disability, compensation is paid in the form of a pension, the Pension Fund being referred to sometimes as a reserve fund, and the claim is made that the Workmen's Compensation Board has built up a large reserve fund of millions of dollars. The Pension Fund is a fund to take care of pensions that have been awarded for accidents that have already happened and is in no sense a reserve fund.

Particular attention is called to the fact that The Workmen's Compensation Board pays for accidents arising out of and in the course of employment. Periodically accidents are reported to the Board and in certain cases the information submitted discloses the fact that the accident was really not due to the injured man carrying out some duty or function in connection with his employment. Such cases are extremely difficult to deal with, because, of necessity, there must be sympathy for the man who has suffered a serious injury. On the other hand, it must always be remembered that The Workmen's Compensation Board is administering an Act and must be guided by that Act.

Medical Aid and Hospital Services

Under the Workmen's Compensation Act, medical aid and hospital services are absolutely unlimited. The Workmen's Compensation Board provides that employer and employee have an equal right in the selection of a doctor and that if the employer and employee cannot agree on the medical man, the Board will appoint one to look after the injury. Too much care cannot be exercised in the selection of a competent medical man to handle compensation cases. The average employer wants to be quite certain that the injured man is receiving all possible care and that he will be returned to work as soon as fit.

Employers in Schedule 1, which includes approximately 22,000 firms under compensation, pay on the collective basis, while employers in Schedule 2, which includes the steam and electric railways, municipalities, school boards, telephone and telegraph companies, etc., as well as Crown cases, pay on an individual basis. (This applies also in the Province of Quebec.) That is to say, if an employee of a telephone company is injured and the total cost of that accident is $5,000, the telephone company employing the man pays that amount to the Compensation Board, plus administration expenses.

The Workmen's Compensation Board provides the employer with certain forms whereupon to report accidents that may happen. The employer gives certain information, such as the name and address of the worker, his age, his allegiance, whether he speaks English or not, and then a brief description of how the accident happened, including date, time, place and the nature of the injury. Similar reports are received from the injured worker, or his dependents, and from the medical man handling the case. It will readily be seen that if the report of the employer, the injured worker and the doctor all agree, there is comparatively little reason for the Compensation Board conducting any further investigation.

Accident Prevention Work

When the Workmen's Compensation Act was being framed, employers asked that they be given some authority to carry on accident prevention work patterned in part on the German plan. It is under Section 114 of the Workmen's Compensation Act that the Industrial Accident Prevention Associations are set up and function. The funds for the operation of the various accident prevention associations are supplied by the Workmen's Compensation Board under the authority of that Section of the Act and are charged against the accident fund of the class; it being generally understood that it is better and cheaper to prevent accidents than to compensate for them.

Accidents

Injuries are usually the result of what we term "accidents." These accidents result from (*a*) inadequate safe practices, (*b*) improper training, (*c*) poor supervision or (*d*) improperly guarded machines and equipment. There have been 58,225 accidents reported to the 31st of October, in 1937, including 301 fatal cases. These represent a great loss to the community and much suffering to injured workers or their dependents. The work of the Industrial Accident Prevention Associations is an effort, on the part of industry, through the authority given in the Workmen's Compensation Act, to cut down these losses, and to reduce this cost. The organization consists of most of the manufacturing classes, and represents something over two-thirds of the total payroll in Schedule 1, under the Act, or, approximately $290,000,000 of payroll. The Directors are representative of the various classes of industry included in the membership, and are elected each year at the Annual Meeting. The Annual Meeting in 1937 was held in Toronto, and during the two days of the Safety Convention held at that time, there was a total registration of 1,800 persons from more than 100 towns and cities.

Roughly, the work of the organization is divided into three phases; first, the inspection services; second, the distribution of safety literature and other material, and last, the general services which include the dissemination of certain forms of information, together with the cost ratio cards received from The Workmen's Compensation Board.

Getting Results

Speaking at a Safety Convention of the Industrial Accident Prevention Associations, Sir Edward Beatty, President of the C.P.R., said:—"In summing up the results of our experience, I think it can be said that the most effective measures, for accident prevention in shops, are the careful supervision of shop practices, the education of the men in the principles of safety, and the responsibility of the immediate officer in charge, for the efficiency of the men under him."

The representative of another large employing group, Mr. H. G. Hilton, Vice-President and Works Manager of the Steel Company of Canada Limited, at Hamilton, said:—"Whatever measure of success we have achieved in accident prevention has been due to the policy of holding superintendents and foremen responsible for safety just as they are held responsible for quality, costs and other routine operations and impressing upon them the fact that a poor accident record will reflect unfavourably upon them just as the case would be if their quality or costs should be unsatisfactory."

Back of the ideas expressed by Beatty and Hilton must, of course, be certain engineering principles, and the following is a quotation from an address by Dr. L. W. Chaney, of the Bureau of Labour Statistics at Washington, in which he dealt with engineering revision: "The foregoing analysis proves quite conclusively that (1) Education and the development of interest among the men will come near to eliminating minor injury. (2) Adequate 'engineering revision' will reduce serious injuries to an as yet undetermined degree. The degree of such reduction is largely conditioned on what shall be regarded as 'adequate.' It is certainly possible to imagine structures and apparatus so strong, so well designed, so intelligently operated, that failure and consequent death will be the rare exception. The possibilities of improvement from an engineering standpoint are almost limitless."

Dr. Chaney's analysis was tied in with the experience of certain of the large iron and steel industries, and it is interesting, for example, to note that under his heading of "Death and Major Mutilation," out of 68 cases, it was calculated that 39 were preventable by engineering revision, 10 by care of the worker and 19 were classed as a trade risk, giving 57 per cent of the fatalities and major injuries as preventable by engineering revision.

Engineers and Industrial Hazards

If the engineer has been rightly described as "the pathfinder of civilization," and as one who "reduces effort, eliminates waste and increases production," it would seem that every engineer should take a practical interest in accident prevention and, at the same time, do something about it in the sphere in which his activities are cast, whether that be civil, electrical, mechanical, or any other type of engineering. Chaney said "The possibilities of improvement from an engineering standpoint are almost limitless." The problem, therefore, becomes largely one for engineering thought and action. All mechanical and physical hazards should be adequately and substantially guarded. Adequate ventilation should be provided, special emphasis being laid on this phase in the dusty industries, and adequate lighting should be available. These matters involve engineering questions to which every engineer can devote a certain amount of attention. The engineer in an industry who takes an intelligent interest in his accident prevention problems must, among other things, become a human engineer, because employees should be assigned to jobs for which they are temperamentally and physically suited and a periodic check of their work and their work practices should be made to see that the job is done in a safe and satisfactory manner. The engineer can make a systematic check of records to determine whether any department or any individual is showing a high frequency rate, and steps then can be taken to adjust such conditions when found. Periodic check over of tools, equipment and plant lay-out becomes an engineering problem, particularly when the elimination of hazardous conditions is included.

Dust offers a serious hazard in certain lines of industry. All dusts are harmful when taken into the human system in quantity, and some dusts are dangerous through the probability of development of industrial diseases such as silicosis and pneumoconiosis. A clean plant is not a dusty plant and the place to trap dust is at the source. The use of respirators and masks may be necessary in some lines of work but regardless of everything else, every effort should be made to keep the dust out of the air. Ventilation and exhaust systems should be installed under the direction of a competent engineer, as they require work of a type that does not fall within the province of a tinsmith or an ordinary mechanic.

Danger Signals

The following points should be looked into by those who investigate accident causes:—

1. Lack of physical and mechanical safeguards.
2. Slack supervision.
3. Insufficient first aid.
4. High accident frequency.
5. Too many medical aid cases.
6. Too many doctors.
7. Compensation awards in excess of assessments levied by the Compensation Board.
8. Medical aid costs too high in relation to awards.
9. Lack of compensation cost and accident records.
10. Accident reports to the Compensation Board signed by a junior clerk.
11. Failure to follow up cases after the injury.
12. The plant manager who does not know what awards have been made for injuries to his people, but who says "the Company has paid the Board plenty," and who really knows nothing about it.

The Workmen's Compensation Act has been a model for all the other provinces. It has insured prompt and certain payment to the injured worker and has not laid an unfair burden on industry. In the 22 years, 1915 to 1936, inclusive, the total benefits awarded by the Workmen's Compensation Board amounted to $116,136,634.61, while the total number of accidents reported to the Board in the same 22 years was 1,182,741, including 8,492 death cases. This made an average of $98.19 per case reported in the twenty-two years.

Safeguarding Machinery

The first requisite for a machine ever since man first began to make them was that it should turn out the work a little quicker, easier, and cheaper than could be done by hand. The designer of the machine probably had these points in mind but the safety of the operator was a subsequent development brought about by two things in industry, namely, the demand for workmen's compensation, and ordinary humanity. Engineers, therefore, have a responsibility to design tools with a wide factor of safety for the protection of the operator, as it has been shown that properly guarded equipment will make production easier, cheaper and quicker.

Summary

It should always be remembered that the Workmen's Compensation Act in Ontario gives protection not only to the worker and to the employer, but to the public as well. For this reason, the Act itself should have the support of all thinking citizens. The organized effort for accident prevention in Ontario has already been mentioned. The work of our Industrial Accident Prevention Associations needs the complete co-operation of engineers, for our Field Force and for our services in those industries included in our membership. Engineers have a responsibility and an opportunity that is not given to the average man in industry. On behalf, therefore, of those who will benefit by the engineer's knowledge, experience and ability, your co-operation is asked in accident prevention work inside your own organization, remembering that accidents are not prevented by meetings and discussions unless someone does something about it subsequently. Huxley said "The great end of life is not knowledge but action." It does no good to hear about accident prevention work and organization—unless each of us does something about it afterwards.

A Brief Study and Comparison of Crushed Rock and River Gravel Aggregates at Edmonton, Alberta

H. R. Webb, M.E.I.C., E. H. Davis, S.E.I.C.,† and G. Ross, S.E.I.C.†.*

The district immediately surrounding Edmonton is poorly supplied with natural deposits of sand and gravel of suitable characteristics for concrete. Most of the deposits which are found have certain local properties which render them questionable. As a result there have been developed certain sources of supply and certain methods of technique in preparing suitable final aggregates.

Practically all of the concrete for important jobs is now supplied by a central mixing plant. Up until recently general contractors on jobs of any size set up their own plant, and made their own concrete, but they now find the aggregate situation so uncertain that they have to turn to the above-mentioned organization for coarse aggregate or concrete, with the natural result that they usually buy concrete.

The local central mixing plant is making the best of a rather difficult situation in regard to coarse aggregate. The one large gravel pit of reasonably suitable material is located some forty to fifty miles west of Edmonton and has not been in active operation since the early years of the depression, so the two sources of rock most easily available have been developed as construction has picked up. These two sources are:

(*a*) field stones from the surrounding area, and
(*b*) river gravel from the North Saskatchewan river.

The field stones are brought in by truck from all directions, and the haulage distance is now about twenty miles. This distance is, of course, increasing steadily with time. A stock pile of several thousand cubic yards of these stones is kept on hand. The material in the stones is largely quartzite and dolomite. They average about nine inches in diameter. (See Fig. 1.)

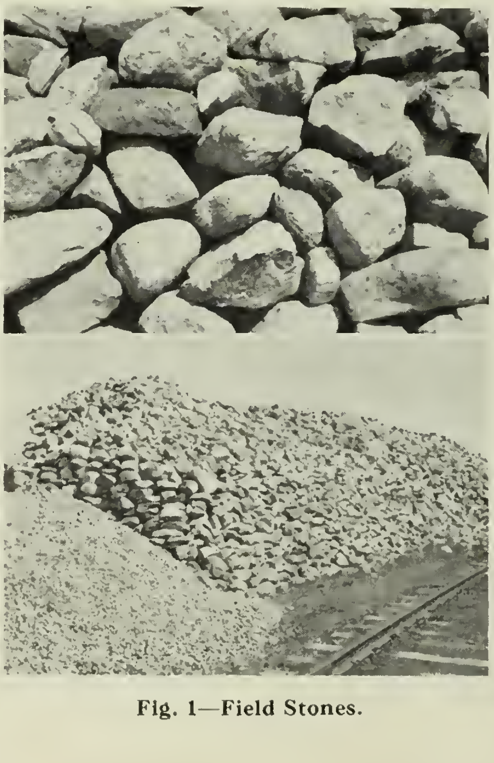

Fig. 1—Field Stones.

The gravel from the river is a well-graded material with very smooth rounded particles. It is removed from the river by bucket and cable, and is then washed and separated into two sizes by a one inch screen. Both of the fractions contain undesirable elements. In the larger size there are lumps of shoft shale, brown pieces of hard clay and some coal. These are picked out by hand by boys placed along the belt conveying the material to the loading hopper. The fraction passing the one inch screen contains considerable coal, most of which lies between the quarter inch and half inch screens. The company's engineer has devised an effective washing system whereby separation of the coal takes place due to its lower specific gravity, and the remaining gravel is then transported to the same hopper. All material from the river below the quarter inch screen is wasted.

For the final concrete aggregate both of the above materials are put through a gyratory crusher. The field stones yield crushed rock with almost no smooth surface or rounded shape. The river gravel contains few stones larger than 1½ in. in dia. so it passes through the crusher almost unchanged. Stones and river gravel are put through the crusher simultaneously, then it passes to screens which separate the product into three sizes, below ¼ in., ¼ in. to 1 in. and 1 in. to 1½ in. The final aggregate then

*Associate Professor of Civil Engineering, University of Alberta.

†Fourth Year Civil Engineering Students, University of Alberta.

contains both crushed material and round gravel. Plain river gravel is also stored separately in a bin feeding to the batching equipment. Concrete is mixed in 1½ cu. yd. batches and in weighing the materials several hundred pounds of river gravel is put into each batch with the crushed mixture in order to smooth up the mix and save on mixing water. Crushed aggregates with some round gravel present are shown in Fig. 2, ¼ in. to 1 in. in Fig. 2a and 1 in. to 1½ in. in Fig. 2b.

Outline of Investigation

In order to obtain information on the effects of variations in the proportion of river gravel and crushed field stones in the aggregate, a small investigation was planned as a laboratory problem for the two last named writers.

Table 1 shows the combinations of aggregates and water-cement ratios selected.

One consistency, that to give a medium slump of 3 to 4 inches and a flow of about 170 to 180 per cent on a flow table using a 6¾ in. by 10 in. truncated cone mould 5 in. high with twenty drops of ½ in. in 30 seconds, was also adopted.

One cylinder was mixed at a time, placed in a 6 in. by 12 in. waxed paper form and rodded according to standard procedure. After 48 hours the form was removed and the cylinder stored in water at 65 deg. F. until tested. All cylinders were tested at 28 days.

For testing, each cylinder was capped on both ends with plaster of paris and machined steel plates, and after one hour was tested under standard conditions.

Fig. 2—Crushed Aggregate with Some Round Gravel Present.

Table I

Test Cylinder Outline

R.G. = River gravel. C.R. = Crushed rock.

Coarse Aggregate	Water-cement ratio by volume				Total
	0.70	0.85	1.00	1.15	
100% River Gravel	4 cyl.	4 cyl.	4 cyl.	4 cyl.	16 cyl
80% R.G. 20% C.R.	4 cyl.	4 cyl	4 cyl.	4 cyl.	16 cyl.
60% R.G. 40% C.R.	4 cyl.	4 cyl.	4 cyl.	4 cyl.	16 cyl.
40% R.G. 60% C.R.	4 cyl.	4 cyl.	4 cyl.	4 cyl.	16 cyl.
20% R.G. 80% C.R.	4 cyl.	4 cyl.	4 cyl.	4 cyl.	16 cyl.
100% Crushed Rock	4 cyl.	4 cyl.	4 cyl.	4 cyl.	16 cyl.
Total	24 cyl.	24 cyl.	24 cyl.	24 cyl.	96 cyl.

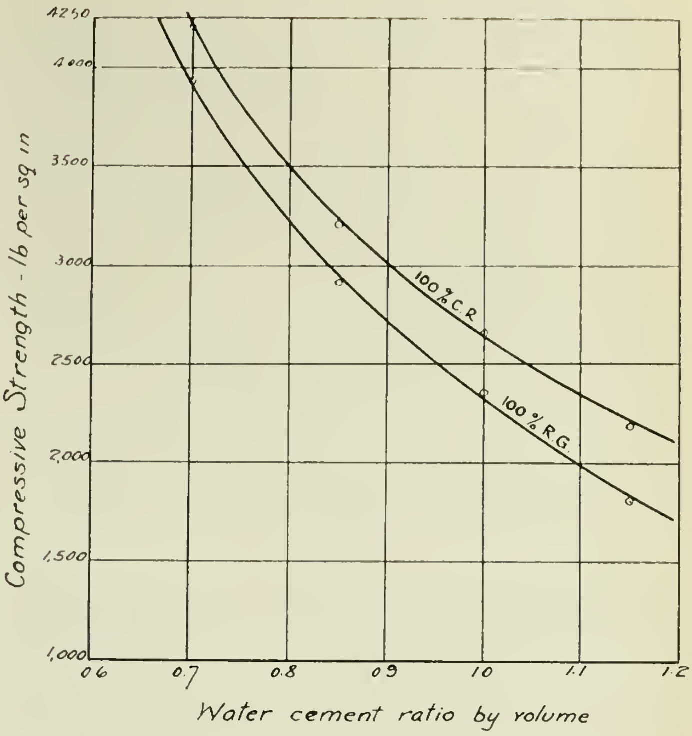

Fig. 3.

The mixes in the top half of Table I were carried out by operator "A," those in the lower half by operator "B." Every attempt was made to keep identical technique throughout.

The properties of the materials used are tabulated in Table II.

Table II

Aggregate Characteristics

		Sand	River Gravel	Crushed Rock
Apparent specific gravity		2.63	2.60	2.63
Unit weight, lb. cu. ft		110.	102.	99.
Per cent voids		33.1	37.0	39.6
Surface moisture		0	0	0
Absorption (lab.)			0.57%	1.33%
Absorption (field)			0.43%	0.89%
Colorimetric test		Dark brown		
	Sieve	Per cent Retained, Cumulative		
		Sand	R. G.	C. R.
Sieve analysis	1½″	0.	0.	0.
	¾″	0.	42.3	42.3
	⅜″	0.6	90.4	90.4
	No. 4	3.2	100.	100.
	" 8	11.4	100.	100.
	" 16	21.2	100.	100.
	" 30	51.3	100.	100.
	" 50	92.5	100.	100.
	" 100	98.0	100.	100.

The sand used in these tests is known locally as "Northern Sand," and occurs in a large deposit about sixty miles north of Edmonton. The sand has a decided rusty colour and contains fine soft coal which greatly affects the colour test. The colorimetric test for this sand runs all the way from a deep straw colour through cherry red to very dark brown.*

Cement conformed to standard specifications and sufficient was obtained to complete the tests.

*Effect of Finely Divided Lignite Coal on the Strength of Concrete, I. F. Morrison and H. R. Webb, M.E.I.C., A.S.T.M. Proc., Vol. 24, p. 841.

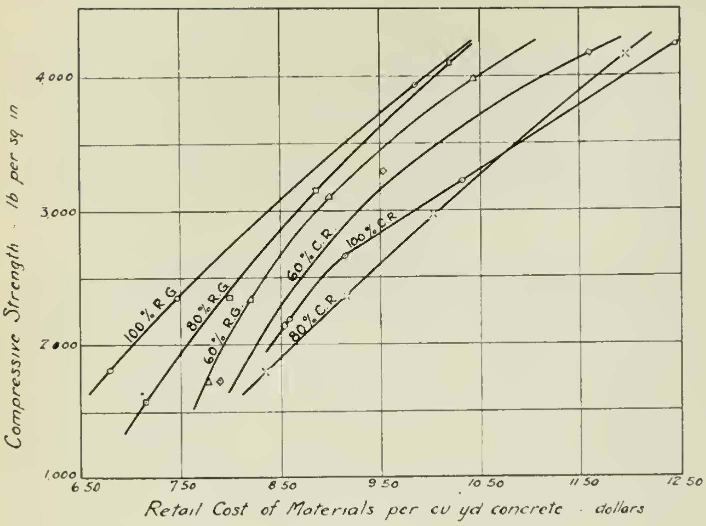

Fig. 4.

The river gravel and crushed rock samples were almost identical in grading, and in order to eliminate grading as a variable the selected grading was taken between the two, and all materials were screened and recombined to the grading shown. In these mixes the crushed rock was hand picked, all round particles being excluded.

Results

(a) Water-cement Ratio and Compressive Strength Relation.

The water-cement ratio-compressive strength curves for the mixes containing 100 per cent C.R. and 100 per cent R.G. as coarse aggregates are shown in Fig. 3. The curves for the other aggregate combinations lie in the space between the two shown. It is thus seen that for any given water-cement ratio, within the limits of this investigation, and approximately equal consistency, local crushed rock results in from 200 to 400 lb./sq. in. higher strength than local river gravel.

(b) Cost-Compressive Strength Relation.

For the computation of cost the yield of each mix was computed and then the cost of materials per cu. yd. of concrete. The prices used were the regular retail prices for these materials on the Edmonton market, and were as follows:

Cement, \$0.95 per 87½ lb. bag,
Sand, \$3.00 per cu. yd.,
River Gravel, \$2.25 per cu. yd.,
Crushed Rock, \$3.50 per cu. yd.

The cost-compressive strength data are plotted in Fig. 4.

The curve for 100 per cent crushed rock appears to be decidedly out of place, and that for 80 per cent C.R. gives approximately a straight line. Examination of the data shows that the average consistency of the 100 per cent C.R. mixes was definitely lower than the others, and so a displacement of the whole curve to the left would be natural.

The same information is shown again in Fig. 5 in slightly different form.

The shape and slope of these curves give definite evidence that economy, as far as compressive strength is concerned, increases with increase in the proportion of river gravel in the aggregate, or decreases with increase in the crushed rock.

These results will prove useful in dealing with these local materials. Probable small differences in technique, as well as the personal equations of operators A and B, have probably introduced uncertainties in some of the plotted values. The mixtures high in crushed rock were harsh, and equal consistencies were not only not completely realized but even if realized might not represent equal placeability. The crusher dust clinging to the crushed rock was dis-

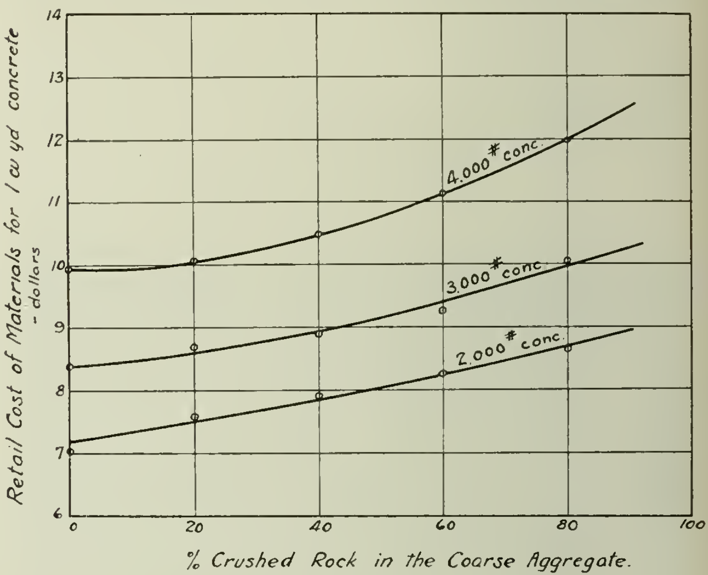

Fig. 5.

regarded in this investigation, although the writers are aware that considerable variation occurs according to whether the field stones and river gravel are wet or dry when passed through the crusher. All of the crushed rock used was taken from the bin at one time.

It is hoped to continue to study these materials, to fill in the gaps in the above and to extend the tests to include other characteristics.

The New 50 kw. Transmitters of the Canadian Broadcasting Corporation

John C. Stadler, A.M.E.I.C.,

Executive Assistant, Canadian Broadcasting Corporation, Montreal.

Paper presented (in French) before the Quebec Branch of The Engineering Institute of Canada, March 17th, 1938.

SUMMARY.—A brief description of the two new stations (CBL and CBF) of the Canadian Broadcasting Corporation, which have been established as part of the Corporation's policy to secure adequate radio coverage in all parts of the Dominion.

The radio picture as visualized in Europe is quite different from that presented in the new world, and day by day the difference becomes more and more apparent.

A comparison between the attitude toward radio in Europe and that which is found in North America, would lead us to believe that broadcasting, if not a very powerful weapon, is at least a factor in greatly influencing the mentality of the people.

Fortunately for us who live in the new world, so free from any overbearing influences from unfriendly neighbouring nations, we are able to consider radio simply as a source of education, merriment and cheer.

Without attempting to describe fully the policy of the Canadian Broadcasting Corporation as regards broadcasting, it is possible to sketch the general plan of the technical achievements which have resulted from the development of radio in Canada since the foundation of the Corporation.

From the beginning, the inadequacy of the number of broadcasting stations in Canada was realized, for neither the outlets of the Corporation nor the private stations were in a position to properly serve the population of Canada.

In the month of December 1936, the total power of the broadcasting stations in Canada amounted to 78.2 kw. and the investment in the Corporation stations and in the private stations, taking depreciation into account, was estimated at $1,900,000.

Thus it was the duty of the Corporation, before proceeding in any other line of endeavour, to extend the coverage of its stations in Canada, so as to assure as wide as possible a distribution of programmes. With this in mind, and as an initial measure, it was decided to proceed with the construction of two 50 kw. transmitters to cover the densely inhabited portions of the Provinces of Ontario and Quebec.

At the time of its inception, the Corporation's listening audience comprised about fifty per cent of the population of Canada. Upon the inauguration of the two regional transmitters now in Toronto and Montreal, the total power of the broadcasting stations in Canada was more than doubled; the value of plant and equipment both of private stations and of the Corporation's stations, was increased by forty per cent, and the coverage of the Corporation's network was extended to eighty per cent of the population of Canada.

These statistics justify the capital expenditure which has been incurred by the Corporation in Toronto and Montreal. The new transmitters are located, with respect to the major centres of population, in such a way as to assure good reception to as great a number of listeners as possible, within the zone known as that of primary service.

At this point one must differentiate between the primary and the secondary zones; the latter, which may extend to about 2,000 miles from the transmitting point, is that in which night time reception alone is possible, whilst the primary zones are those areas in which continuous daytime and night time reception is possible.

Engineering studies are being carried out with the object of securing primary zones as large as possible, whilst at the same time retaining a secondary zone of satisfactory proportions.

Progress in radio engineering, as in all other branches of engineering, has led to the standardization of equipment and specifications and accordingly a standard series of power-ratings of transmitters has been generally adopted. Normally, transmitters are rated in powers of 100, 500, 1,000, 5,000 and 50,000 watts; from this point the next step is to 500,000 watts. This represents the practice followed in America, although in European countries, between the 50,000 and the 500,000 figures, intermediate steps of

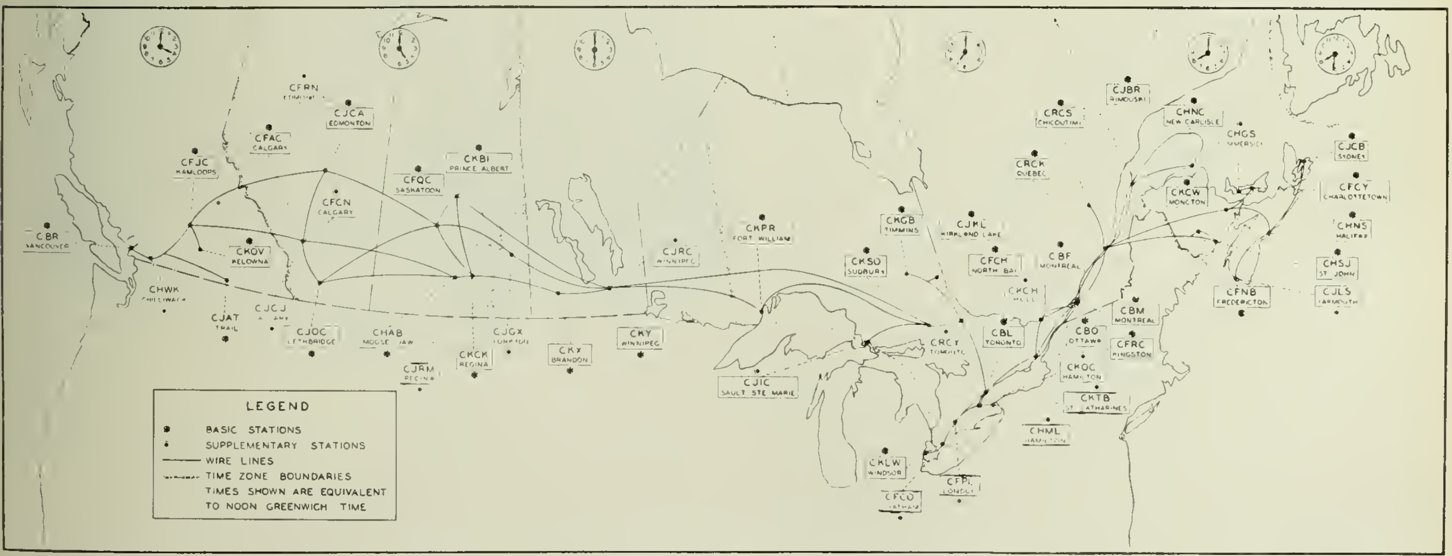

Fig. 1—Canadian Broadcasting Corporation Network (Corrected to April 1st, 1938).

100,000 or 150,000 watts are set. The following stations are examples of the above ratings of powers:

CRCS	Chicoutimi	100 watts
CKCK	Regina	500 "
CFQC	Saskatoon	1,000 "
CKAC	Montreal	5,000 "
CBF	Montreal	50,000 "
WLW	Cincinnati	500,000 "

Fig. 2—View of Transmitter Main Panel and Central Room.

The choice of the factor of 10, whilst arbitrary in appearance, in reality is not so; it results quite logically from technical studies. It should be noted that in the zone of effective reception, multiplication of the transmitting power by 10 will result in giving $\sqrt{10}$ times the former signal voltage.

The intermediate steps of 100,000 and 150,000 watts which are utilized in certain countries have been adopted as a compromise produced by the lack of or prohibitive cost of larger equipment in those localities.

The new transmitting stations of the Corporation (CBL and CBF) are located a few miles from Toronto and Montreal respectively, and are of similar design. As the buildings which house the broadcasting equipment are intended for special purposes they depart somewhat from the practices ordinarily followed in construction and design.

The construction of the Verchères station was commenced in the month of June 1937 and by the end of November the work was almost terminated. The Verchères transmitter was actually inaugurated on the 11th of December 1937 and that at Hornby on Christmas Day 1937.

In each case the main building houses the 50,000 watt transmitter as well as the auxiliary equipment, and provides at the same time for the future installation of a short wave transmitter.

The auxiliary equipment comprises substation transformers, a workshop, stores for spare parts and spare tubes, cleaning and ventilating equipment; limited accommodation for the personnel and a garage is also provided.

The building is of reinforced concrete of the monolithic type of construction. The reinforcing bars used are all tied to the grounding system of the transmitter.

The walls and ceilings are covered with insulating material: the walls by 2 in. of rockwool and ½ in. of fibre board, and the ceilings with a special sound-absorbing plaster called zonolite, 4 in. thick. The lighting of the control room of the transmitter is provided for by a glass-brick wall, comprising one complete side of the room. To give necessary security, the metallic bars of the window frames are close enough together to prevent the passage of a person in case the glass is broken, and the window locking devices are so arranged as to render them inaccessible from the outside if the glass is broken.

The heating of the various rooms of the building is effected by radiators as well as by air ducts. The air carried by the air ducts is heated during winter and cooled during summer. The necessary heat for this air is partly obtained from the cooling water which cools the plates of the tubes in the final stages; this results in a saving of approximately 1,000 gal. of oil per year.

The electrical installation of Verchères and Hornby involve practically all phases of electricity as well as of communications engineering.

As regards power, the transmission lines and station mains have to provide for several hundred kilowatts and the service must be continuous and uninterrupted. So as to prevent any interruptions in the operation of the station, the transmission lines have been set up in duplicate. At Verchères, for example, the internal mains carry 3 phase current at 460 volts. The total load is approximately 200 kw. and the power factor is better than 90 per cent. A further block of power of 50 kva. has been provided for to supply the short wave transmitter which would be fed from the 460 volt bus. The lighting and domestic loads such as heating, air conditioning, etc. amount to about 50 kva. The Shawinigan Water and Power Co. and the Southern Canada Power Co. deliver power at the exterior substation at 13,200 volts, which is stepped down to 460 volts for the station mains. Within the building itself, circuit breakers and cutouts, as well as the auxiliary equipment, are provided.

For satisfactory service the voltage of the 460 volt bus must not vary more than 4 per cent and the load varies syllabically from 120 to 180 kw. These are conditions which are quite exacting and which require the installation of load impedance transformers in the substation.

The transmitters were built by the Northern Electric Company. The high efficiency circuit used in the final stage of the transmitters was developed by Mr. W. H. Doherty of the Bell Telephone Laboratories, and is an example of the most recent advance in radio engineering.

The transmitting equipment consists of a quartz-crystal-controlled oscillator feeding a three-stage radio-frequency amplifier; a three-stage audio-frequency amplifier, the water cooled modulator stage and the final high power stage; the necessary equipment for providing D.C. voltages as well as A.C. voltages of different values, the rectifying unit, the antenna coupling unit and the water cooling system for the tubes.

These various elements are combined and connected so as to produce a carrier wave having a stability of the order of one part in 100,000, which will be modulated, that is varied in amplitude, by the programme signal, and so as to amplify this modulated carrier wave and feed the vertical antenna, from which electro-magnetic radiation takes place. The power of the unmodulated carrier wave is 50 kw.

To prevent accidental contact with various high voltages, special protective devices are installed on the various parts of the transmitter. The transmitter itself is totally enclosed and the enclosure is provided with doors electrically interlocked with the high voltage system; this prevents the application of any dangerous voltages when the doors are opened.

Other relay-operated protective devices permit the grounding of certain parts of the high voltage system to complete the scheme of protection.

The starting of the transmitter is controlled by a relay-operated sequence from a main control panel. Circuit conditions and relevant information pertaining to the various parts of the transmitter are indicated by meters and by various signal lights.

The radio-frequency portion of the transmitter is installed in four panel units located on the main floor of the building; these metallic panels form a continuous front panel. The high voltage transformers, regulators, choke coils and protective devices, etc., as well as the water cooling system are all located in the basement.

The high voltage rectifiers as well as the grid bias rectifiers and filter condensers are located in the main enclosure.

The first panel unit comprises two quartz-crystal-controlled oscillators, one of which can be used in case of failure of the other unit, a three-stage radio-frequency amplifier, a three-stage audio-frequency amplifier, the various rectifying units for the high voltage required for these circuits as well as the control equipment of the various circuits.

The second panel unit contains a high power modulating unit composed of two water cooled tubes; the third and fourth panel units form the output radio frequency stage where the two 100 kw. water cooled tubes, shielded input and output circuits as well as the tuning controls and accessory equipment of this amplifier are located.

The concentric transmission line which connects the final stage to the antenna, and the one-quarter wave length harmonic shunt connects directly with the output terminals of this amplifier.

The equipment for the circulation and cooling of the water used in the water cooled stages consists of two pumps, of which one can be used as a spare, two air blast radiators with blower motor and the associated disconnects, storage tank and necessary dials and fittings; this equipment is located in the basement.

The dissipation of the heat produced in the water cooled tubes requires a circulation of 40 gal. of water per min. At the outlet of the water cooling jackets, the temperature is approximately 88 deg. F.; after having gone through the

Fig. 3—Tuning House. Co-axial Feed Line, Rear of Transmitter Building and Substation.

heat recovery radiators, the temperature at the outlet of the storage tank is approximately 80 deg. The normal temperature in the water cooling jackets is between 80 and 85 deg., depending on outside temperature.

The regulation of the voltage on the 460 volt bus is effected by a regulator with a normal rating of 27 kva. and provides for a variation of 45 per cent in the voltage, that is 22½ per cent buck or 22½ per cent boost. A secondary

Fig. 4—Blower and Pump Room. Heat Recovery Radiators on Left.

regulator is provided to control the transformers which provide filament voltages because the life of the tubes is more or less a direct function of the voltage stability.

Insofar as actual radio frequency energy is concerned, the latest practice has been followed, that is, the use of a radiating mast. At Verchères a structural steel mast 585 ft. high, properly guyed and resting on an insulator, forms the antenna system. This mast is connected to the transmitter by a co-axial line, and the coupling of the mast to the transmission line is done in a tuning house located near the mast.

The grounding system is composed of approximately 19 miles of wire buried underground to form the spokes of a wheel, the centre of which is the base of the antenna; 120 spokes are 600 ft. long and other shorter ones are placed in between.

All metallic parts of the building, as well as water pipes, window frames, etc., are tied to this ground system. This grounding of all metallic parts insures against the loss of expensive radio-frequency energy within the building itself. Experience has shown that a good ground system has the same effect as increasing the power of the station.

Since a tower of this height constitutes a danger to aviation service, lights have been placed at every 100 ft. on the mast in such a way as to be visible from all directions. A beacon is installed on the top of the mast itself.

A broadcast transmitter is composed of networks and circuits of a complex nature, which require electrical energy at various voltages, and of different natures. These voltages are supplied through conduits which must meet the requirements of the Quebec Electrical Inspection authorities. The various control circuits can be operated from the operator's desk from which proper supervision of all the various parts of the transmitter can be had.

The programmes carried by wire circuits from the Corporation's studios in Montreal, Toronto or from elsewhere, must be amplified to compensate for the loss that occurs in all line transmissions. So as to check and maintain the signal level fed to the transmitter, the necessary indicating apparatus is installed on the operating table and assures a continuous check of the signal level and the quality of the programmes.

The duties and responsibilities of the engineering staff of the Corporation did not end when the transmitting stations were built. The daily schedule of operation and the maintenance of a broadcast plant such as that which is found at Verchères, requires the continuous attention of several engineers and technicians. CBF operates at present 13 hours a day; during the period of operation, no inspection can be performed, which means that to assure a continuous service for a period of 16 hours, a daily work schedule of approximately 24 hours is required.

During broadcast time, two operators, under the Chief Engineer or his assistant, are always on duty.

The personnel of the Corporation working at the Verchères station comprises eight men. This allows two shifts of two men in the 16 hours of operation and also provides for the maintenance and routine inspection work which has to be carried out during the remaining eight hours. Regular control of the quality of the signal is effected; normally the quality, or the fidelity of the transmitter is checked by a series of observations at predetermined frequencies, and the depth of modulation is checked by a cathode-ray oscilloscope.

Insofar as coverage of CBF is concerned, when the plans were prepared by the engineers of the Corporation, it had been anticipated that in Quebec City the signal strength would be about one half millivolt. Measurements carried out during the week of March 6th, 1938, indicate that nowhere in Quebec City was the signal below 0.63 millivolt. This gives tangible evidence that the hopes of the Engineering Department have been more than realized. As an indication of what this signal level means, it will be sufficient to mention that no outside station provides in Quebec a signal better than 0.2 millivolt. Consequently, CBF is in a position to provide perfect reception to all listeners in that city.

This is but a brief sketch of the outline of the Corporation's Verchères station, or for that matter, at Hornby, which is exactly the same; the technical details and refinements which the Corporation has been able to include in each of these stations, would in themselves be the subject of several papers.

Without any doubt whatever, the Corporation possesses at Verchères and Hornby two broadcasting stations that can be compared with any other station in North America. The installation of these two stations is an indication of the intention of the Corporation to build, maintain and operate, throughout Canada, a sufficient number of high powered stations that will bring Canadian programmes to all Canadian listeners.

The Importance of Research and Development in Maintaining Technical Progress

M. W. Smith,

Manager of Engineering, Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa., U.S.A.

Paper presented before the Seventh International Management Congress, Washington, D.C., September 19th-23rd, 1938.

SUMMARY.—Research and development work are usually regarded as very technical subjects and are generally so treated, but it is recognized that Management has a very definite interest in their influence on technical progress, particularly in the industrial fields. This discussion is presented with this point in mind, and various suggestions and illustrations as to how this kind of activity may be stimulated and more effectively controlled are offered.

Research and allied developments are among the greatest factors contributing to the advancement of our standard of living. Through inventions resulting from its application we have travelled farther along the road of technical progress to a safer and more enjoyable life in the past hundred years than in all the preceding time. The last twenty-five years have surpassed all others and we can expect technical development to progress at an even faster rate in the future.

The scope of research is almost unlimited. It is effectively applied in almost every branch of the basic sciences. It influences the progress and trends of our industries, commerce, agriculture, public health and safety, employment, and even our national defence. While these various branches of research are broadly related and would be very interesting to discuss, it is considered desirable to limit this discussion to the field of industrial research with which the author is best acquainted, so as to indicate better in more specific terms some of the problems and responsibilities of Management in the planning and administration of these functions.

Industrial Research and Development

There was a time, not so many years ago, when industry looked to the laboratories of the universities and endowed foundations for its research work, particularly in the fields of basic sciences. While it still recognizes the value of research done by these institutions and attempts to follow it closely through co-operation with them, industry is gradually assuming this responsibility even on fundamental work because results can usually be obtained more promptly by a more concentrated and continuous effort and by limiting the choice of fields of endeavour to those of greatest interest to the particular industry concerned. Although industry may concentrate its research in fields of its immediate interests, progressive companies also follow the work done in allied fields and in basic sciences even to the extent of maintaining fellowships in universities and other independent research organizations. They also maintain close contacts with foreign developments, and history reveals many instances where discoveries were made in one country and subsequently developed and commercialized in another.

Research is one of the most effective and certain means of protecting capital invested in industry from the decay of obsolescence. Reference was recently made in one of the financial papers to an investigation made by the investment divisions of several large insurance companies, to determine from an actuarial standpoint the mortality rate of certain kinds of businesses. One point on which they all agreed and placed considerable emphasis was that the companies which died invariably did little or no research. These companies just gradually "went to seed" with old products which were made obsolete by competitors who developed new methods, processes and machinery to build products with more desirable performance and characteristics. A progressive company must not only protect itself against the creation of obsolescence from a competitive standpoint but industry in general must strive toward the creation of obsolescence as one of the most effective means of stimulating new business and prosperity. If new business had to depend entirely on the replacement of equipment and commodities which had been worn out or consumed, our progress would indeed be slow and our standard of living and employment would be stagnant. Only through the creation of obsolescence by the introduction of new and improved products can business expect to grow.

Unless we stop and reflect, we are likely to get the impression that our present industries and products have always been in existence, when as a matter of fact, probably one-fourth of our present production is of products entirely unknown fifty years ago, and even those that were known at that time have been modified and improved to such an extent that they can hardly be recognized as the same.

There was a time when business enterprises were quite firmly established and maintained for generations, but the last few decades have seen whole industries wiped out by the forward march of progress. Business men have not fully recognized this danger and adjusted themselves to it. There is still an instinct in the old to fight the new, but nothing except ruin can result from a strict adherence to such a viewpoint or policy where the new is something inevitable because of its economic advantage. A business man is not justified in abandoning an old, established business at the first sight of a substitute product, but neither is he justified in assuming that because it is a substitute for his product it is necessarily an enemy of his. By absorbing it or modifying his product through development work, he may find the opportunity to make his business more profitable than ever.

Aviation may seriously alter the railroad passenger business, but the railroads which have invested in aviation lines will win no matter which way the tide turns. Buses and trucking might put some railroad lines out of business but the railroads which own large bus lines and big trucking routes will carry the traffic in any event. That's the difference between just being in the railroad business and being in the transportation business.

Shortly before the advent of radio broadcasting, there were probably at least fifty companies in the United States manufacturing phonographs. For a quarter of a century, many of them had done little or no research or development work. Almost over night, a new form of audio entertainment appeared in the home. It immediately became apparent that the radio music and speech quality was vastly superior to that of the phonograph. Greatly decreased sales resulted in serious financial difficulty in spite of frantic advertising. However, a few of the most progressive companies promptly got in contact with radio experts, and after intensive research, incorporated in their apparatus electronic amplifiers, scientifically designed loud speakers and electric recording with an astonishing improvement in quality. These companies soon began to prosper once more, while the others who ignored research and development promptly disappeared.

These illustrations emphasize the important part research and development play in the growth of industrial organization, but at the same time it must be recognized that even this activity can be carried to an extreme. Companies can also fail because of too much engineering and development expense if it is not effectively and efficiently controlled.

Types of Research

Depending upon its purpose, research and development in industry can be considered from various viewpoints, but for the purpose of analysis and study of functions and operations, it may logically be considered from the following three viewpoints:

1. Basic, or fundamental, research which involves studies and investigations at the frontiers of the basic sciences of physics, chemistry, etc., to determine the properties, characteristics and behaviour of matter quite without regard to any immediate or specific commercial uses or application.
2. Specific, or applied, research which is conducted to obtain definite information, solve a particular problem, improve an old product, or develop a new product or line of equipment.
3. Commercial development, which has for its purpose extensions to existing lines of products and improvements in their characteristics and performance. This type of development is not directed toward the discovery or perfection of new kinds of products, but toward improvements and cost reductions in existing ones so as to enhance their competitive standing or value.

Fundamental Research

The nature of fundamental research requires that it be undertaken on a comparatively long-range basis and it should be recognized that important results or achievements may not be realized for several years. Here the problem of Management is largely one of the proper selection of personnel and general fields of investigations. The success of this kind of work is largely dependent upon individual effort and Management can provide only limited detail supervision. The personnel must be selected with this point in mind. In addition to good technical ability and qualifications, men for this work should have an abundance of initiative, enthusiasm, courage and imagination. The recognition of the importance of the selection and development of men for research work has been demonstrated by the establishment of special training courses and opportunities to do advanced work in industry.

For instance, the Company with which the author is associated recently adopted a plan for the establishment of ten positions in its Research Laboratories, to be known as "Research Fellowships." These Fellowships will be open to young scientific workers in physics, chemical physics, physical metallurgy, etc., enabling them to carry on studies of pure scientific value in these fields. Appointments will be made for a one-year period, with the possibility of renewal for a second year. Applicants are required to have training equivalent to a doctor's degree and have already demonstrated ability of a high order in scientific research. In this way it is hoped that a steady stream of the best young scientists will pass through the Laboratories in years to come. While there are no definite commitments, it is expected that some of these men will want to remain on the regular staff of the Laboratories. Others will return to academic work in leading universities and other institutions after having acquired an insight into the scientific problems of the electrical industry. While the Research Fellows will be given considerable freedom as to the particular research problem on which they will work, it is expected that in all cases, the broad field of work will correspond to one of the existing activities of the Laboratories. It is planned to keep the working programme as flexible as possible in order to adapt it to current progress in physics and chemistry. Experience indicates that important advances in industry may be expected from fundamental knowledge gained through such a programme and the operation of this projected Fellowship Plan should also serve to keep the Laboratories in closer contact with other scientific institutions with which these men may later become associated.

Specific or Applied Research

Although specific, or applied, research cannot in all cases be sharply distinguished from fundamental, or pioneering, research, its purpose is different in that it is usually conducted with a definite objective in mind and with the idea of early application. It represents the major activity of most industrial research laboratories because it is usually directed toward improvements in established lines of equipment. For instance, because of troubles experienced on a new product or because of the desire to extend the application of an existing product into new fields of application beyond previous limits of knowledge and experience, certain information and data may be necessary. This may require some fundamental research but it is largely a question of finding the answer to a problem which already exists and is not of a pioneering nature.

Because of its nature, applied research is often subject to the pressure of production from other divisions of the Company, which have a commercial interest in the project. This condition, together with the fact that the Management has an appreciation of the nature and scope of the problem, presents the opportunity, and even necessity, for much more supervision and direction of the work than can be expected on fundamental subjects. This kind of work must be followed closely and actively by the Management to see that it progresses with reasonable speed and that specific projects are not drawn out beyond profitable limits. It is just as important to know when to stop an unpromising project as it is to start an attractive one. Moreover, the pressure for immediate results on specific subjects should not be allowed to crowd out fundamental work which is likely to be neglected because of budget limitations or because immediate requirements or prospects do not appear urgent.

Effective and efficient operation requires careful consideration of the organization and personnel and the classification of the types and scope of the work. In a large laboratory it is usually advisable to group the organization into several divisions with personnel and equipment best suited for work in a particular field or branch of science. This is particularly desirable if there are a large variety of subjects to be treated which can be grouped into general classifications. On the other hand, care must be used to avoid building barriers between divisions which will unduly limit the exchange of knowledge and experience between them. Quite often the knowledge obtained or the method of analysis or approach used in the solution of one problem may be quite helpful in attacking another. It is therefore desirable to set up effective systems and regulations for exchanging and disseminating information and results of investigations throughout the organization by means of adequate records, reports, seminars, conferences, etc. Adequate library facilities are also essential in this plan. All current literature should be carefully scanned and items of interest on various subjects should be summarized and referred to those particularly interested in or engaged in work on the subject. The practice of becoming thoroughly acquainted with the status of the art through surveys of existing literature before work on any new project is actively started should be encouraged.

Incubation of New Products

Out of basic fundamental research or even as a by-product of some specific research on another subject may come a new idea or product which has the possibility of commercial development and exploitation. Here Management has a very definite problem and responsibility which is often neglected. A review of products which have come out of research indicates that few of them seemed to be important at the time they were first conceived. It is beyond the power of human conception and vision to recognize the future value and possibilities of many such developments and it is only after they have had an opportunity to spread their effect over a period of time that they are fully appreciated. Nevertheless, Management must continually be alive to its obligations and take steps to encourage the practical development of new ideas and eliminate barriers which too often exist in their path.

An illustration of the obscure nature of discoveries is found in the phenomena connected with the discharge of electricity through gases. The faint glow discharges which it is possible to get in tubes with gas at low pressures first attracted only the scientists and physicists in the laboratory nearly fifty years ago. This toy of the scientist, however, led to two outstanding discoveries. The first was the discovery of the electron by Thompson, which historians will probably regard as the most important technical event to date. The second was the discovery of the x-ray by Roentgen, which has done much to alleviate human suffering and to prolong life, primarily because of its use for diagnostic purposes but also through direct treatment of disease.

The first attempts to use these glow discharges commercially were in the field of lighting, through the work of Moore and Hewitt in developing the mercury vapour lamp. Today it is not the high efficiency which makes this type of light attractive, but the brilliant and unusual colours which are obtained in neon signs. Another development coming from these gas discharges is the form of rectifiers and inverters for the electrical power field. One of the most recent applications of the gas discharge principle, unforeseen in the early days, is the development of a special tube by Rentschler and James, which has very high lethal, or germicidal, powers.

Sometimes a specific development is not complete within itself, and other developments requiring research in allied fields must be completed and combined with it before a commercial success can be made of the idea. A better realization of this condition and responsibility by those in charge of the over-all activity should work toward the elimination of unnecessary delays in the progress of commercial development.

In 1880, a man by the name of Fritts, a pioneer inventor, filed a patent application on talking motion pictures. A review of this case will show that it contained practically all of the fundamental features which exist in the art at the present time. Yet the commercial application of talking pictures was delayed a generation because the elements called for were not promptly developed. For example, his photo-sensitive device would not respond to the frequencies of speech and music.

It is recognized that the progress of such basically new ideas must necessarily be slow because of human limitations and lack of appreciation of future commercial possibilities. However, a better realization of this lack of appreciation and the acceptance of the responsibility on the part of Management to see that steps are taken to develop component parts and principles instead of allowing new ideas and products to flounder around in the laboratories for lack of attention, should go a long way toward accelerating the progress of new developments.

Pilot Plants

Sometimes the difficulties encountered in promoting a new product of the laboratories are much more real and specific than the lack of vision to perceive their potential possibilities. Large industrial companies are usually organized into divisions which are responsible for the design, manufacture and sale of established lines of products. They are likely to be reluctant to take over a new product until its market and profit possibilities have been determined. This condition often results in a long delay between the research development stage and the commercial application of the product.

To eliminate this unsatisfactory condition usually requires some intermediate stage of development. It is not practical to do commercial development work involving the study of manufacturing processes and cost reduction methods in a research laboratory. On the other hand, established operating divisions of a company, which are charged with the responsibility of making a satisfactory profit, cannot be expected to take over a new product until its commercial possibilities have been investigated. An intermediate organization is therefore desirable to carry the new product through the necessary incubation stage to determine its commercial value. Many of the chemical industries have solved this problem satisfactorily by the establishment of "pilot plants," where new processes are developed on a commercial scale. This general idea is now being successfully applied in other types of industries and can be expected to accelerate technical progress and developments in the future.

Very careful consideration and good business judgment must be exercised in the selection of new projects to be reasonably certain that they have sufficient merit and commercial possibilities even to justify carrying through an incubation stage. Here Management has a difficult and somewhat paradoxical problem of not being over-persuaded by the enthusiasm of the inventor and at the same time maintaining the enthusiasm of the research personnel when their projects, in which they are personally interested, are turned down for lack of economic or commercial value. While the maintenance of an optimistic point of view is desirable, business cannot ignore economic considerations. The morale of the research group can usually be maintained in such cases by a frank discussion of the reasons for the decision. It should be realized that in spite of careful selection and accelerated progress, unprofitable operation on new products for prolonged periods is the rule which in turn increases the risk industry must continually assume and is a fact which is not generally appreciated by the public.

Commercial Development

In the final analysis, the climax to all industrial research and development work is the purchase and use of a new product by the ultimate consumer. It is therefore essential to study the consumer's needs and desires as a guide in the development of new products and to follow his reactions to newly developed products to determine their acceptance. The increasing importance of this viewpoint has been recognized and market analyses and studies of the trends of consumers' needs and desires are being reflected back down the line in such a way that they have a large influence on commercial development.

In large industrial organizations, commercial development work is usually conducted outside the research group and by the Operating Divisions who are responsible for the design, manufacture and sale of various lines of established products. This work is largely directed toward the elimination of minor troubles and the application of improvements in performance reliability, appearance, etc., so as to increase the public appeal and acceptance of a product. It involves the study of material processes and standardization, manufacturing methods and procedures, tool equipment and production methods, and cost reductions of all kinds. Although this kind of work has a very definite and specific objective, it often brings out limitations and lack of knowledge and information which lead to research work of the types described above.

Influence of Patents

A discussion of the subject of technical progress would hardly be complete without emphasizing the important influence of the patent system, particularly at this time when there seems to be so much agitation in some circles to place limitations on private research and patent rights. It has been stated that "no fewer than fifteen bills to prohibit the patenting of labour-saving machinery or improvements thereof have been introduced during the present Congress." A great deal of our technical progress in America can be credited to our patent system, and any action to limit its protection would indeed be regrettable. It costs money to develop and exploit inventions. The protection afforded by patent claims provides incentive to develop new things and under such conditions they may be exploited for a long enough time to become established. Without such protection, capital could not afford to venture into new fields, and industrial research would become very secretive, and because of the resulting lack of co-operation, our great advances in living standards and human comfort would be seriously handicapped. Let us be determined to support and encourage individual and private initiative rather than curb it, so long as it is based on sound economic foundations. Scientific advances based on economic improvements are inevitable. Economic laws and human nature cannot be effectively legislated against.

Attitude of Management Important

In this discussion, development activities and functions have been broken down to some extent in an effort to clarify and illustrate methods of control and supervision, but it is recognized that close co-operation and co-ordination of all phases of the work are essential to successful operation. Francis Bacon recognized the importance of organized research as far back as 1620, when he said:

> "If many useful discoveries have been made by accident or upon occasion when men were not seeking for them but were busy about other things, no one can doubt but that when they apply themselves to seek and make this their business, and that, too, by method and in order and not by desultory impulses, they will discover far more."

It is almost axiomatic that technical progress is dependent entirely on progress or accomplishments in research and development work in the various branches of science, and unlimited illustrations could be supplied to substantiate this claim. It therefore appears that the greatest responsibility—or probably we should say opportunity—of Management in maintaining technical progress is to accelerate research and development work through better administration and control of organizations engaged in this kind of work. In addition to a more rigid application of the usual principles of efficiency and economy of operation, a sympathetic and encouraging attitude on the part of the top Management of a company is considered essential. This promotes co-operation and teamwork among the personnel of research groups and is conducive to good performance, which, after all, is a large factor in the determination of the rate of our future progress.

No invention or development is an unmixed good even though it may be based on sound economic principles. As inventions enlarge our activities and broaden our lives in one direction, they cause shrinkage and distress in another. It is the gradual but positive net progress over a long period of time which counts and we must not become disturbed and thrown from our long-range course by temporary upsets in our social and economic progress. Any basically new idea is really beyond our comprehension and vision. If we could visualize it, it would be immediately developed. However, we may be sure that engineers and scientists will continue to make new discoveries—new ways to heal and save, new ways to kill and destroy; and out of it all we will have new joys and new sorrows along the road of progress to better standards of living.

An Estimate of the Uplift on Piers Between Sluice Gates

Jeffrey B. Macphail, A.M.E.I.C.,
The Shawinigan Engineering Company, Montreal.

In designing gravity dams, it is customary to assume that hydrostatic uplift may act on any horizontal joint, varying linearly from full head at the upstream end to zero or to tailwater head at the downstream end of the joint. To this may be applied a coefficient of reduction, equivalent to the assumption that this uplift acts only over some fraction of the width of the joint. These assumptions should logically be brought into the design of the other hydraulic structures associated with the dam. The purpose of this paper is to show how this may be done for piers between open sluice gates, using a method which is valid for other structures as well; and not to discuss the general concept of uplift or the extent to which it is reduced by drainage and grouting.

On our sluice pier, the uplift on any horizontal joint may be considered to be equal to full head from the nose back to the plane of the gate seats, diminishing thence to zero at the sides and end of the joint downstream linearly with the length of path. The magnitude and position of the total uplift force upstream from the gate seats is determined by mere inspection, and our problem is to find similar values for the part of the joint downstream.

The linear variation of uplift pressure involves the tacit assumption of the law of capillary flow, wherein pressure is inversely proportional to length of path, and velocity is directly proportional to difference of pressure. This law incidentally causes one to doubt the validity of the assumption of a parabolic variation of uplift, which is occasionally found in technical literature. It also suggests that the coefficient of reduction should be applied to the width of the joint rather than to the upstream head, for precision of language only, because uplift over half a joint causes the same moments and forces as half uplift over the whole joint.

In the flow of heat, temperature is likewise inversely proportional to length of path, and velocity directly proportional to difference in temperature. Hence some of the equations already obtained by the mathematical physicist for the flow of heat can be used for uplift by taking pressure as the analogue of temperature.

In the present case of a horizontal joint in a sluice pier, the heat analogy is the steady state problem of the distribution of temperature in a long, thin conducting strip, with both faces insulated, the sides kept at temperature zero, and one end, representing the trace of the plane of the gate seats, kept at some non-uniform temperature $u = f(x)$, later made constant at $u = h$, all as shown in Fig. 1 (a). In theory a closer approximation would be obtained by giving $f(x)$ the discontinuous values shown in Fig. 1 (b), to provide for the fact that the gate seats are inside the pier sides, but neglect of this point is on the side of safety, and it saves much analytical complexity. The solution is given by R. A. Houston*, with a result in a form which requires only an easy integration of a series to make it suitable for numerical calculation in the present case; and it was afterwards found to have been well treated by Sokolnikoff and Sokolnikoff.†

An account of the development will be given from these and other sources, in response to the editorial suggestion that the use of a little more space for the purpose would be justified by convenience to some readers to whom the references are not readily available.

*An Introduction to Mathematical Physics, p. 84.

†Higher Mathematics for Engineers and Physicists, p. 313.

The analysis begins with an equation expressing the simple fact that inflow to an element equals outflow, when conditions have become steady and there is no generation or absorption within the element. This equation, the equation of continuity, is of very general application in many cases of flow, such as the flow of fluids and of electricity as well as of heat, and its derivation in a form which can be reduced, using δ as a symbol for partial differentiation, to

$$\frac{\delta^2 u}{\delta x^2} + \frac{\delta^2 u}{\delta z^2} = 0 \qquad (1)$$

can be found in many text-books on these branches of physics. We require a solution in the form $u = F(x, z)$ so that the temperature at any point can be found by mere substitution of numerical values of the coordinates of the point, including of course the points of known temperature at the boundaries. Otherwise expressed, the solution is a function of x and z which satisfies the equation and also the boundary conditions. There is no general way of building up a solution by taking the boundary conditions as a starting point: it is necessary to select, from a certain infinite class of functions which satisfy the equation, the particular one which satisfies the boundary conditions. It can fortunately be shown that a solution thus obtained is unique. This process has long been an important part of mathematical physics, and many solutions have been published, some of them, particularly in the field of capillary

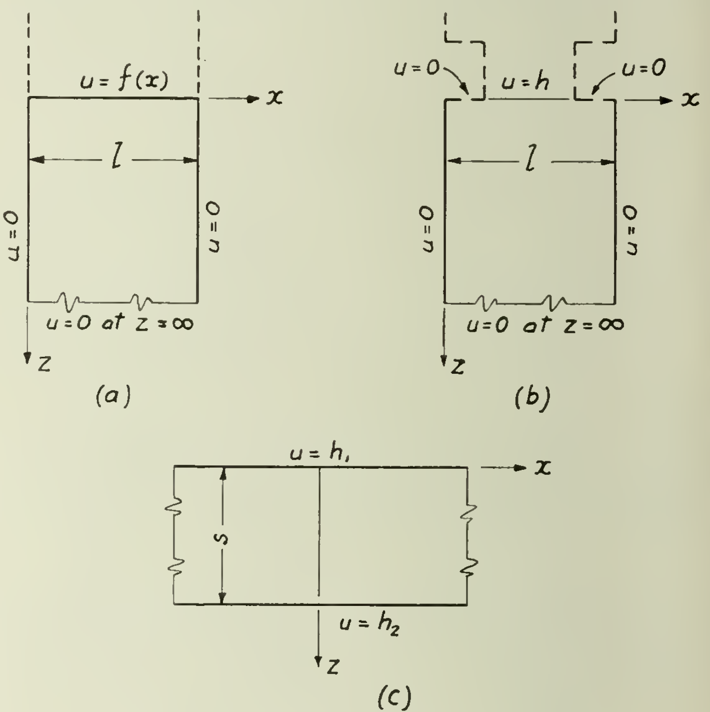

Fig. 1.

flow around cut-off walls in dams on permeable soil, of such complexity that one is amazed to find them confirmed by experiment.

A simple example, from the sources mentioned, may be useful. In Fig. 1(c) is shown a long strip, of width s insulated on both faces and subjected to the edge temperatures shown. The origin 0 is supposed to be far enough from the ends to be unaffected by temperatures there.

Hence $\delta u/\delta x = 0$ and the equation of continuity becomes simply $\delta^2 u/\delta z^2 = 0$ which on integration becomes $u = Az + B$. Introducing the boundary conditions and solving for the constants we get $u = h_1 - (h_1 - h_2)\, z/s$, a simple linear distribution of temperature. The analogy with the linear uplift in dams is obvious.

Returning to the particular case of Fig. 1(a) we require a function which satisfies equation (1) and also satisfies the boundary conditions

(a) $u = f(x)$ for $z = 0$
(b) $u = 0$ for $z = \infty$
(c) $u = 0$ for $x = 0$
(d) $u = 0$ for $x = l$

By trial it is seen that $u = be^{-\beta z} \sin \beta x$ is a particular solution of equation (1) which also satisfies conditions (b) and (c), where b and β are constants, and it is worth further investigation for possible adjustment to the other two conditions. Condition (d) can be met by putting $\beta = m\pi/l$. Equation (1) is linear, so a constant times a solution is a solution, and the sum of any number of such solutions is a solution. Hence giving m all possible values, and putting $e^z = \exp(z)$ for ease in printing we get a solution

$$u = \sum_{m=1}^{m=\infty} b_m \exp(-m\pi z/l) \sin(m\pi x/l)$$

When $z = 0$ this becomes

$$u = \sum_{m=1}^{m=\infty} b_m \sin(m\pi x/l)$$

and it must reduce to $f(x)$ to fulfil condition (a). This can be done by adjusting the values of the constants b in this series so that the sum will be $f(x)$ and by a theorem in Fourier series this will be so if the constants are given the values

$$b_m = \frac{2}{l}\int_0^l f(x) \sin(m\pi x/l)\, dx$$

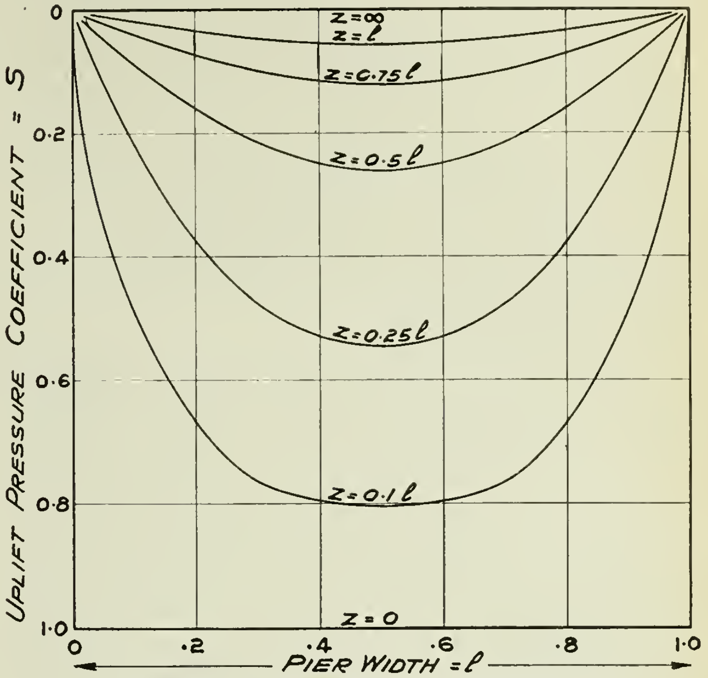
Putting $f(x) = h$ the successive values of b are found by integrations, and are then substituted in the solution to give

$$u = (4\ h/\pi)\Big(\exp\ (-\pi z/l)\ \sin\ (\pi x/l) + \frac{1}{3}\exp\ (-3\ \pi z/l)$$
$$\sin\ (3\ \pi x/l) + \frac{1}{5}\exp(-5\ \pi z/l) \sin\ (5\ \pi x/l) + \ldots\ldots\Big)$$
$$= h\,S$$

an infinite series in two variables from which the temperature at any point can be calculated by substituting the appropriate values of the coordinates. The convergence is rapid, so numerical work is not difficult with proper tables of functions. Care should be taken with the signs of the sine terms as they change with the size of the arguments.

For our purposes, u is taken as the pressure at any point, and h as equal to the external hydrostatic pressure on the joint upstream, both measured in feet of water. Actually h might be taken a little smaller, because it is not measured to a free surface, but the error is small, and again on the side of safety.

A calculation of the pressures at different points on the base downstream from the gates is shown in Fig. 2. The pressure along the axis of the joint is seen to decrease rapidly with the distance, so that it is less than 5 per cent of the head at one pier-width downstream from the gates. This is of an order comparable with the uncertainty in the unit weight of the pier material, so uplift further downstream can be neglected. To escape this approximation the solution can be made to apply to a pier of any finite length by adding a set of hyperbolic function multipliers, but the



CURVE OF UPLIFT COEFFICIENT AT VARIOUS POSITIONS ON HORIZONTAL JOINT

Fig. 2.

process of taking a joint of infinite length and neglecting the unimportant pressures gives a slightly larger uplift, an error again on the side of safety.

By graphical integration, the uplift on the square area mentioned, taking w as the weight of a cubic foot of water, is found to be 0.26 whl^2 lb. acting at a distance 0.263 l feet from the gate seats. For practical purposes one would probably take both these numerical coefficients as 1/4.

The problem has then been solved by a method which appears rational. If the objection be raised that it is a lot of trouble to take over a small point, the answer is that it represents the cost of only a few yards of concrete, a very small proportion of the waste caused by an arbitrary assumption which would probably err on the side of excessive safety through apprehension of the associated uncertainty.

The same principle of course applies to other forms of joints which might occur at intakes or unusual corners. If the solution can be taken or easily built up directly from a good text book as in the present case, little time need be spent: if not, recourse to the electrical analogy of potentials between suitable conductors in a tray of salt solution will give satisfactory results much more quickly than would a purely analytical treatment.

Abstracts of Current Literature

Economics of High Pressure Steam for Paper Mill Power Plants

By Alf Kolflat, Paper Trade Journal, September 15th, 1938.

Abstracted by H. O. Keay, M.E.I.C.

Economics of high pressure steam for paper mill power plants is the subject of an article of especial interest to engineers and operators who are confronted with the problem of a new or revamped steam plant in the paper industry.

While steam pressure of 1,200 lb. per sq. in. and temperatures of 925 deg. F. are becoming quite common in the central stations of the utility companies, in the mills of the paper industry pressures of 450 lb. and 650 lb. and steam temperature of 725 deg. F. may be considered high in comparison with the 100 lb. and 150 lb., with no superheat, in most of the older plants.

In discussing the heat economy of high pressure steam in general, the author differentiates between "Condensing Power," characteristic of the central stations, and "By-Product Power" generally employed by industrial plants where a considerable demand for lower pressure steam for heating and drying processes obtains. When steam is used for the generation of power alone, approximately one-third of the heat in the steam can be converted into power and the remaining two-thirds of the heat is lost to the circulating water in the condensers. On the other hand, when steam is generated not only for producing power but also to supply process and heating requirements, then most of the heat which otherwise would be discharged to the condensers can be used in the process. If all of the steam from the engines or turbines is used in the process, then the fuel requirement for the generation of "by-product power" is roughly one-third of the fuel requirement for condensing power.

On account of the considerable demand for power in the production of mechanical pulp in most paper mills, there are few cases where the ratios between power and process steam are such that all of the power required can be made as "by-product power," so a part of the total requirement has to be made in the condensing steam plant or obtained through purchase of hydro-electric power.

In his calculations the author has selected 150 lb. gauge pressure and 450 deg. F. steam temperature as a basis, partly because this is the practical safe limit for the cast-iron fittings and valves with which most paper mills have been equipped, and partly because this pressure-temperature relationship is well suited to the different processes involved. On the assumption of constant turbine efficiency, three interesting sets of curves are plotted, showing the relationship: (1) between steam pressure, steam temperature and heat content in relation to pressure, (2) between steam pressure and relative turbine water rates for various throttle pressures and exhaust pressures, and (3) between steam pressures and relative heat rates for condensing cycle at 2 in. Hg. exhaust pressure.

Variation in turbine efficiency with size and steam pressure is noted, and curves are drawn showing the relationship between steam pressure at the throttle and turbo-generator basic efficiency for units of 1,000 kw., 3,000 kw. and 7,500 kw. capacity.

The adoption of high pressure steam for industrial turbines has led to the use of automatic extraction pressure machines wherein a variable amount of steam can be extracted for process uses at any desired intermediate pressure which can be maintained at all loads. In this connection the author points out that the machine should be as well adapted as possible to the prevailing steam flow conditions of the particular plant, and that where a number of extraction pressures are desired a better over-all turbine room efficiency will usually be obtained if these openings are divided between different machines instead of designing each machine for more than one automatic extraction opening. Curves are drawn showing the relationship between steam pressure and relative over-all plant heat rate, and the cost of different size steam generating units as well as construction costs of complete turbine and boiler plants.

While emphasizing the fact that each installation is a problem in itself and can only be analyzed as such, the author arrives at the following general conclusions:

1. For a new paper mill power plant with approximately 2,500 kw. turbine capacity and approximately 75,000 lb. per hr. steam capacity, the most economical steam pressure is between 400 and 450 lb. gauge pressure.
2. With a turbine room capacity of 5,000 kw. and a boiler room steaming capacity of approximately 150,000 lb. per hr., the most economical steam pressure is between 600 and 650 lb. gauge, but the net annual saving, after allowing for fixed charges, over that which would be obtained with the 450 lb. installation is small.
3. With a turbine room capacity of approximately 12,500 kw. and a boiler room capacity of 375,000 lb. per hr., the maximum economy is obtained with a steam pressure approximating 850 lb. gauge, but the net savings over 650 lb. gauge pressure are small.

Transmission Line in Mountainous Country

By Earl Baughn, Electrical World, July 2nd, 1938

Abstracted by H. S. Grove, A.M.E.I.C.

A 53-mile, 110-kv., wood-pole transmission line, built in mountainous country and along the almost inaccessible rocky shores of a lake, is described by the author. The conductor, 0.444 in. dia., is composite stranded of 5 strands, galvanized S.M. steel, 2 strands tinned H.D. copper, with a breaking strength of 9,000 lb. and a conductivity equivalent of No. 3 copper. Joints are made with twisted copper sleeves, tinned to prevent contact between the copper of the sleeve and the galvanizing of the steel.

Structures are, in general, two-pole H type, class 3, pentrex treated, Western red cedar. Horizontal spacing is 10 ft. 6 in. on all spans up to 1,800 ft., increased to 15 ft. on longer spans, the maximum span being 2,683 ft. Loading is N.E.S.C. medium and an average span of 938 ft. is obtained. Small angles are made on modifications of the two-pole tangent structure, and large angles on three-pole structures. Dead-end structures are used only where necessary. At 1½ mile intervals a "storm structure" is employed, consisting of a modified tangent H structure with suspension insulators on double crossarms good for full conductor tension and guyed four ways. Where double crossarms are bolted together with wooden blocking between, split timber-rings are used. These serve the double purpose of giving shear strength and of separating the timber by ¼ in. to arrest decay.

Side hill structures are framed with crossarms parallel with the ground where the slope is less than 2 to 1, thereby saving the cost of longer poles for the downhill side. On steeper side hills crossarms are framed at two levels 5 ft. apart. At two places it was necessary to string the line along the face of a cliff. Here the conductors were suspended from 8 in. pipe booms extending horizontally and guyed to rock anchors.

There is one lake crossing of 4,651 ft. span, with the incoming and outgoing line making approximate right angles with the line. Crossing structures consist of three 50 ft. steel masts at each shore, guyed three ways. The crossing conductors are 30 per cent all copperweld, 9/16 in. dia., with a breaking strength of 25,000 lb. The conductor separation is 50 ft.

Engineering and Health

By Harvey N. Davis, Mechanical Engineering, September 1938

Abstracted by L. M. Arkley, M.E.I.C.

In an article on Engineering and Health Mr. Davis, who is President of the American Society of Mechanical Engineers, compares, in an interesting way, the relative merits of the doctor and the engineer as promoters of health. At first thought it would appear that the medical man would have the better of the argument, but the author makes out a very good case for the engineer. In the first place he calls attention to the great personal appeal of the doctor, who comes to the patient at a time when weakened resistance and uncertainty of the future renders the ministrations of the doctor a wonderful help; not so the case of the engineer, who is not dealing with the individual but with the health of masses of people, the majority of whom never know to whom they are indebted for their freedom from disease or improvement in health.

In making this comparison there are two factors which must be considered and the product of these factors gives the final result; there is an intensity factor and a quantity factor. The intensity factor of the doctor with his personal contact may be very high, while the quantity factor of the engineer dealing with masses of people may be much higher than that of the doctor.

Sanitation

The greatest contribution of the engineer to the promotion of health lies in the field of sanitation and under this head may be included water supply, sewerage and sewage disposal plants. By bringing abundant supplies of pure water into towns and cities, a boon that only those who have lived in arid regions can appreciate, by building sewers and sewage-disposal plants, by modern methods of refuse collection and disposal, by the invention and fabrication of modern plumbing fixtures which make cleanliness easy and by a patient persevering fight against atmospheric and stream pollution, engineers have undoubtedly saved many lives and relieved the world of much suffering.

Diet

In the important field of diet the engineer has played an outstanding part. By the development of tin plate and of intricate machines for fashioning it, he has made possible the canning of food on a tremendous scale and thus increased the distribution of health giving materials. Along this same line may be mentioned the invention and manufacture of refrigeration machines and their application to cold-storage warehouses, to trains, ships, motor trucks and all means of transportation of perishable food products. By these means engineers have profoundly affected the dietary habits of whole nations and have made possible the elimination of deficiency, diseases, and of the lowered resistance to infection that malnutrition causes.

Housing

In the matter of housing engineers have improved both the materials and methods of construction; they have flooded houses, offices and workships with eye-saving light, they have provided the central heating plant and air conditioning is just around the corner.

National Standard of Living

The author states that "the standard of living of a community is nothing else than its production of goods and services per capita per year." And the above depends on the production per man hour of expended labour and this can be increased by giving the producer help in the form of inanimate slaves such as horse-power and kilowatts (1 hp. per day = work of 30 men) and also by giving him better tools with which to work. Only by such means as these can the standard of living of any community be permanently raised and this in turn will raise the health of the whole population and only the engineers can do this.

Mental Health and Physical Health

All that has been said so far concerns our physical health, but what is of even more importance is our mental health. Always important in itself it often influences if it does not completely dominate physical conditions. There are at least two contributing factors to mental ill-health in which engineers should be interested. The first depends on the fact that a large proportion of men and women spend more than one third of their waking hours in an industrial job of some sort.

Enjoying one's work is greatly enhanced by, if it is not actually dependent on, having a job that one can do well. This is where the engineers come in. They are beginning to feel their way into new fields of management which involve both adjusting jobs to their holders and assigning men to the right jobs, and the effect of this is to greatly improve the mental health of the workers. The second and more serious cause of mental ill-health is what might be termed social insecurity. There is no worry so insistent as that which besets a self-respecting industrial worker and his family if there is danger of him losing his job, so engineers should concentrate on this question and try to improve working conditions so as to give greater security to the workers.

Speed in Relation to Signalling

Abstract of an article appearing in The Railway Gazette, October 7th, 1938, which in turn is an abridgement of a paper by A. W. Woodbridge, M.S.C., read before the Institution of Railway Signal Engineers.

Abstracted by J. L. Busfield, M.E.I.C.

The fundamental axiom of train working, that one train only shall occupy a section of track at one time, implies that a following train can be brought to a stand before colliding with it. The article discusses the factors involved in bringing a train to a stand, which in turn have a considerable bearing on the capacity of a railway line.

There are three distances to be considered when stopping a train, the first is what is known as overlap, being the nearest point to which a following train can be allowed to approach under block signal work, and may vary from practically zero to a quarter mile. The second is braking and sighting distance, the former being the actual distance which a train can be brought to a stand, the latter corresponding to the time in which a driver can see the visual signal and take action. Visual signal reaction times are discussed, together with the corresponding effect in train movement.

While the stopping of a train is of very great importance, the effect of the signalling system in through running must not be overlooked, and formulae are developed in connection with this phase of the problem, especially for determining the minimum distance a first train must travel before a second enters its section.

Britain's First Oil Well

The Petroleum Times, August 13th, 1938.

Abstracted by A. A. Swinnerton, A.M.E.I.C.

Following a two-year search for oil in Great Britain, the first well has been struck at Dalkeith near Edinburgh, Scotland, according to an article in the August 13th issue of The Petroleum Times. This well, known officially as the Anglo-American Company's Midlothian No. 1, first struck oil on June 27th at a depth of 1,733 ft. In the 5-day period, July 4th to 9th, 42 barrels were produced by "swabbing." In order to increase production, it was decided to "shoot" the well. The hole was cleaned out, and on July 14th the well was shot with a 450-lb. charge of blasting gelatine and dynamite. The well was then cleaned out to the 1,760 ft. depth by a rotary drill, and pumping was started. Pumping 16 hours a day, the well yielded 59 barrels of clean oil in 9 days.

A sample of the oil was sent to the Anglo-American Company's laboratory for analysis, the published result being:

Specific gravity at 1.5 deg. C......	0.823	
Petrol...........................	11	per cent
Kerosene.........................	13	" "
Gas oil, estimated................	10-15	" "

and the remainder, fuel oil.

The Anglo-American Company are now going to further test the zone between 2,050 and 2,150 ft., where promising shows were indicated by test boring.

Automatic Operator for Water-gas Plants

The Engineer, September 9th, 1938

Abstracted by A. A. Swinnerton, A.M.E.I.C.

An illustrated article in "The Engineer" of September 9th, 1938, describes the arrangement and details of a machine for the automatic operation of small and medium sized water-gas plants. The device incorporates a rotary cam mechanism, which is rotated intermittently by a motor gear unit, the circuit of which is periodically closed and interrupted to start and stop the motor. A solenoid switch is provided for switching on the motor current, the closing of the solenoid switch being effected by a time clock at predetermined times in accordance with the requirements of the operation of the plant; the motor is switched off by means of a commutator.

With water-gas plants, which are not automatically charged with fuel, there is a setting of the various operating valves, called the "no run" position, at which it is usual to shut down the plant or charge it with fuel. The automatic control mechanism herein described is adapted to effect the stoppage of the mechanism automatically at the "no run" position when desired. The closing of the solenoid switch is effected at predetermined intervals by a contact clock. This clock contains a time wheel, which is rotated at a uniform speed by an eddy current motor; on the periphery of this time-wheel there are several adjustable strikers. These strikers close the contact for one or two seconds; this starts the motor which rotates the valve-operating cams, when the shaft has made a partial revolution the contact is broken and the motor stops. The next partial rotation and operation of the valves is effected as soon as the succeeding striker on the time-wheel closes the time switch contacts.

To effect the stoppage of the motor when the "no run" position is reached, an additional contact disc is provided, which is in circuit with a lamp or other visual indicator. When the lamp goes out, the attendant opens a switch, stopping both the time clock and the automatic operator. This enables the plant to stand in a condition in which it can be safely clinkered, charged with fuel, or left idling. When the plant is to be re-started, the attendant rotates the cam shaft by hand from the "no run" to the "blow" position, and then closes the switches. The plant is then put on automatic operation and commences to carry through the cyclic operation according to the setting of the time clock strikers. Suitable provision is also made for operating the valve mechanism, by hand, if necessary.

Active Carbon from Bituminous Coal

The Engineer, September 9th, 1938

Abstracted by A. A. Swinnerton, A.M.E.I.C.

A new process for the production of active carbon from graded lump coal has been developed as a result of joint investigations by the Fuel Research Organization of the Department of Scientific and Industrial Research and the Chemical Defence Research Department. An account of the inquiry is given in a Fuel Research Technical Paper issued by the Department. Active carbon has been produced in England for some time by a process which involved the very fine grinding of the coal, briquetting at high pressure without a binder, carbonizing at a relatively low temperature, and activating the resulting coke with steam. The investigation was undertaken with the object of using carefully graded lump coal so that the necessity for grinding and briquetting would be eliminated. It was found that coals were available in that country which had, as a natural property, the correct degree of caking power to give a strong hard coke, without a large cell structure, which is necessary for producing the active carbon. In the early stages of the investigation, when the quantities of coal for trial were usually small, coal was carbonized at about 480 deg. C. in small-scale retorts at the Fuel Research Station at Greenwich and the resultant coke activated in laboratory apparatus at the Chemical Defence Research Department's laboratories. In the later stages of the investigation, when sufficiently large supplies of coal were available, the activation was carried out in semi-technical plant at the Fuel Research Station. For full-scale experiments two retorts, erected for experiments on the production of smokeless domestic fuel, were used. Here it was found that a coke prepared at 650 deg C. gave just as active a carbon as that prepared at 480 deg., while the strength of the product was greater. In tests made to ascertain the suitability of the carbons for industrial use, it was found that in connection with solvent recovery the activity of the best carbon made was about 75 per cent of that of good commercial carbons now available. Other tests showed the new product to be almost equal and in some cases superior to the carbon commonly employed.

FIFTY-THIRD

ANNUAL GENERAL MEETING

and

GENERAL PROFESSIONAL MEETING

Under the Distinguished Patronage of

HIS EXCELLENCY THE GOVERNOR-GENERAL

OTTAWA— TUESDAY AND WEDNESDAY FEBRUARY 21 and 22, 1939

Every member of The Institute should try to make plans to attend this meeting. The hospitality of the Ottawa Branch has been proved at former meetings, and members are assured that this meeting will be no exception. Attendance at an Annual Meeting is one of those occasions at which members are given the opportunity not only of enhancing their engineering knowledge, but also of renewing old friendships, establishing new acquaintances. The meeting offers a change from the daily routine of dealing with the forces of nature to the more human side of engineering affairs which should be of no little benefit to all members of the profession.

There will be many special guests of The Institute and prominent visitors representing American and other engineering societies.

FEATURES

Report of Council for 1938

Retiring President's Address

Scrutineers' Report

Induction of New President

The Institute Banquet

A comprehensive series of Papers on The Western Drought Situation and other important subjects

Prize, Medal and Honorary Membership Awards

Smoking Concert

Luncheons

Watch for further announcements in The Journal

THE ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

VOLUME XXI NOVEMBER, 1938 No. 11

The Institute and the Young Engineer

The welfare of the recent graduate in engineering has always been a matter of concern to the senior engineer. The amount of this concern has not been a fixed quantity, but has varied between rather high and low limits, but to-day the interest is again approaching the upper levels, and within The Institute has become a matter of considerable importance. Much consideration has been given to it and attempts are being made now to formulate plans that will enable The Institute to do a real work for the young man within the organization.

The subject is not an easy one with which to deal. There are many factors that enter into it, which are not apparent at first glance, and the further the investigation is carried the more complicated become the considerations. It is not easy to determine how far this interest in the recent graduate should go; which of his several needs should be catered to first; how this assistance should be made available; who shall carry on the work, and how it can be made to apply with equal facility to all parts of Canada. These are some of the points which have to be settled before any real progress can be made, and which are being wrestled with at the moment.

Similar problems exist in other parts of the world, and one of the first approaches to the Canadian situation is a study of what has been done or is being done in other places. Much of the history of other movements has already been digested, and much more lies ahead for further study, but an unusual opportunity to see from the inside what is being done along these lines in the United States was afforded The Institute recently in New York as an outcome of a secretarial meeting in Washington during the Seventh International Management Congress.

The Institute was invited to send observers to the annual meeting of the Engineers' Council for Professional Development, well known as the E.C.P.D., in order that the deliberations and findings of that body which is dealing with the same problems in the States that we have in Canada, might be made available to The Engineering Institute of Canada. This was a splendid privilege. To sit in with a group of engineers as prominent as this in educational matters and in practice, backed up by the support of the leading professional societies of the country, was an opportunity that does not come to many people. The Institute is greatly indebted to the E.C.P.D. for their helpful attitude, and once more makes grateful acknowledgment of an international relationship that is priceless in its value.

A meeting that was attended by such educationalists as the presidents of the Massachusetts Institute of Technology, the Carnegie Institute of Technology, the Polytechnic Institute of Brooklyn, the Case School of Applied Science, and deans of such schools of engineering as Columbia, Cornell, Yale, Missouri, Kansas, by such engineers as the president of the Bell Telephone Laboratories and vice-president of the American Telephone and Telegraph and winner of the 1938 award of the John Fritz Gold Medal, the highest American engineering honour, was certain to contribute great things to the cause of engineering education and welfare.

The representative of The Institute gained a great insight into the operations of this important body that is trying so hard and doing so much to improve conditions for the student and the engineer. The policy of The Institute will be greatly affected by what was learned at this all-day meeting of the E.C.P.D. The Journal hopes at a later date to publish much material on this important phase of Institute activities.

Engineers and the Peace of the World

EDITOR'S NOTE:—At this time of stress, no apology is needed for presenting to our members the following timely and thought-compelling extracts from a recent leading article in the editorial columns of *The Engineer.*

"The war that never began is over. The gas barricades in city offices are down again, the blankets are stowed away, and the sand bins are emptied. We all are sleeping once more peacefully in our beds; the conversation in omnibus and train has no longer a sable refrain, and the country is returning to its normal vocations. Only here and there may you hear a long-faced pessimist dolefully proclaiming that we have only put off the evil day, as if, for all the world, that were not a good thing in itself. Ills that are postponed long enough may never come at all, unless engendered by our own folly or supineness. Let us then rejoice that one evil which was waiting at the window sill, nay, tapping at the window, has been exorcised. Let us seek peace and ensue it, not by living in continual suspicion and dread of our neighbours, but by winning their esteem and their confidence and extending to them an equal measure of sympathy. That is the gold Mr. Chamberlain aimed at in his Anglo-German agreement. His arrow will never reach it if it is winged with distrust and tipped with the hatred of a political system which differs from our own . . . There is more hope in the present solution than in any that might have been wrought . . . through the destruction of great cities, invaluable treasures of art, the retardation of the world's progress towards contentment, and the sacrifice of millions of those young lives in whose laps the future lies. Tell us not that this Peace will break down as others have broken down, that aggressors will arise, and that the force of arms will once again embroil the world in a greater Armageddon . . .

"Mr. Chamberlain has shown us that a better way is possible, but his never to be too greatly praised effort would not have achieved success had not all the peoples of Europe been opposed to war. It would be fruitless now to discuss the remarkable and by many unanticipated resources for the protection and organization of this kingdom against invasion which the crisis revealed; just as it would be valueless to discuss the resolution with which the people were determined to pursue the war had it come upon them. The bald fact, which there is no blinking, is that every nation of Europe is terrified at the thought of a war carried on with all the horrid means which scientists and engineers have evolved. Above all, the aeroplane, with its cargo of deadly gas and incendiary bombs, has brought such terror to the peoples of Germany and Great Britain, with their dense populations, that neither nation would readily enter into conflict with the other.

"In a sense, therefore, it may be said that we have come one step nearer that consummation so often foretold when war would have such terrors that it would never be incurred. For that we have, paradoxically, to thank the scientists and engineers. If they have not made war impossible they have made it well nigh unthinkable. And, having got that far, cannot they carry their beneficent work to a further and better stage? It is the merest truism to say that there is no single industry that does not rely and depend upon the services of engineers. The rise, progress, and development of all nations is in their hands. Within the ambit of their proper functions they, from all nations, meet in friendly concourse for the discussion of technical questions. Science binds them into a single whole. Cannot that great unity be turned to an international purpose of incalculable importance and grandeur? Cannot it be used for the perpetuation of peace? It would be inopportune to discuss at this stage the manner in which the combined influence of the scientists and engineers, industrial and professional, of all nations might be exerted to prevent the outbreak of hostilities, but it is not inopportune to suggest that the potential power which resides in the internationality of technical science is so great that its ability to enforce peace, even upon military dictatorships, is incalculable. Yet we look not so much to its power to restrain force, as upon a better and greater power, the power to engender such friendliness and unanimity between all nations that the thought of war would be intolerable to all alike. After all is said and done, and whether a nation be democratic, autocratic, or republican, it is in these days the people themselves who must suffer and prosecute the war, and it is therefore to their friendliness and to their mutual toleration that we must in the end look for the reign of perpetual peace. It is our confirmed belief that in the encouragement of better international understanding the engineer, with his mind trained to reason, can play, and will play, a splendid part."

—*The Engineer*, October 7th, 1938.

The St. Lawrence Waterways

Proposals as Affecting the Dominion of Canada

At a recent dinner meeting of the Hamilton Branch, held in honour of Dr. Challies, the speaker called attention to certain provisions in the St. Lawrence Waterways Treaty in the form now being suggested in the United States, which, in his opinion, are open to serious objection when looked at from the Canadian point of view.

The following notes give in brief the features in regard to which he considers the new proposals detrimental to Canadian interests. None of these are concerned with the engineering phases of the St. Lawrence development, as regards which there is practical unanimity. Certain of the new proposals, however, bring up legal and economic questions which vitally affect the status of the Dominion and the purse of every Canadian taxpayer.

Many years in the service of the Dominion government in charge of federal water power branches, and consulting engineer to the Department of External Affairs regarding international waterway matters, Dr. Challies is recognized as an authority upon administration, investigatory, and international features of water power resources. He remarked that in the new proposals the basic conclusion, payment in proportion to benefit, which was reached by the International Joint Commission of 1921, has been thrown overboard, and in its place parity of capital expenditure and less than parity in maintenance and operating charges has been suggested. Thus the first point raised by Dr. Challies was that the fundamental principle of sharing cost in proportion to benefits has been abandoned. In his opinion a fifty-fifty division of the capital cost (as now proposed) would be unfair to Canada because no credit is given the Dominion for $34,000,000 spent upon a ship canal below Montreal. Only partial credit is given for the $70,000,000 spent by this country on the St. Lawrence and early Welland canals, all of which have been free and open to and extensively used by American shipping.

Next the speaker pointed out that Canada would be burdened unduly by the proposal that each country will for ever maintain and operate the canalization works in its own territory. An official estimate of these charges indicated that Canada would have to pay about $2,000,000 per annum and the United States $750,000. It had been estimated that the American traffic which may be expected to use the new waterway will be from three to eight times as great as the Canadian. Thus the relative annual expenditures contemplated seem entirely out of line with the benefits obtained.

The speaker further considered that there were two serious legal objections to the proposed treaty. At the present time the United States had no legal right, by treaty or convention, to the use of the St. Lawrence canals. The Roosevelt treaty, however, would in the most definite and complete manner give the United States perpetual equal rights with Canada in the use of all the projected St. Lawrence canals, and this enlargement of American rights in the Canadian reaches of the St. Lawrence would be strongly resented in the province of Quebec. Another legal objection to the treaty was that Canada's persistent protests against the withdrawal of water from the Great Lakes through the Chicago diversion canals would be compromised in a way greatly favouring the United States.

Dr. Challies highly commended the action of the Hamilton Chamber of Commerce in establishing a committee headed by F. I. Ker, M.E.I.C., for the purpose of making a special study of the proposals for the Great Lakes to Ocean Waterway.

Joint International Meeting

Invitations have been received, and accepted, from the American Society of Civil Engineers and American Society of Mechanical Engineers to participate with them in meetings with the English Institutions of Civil and Mechanical Engineers, to take place in New York in September of next year, during the World's Fair. So far not many details have been completed, but the portions of the general plans which have been disclosed, indicate that it will be a most unusual occasion.

Preliminary discussions have already taken place with the mechanicals in Washington and with the civils in Rochester, and on October 21st, a real committee meeting was held at the Engineers' Club in New York. The Institute was represented by President Challies, Past President J. M. R. Fairbairn, Chairman of Committee on International Relations, the Presidential nominee H. W. McKiel and the General Secretary. The committee in charge for the American Society of Civil Engineers is headed by Malcolm Pirnie, Vice-President of the Society.

It is expected that another meeting will take place in late November or December, at which all plans will be finalized. At that time a detailed announcement will be made in The Journal. In the meantime members are advised to keep the week of September 4th, 1939, clear of other engagements. The World's Fair is said to be the greatest ever yet attempted and this joint meeting of engineers seems to deserve the same enthusiastic description.

Headquarters Staff

Organization

Council having decided to fill, early in 1939, the vacant position of assistant to the general secretary of The Institute, has requested the Executive Committees of the branches to advise the General Secretary by the 15th of December of any branch member who may desire to be considered for the vacancy. Any interested member of The Institute should communicate at once with the General Secretary of The Institute or with the Secretary of his branch who will be glad to furnish application forms. As it is the desire of Council that all applications be passed upon in the first instance by the Executive Committee of the applicant's branch, it is necessary that all applications reach Headquarters through a branch secretary. Should any applications reach Headquarters direct, they will be promptly remitted to the secretary of the applicant's branch for the preliminary consideration of that Executive Committee.

Application forms and other relative information have been placed in the hands of the branch secretaries. For the guidance of prospective candidates the following list of desirable qualifications is given:

The applicant should be—

1. A member of The Institute.
2. A member of a Provincial Professional Association.
3. A graduate in engineering of a recognized Canadian University.
4. Actively interested in Institute affairs.
5. Experienced in journalism.
6. Experienced in public speaking.
7. Of good appearance, pleasant personality, and good health.
8. Proficient in French or prepared to become so.
9. Between the ages of thirty and thirty-five.

Presidential Activities in October

At the joint meeting of the Montreal Branch of The Institute with the Montreal Chapter of the American Society of Heating and Ventilating Engineers on the evening of October 6th, the President had an opportunity to welcome to The Institute's Headquarters one of the newest professional engineering bodies with international membership. An interesting feature of this occasion was the fact that the new president of the American Society of Heating and Ventilating Engineers, Mr. Holt Gurney of Toronto, was a classmate of the President.

On Saturday, October 8th, accompanied by Councillor Newell and the General Secretary, the President attended a supper meeting of the St. Maurice Valley Branch at the Cascade Inn, Shawinigan Falls. Following supper, the Chairman of the Branch, Mr. Ward, skilfully conducted a round-table discussion regarding the "Status of the Engineer," participated in by the President, Councillor Newell, Vice-President Keay, Councillor-elect Wardle, Branch Vice-Chairman Bradshaw, John Fregeau and the General Secretary.

At Rochester, on Thursday, October 13th, the President and the General Secretary conferred with officers of the American Society of Civil Engineers regarding arrangements for a congress of engineers in connection with the World's Fair in New York next September, under the auspices of the Institution of Civil Engineers of Great Britain, the American Society and the Canadian Institute.

Friday, the 14th of October, will never be forgotten by J. B. Challies. That afternoon his Alma Mater conferred upon him the honorary degree, Doctor of Engineering. His "Graduating Class," as His Excellency the Governor-General so aptly termed it, consisted of the Lady Tweedsmuir, the High Commissioner to Great Britain from India, Malik Sir Firozkhan Noon, the Rt. Hon. Ernest Lapointe, and President Fox of the University of Western Ontario, all of whom were awarded LL.D.'s.

President Cody in presenting Mr. Challies read the following citation:

"The engineer has played a notable part in developing and conserving the material resources of Canada. In a country like Canada which has in its rivers and lakes about half the fresh water on the surface of the globe, the hydraulic engineer is indispensable to the generation and application of power derived from descending water. Today the University honours an outstanding member of this profession in the person of John Bow Challies, one of our graduates of the ancient vintage of 1903. Soon after his graduation he entered the Dominion Civil Service in the Department of the Interior, water-power branch, of which he ultimately rose to be chief shortly before the War. He built up a highly efficient organization, which included a hydrographic survey of the rivers and water supplies of our vast Dominion. Later this developed into the Water Resources branch of which he became director. He was recognized as an authority on the conservation of water power resources, especially in their international significance, and has contributed to scientific magazines many articles on this subject.

University of Toronto Convocation for the Conferring of Honorary Degrees.

Left to right: Right Honourable Ernest Lapointe, K.C., B.A., LL.D., Minister of Justice and Attorney-General of Canada; John Bow Challies, C.E., M.E.I.C., President of The Engineering Institute of Canada; Malik Sir Firozkhan Noon, K.C.I.E., M.A., High Commissioner for India in Great Britain and Northern Ireland; Henri Jordan, Conductor of the Schubert Choir of Brantford, and William Sherwood Fox, M.A., Ph.D., D.Litt., LL.D., F.R.S.C., President of the University of Western Ontario.

"He retired from Government service to become a departmental manager of the Shawinigan Water and Power Company in charge of water resources, and later assistant general manager.

"This year he has by his fellow engineers been elected to be president of the Engineering Institute of Canada—the highest position—in the gift of his profession.

"I present to you John Bow Challies, a great civil servant, an eminent hydraulic engineer, and the official head of the engineering profession in Canada, that he may receive at your hands the degree of Doctor of Engineering, *honoris causa.*"

After Convocation, accompanied by Past-President Gen. Mitchell, Vice-Presidents McCrory and Buchanan, several Councillors and Chairman Sisson of the Toronto Branch, and the General Secretary, he motored to Hamilton where some 150 engineers from south-western Ontario were gathered to celebrate his so recently acquired honour. The following evening, the President was host at a dinner at the University Club, Toronto, tendered the members of the Faculty of Engineering and the executive officers of the various engineering organizations centering in Toronto. Some 66 engineers participated in a round-table discussion regarding the contribution which the various engineering bodies could make in advancing the prestige of the profession and in increasing its usefulness to the public.

On Thursday evening, October 20th, at a house-warming to celebrate the renovations at Headquarters, the President introduced the presidential nominee, Dean H. W. McKiel, to a large gathering of the Montreal Branch.

On Friday, October 21st, a delegation from The Institute, consisting of the President, Past-President J. M. R. Fairbairn, the presidential nominee, Dean McKiel, and the General Secretary conferred in New York with a committee of the American Society of Civil Engineers regarding a Congress of British, American and Canadian engineers to be held in New York in September, 1939. By invitation this delegation was afforded an opportunity to sit in upon an important conference of representatives of the Founder Societies and other important engineering organizations in the United States, regarding the Engineering Council for Professional Development.

The President and the presidential nominee, Dean McKiel, accompanied by a large delegation of Montreal engineers, attended a complimentary banquet of the Kingston Branch to Prof. Malcolm on Saturday evening, October 22nd, in celebration of his appointment as Director of the Department of Civil Engineering of Cornell University.

On October 24th, President Challies left to visit the Western Branches.

Meeting of Council

A meeting of Council was held at Headquarters on October 7th, 1938, with President J. B. Challies in the chair, and ten other members of Council present.

Resolutions were passed recording the regret of Council on hearing of the deaths of H. L. Swan, M.E.I.C., of Victoria, an active member of Council during the years 1934 to 1937, and C. C. Ross, M.E.I.C., of Calgary, lately an administrative officer of the government of the province of Alberta. The Secretary was directed to convey these messages of sympathy to the families of the deceased members.

The President reported that following the award of the Sir John Kennedy Medal to Past-President Dennis, and as Colonel Dennis would not be able to attend the forthcoming Annual Meeting, arrangements were being made to present the medal to him during the President's forthcoming visit to the Victoria Branch.

Arrangements were completed for a joint committee of Council and the Ottawa Branch to look after the preliminary arrangements for the various functions of the forthcoming Annual General Meeting at Ottawa.

Vice-President Buchanan reported that a most enthusiastic and successful joint meeting of the Border Cities and London branches had been held in Sarnia on September 24th, with a full attendance from those branches and representatives of the Sault Ste Marie branch. This report was received with appreciation.

The results of the ballots of corporate members of The Institute in Saskatchewan and of members of the Association of Professional Engineers of Saskatchewan were reported, showing in each case an almost unanimous vote in favour of the proposed agreement. Following this report, it was unanimously resolved that the President and the General Secretary be duly authorized to sign the agreement between The Engineering Institute of Canada and the Association of Professional Engineers of Saskatchewan, the ceremony to take place at Regina during the President's forthcoming western visit.

The President expressed the hope that as many members of Council as possible would make an effort to attend the special dinner meeting of the Kingston Branch to be held on October 22nd to celebrate Dr. W. L. Malcolm's appointment as Director of the School of Civil Engineering at Cornell University.

F. S. B. Heward, M.E.I.C., The Institute's representative on the National Board of the Canadian Chamber of Commerce, presented an interesting report of the recent Convention of the Chamber at the Seigniory Club, which he had attended with the President. He drew attention to the excellence of the papers which had been presented, and the discussions thereon. The President remarked on the valuable brochure which had been prepared by the Chamber of Commerce containing a summary of all the briefs which had been presented to the Rowell Commission on Dominion-Provincial Relations. It was decided that this brochure should be circulated among members of Council and branch chairmen.

A report was presented from Mr. Busfield, chairman of the Publication Committee, announcing that the winner of the competition for the design of a cover for the Engineering Journal was John G. Hall, M.E.I.C., and that abstracts had already been received from some of the recently appointed advisory technical editors.

The Secretary reported that replies had now been received from twenty branches regarding the proposed reorganization of Council as suggested by Professor Spencer's Committee on Membership and Management. Twelve of the branches who had replied had indicated their approval of the proposal. It was decided that all replies received should be referred to Professor Spencer's committee for consideration.

A resolution was presented from the Montreal Branch commenting with approval on the larger number of Council meetings which were now being held away from Headquarters, and the wider circulation which was being given to minutes of Council.

Two resignations were accepted; three reinstatements were approved; the names of five Students in arrears were removed from the list of members; four special cases were considered and decisions reached in accordance with their merits.

Approval was given to the recommendation of the Finance Committee that a list of members be published in the December Journal.

Discussion took place regarding the appointment of an assistant to the General Secretary, after which it was resolved, with one member of Council dissenting, that steps should be taken to secure the names of suitable candidates for this appointment, the appointment not to be actually made until authorized by a letter ballot of all members of Council.

The General Secretary reported regarding his attendance at the Seventh International Management Congress held in Washington, D.C., on September 19th to 23rd, 1938, during which he had been able to meet officers of other societies interested in industrial management with a view to formulating a workable policy for The Institute with reference to this important subject. He had also been able to discuss the possibilities of The Institute's co-operation with the Engineers' Council for Professional Development. In regard to all these matters, most gratifying offers of assistance had been received from the distinguished American engineers present at the Congress. Council expressed appreciation of the kind reception which had been accorded to Mr. Wright on this occasion.

A number of applications were considered, and the following elections and transfers were effected:

Elections		*Transfers*	
Member	1	Assoc. Member to Member	1
Associate Members	4	Junior to Assoc. Member	2
Juniors	7	Student to Junior	1
Students admitted	4		

The Council rose at eleven o'clock p.m.

OBITUARIES

James Henry Barber, M.E.I.C.

We regret to learn of the death of one of the Life Members of The Institute, Mr. James Henry Barber, in Toronto on August 24th. Mr. Barber was born at Coburg, Ont., in 1857. He attended Upper Canada College, Toronto, and later studied at the University of Toronto and the College of Technology. His first engineering experience was obtained as rodman on the reconstruction of the Cobourg and Peterborough Railway in 1873. He spent the following year in Montreal in the office of W. L. Kinmond and Company, engineers. In 1875 he entered the service of James Ross, chief engineer of the Victoria Railway, and was appointed a year later to the position of assistant engineer on the construction of the railway. In 1879 he became assistant engineer on the Credit Valley Railway and had charge of construction between Milton and Galt and remained here a year. In 1881 he was made assistant engineer and afterwards engineer in charge of the St. Thomas extension of the Credit Valley Railway. In the same year he began a three year connection with the Ontario and Quebec Railway first as engineer in charge of a location party and afterwards as division engineer. From 1884 to 1886 he was resident engineer on the Burks Falls Division of the Northern and Pacific Junction Railway, becoming in the following year division engineer on the West Ontario Pacific Railway between London and Woodstock.

Mr. Barber's connection with the Canadian Pacific Railway lasted more than 35 years. During this time he was in charge of many important construction projects on the system, taking part in the laying of steel through the Selkirk Mountains in British Columbia. He later transferred to bridge construction and supervised foundation work on many of the line's important bridges, including the Lachine bridge. Mr. Barber has been residing in Toronto since his retirement from the Canadian Pacific Railway in 1922.

He joined the Canadian Society of Civil Engineers in 1887 and became a Life Member of The Institute in 1922.

Henry Wardlaw McAll, M.E.I.C.

The death of Henry Wardlaw McAll, M.E.I.C., occurred September 29th at his home in Toronto. He was born at Leeds, England, April 26th, 1869. He received his technical education at the City and Guilds Technical College from which he received a diploma in 1869. In 1891 he gave up his work in England and came to Canada where he joined the engineers staff of the Canadian Pacific Railway at Crow's Nest Pass. In 1903 he came to Montreal as assistant resident engineer with the Grand Trunk Railway. He was soon transferred to the Middle Division, Toronto, where he remained until 1906 when he was again transferred, this time to the Northern Division. In 1912 he became associated with the Toronto Works Department. During the construction of the waterfront viaduct he acted as resident engineer. He has also held the position of assistant engineer of the Department of Railways and Bridges of the City of Toronto.

Mr. McAll joined the Canadian Society of Civil Engineers as an Associate Member in 1912, becoming a Member in 1913.

Hamilton Lindsay Swan, M.E.I.C.

Great regret will be felt at the death of Hamilton Lindsay Swan, M.E.I.C., which occurred on August 25th in Vancouver, B.C. He was born at Gilford, County Down, Ireland, on August 29th, 1890. He received his technical training at the Crystal Palace School of Engineering, Norwood, England, following their short course from 1905-07. He then served a three-year apprenticeship to Beyer Peacock and Company, engineers, Manchester, England, and obtained a certificate in advanced applied mechanics from the Manchester School of Technology.

In 1910 Mr. Swan came to Canada and settled at Penticton, B.C. Until 1916 he worked on the construction of the Kettle Valley Railway, leaving then to join the Canadian Engineers with whom he served overseas until 1919. On his return to Canada he worked for a year as

H. L. Swan, M.E.I.C.

chief draughtsman for the Kettle Valley Railway Company at Penticton, B.C., before going into private practice there as a partner in the firm of Swan and Augustine, civil engineers and land surveyors. In 1924 he was made chairman of the Board of Works and acting Municipal Engineer. The following year he became resident engineer, Department of Public Works, B.C., working on the Cariboo highway and Alexandra bridge, Spuzzum, B.C. He served in the capacity of assistant district engineer for the Department of Public Works in the Yale, New Westminster, Merrit and Cranbrook districts, becoming district engineer of Engineering District No. 1, Victoria, B.C. in 1930.

J. H. Thompson, A.M.E.I.C.

In the spring of 1938 Mr. Swan relinquished his post as district engineer and accepted the appointment of administrator of the highway traffic branch of the Department. It is regrettable that he was unable to be longer in this position. He had filled all others so well.

Mr. Swan joined The Institute as an Associate Member in 1915, transferring to Member in 1928. In 1932 he served as chairman of the Victoria Branch. He will be indeed missed by members of the Western Branches as well as mourned by all members of The Institute.

John Henry Thompson, A.M.E.I.C.

The death of John Henry Thompson, A.M.E.I.C., chief engineer of the Canadian Marconi Co., occurred at his home in Montreal West on October 29th. Born in Durham, England, on September 15th, 1883, Mr. Thompson graduated from Durham University in 1910 with the degree of B.Sc. and the following year joined the Canadian General Electric Company, Limited, in Toronto. He enlisted in 1914 in the R.C.N.V.R. and served in the submarine service before being transferred to the radio signal service with the rank of lieutenant.

After the war, Mr. Thompson was appointed chief radio engineer in Ottawa with the Department of Marine and served in this capacity until 1922 when he joined Canadian Marconi, as chief engineer, a position which he filled admirably for 17 years. He attended world radio conferences in Madrid, Cairo and other European countries forming part of the Canadian delegations as one of their radio engineering advisers.

Mr. Thompson joined The Institute in 1917 as an Associate Member.

PERSONALS

P. S. Gregory, M.E.I.C., assistant general manager, the Shawinigan Water and Power Company, was elected to the board of directors of the Fairchild Aircraft Limited.

James H. Wheatley, A.M.E.I.C., has been appointed to the position of superintendent, general shops, replacing the late E. J. Turley. He graduated from McGill University in 1912 with degree of B.Sc. in mechanical engineering, he entered the Northern Electric Company as assistant cable engineer and remained here until 1915 when he was appointed superintendent of time fuse production with the British Munitions Company of Verdun. Enlisting with the Canadian Engineering Corps, he was on his way overseas when the Armistice was signed. After the war he rejoined the Northern Electric Company in the power apparatus sales division. Following a short time spent in the United States, he was associated with the Steel Company of Canada as superintendent of the bolt and nut works division. In 1926 he was appointed superintendent of Domestic Gas Appliances, Limited.

Edward C. Hay, Jr.E.I.C., has been transferred by the Canadian Westinghouse Company Limited, Hamilton, to assume charge of the company's office in Regina as sales engineer of the Province of Saskatchewan.

Dr. T. Kennard Thomson, M.E.I.C., and Mrs. Thomson celebrated their golden wedding anniversary in New York on September 26th. Dr. Thomson is a well-known consulting civil engineer of New York and a Life Member of The Institute, to which he was admitted in 1888 as a Member.

F. C. Mechin, A.M.E.I.C., manager of the Montreal Refineries of the Imperial Oil Company, was present at the launching of the all-welded steel oil tanker *Petrolite* at Sorel on October 22nd. This vessel, costing $465,000, is Canadian designed and built and will be used off the coast of Peru. At the ceremony, Mr. Mechin made a short speech of thanks for the honour which they conferred on his daughter, Miss Marilyn Grant Mechin, in asking her to sponsor the *Petrolite*, and congratulated the shipping company on the completion of such a fine vessel.

Promotion in the R.C.A.F.

The Institute takes this opportunity to congratulate the following members who have been promoted in the Royal Canadian Air Force.

Air Vice-Marshal G. M. Croil, A.M.E.I.C., has been advanced from Air Commodore and **Air Commodore E. W. Stedman,** M.E.I.C., from Group Captain. **Air Vice-Marshal J. Lindsay Gordon,** A.M.E.I.C., was formerly District Officer Commanding Military District No. 10. **Group Captain W. R. Kenny,** A.M.E.I.C., has been promoted from Wing Commander, **Wing Commander D. C. M. Hume,** A.M.E.I.C., from Squadron Leader, **Squadron Leader H. B. Godwin,** A.M.E.I.C., from Flight Lieutenant, and **Flight Lieutenant M. M. Hendrick,** Jr.E.I.C., from Flying Officer.

Visitors to Headquarters

C. C. Kirby, M.E.I.C., President of the Dominion Council of Professional Engineers, came to Headquarters on October 4th.

Alex. T. Cairncross, A.M.E.I.C., is now at his home in Long Branch, Ont., on a furlough from China, where he has been technical adviser, Department of Engineering of the Generalissimo's Staff, National Government of China, Chengtu, Szechewan, and later with the Municipal Council, Department of Finance at Shanghai. He called at Headquarters on October 17th.

Spencer G. Scoular, city engineer designate, Dunedin, N.Z., was present at the meeting of the Montreal Branch on October 20th. He has been sent on a seven months' trip to investigate municipal works in other parts of the world. P. E. Jarman, M.E.I.C., general manager of the City of Westmount, acted as guide for Mr. Scoular during his stay in Montreal.

D. S. Waters, S.E.I.C., spent some time in Montreal during his vacation and visited Headquarters on October 4th. He is with the Canadian Bridge Company at Walkerville, Ont.

W. C. Tatham, S.E.I.C., has now returned to Canada, and visited Headquarters on October 3rd. For the past three years he has been in South Africa, for a time with the East Geduld Mines Limited, Springs, Transvaal, and later as ventilation officer, Grootvlei Proprietary Mines Limited, in the same place. Before returning he spent some time at Entebbe, Uganda, B.E.A.

Ceremonies Marking First Co-operative Agreement Heard Over National Broadcast from Regina

On Saturday evening, October 29th, a number of members of the Montreal Branch and their wives gathered at Headquarters to hear a Dominion-wide radio broadcast of the addresses given by Mr. J. W. D. Farrell, President of the Association of Professional Engineers of Saskatchewan, and Dr. J. B. Challies, President of The Engineering Institute of Canada, at a banquet held in Regina, forming part of the ceremonies marking the consummation of the first Co-operative Agreement between The Engineering Institute of Canada and a Provincial Professional Association. This national hook-up was made possible through the kindness of Dr. A Frigon, M.E.I.C., of the Canadian Broadcasting Commission, and by an instrument installed at Headquarters through the courtesy of the Northern Electric Company.

ELECTIONS AND TRANSFERS

At the meeting of Council held on September 9th, 1938, the following elections and transfers were effected:

Member

JONES, Reginald Elsdon, (Univ. of Toronto), asst. engr., Hydro-Electric Power Commn. of Ontario, Toronto, Ont.

Associate Members

BLOXHAM, Horace William, (Coventry Tech. Inst.), res. engr., subway constrn., Bruce Divn., C.P.R., Hamilton, Ont.

BURGESS, Frederick Victor, (Mount Allison Univ.), chief dftsman., mech. dept., Dominion Coal Co. Ltd., Bridgeport, N.S.

SIMPSON, Frederick Creswell, (Robert Gordon Tech. Coll.), field engr., Herbert Morris Crane & Hoist Co. Ltd., Niagara Falls, Ont.

YOUNG, John Paterson, B.Sc., (Queen's Univ.), asst. supt. of constrn., Dept. of Public Works, Kingston, Ont.

Junior

WANLESS, Graham George, B.Sc., (McGill Univ.), mech. dept., Dominion Rubber Co. Ltd., Montreal, Que.

Transferred from the class of Associate Member to that of Member

GEIGER, Douglas George, B.Sc. (E.E. & M.E.), (Queen's Univ.), transmission engr., gen. engrg. dept., Bell Telephone Co. of Canada, Toronto, Ont.

McCOLOUGH, Reginald Walker, S.B., (N.S. Tech. Coll.), chief engr., Nova Scotia Dept. of Highways, Halifax, N.S.

WALLACE, Gordon Leslie, B.A.Sc., (Univ. of Toronto), consltg. engr., 36 Evelyn Crescent, Toronto, Ont.

WILLIAMS, Edward Clifford, (City & Guilds of London), mgr., air conditioning divn., Can. Gen. Elec. Co. Ltd., Toronto, Ont.

Transferred from the class of Junior to that of Associate Member

CULLWICK, Ernest Geoffrey, B.A., M.A. (Engrg.), (Cambridge Univ.), professor and head of dept. of electrical engrg., University of Alberta, Edmonton, Alta.

GRANT, Alex. J., Jr., B.Sc. (Civil), (McGill Univ.), engr., Angus Robertson Ltd., Montreal, Que.

Transferred from the class of Student to that of Associate Member

AYER, Thomas H., B.Sc. (E.E.), (N.S. Tech. Coll.), shift operator, Shawinigan Water & Power Company, Rapide Blanc, Que.

Transferred from the class of Student to that of Junior

DOBBIN, Davin Crawford, B.Eng., (McGill Univ.), time study man, Dominion Rubber Co. Ltd., St. Jerome, Que.

GERSOVITZ, Frank, B.Eng., (McGill Univ.), private practice, 3980 Cote des Neiges Road, Montreal, Que.

LANGSTON, John Francis, B.Sc. (Civil), (Univ. of Alta.), Lane Wells Co., Okotoks, Alta.

McCOLL, William Ross, B.A.Sc., (Univ. of Toronto), asst. to the supt., Ontario works, Steel Company of Canada, Hamilton, Ont.

McKNIGHT, Charles Ernest Voyle, B.Sc., (Queen's Univ.), safety director, Lake Shore Mines Ltd., Kirkland Lake, Ont.

Student Admitted

MACKINNON, Donald Lauchlan, (Univ. of N.B.), 550 Charlotte St., Fredericton, N.B.

At the meeting of Council held on October 7th, 1938, the following elections and transfers were effected:

Member

BURNETT, Francis C. E., (Heriot Watt College), 145 Percival Ave., Montreal West, Que.

Associate Members

EMERY, Roy William, B.A.Sc. (Civil), (Univ. of Toronto), designer and dftsman., Toronto Iron Works, Toronto, Ont.

TASCHEREAU, Joseph Roger Charles, B.A.Sc., C.E., (Ecole Polytechnique, Montreal), mgr., contract divn., commercial and distribution dept., Shawinigan Water & Power Company, Montreal, Que.

WING, Ernest, plant engr., Canada and Dominion Sugar Co. Ltd., Montreal, Que.

YOUNG, Ross A., B.Sc. (C.E.), (Univ. of Man.), dftsman., Canadian Car and Foundry Co. Ltd., Montreal, Que.

Juniors

BRADLEY, Joseph Gerald, (McGill Univ.), asst. supt., Sherwin Williams Co. of Canada, Red Mill, Que.

CLARKSON, Arthur Grant, B.A.Sc. (Mech.), (Univ. of Toronto), junior dftsman., Algoma Steel Corporation, Sault Ste Marie, Ont.

LAYTON, Michael Shakespear, B.Sc., (McGill Univ.), asst. chemist, Steel Company of Canada, Montreal, Que.

MARCOTTE, Roland, B.Sc. (Elec.), (Milwaukee Sch. of Engrg.), asst. to power engr., Saguenay Power Co. Ltd., Arvida, Que.

MELDRUM, Alan Hayward, B.Sc. (Chem.), (Univ. of Alta.), observer, Algoma Steel Corporation, Sault Ste Marie, Ont.

McMULKIN, Francis John, B.S. (Metal.), (Mich. Coll. of Mining), asst. metallographer, Algoma Steel Corporation, Sault Ste Marie, Ont.

SIBBALD, Stanley W., B.A.Sc. (Chem.), (Univ. of Toronto), chemist, coke oven dept., Algoma Steel Corporation, Sault Ste Marie, Ont.

Transferred from the class of Associate Member to that of Member

WHITMAN, Karl Ewart, B.Sc. (Civil), (N.S. Tech. Coll.), chief designing engr., Nova Scotia Power Commission, Halifax, N.S.

Transferred from the class of Junior to that of Associate Member

JEPSEN, Viggo, (Horsens Tech. School), chief dftsman., Consolidated Paper Corpn. Ltd., Grand Mere, Que.

WARNOCK, Robert Nicholson, B.Sc. (Civil), (McGill Univ.), vice-president, Chas. Warnock & Co. Ltd., Montreal, Que.

Transferred from the class of Student to that of Junior

TINKLER, Howard H., B.Eng., (McGill Univ.), asst. engr., Montreal branch, Iron Fireman Mfg. Co. of Canada, Montreal, Que.

Students Admitted

CALDER, John, (McGill Univ.), 772 Sherbrooke St. W., Montreal, Que.

JESS, Robert Edmond, (McGill Univ.), 3592 University St., Montreal, Que.

PHRIPP, Clarence Frank, (Univ. of Toronto), 286 Dupont St., Toronto, Ont.

WRIGHT, Austin Meade, (McGill Univ.), 2349 Grand Blvd., Montreal, Que.

BOOK REVIEW

The Canada Year Book 1938

Canada Dominion Bureau of Statistics, Ottawa, Ont., 1938. 1,141 pp., 9 x 6½. $1.50, cloth.

The Canada Year Book is the official statistical annual of the country and contains a thoroughly up-to-date account of the natural resources of the Dominion and their development, the history of the country, its institutions, its demography, the different branches of production, trade, transportation, finance, education, etc.—in brief, a comprehensive study within the limits of a single volume of the social and economic condition of the Dominion. This new edition has been thoroughly revised throughout and includes in all its chapters the latest information available up to the date of going to press.

The 1938 Canada Year Book extends to almost 1,200 pages, dealing with all phases of the national life and more especially with those susceptible of statistical measurement. A statistical summary of the progress of Canada is included in the introductory matter. This gives a picture in figures of the remarkable progress which the country has made since the first census of the Dominion was taken in 1871, sixty-seven years ago.

Attention may be called to some of the more important features of the present volume.

In Chapter I, which treats of Physiography, a revised article on the Geology of Canada appears at pp. 16-27; Part III—Seismology—last published in the 1931 Year Book is brought up to date this year; and a special article, "The Flora of Canada," prepared by John Adams, M.A. (Cantab.), Division of Botany, Experimental Farm, Ottawa, appears at pp. 30-59 as Part IV. In Part VII, which deals with Climate and Meteorology, a new section and tables on Times of Sunrise and Sunset in Canada are given.

At pp. 78-90, an additional Part on Historic Sites and Monuments in Canada is added to Chapter II. A section on the Government of Canada's Arctic Territory has been added to Chapter III at pp. 92-93, and at pp. 110-119 the provincial legislatures from 1924 to the present are tabulated, tying-in with the series from Confederation to 1923 published in the 1924 Year Book.

A special feature of Chapter VIII—Agriculture—this year is the article appearing at pp. 223-230 dealing with the Prairie Farm Rehabilitation Program inaugurated by the Dominion Government to alleviate the conditions brought about by the incidence of the recent agricultural crisis in the West, and to provide for permanent improvements in areas suffering from drought and soil-drifting.

All the space that could be spared in Chapter XIX—Labour and Wages—has been given to a summary review of Labour Legislation in Canada, which appears at pp. 787-796, and to an extended treatment of Mothers' Allowances by individual provinces.

In addition to the special features mentioned, some progress has been made in filling in the new framework of Chapter XVIII—Transportation and Communications—as it was recast last year, but unfortunately certain of the statistical series are not yet complete. The section of Chapter XXI—Public Finance—which deals with Capital Investments in Canada and Canadian Investments Abroad, has been completely revised and a new series of historical statistics on a comparable basis, which entirely replaces all earlier figures, is now presented for the years 1926 to 1935 at pp. 896-899. In Chapter XXIII—Currency and Banking—the tables concerning Loan and Trust Companies have been recast, statistics regarding Small Loans Companies separated therefrom, and a separate section on Small Loans Companies added: the business of these companies has now reached considerable proportions and, in view of the special legislation governing their incorporation and operation, the separation is desirable. The review of life insurance given in Chapter XXIII has been rounded out by the inclusion of text and tables covering the business of Canadian companies abroad and Chapter XXV—Education—has been recast, both in regard to textual treatment and tabular presentations.

A list of special articles appearing in past editions from the year 1922-23 to 1937 will be found at page vi immediately preceding the map of Canada.

There are over thirty maps and charts contained in the volume, and two photo-gelatine inserts illustrating the sections on "The Flora of Canada" and "Historic Sites and Monuments," respectively. Three lithographed maps are included.

Persons requiring the Year Book may obtain it from the King's Printer, Ottawa, as long as the supply lasts, at the price of $1.50, which covers merely the cost of paper, printing and binding. By a special concession, a limited number of paper-bound copies have been set aside for ministers of religion, *bona fide* students and school teachers, who may obtain copies at the nominal price of 50 cents each.

ADDITIONS TO THE LIBRARY

Proceedings, Transactions, etc.

Canadian Electrical Association: Proceedings, 48th Annual Convention, 1938.

New Zealand Institution of Engineers: Rules, 1938; Year Book and List of Members, 1937.

Reports, etc.

American Library Association: The Annex of the Library of Congress, 1938.

Canada Department of Labour: Investigation into an alleged Combine in the Distribution of Tobacco Products, 1938.

Canada Geological Survey: Lake Etchemin Map-Area, Quebec; Cranbrook Map-Area, British Columbia; Thetford, Disraeli, and Eastern Half of Warwick Map-Areas, Quebec; Fossil Flora of Sydney Coalfield, Nova Scotia; Mining Industry of Yukon, 1937. (Memoirs 199, 207, 211, 215, 218.)

Canada Bureau of Mines Explosives Division: Annual Report, 1937.

Canada Lands, Parks and Forests Branch: Brown-Stain in Sugar Maple, W. E. Wakefield. (Dominion Forest Service Circular 53.)

Electrochemical Society: Use of the Glass Electrode to Evaluate Quinhydrone Electrode Errors in the Examination of Canned Foods; Brighteners in Silver Plating Solutions; Silver Plating from Acid Complex Iodide Baths; Dielectric Tests on Films of Shellac Varnish; Polymerization of Acetylene by Slow Electrons; Silver Membranes; Properties and Applications of Some of the Vinyl Resins; The Nkana Copper Refinery of Rhokana Corporation Limited; Corrosion of Silver Anodes in Potassium Silver Cyanide Plating Solution; Thermosetting Resins; Anodic and Ordinary Corrosion of Ferrous Metals in Various Acids; Studies of Electrochemical Polarization; Dielectric Constant and Loss of Plastics as Related to their Composition; Alloys of Silver and Iron; The Electro-deposition of Chromium from Trivalent Salt Solutions. (Preprints 74-12 to 74-26.)

Canada National Research Council: Annual Report, 1936-37.

Ontario Department of Mines: Annual Report, 1937.

Quebec Ministère de la Voirie: Convention des Ingénieurs, 1937.

U.S. Geological Survey: Gold Placers of the Fortymile, Eagle, and Circle Districts, Alaska (Bulletin 897-C); Geology of the Marathon Region, Texas; Oligocene Foraminifera from Choctaw Bluff, Alabama; the Force Required to Move Particles on a Stream Bed (Professional Papers 187, 189-D, 189-E); Surface Water Supply of the United States, 1936, Pt. 2 South Atlantic Slope and Eastern Gulf of Mexico Basins, Pt. 5 Hudson Bay and Upper Mississippi River Basins; Surface Water Supply of Hawaii, July 1, 1935 to June 30, 1936 (Water-Supply Papers 802, 805, 815).

University of Illinois: Two Investigations on Transit Instruments; Papers Presented at the 25th Annual Conference on Highway Engineering, March 2-4, 1938; The Chemical Engineering Unit Process-Oxidation; Factors Involved in Plate Efficiencies for Fractionating Columns. (Bulletins.)

World Power Conference: (Sectional Meetings, Vienna, 1938): General Report: Section A Supply of Energy for Agriculture, Section B Supply of Energy for Small-Scale Industries, Section C Supply of Energy for Household Purposes, Section D Supply of Energy for Public Lighting, Section E Supply of Energy for Electric Railways.

Technical Books, etc.

The Consulting Engineer, prepared by George C. Diehl and Robert Ridgway. N.Y. American Institute of Consulting Engineers, 1938. 18 pp., 9 x 6 in., paper.

This brochure contains contributions from six eminent engineers on the training, experience, accomplishments and industries of the consulting engineer.

Design of Steel Buildings. By H. D. Hauf. 2nd ed. N.Y., John Wiley and Sons, 1938. 232 pp., diagrs., charts, tables, 9 x 6 in., cloth, $2.75.

General principles of structural steel design as applied to the commoner types of buildings, with consideration of the various structural units, elements and stresses which enter into such work. Since it is intended to be used in conjunction with the structural steel handbooks, the book contains but few tables of structural shapes and analogous materials.

Elements of Water Supply Engineering. By E. L. Waterman. 2nd ed. N.Y., John Wiley and Sons, 1938. 329 pp., illus., diagrs., charts, maps, tables, 9 x 6 in., cloth, $3.50.

The aim of this text is to provide a work upon the fundamentals of the subject which can be covered thoroughly in the time usually allotted to courses in civil engineering. The topics are arranged in the order in which they appear in the development of a system, the public water supply being followed from source to customer.

Manuel de Savonnier. By A. Matagrin. Paris, Gauthier-Villars, 1938. 268 pp., illus., 7 x 5¼ in., paper.

American Society of Mechanical Engineers **Mechanical Catalog and Directory,** 1939. N.Y., The Society, 1938. 478 pp., illus., 11½ x 9 in., cloth.

Mechanics of Materials. By P. G. Laurson and W. J. Cox. N.Y., John Wiley and Sons, 1938. 408 pp., illus., diagrs., 9¼ x 6 in., cloth, $3.75.

Structural Design. By C. T. Bishop. New York, John Wiley & Sons, 1938. 254 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $3.50.

This book is intended for basic courses in the design of steel structures. The fundamental principles of design are first applied to detached individual members without regard to their relation to other members in a structure, a plan that enables the student to concentrate his attention upon the few new principles involved in each case. The application of these principles is then illustrated by the design of interconnected members of typical structures.

Thermodynamics Fluid Flow and Heat Transmission. Huber O. Croft. N.Y., McGraw-Hill, 1938. 312 pp., illus., 9¼ x 6 in., cloth, $3.50.

U.S. Works Progress Administration **Bibliography of Aeronautics,** Pt. 18—Laws and Regulations, Pt. 24—Air Mail. N.Y., W.P.A., 1938.

MEETINGS

American Society of Heating and Ventilating Engineers—Annual Meeting, January 23rd to 26th, 1939, William Penn Hotel, Pittsburgh, Pa.

Canadian Construction Association—January 10th-12th, at Winnipeg, Man.

The Canadian Institute of Mining and Metallurgy—Annual Western Meeting, November 9th, 10th, 11th, at Vancouver. H. Mortimer Lamb, Vancouver Secretary, British Columbia Division.

Canadian Institute on Sewage and Sanitation—October 20th-21st, at the Royal York Hotel, Toronto. Secretary, Dr. A. E. Berry, M.E.I.C., Ontario Department of Health, Parliament Buildings, Toronto, Ont.

The Engineering Institute of Canada—Annual General and Professional Meeting, February 20th-22nd, 1939, at Ottawa.

E.I.C. Peterborough Branch—Annual Banquet in the evening and Special Meeting of Council in the afternoon, November 26th.

Thirteenth Exposition of Power and Mechanical Engineering—December 5th to 10th, 1938, Grand Central Palace, New York.

Twelfth National Asphalt Conference—February 20th to 24th, 1939, Biltmore Hotel, Los Angeles, Calif.

Additional information about any of these functions may be secured from the General Secretary.

BOOK NOTES

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet, the books are not in The Institute Library, but inquiries will be welcomed at Headquarters, or may be sent direct to the publishers.

About Petroleum. By J. G. Crowther. London, New York, Toronto, Oxford University Press, 1938. 181 pp., illus., diagrs., 9 x 6 in., cloth, $2.25.

A very simple description of the petroleum industry, intended for those who are curious about what petroleum is, where it comes from, how it is produced, and how it is transformed into the familiar commercial products. Such special phases as geophysical prospecting and knock phenomena in engines are briefly treated.

Advanced Mathematics for Engineers. By H. W. Reddick and F. H. Miller. New York, John Wiley & Sons, 1938. 473 pp., diagrs., cnarts, tables, 9 x 6 in., cloth, $4.00.

Differential equations, vector analysis, probability, operational calculus, and the more complex mathematical functions and series are discussed, emphasis being placed on physical applications by illustrating each principal topic by problems relating to civil, electrical, mechanical and chemical engineering. Definitions, physical laws, theorems and physical units are presented with particular care.

Air Conditioning. By C. A. Fuller with collaboration of D. Snow. New York, Norman W. Henley Publishing Co., 1938. 577 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.00.

In addition to the customary information concerning thermodynamic fundamentals, design of distributing equipment, principles of condensers, evaporators, etc., and descriptions of installations, the subject of codes and ordinaces covering air conditioning is discussed. The non-technically trained reader has been primarily considered.

Airplane Design. By K. D. Wood. 3 ed. June 1938, published by the author at Purdue University, Lafayette, Ind., distributed by the Cornell Co-Op. Society, Ithaca, N.Y. Illus., diagrs., charts, tables, 11 x 9 in., paper, $4.00.

A textbook of airplane layout and stress analysis calculations with particular emphasis on economics of design. Load factors, materials, costs, and drafting procedure are discussed, as well as the actual work of technical design for the various component parts. Appendices contain design data for practical work.

Applied Mechanics. By H. F. Girvin. Scranton, Pa., International Textbook Co., 1938. 336 pp., diagrs., tables, 9 x 6 in., cloth, $3.00.

A comprehensive treatment of the subject, containing a very large number of descriptive problems. The material has been so arranged that the chapters covering graphical solutions may be used as a text for a course in Graphic Statics, being segregated from the purely mathematical treatment.

Atomic Structure. By L. B. Loeb. New York, John Wiley & Sons, 1938. 446 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.50.

This textbook is intended to supplement a basic course in physics and to provide students who have a working knowledge of the calculus with a thorough grounding in atomic structure. The subject is developed on an essentially experimental and historical basis. Starting with an account of early discoveries and the prenuclear atom, the author discusses the nuclear atom, the electrical properties of atoms, the kinetic nature of a gas, the electron theory of metals and the wave mechanical concept of the metallic state. There is a bibliography.

Bibliography on Industrial Radiography. (Document 1139). By H. R. Isenburger. Washington, D.C., American Documentation Institute, 1938. 52 pp., typewritten, 12 x 9 in., paper, $0.72 in microfilm, or $3.32 in black and white prints.

This supplement to St. John and Isenburger's book, "Industrial Radiography," contains 776 references, arranged chronologically and covering material from early 18th century general theory to the most recent 1938 applications.

British Chemical Industry, its Rise and Development. By Sir G. T. Morgan and D. D. Pratt. London, Edward Arnold & Co.; New York, Longmans, Green & Co., 1938. 387 pp., illus., diagrs., charts, tables, 10 x 7 in., cloth, $6.25.

This work presents the substance of a series of public lectures at the University College of Wales. The factors underlying the origin and development of the principal chemical industries of Great Britain are presented in clear, simple language, and an excellent picture of present conditions is given.

The **Brunels,** Father and Son. By C. B. Noble. London, Cobden-Sanderson, 1938. 279 pp., illus., diagrs., 9 x 6 in., cloth, 15s.

An account of the lives of two men who contributed some of the most notable engineering feats during the early and middle nineteenth century, including the original Thames tunnel and the Great Eastern steamship. Contains much original material from diaries, letters, etc.

La Corrosion en Métallurgie. By C. Grard. Paris, Éditions Berger-Levrault, 1936. 345 pp., illus., diagrs., charts, tables, 10 x 7 in., paper, 50 frs.

A comprehensive textbook of the corrosion of metals when exposed to moisture, the atmosphere or salt water. The book is based upon the results obtained by the various research institutions studying this problem, especially those of Commission Française de Corrosion, of which the author is President.

Davison's Textile Blue Book, United States, Canada and Mexico. Handy edition, Seventy-third Year, July 1938 to July 1939. Ridgewood, N.J., Davison Publishing Co., 1938. 1,234 pp., maps, 8 x 5 in., cloth. $5.00.

An annual publication containing lists of manufacturers of cotton, rayon, silk and knit goods, and of dyers and finishers, geographically arranged. Commission merchants, dealers and importers are listed, also domestic and foreign raw cotton firms, cotton compresses and warehouses. Two special lists cover pertinent associations and railroads serving the various mills.

Decibels and Phons, a Musical Analogy. By L. S. Lloyd. London, New York and Toronto, Oxford University Press, 1938. 18 pp., tables, 9 x 6 in., paper, $0.50.

An explanation of the meaning of the terms "phon" and "decibel" by considering the phon as a loudness-interval, comparable to the musical interval of a major third, and the decibel as representing the energy-interval which produces the phon.

Diesel Engines. By B. J. von Bongart. New York, D. Van Nostrand Co., 1938. 335 pp., illus., diagrs., charts, tables, 10 x 6 in., cloth, $5.50.

Primarily designed as a text for the study of internal combustion engines of the compression-ignition type, this book covers general principles, the customary equipment, and the various types of engines within this field. There are also embodied the results of certain researches by the author and others on particular problems in Diesel engineering.

Direct-Current Machinery. By T. C. McFarland. Scranton, Pa., International Textbook Co., 1938. 439 pp., diagrs., charts, tables, 9 x 5 in., lea., $4.00.

As a matter of review, the first chapter of this text is devoted to the fundamental concepts of electricity and magnetism. In treating of direct-current machinery a physical picture of the assembly is first presented, then operating characteristics and control, proceeding from no-load characteristics to load characteristics are discussed. Material on the no-load saturation curve and armature reaction is included.

Edison's Open Door. By A. O. Tate. New York, E. P. Dutton & Co., 1938. 320 pp., 9 x 6 in., cloth, $3.00.

The author was intimately associated with Edison between the years 1883 and 1894, being for the greater part of that time his private secretary and an officer in his various personal corporate enterprises. His narrative is an informal account of Edison during one of the most dramatic periods of his life, based upon personal knowledge. Incidentally, many other interesting characters and events are discussed. The book is a readable, welcome addition to Edisonia.

Electric Power Circuits, Theory and Applications. Vol. 2 **Power System Stability.** By O. G. C. Dahl. New York and London, McGraw-Hill Book Co., 1938. 698 pp., diagrs., charts, tables, 10 x 6 in., cloth, $7.00.

The subject of power system stability is very fully treated, with a wealth of diagrams, tables and mathematical analyses. There are several chapters on each of the following topics: steady-state power limits, steady-state stability and transient stability, considering carrying conditions and different methods of analysis. Other chapters cover load characteristics, circuit equations for faulted networks, exciter analysis, damper windings, inertia and grounding.

Electromagnetics. By A. O'Rahilly, with a foreword by A. W. Conway. London, New York and Toronto, Longmans, Green & Co., 1938. 884 pp., diagrs., tables, 9 x 6 in., cloth, $12.50.

A critical review of the classical theory of electricity, discussing fundamentals, and the work of the men who have had an important influence on the thought and action in this field of physics. At the end of this comprehensive survey appear two chapters in which a radical exposition of the meaning of the symbols of physics is worked out and the question of basic units and dimensions is treated. There is a large bibliography.

Electro-Plating, a Survey of Modern Practice including Nickel, Zinc, Cadmium, Chromium, and the Analysis of Solutions. By S. Field and A. D. Weill. 3 ed. rev. London, Sir Isaac Pitman & Sons, Ltd.; New York, Pitman Publishing Corp., 1938. 381 pp., illus., diagrs., charts, tables, 8 x 5 in., cloth, $4.00.

This volume is intended to provide the electroplater with a simply worded, practical account of recent advances in the art. The scientific principles involved are revised, advice is given on equipment and solutions, and methods for depositing the usual metals are described in detail. A chapter on metal colouring is included. The new edition has been enlarged, chiefly by more scientific data and by material on the chemistry of plating solutions.

The Elements of Ferrous Metallurgy. By J. L. Rosenholtz and J. F. Oesterle. 2 ed. New York, John Wiley & Sons, 1938. 258 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $3.00.

A general elementary treatment for students not specializing in metallurgy. Blast furnace practice, steel-making processes, heat treatment, the structure and working of various steels, and iron foundry work are treated concisely and clearly.

Elements of Ordnance, prepared under the direction of Lt.-Col. T. J. Hayes. New York, John Wiley & Sons, 1938. 715 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $6.50.

This textbook, intended for use at West Point, is essentially a revision of McFarland's "Textbook of Ordnance and Gunnery." It aims to give the student a broad foundation, upon which further technical studies can be based.

Engineering Mechanics. By S. Fairman and C. S. Cutshall. New York, John Wiley & Sons, 1938. 267 pp., diagrs., tables, 9 x 6 in., cloth, $2.75.

The object of this elementary text is to present only as much material as can be conveniently covered in the time available for a basic course. Topics covered in prerequisite courses and material which may be deferred to more advanced courses are consequently omitted. Otherwise the book contains the customary treatment of statics and kinetics, numerous problems being included.

Engineering Terminology, Definitions of Technical Words and Phrases. By V. J. Brown and D. G. Runner. Chicago, Gillette Publishing Co., 1938. 310 pp., illus., diagrs., 9 x 6 in., cloth, $3.50.

A list of terms often used in technical writing and specifications, with definitions obtained from the usage of various trade and engineering organizations. The terms apply especially to civil engineering and architecture. In addition the book contains a concise Spanish-English and English-Spanish dictionary of highway terms, a brief German-English dictionary of terms for mineral aggregates and several tables of technical symbols, abbreviations, conversion factors, etc.

Farm Gas Engines and Tractors. By F. R. Jones. 2 ed. New York and London, McGraw-Hill Book Co., 1938. 486 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $3.75.

The first part of this text deals with the fundamentals involved in the construction and operation of the simple internal-combustion engine, with particular application to the small stationary engine for farm use. Part two deals with the construction and operation of the various types of farm tractors. The text is clear and practical and the various topics are treated in detail.

Fluid Mechanics for Hydraulic Engineers (Engineering Societies Monographs). By H. Rouse. New York and London, McGraw-Hill Book Co., 1938. 422 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $5.00.

Intended specifically for graduate students and practising engineers, this volume presents in systematic detail the fundamental principles of fluid motion and their application to various phases of hydraulic engineering. Emphasis is placed upon sound physical analysis of actual flow phenomena, in the effort to provide more dependable methods of approach than empirical hydraulics can afford.

Foremanship and Supervision. By F. Cushman. 2 ed. New York, John Wiley & Sons, 1938. 286 pp., illus., diagrs., charts, tables, 8 x 5 in., cloth, $2.50.

A practical handbook for foreman conference leaders and supervisors of vocational education. It deals with the conference type of educational procedure, which is distinguished by the stimulation of a group to active thought through the efforts of a leader who encourages and guides discussion, as opposed to other types in which the leader acts as instructor.

Great Britain. Dept. of Scientific and Industrial Research. **Lubrication Research** Technical Paper No. 3. The **Friction** of an **Oscillating Bearing**, by A. Fogg and C. Jakeman. London, His Majesty's Stationery Office; [obtainable from British Library of Information, 270 Madison Ave., New York], 1938. 28 pp., illus., diagrs., charts, tables, 10 x 6 in., paper, $0.30.

The purpose of this investigation was to determine the characteristics of the friction of a journal bearing subjected to oscillating motion under different conditions of load, temperature and frequency of oscillation, and to examine the effect of different lubricants on the friction.

Great Britain. Dept. of Scientific and Industrial Research. **Road Research** Technical Paper No. 5. **The Grading of Aggregates** and **Workability of Concrete.** London, His Majesty's Stationery Office; [obtainable from British Library of Information, 270 Madison Ave., New York], 1938. 42 pp., illus., diagrs., charts, tables, paper, $0.45.

Gives the results of an investigation of the effect of the grading of the aggregate upon the strength and workability of concrete. A new conception of workability is given, a method for measuring it is described, and a wide range of cement contents, aggregate gradings and types is examined.

Handbook of Aeronautics, Vol. 3. **Design Data and Formulae—Aircraft and Airscrews.** Ed. by The Royal Aeronautical Society and the Institution of Aeronautical Engineers. London, Sir Isaac Pitman & Sons; New York, Pitman Publishing Corp., 1938. 250 pp., diagrs., charts, tables, 9 x 6 in., cloth, $6.00.

BRANCH NEWS

Border Cities Branch

J. F. Bridge, A.M.E.I.C., Secretary-Treasurer.

London Branch

D. S. Scrymgeour, A.M.E.I.C., Secretary-Treasurer.
Jno. R. Rostron, A.M.E.I.C., Branch News Editor.

The opening meeting of the fall season was featured by a joint Professional Meeting of Border Cities Branch and the London Branch at Sarnia on September 24th, 1938. A full account of which appeared in the October number of The Journal.

Invitations had been sent out to other branches of The Institute and to the Association of Registered Professional Engineers of Ontario. The following list shows the localities represented and the number attending from each: London 31, Windsor 29, Sarnia 15, Toronto 7, Montreal 5, Port Huron 4, Walkerville 4, Woodstock 3, St. Thomas 3, Sault Ste. Marie 2, Chatham 2, Detroit 2, Stratford 2, Hamilton 1, Marysville 1, Wayne 1. Total registration 112.

Hamilton Branch

A. R. Hannaford, A.M.E.I.C., Secretary-Treasurer.
W. E. Brown, Jr.E.I.C., Branch News Editor.

The regular monthly meeting took the form of a joint meeting of the Hamilton group of the American Institute of Electrical Engineers and the Hamilton Branch, E.I.C., and was held in Convocation Hall, McMaster University, on October 6th, 1938.

Mr. T. A. Boyd, of the Research Department, General Motors, Detroit, addressed the meeting on the subject "The Place of Research in the Evolution of the Automobile." The speaker asked the question, "What is the use of Research?", pointing out that the average man thinks of the automobile today as being perfect and yet automotive engineers in 1909 thought they had achieved perfection.

In answer to his own question, Mr. Boyd first traced the history of the development of the automobile, pointing out that in itself the automobile is not an invention but rather the product of a long genealogy. The essential features of the motor car had been invented long before the motor car became a reality.

Probably the forerunner of our automobile was the Nuremberg carriage of 1649 with its human engine, and about the same time a sailing carriage was developed, propelled by a sail. Early steam carriages gave us the cylinder and piston, crank and connecting rod, change gear and differential gear, and even front drive steering wheel.

Lenoir's gas engine in 1860 and Otto's gas engine in 1876 with its compressed charge were important developments, to be followed by the Panhard and Levassor car, the pioneer of the modern car. Tribute was paid to Charles Goodyear's contribution, namely, the means of vulcanizing rubber. The last important development cited was Kettering's electric self-starter. The speaker illustrated all these developments with slides.

Mr. Boyd then took his audience on a rapid tour of a research laboratory, showing the facilities for testing the performance of a car and its component parts, such as the dynamometer, the spectroscope, the cold room, means of testing brakes, gears, lubrication, springs, finish and plating. Finally the speaker showed views of the "proving grounds," where the cars undergo actual road tests. Here there are grades of various degrees, speed bed, mile long straightaways, skid pad and bath tub, all designed to subject the car to extreme operating conditions in order to test its performance.

The foregoing is a cross-section of the part research and engineering have played in producing our automobile. Their improvements have reduced the price per pound from 50c to 20c for cars in the lower price bracket and have saved car buyers in Canada and the United States a billion dollars per year.

Mr. Boyd pointed out that the future for research in the automotive industry is just as glorious as the past, despite the fact that there are already 100,000 U.S. patents related to the automobile. There is a need for a lighter and more efficient engine, lighter metals, steel which will withstand rust and a lubricant which will carry higher bearing pressures.

The meeting was opened by D. W. Callander, Chairman of Hamilton group A.I.E.E., who then turned the chair over to W. Hollingworth, M.E.I.C. Mr. Boyd was introduced by Emil L. DuBois, president of the Hamilton Motor Products, Limited. The attendance was 218.

October the 14th was arranged as a special day of activities to honour our President, J. B. Challies, M.E.I.C., and also an occasion of welcome to our General Secretary, L. Austin Wright, A.M.E.I.C.

Special representations came from the following Branches: London, Niagara Peninsula, Toronto; and also the Grand Valley Group of Registered Professional Engineers and numerous friendly Engineering Societies.

During the afternoon about 85 engineers and visitors made tours of inspection through the plants of the Steel Company of Canada, The Dominion Foundries and Steel Company and the Burlington Steel Company.

At 6 o'clock members assembled in the Laura Secord room of the Royal Connaught hotel for the reception of the President who was coming from Toronto where, during the afternoon, he had been honoured by the University of Toronto with the honorary degree of Doctor of Engineering. Dr. Challies arrived at a few minutes to seven and his entrance was made to the lusty strains of "For he's a jolly good fellow."

At 7 o'clock, 122 sat down to dinner in the dining room and to enjoy a evening that will long be remembered by the Hamilton Branch.

The speaker of the evening, Dr. Challies, was introduced by Major Hugh Lumsden, M.E.I.C., in his most sincere and affectionate manner.

Dr. Challies gave us a stirring address on matters concerning the engineering profession and cited some of the policies that The Institute is trying to effect. He challenged engineers throughout the Dominion to assist the movement to bring the profession to its rightful status. He pointed out that 71 years ago there was no engineering or engineering faculty at any school in Canada; that 53 years ago there was no engineering society in Canada and that only within very recent years has the engineer been accorded any professional status.

He urged members of The Institute to co-operate with all other groups of authorized engineers and to follow these four ideals: support the Provincial Associations; sustain the National Association; encourage the young engineers; take part and give leadership where possible in public service as our contribution to good government.

Dr. Challies continued with an interesting talk on the St. Lawrence Waterways proposals, and an abstract of this portion of his talk will be found elsewhere in this issue.

E. P. Muntz, M.E.I.C., moved a vote of thanks to Dr. Challies.

Mr. Wright, in a few well chosen words, expressed his pleasure in being with us and hoped for an invitation to say more at some future time, which opportunity he will surely get.

W. J. W. Reid, M.E.I.C., our Chairman, introduced Mr. McCulloch, of the Hamilton *Spectator*, who gave the gathering a very skilful picture of the affairs of the world as seen by those who are perhaps able to see some distance through the maze of swiftly moving events of the present weeks and months.

Kingston Branch

R. A. Low, A.M.E.I.C., Secretary-Treasurer.

The Members of the Kingston Branch and their guests met at the Kingston Badminton Club on the evening of October 22nd to honour Dr. W. L. Malcolm, M.E.I.C., past Professor of Municipal Engineering at Queen's University, recently appointed Director of the School of Civil Engineering, Cornell University; and Dr. J. B. Challies, the President, on his annual visit to the Branch.

Among the many guests, prominent in Canadian educational and engineering circles, were: Principal R. C. Wallace, Vice-Principal W. E. McNeill and Dean A. L. Clark, of Queen's University; Brigadier H. D. G. Crerar, Commandant, and Prof. L. N. Richardson of the Royal Military College; Dean H. W. McKiel, M.E.I.C., of Mount Allison University; J. A. McCrory, M.E.I.C., Vice-President for Quebec; Fraser Keith, M.E.I.C., Ross Dobbin, M.E.I.C., former Vice-President for Ontario, and others from the Montreal, Peterborough and Ottawa branches.

Numerous letters were received, expressing regret at being unable to attend, and extending heartiest good wishes to Dr. Malcolm in his new sphere.

Major H. H. Lawson, M.E.I.C., Chairman of the Kingston Branch, presided.

After the Toast to the King, Lt.-Col. L. F. Grant, M.E.I.C., in proposing the toast to Dr. Malcolm, outlined his career and his outstanding services as a scholar, teacher, engineer, soldier and gentleman. "At a time of life when most men would be content to rest on their laurels, Dr. Malcolm had forged steadily on in his chosen field, and through his efforts Queen's today had one of the outstanding Sanitary Engineering laboratories on this continent." The speaker concluded by expressing the deep regret that Dr. Malcolm's colleagues, fellow engineers and friends had felt at his departure, but said that in attaining this high position at Cornell, he had brought honour not only to himself, but to Queen's and Canadian engineers. A hearty "For He's a Jolly Good Fellow" followed.

Dr. Malcolm expressed his deep appreciation for the many tributes that had been paid him and voiced his regret at having to leave his colleagues and friends at Queen's, the Royal Military College and Kingston. He spoke of happy days spent at Queen's and the cordial relations existing there, and then briefly outlined his work at Cornell, as Director of the Civil School, contrasting the Canadian and American universities. He paid tribute to Principal Wallace, Dr. McNeill, Dean Clark and T. A. McGinnis, for their counsel and assistance in making possible the construction of the Sanitary Engineering laboratory. He expressed the hope that greater co-operation would result between Queen's and Cornell, in view of the fact that Prof. Baty, his successor at Queen's, was a Cornell Graduate and several of the Queen's staff were also graduates of the same school, and, he added, he hoped as an individual to assist in the promotion of good relations between Canadian and American universities. Dr. Malcolm asked all his colleagues and friends to remember that Cornell is not far distant and that they would always be very welcome guests. He voiced his intention of forever maintaining his relations and friendships in Canada and concluded with an "Au Revoir, Not Goodbye."

The Toast to the Profession was proposed by Lt.-Col. W. P. Wilgar, M.E.I.C., who paid tribute to Dr. Malcolm and his work at Queen's. In his own inimitable style, he then introduced the President, Dr. J. B. Challies, as one of the famous class of '03 engineers from Varsity, Queen's and McGill, and as one who had devoted much of his time to the service of The Institute.

Dr. Challies in responding to the toast to the profession outlined the great advance of the engineering profession that has been made in the last sixty years, and alluded to the fact that at the time of Confederation there was not one Engineering School in Canada. For decades, no engineers had entered public life, but now many engineers held high public positions and, he added, that we as engineers had gained equal status with other professions. He discussed at length the progress made in bettering relationships between the provincial bodies and The Institute, and stated that in Saskatchewan reciprocal membership had now been provided for. He looked forward to a much closer co-operation with all the provincial associations. A policy of assisting the young engineer in becoming established after graduation was, the speaker remarked, an essential one for The Institute, and one that should be adopted at an early date. In concluding, Dr. Challies paid high tribute to Dr. Malcolm, and said that we had in him a worthy ambassador of good will to further strengthen the bond of friendship between the United States and Canada.

Others who spoke briefly were Dean McKiel, Mr. Ross Dobbin, Mr. McCrory and Mr. Austin Wright, General Secretary.

After the dinner, guests and members met in the lounge and enjoyed a pleasant get-together which gave all an opportunity of extending their best wishes to Dr. Malcolm and also of greeting Dr. Challies and Mr. Wright.

Montreal Branch

E. R. Smallhorn, A.M.E.I.C., Secretary-Treasurer.

Visit to Shawinigan Falls

On Saturday, September 17th, 1938, about 65 members left Windsor Station at 9.15 a.m. for Shawinigan Falls. Some years had elapsed since the last visit to this district, and it was felt that while the trip would be new to many, even those who had been there before would be interested in again making a visit. This proved to be so, as most of those who went were senior members.

The Montreal Branch was pleased to accept the kind invitation of the Shawinigan Water and Power Company, who were the hosts from the time the train arrived until it departed. They met the train with a fleet of automobiles, entertained the party at luncheon and tea at the Cascade Inn, and transported everybody between the various plants, the Inn, and back to the train.

Arriving at Shawinigan Falls shortly after noon, the first event was the luncheon at the Inn. J. A. McCrory, M.E.I.C., vice-president of the Shawinigan Water and Power Company, welcomed the party on behalf of his Company. B. R. Perry, M.E.I.C., Chairman of the Montreal Branch, and H. J. Ward, A.M.E.I.C., Chairman of the St. Maurice Valley Branch, spoke briefly. Both expressed thanks to the Shawinigan Company for their hospitality, and both expressed pleasure in the opportunity afforded by the occasion to the members of both branches to become better acquainted. Mr. Perry also thanked the management of the Consolidated Paper Corporation for the arrangement they had made to operate the Belgo Mill on Saturday afternoon—contrary to their usual practice—for the benefit of the party.

After luncheon the party visited the paper mill, Shawinigan Power House No. 1 and the Carbide Company. At each plant guides were ready to receive the party, and as there was one guide to every six or seven visitors, the plant inspections were in the nature of a personally conducted tour. At each plant every department was operating, and the visit to the Carbide Plant was timed so that everybody saw a carbide furnace being tapped.

The party was then driven back to the Inn, where cocktails, etc., and tea were served until train time, 7.30 p.m.

It was only by careful scheduling that such an ambitious programme was covered in such a short time, and appreciation was expressed to those members of the Shawinigan staff who were responsible for the arrangements.

The party travelled to and from Shawinigan Falls in special chair cars. These cars went direct from Montreal, and waited at Shawinigan for the party for the return trip.

On the way back the committee of the Branch in charge had provided refreshments aboard the train, playing cards, etc. As a result, the return journey passed quickly and pleasantly.

The whole trip was very enjoyable, and the Branch have already conveyed their thanks to the Shawinigan Water and Power Company for their hospitality, and careful preparation of the programme, and to Dick Heartz and his committee for their work in co-operation with the Shawinigan Company with the Railway Company.

Joint Meeting with the Montreal Chapter of the A.S.H.V.E.

On October 6th a joint meeting of the Montreal Branch with the Montreal Chapter of the American Society of Heating and Ventilating Engineers was planned to take advantage of the fact that the officers and members of Council of the A.S.H.V.E. were in Montreal, holding their quarterly meeting under the presidency of E. Holt Gurney, of Toronto, the first Canadian to head the Society.

Two papers were presented before the meeting, "Air Conditioning in Glass Brick Building," by J. Herbert Walker, Member of Council, A.S.H.V.E., and engineering assistant to the general manager of the Detroit Edison Company, and "The Architect and the Engineer," by James F. McIntire, Member of Council and 1st Vice-President A.S.H.V.E., and Vice-President of the United States Radiator Corporation.

B. R. Perry, M.E.I.C., Chairman of the Montreal Branch, E.I.C., and G. Lorne Wiggs, M.E.I.C., Member of Council, A.S.H.V.E., were the joint chairmen of the meeting. President Challies extended a welcome to the visitors on behalf of The Institute.

Some Psychological Aspects of Scientific Management

The meeting on October 13th was addressed by L. P. Alvin, an engineer from Paris who holds the position of Paris Director of the Cie Generale de Traction sur les Voies Navigables. Mr. Alvin is widely known on the continent in transportation and engineering circles and in 1935 was awarded the Inland Water Transport Medal of the French Institute of Transport. He had been attending the International Management Congress in Washington, September 19th-23rd. In his paper Mr. Alvin stressed the importance of considering the workers' psychology in planning any scheme of factory organization. Social consequences of reorganization should be considered both from the aspect of improved efficiency and from the standpoint of the workers' wellbeing. Science and psychology in industry are inseparable, especially in the case of smaller firms, and technical superiority alone is not sufficient to ensure the success of a scientific management scheme.

Prior to the meeting, a courtesy dinner was held at the Windsor hotel, 6.30 p.m. J. S. Cameron, M.E.I.C., acted as chairman of the meeting.

Junior Section

On Monday, October 17th, the first meeting of the fall session of the Junior Section of the Montreal Branch was addressed by A. N. Farrell, A.M.E.I.C., on the subject of "Scientific Property Management." Mr. Farrell graduated from McGill University in civil engineering in 1924 and for the past ten years has been with the Royal Trust Company, Montreal, supervising property, maintenance and repairs. Following this interesting address a Bethlehem sound film on "Structural Shapes" was shown. Refreshments were served after the meeting.

Technical Film

"Steel, Man's Servant" was the title of the film shown to the Montreal Branch meeting on October 20th through the courtesy of the United States Steel Corporation. This was the first meeting held since the completion of the renovations at Headquarters and following the showing of the film an informal evening was spent and refreshments served. President Challies introduced the president elect, Dean H. W. McKiel, to the 350 members present, and altogether it was a most enjoyable gathering.

R. E. Heartz, M.E.I.C., acted as chairman.

Ottawa Branch

R. K. Odell, A.M.E.I.C., Secretary-Treasurer.

Electrification of Canals in France

On the evening of October 12th, at the auditorium of the National Research Laboratories, L. P. Alvin, noted French engineer from Paris, France, gave an address on transportation in France with particular reference to the system of canals in that country used largely for the transport of bulk freight. Mr. Alvin stated that there were various problems common to rail, road, and water systems of transportation in connection with the attainment of a high commercial speed.

The main problems he enumerated as:

1. Speed in free circulation.
2. The operation of the carrying units whether singly or coupled together in "trains."
3. The spacing of the units in travel so as to obtain the greatest freedom in motion and efficiency.

In an endeavour to obtain the best solution for these problems, so far as the canal system is concerned, there has been effected an electrification, that is, barges are drawn through canals by the use of electrical engines, travelling on railroad tracks placed alongside of the canal shores. In this particular regard France is the most advanced country in the world, another notable example of electrification being at the Panama Canal where, however, it is operated in certain sections only. For the greater part of the canal system it has been found more expedient to operate the barges singly.

The address, which was illustrated with lantern slides, dealt largely with the methods used and types of equipment employed in carrying on this electrification work.

The chairman of the Branch, W. F. M. Bryce, A.M.E.I.C., presided, and the vote of thanks to the speaker at the conclusion was moved by G. J. Desbarats, Hon.M.E.I.C., and seconded by J. J. Murphy, M.E.I.C. Following the address proper, a very interesting period of discussion ensued when many questions bearing upon the subject of the address—in some cases rather remotely—were discussed.

Peterborough Branch

A. L. Maltby, Jr. E.I.C., Secretary-Treasurer.
J. L. McKeever, Jr. E.I.C., Branch News Editor.

The opening meeting of the 1938-39 season took the form of a supper and social gathering at the Kawartha Golf and Country Club on Thursday, September 29th. For the past few years the opening meeting has taken this form and a number of the members have been asked to invite as their guest a junior engineer, usually a student on the C.G.E. Test Course, who is not yet a member of the Branch. This gives the young engineer a chance to meet the members and to gain an idea of the objects and activities of The Institute with the hope that he may feel the urge to join the Branch. Past meetings of this type have been highly successful and the present one was no exception.

After the supper the Branch chairman, W. T. Fanjoy, A.M.E.I.C., gave a short outline of the activities of the Branch, following which our Councillor, A. B. Gates, A.M.E.I.C., outlined the work of Council and gave his ideas as to probable future relations between The Institute and the Professional Associations. The guests were then introduced to the meeting by I. F. McRae, A.M.E.I.C., who at the same time gave a short summary of the more lurid details in their respective pasts.

The remainder of the evening was spent in viewing films and playing table-tennis. The attendance was 53.

The first technical meeting of the 1938-39 season was held on Thursday, October 13th, at which the speaker was Mr. J. M. Somerville of the engineering staff, Canadian Porcelain Company, and his subject:

The Manufacture of High Voltage Wet Process Insulators

Mr. Somerville was able to show samples of the various ingredients of porcelain and his talk was well illustrated by slides picturing all the stages of the manufacture. He described the grinding of the materials in the ball mills, the mixing, and pumping of the mix through the filter presses. The cake taken from the filter presses is treated according to the product to be made, for instance some types of insulators are moulded while others are moulded and turned in a lathe.

The firing of the insulator is an extremely important part of the manufacture and must be carefully controlled while sampling and testing is carried out in all the various stages. The finished insulator is tested both mechanically and electrically and a very small percentage of defects in a batch may mean the scrapping of the whole batch. Standard electrical tests consist of high frequency and both wet and dry normal frequency flashover.

By means of his slides the speaker described the various designs of suspension and pin type insulators in use with comments on the special designs suited to locations where fog or conducting-fumes are present.

The numerous questions asked of the speaker after the presentation of his paper indicated the interest with which it was received by the Branch. The attendance was 36.

Saguenay Branch

F. T. Boutilier, A.M.E.I.C., Secretary-Treasurer.
J. W. Ward, A.M.E.I.C., Branch News Editor.

Operating Experience with Rotary Converters

The regular monthly meeting of the Saguenay Branch was held in the main office of the Aluminum Company of Canada at Arvida, Que., on Friday evening, August 5th, 1938. The guest speaker for the evening was Mr. William Fraser, electrical engineer with the Aluminum Company of Canada Ltd., who spoke on "Operating Experiences with Rotary Converters."

Since aluminum is manufactured by the electrolytic process and requires a large amount of direct current, rotary converters are an important unit in the process. Mr. Fraser has had considerable experience in this field and his remarks were extremely interesting and instructive. Some of the most important points brought out are as follows:

The absence of commutating difficulties, due to field distortion. This objectionable characteristic of D.C. motors and generators is practically eliminated in rotary converters because the windings carry the difference between the alternating and direct currents. A.C. brush wear has been reduced by helical grooves cut on the face of the slip rings. These grooves pass over the face of the brush and allow the local hot spots to cool off and distribute the contact points over the entire brush face. The method used to cut the grooves with the armature in place was clearly illustrated with lantern slides.

Flash-over is produced by short circuit currents flowing through the brush face and striking an arc between the bars of the commutator. These arcs fill the space between the brush arms with ionized gases and flash-over occurs either between the brush arms or between a brush arm and ground. The short circuit currents through the brush face are produced by distortion of the magnetic field when synchronizing currents flow in the armature conductors. These synchronizing currents may be due to outside A.C. line disturbances or rapid fluctuations in load on the D.C. side of the converter. Flash-over due to field distortion can be minimized by setting the brushes slightly off the neutral position.

At full load a rotary converter should be run at unit power factor. If the power factor were changed from unity to say 95 per cent in an alternator or synchronous motor, the heating of the coils would be increased approximately 11 per cent while in a rotary converter the heating of certain of the coils would be increased 85 per cent.

A meeting of the Saguenay Branch was held in the main office of the Aluminum Company of Canada, Ltd. at Arvida, Que., on Wednesday evening, September 7th, 1938.

Two sound pictures supplied by Imperial Oil Company, namely "The Inside Story" and "Design for Power," were presented to the gathering, and were extremely interesting both from the technical point of view and from the point of view of the layman.

"The Inside Story" dealt with the lubrication of all types of equipment, showing clearly why lubrication was necessary and the results of poor and good lubrication.

"Design for Power" dwelt primarily on the lubrication and combustion features of the automobile engine, and showed how lubrication and gasoline quality had such a major part in bringing the automobile engine to the high point of efficiency it has reached today.

When the pictures had been run, Mr. Tanner of the Imperial Oil Company Staff answered a large number of questions brought up by some of the members.

Saint John Branch

F. A. Patriquen, Jr.E.I.C., Secretary-Treasurer.
F. L. Black, Jr.E.I.C., Branch News Editor.

Thirty members of the Saint John Branch attended the opening meeting of the winter season in the Admiral Beatty hotel on Thursday, October 13th, 1938. The meeting was preceded by a dinner which started at 6.00 p.m. This is the first time that a dinner has been held in connection with a regular monthly meeting of the Branch, the idea of the change being, that it leaves the evening free after 8.00 or 8.15 p.m. for other engagements of the members.

The Branch chairman, W. H. Blake, A.M.E.I.C., was in the chair, and Mr. L. W. Simms, President of the T. S. Simms and Company, manufacturers of brushes and brooms, addressed the Branch on "Research in Industry." His talk outlined the part that engineers, their reports and their time studies played in the very diversified processes of manufacture carried on by his company. Mr. Simms also outlined the history of the company, its different products or "lines" and the difficulties in keeping costs on the various products.

After a very hearty vote of thanks, the meeting adjourned at 8.00 p.m.

St. Maurice Valley Branch

L. B. Stewart, Jr.E.I.C., Secretary-Treasurer

On October 8th, 1938, the St. Maurice Valley Branch, E.I.C., had the pleasure of entertaining the Presidential party at a Branch dinner at the Cascade Inn, Shawinigan Falls. The party consisted of the President, J. B. Challies, M.E.I.C., the General Secretary, L. Austin Wright, A.M.E.I.C., and the Chairman of the Committee on Professional Interests, Fred Newell, M.E.I.C.

The Chairman of the Branch, H. J. Ward, A.M.E.I.C., and 28 members were present to honour these distinguished guests.

In introducing the President, Mr. Ward expressed the pleasure of the Branch at being privileged to hear of the work of The Institute from these important Headquarters officials. He referred to the high standing of Mr. Challies in the profession, and offered congratulations for the honour which was about to be bestowed upon him by the University of Toronto, an honorary Doctor of Engineering.

Mr. Challies thanked the Branch for their invitation to visit here, and remarked that, because of his business connection, he felt quite at home in this district.

He spoke of the many reasons engineers have for being thankful at this thanksgiving season, and reported on the success of the E.I.C. in its various branches of endeavour. He mentioned his recent visit to the Maritime Branches and of his proposed trip to Ontario and the West.

He paid a fine tribute to Professor McKiel, of Sackville, N.B., the unanimous nominee of the Nominating Committee for President next year. He said that Professor McKiel's ideal was to look after the young engineer, and that this should be the primary purpose and opportunity of The Institute as a whole.

He spoke of the prestige of the E.I.C. both in this and in other countries, and of the many Canadian engineers who are holding key positions in industry and in finance and in various provincial and federal governments.

In closing he paid tribute to the work on Council of Vice-President Keay and of Councillor Wardle, both members of this Branch.

On request of the Chairman, Mr. Challies introduced Mr. Newell, stating that he is Chief Engineer of the Dominion Bridge Co., and Chairman of the E.I.C.'s Committee on Professional Interests.

Mr. Newell spoke on the negotiations that have been carried on in regard to "Co-operation" between The Institute and the professional associations of the various provinces. He described the success of these negotiations in some provinces and the difficulties that have been met with in others.

Mr. Ward then introduced Mr. Wright, giving a brief résumé of his career and attainments.

Mr. Wright spoke on the value of membership in the E.I.C., naming and illustrating many advantages that accrue from such membership.

He mentioned the services supplied by The Institute to its members, such as Employment, the Library, the guidance of students, introductions to outside organizations and to foreign countries, etc., etc., and explained how these services are being increased and improved.

After a few closing remarks the Chairman adjourned the meeting at 10.30 p.m.

Toronto Branch

J. J. Spence, A.M.E.I.C., Secretary-Treasurer.
D. D. Whitson, A.M.E.I.C., Branch News Editor.

On Tuesday, September 13th, 1938, the branch held its first meeting of the 1938-39 season in the form of a golf tournament and dinner at the Islington Golf Club. Dull skies held the number of players to thirty, but the competition was keen, and good fellowship reigned to such an extent that the tournament promises to be an annual event. Percy Dobson, M.E.I.C., showed the members how to play, touring Islington's long fairways in 88, taking the low gross prize, with Hew Scott, M.E.I.C., in second place, and S. R. Frost, A.M.E.I.C., lately of the Niagara Branch, getting low net among the handicap players. At dinner the numbers had increased to 45. There were many short speeches, one of the most enjoyable being by Eric Muntz, M.E.I.C., of the Hamilton Branch. Harry Brandon, A.M.E.I.C., was chairman of the committee in charge, and was ably assisted by Nichol MacNicol, M.E.I.C., and Barry Watson, A.M.E.I.C.

New and Revised Specifications

British Standard Specifications are kept on file and may be consulted at the following offices: H.M. Senior Trade Commissioner, 1111 Beaver Hall Hill, Montreal; H.M. Trade Commissioner, 67 Yonge Street, Toronto; H.M. Trade Commissioner, 703 Royal Bank Building, Winnipeg; H.M. Trade Commissioner, 850 Hastings Street West, Vancouver.

Canadian Engineering Standards Association: S47T-1938 Standard Specifications for Welded Steel Buildings, Welding by the Metallic Arc Process, Tentative Welding Qualification Code for Fabricators, Contractors, Supervisors and Welders; S48T-1938 Tentative Specification for Metallic Arc (Iron and Steel) Electrodes for Welded Steel Buildings. The scope of these specifications applies specifically to steel structures for buildings and does not include welding of bridges, pressure vessels or mechanical equipment.) C22.2 No. 7-1938 Portable Electric Displays and Incandescent-Lamp Signs. These specifications are $0.50 each.

Canadian Government Purchasing Standards Committee: Specification for Gasoline; Fuel Oil; Illuminating Oils; Petroleum Lubricating Oils; Aviation Fuel; Diesel Fuel Oil. Procedure for the Determination of Gum Content of Gasoline in the Presence of Top Cylinder Lubricant (tentative); Procedure for the Determination of Gum Stability of Gasoline (tentative).

U.S. Department of Commerce National Bureau of Standards: Building Materials and Structures, Report BMS2 Methods of Determining the Structural Properties of Low-Cost House Constructions; Report BMS3 Suitability of Fiber Insulating Lath as a Plaster Base.

Preliminary Report Issued on Fallentimber Area, Alberta

Oil and gas possibilities of structures in the Fallentimber area, fifty-five miles northwest of Calgary in Alberta, are discussed by B. R. MacKay in his preliminary report (Paper 38-23) on the geology of the area issued recently by the Geological Survey Division, Department of Mines and Resources, Ottawa.

Geological interest in the 370 sq. mi. area is centred chiefly on four anticlinal structures, cross sections of which appear on a map accompanying the report, which also shows the geology of the area. Two of these structures have been partly tested by drilling, but the depth of the Palaeozoic limestone is as yet a matter of inference, as no holes sufficiently deep to tap this formation have been drilled. However, from the geological studies the minimum distance to the limestone is estimated to be at least 7,500 ft.

A well put down on the Monarch anticline in 1914 tested this structure only to a depth of 3,500 ft. A small seepage of crude oil was reported to have been struck at a depth of 808 ft., and in some of the lower sandstone horizons a number of other small seepages of oil and sufficient flows of gas to supply light, heat and power for the drilling plant were encountered.

Fallentimber area lies fifteen miles west of the Calgary, Red Deer and Edmonton Branch of the Canadian Pacific Railway, and twenty-five miles north of the Calgary-Banff highway. Good motor roads run west into the area from Olds, Didsbury and Carstairs, the road from Olds being the one most widely travelled. Supplies are obtained chiefly from Sundre and Cremona.

Copies of the report and accompanying map may be obtained from the Director, Mines and Geology Branch, Department of Mines and Resources, Ottawa.

Preliminary Notice

of Applications for Admission and for Transfer

October 26th, 1938.

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in December 1938.

L. Austin Wright, General Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

DRAKE—EDWARD MICHAEL, of 3484 Westmore Ave., Montreal, Que. Born at Blaine Lake, Sask., Dec. 1st, 1911; Educ.: B.Eng., McGill Univ., 1934; 1934-35, student engr., 1935-37, sales engr., A. Reyrolle & Co., Hebburn-on-Tyne, England; 1937 to date, sales engr., Northern Electric Co. Ltd., Montreal, Que.

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted after a lapse of one month, upon request.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

Situations Vacant

GRADUATE ENGINEER, for experimental and design work in metal working plant. Must have some practical engineering experience. Applicant should state age, experience, and salary requested. Apply to Box No. 1805-V.

SALES ENGINEER. Qualified engineer with sales ability and experience in conbustion problems Preferably under 40 years of age. Apply to Box No. 1810-V.

VACANCIES WITH THE AIR MINISTRY, LONDON, ENGLAND

We have been advised by the Department of National Defence, that the Air Ministry will be willing to consider applications from graduates of Canadian universities with honours degrees in engineering or physics or equivalent, together with either research or practical engineering experience, in connection with a number of vacancies that exist for technical appointments. Information circulars may be secured from The Engineering Institute of Canada, or the Department of National Defence, "Air Force," Ottawa, Ont.

Situations Wanted

ENGINEER, A.M.E.I.C., Combustion specialist heat balance. Steam, Mechanical. Refrigeration. Office routine. Correspondence. Plant layout. Apply to Box No. 5-W.

ELECTRICAL ENGINEER, JR.E.I.C., B.SC.; age 31; at present employed, desires change in location. Experience includes; three summers experience in power conduit construction; two years in telephone engineering; four years experience in radio, both development engineering and production; two and one half years in a paper mill on electrical maintenance, with a short time in the cost accounting and draughting departments. Would be interested primarily in electrical maintenance. Apply to Box 12-W.

PAPER MILL ENGINEER A.M.E.I.C., Married, Ten years experience in the design, construction, maintenance and costs of pulp and paper mills is seeking a permanent position. Available on short notice. Apply to Box No. 150-W.

SALES ENGINEER REPRESENTATIVE. Mechanical graduate with fifteen years experience in Eastern Canada in sales and service of mechanical equipment; full details upon request to Box No. 161-W.

ENGINEER-DRAUGHTSMAN, experienced in design of machines for widely varied purposes and arrangement of motor drives. Accustomed to layout of small mill buildings, steel and timber Good references. Present location Montreal. Apply to Box No. 329-W.

CIVIL ENGINEER, M.A.SC., A.M.E.I.C. eight years survey and municipal engineering experience, and three years draughting, detailing steel, concrete, and timber structures. Apply to Box No. 467-W.

Situations Wanted

CIVIL ENGINEER, B.SC. (McGill '20), A.M.E.I.C. Married. Twelve years experience in pulp and paper mill design, and six years general construction. Available immediately. Location immaterial. Apply to Box No. 547-W.

ELECTRICAL ENGINEER, B.SC. E.E., Age 39. Married. Seven years experience in operation, maintenance and construction of hydro-electric plants, and sub-stations. Five years maintenance and installation of pulp and paper mill electric equipment. Reliable and sober, with ability to handle men. Best references. Any location, at once. Apply to Box No. 636-W.

ELECTRICAL ENGINEER, B.SC. '28. Two years student apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660-W.

CIVIL ENGINEER, B.A.SC. (Toronto '27), age 34, married. Five years railway and construction work as building inspector and instrumentman. Level engineer and on construction of a long timber flume for a pulp and paper mill. Field engineer for a sulphite company, in charge of the following mill buildings, acid, digester, blow pit, barker room, chip storage and acid towers. Available immediately. Apply to Box No. 714-W

ELECTRICAL ENGINEER, B.SC. '31 (U.N.B.), JR.E.I.C. Age 30 years. Single. Experience in electrical wiring, construction of concrete wharves, inspection of piling, rip rap, concrete reinforcing, forms, and dredging. Also junior engineer. Available at once. Apply to Box No. 722-W

CIVIL ENGINEER, B.SC., M.SC., P.P.E.; Lieut. C.E., R.O. Sixteen years municipal, highway and construction. Five years overseas. Married. Read, write and talk French. Will go anywhere. Apply to Box No. 737-W.

CIVIL ENGINEER, A.M.E.I.C. Experienced in general construction, buildings, gravel and asphalt roads. Acting in charge P.W.D. West Africa. Chief field engineer refinery construction. Survey Angola Rly. West Africa. General Office work. Apply to Box No. 765-W.

ELECTRICAL ENGINEER, B.SC. '29, age 30. Single. Eight and a half years experience on maintenance, on construction, floorman and operator on hydro-electric system. Desires construction, service, sales or research work. Any location. Excellent references. Apply to Box No. 1062-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 41. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experience in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

Situations Wanted

TECHNICALLY TRAINED EXECUTIVE. General experience administrative, organization and management in business and industrial fields, including; business, plant, property and estate management; plant maintenance, modernization, production and personnel; economic studies, company reorganizations and amalgamations, valuations; railroad, highway, hydro, pulp, newsprint, housing, industrial surveys, investigations and construction; B.Sc. degree in engineering, age 49, married, Canadian. Apply to Box No. 1175-W.

CHEMICAL ENGINEER, grad. McGill '34, experienced in meter repairs, control work; and also chemical laboratory experience. Apply to Box No. 1222-W.

ELECTRICAL ENGINEER, B.SC. '31. Age 35. Experience in oil field work and railways construction survey. Two years on installation and maintenance of mine equipment, and two years industrial plant engineering on design and layout of equipment. Available immediately. Will go anywhere. Apply to Box No. 1249-W.

FIELD ENGINEER AND DRAUGHTSMAN, A.M.E.I.C. Age 36. Married. Fifteen years experience in civil engineering, general draughting and instrument work. Experience covers office and layout work on construction of sewers, water mains, gas mains, (6" to 30" dia.) and transmission line structures; topographic and stadia surveys. Draughting covers general civil, reinforced concrete and steel design, mechanical detailing and arrangements, and mapping. Present location Montreal, but willing to locate anywhere. Available at once. Apply to Box No. 1326-W.

CIVIL AND ELECTRICAL ENGINEER, JR.E.I.C. (Univ. of Man.). Married. Age 25. Good draughtsman. Four months draughting, one year instrumentman on highway location and construction, inspection and miscellaneous surveying and estimating. Six months as field engineer on pulp and paper mill construction. Prefer electrical or structursl design. Available at once. Apply to Box No. 1633-W.

CIVIL ENGINEER, B.SC. in C.E. '34. S.E.I.C. Age 27. Five years experience, including harbour construction, highway paving, one and a half years paper mill construction, instrument work, draughting, estimating, interested in design. Available on short notice. Apply to Box No. 1737-W.

CHEMICAL ENGINEER, graduate, Toronto '31. Seven years experience in paper mill, meter maintenance, control work and chemical laboratory. Speaking French and English. Location immaterial. Available at once. Apply to Box No. 1768-W.

CIVIL ENGINEER, B.A.SC., JR.E.I.C. (Toronto '35). Age 24. Experience in structural design, construction and surveying, including one year in South America. Details on request. Apply to Box No. 1784-W.

ELECTRICAL ENGINEER, JR.E.I.C. B.SC. Age 25. At present employed, but desiring change of location. Three years maintenance and test work, toll and automatic telephone equipment; two years sales engineering, telephone and electrical equipment. Prefer to remain in telephone field, but would be interested in any opportunities in electical engineering. Apply to Box No. 1817-W.

CIVIL ENGINEER, B.E., JR.E.I.C., 28 years of age. Married. Desires position with reliable construction firm. Intends to make construction life work. Over five years experience on permanent highway construction, inspection, estimates and instrument work. Available on short notice. Apply to Box No. 1820-W.

ELECTRICAL ENGINEER, B.A.SC. '33. Age 27. Married. JR.E.I.C. One year's experience in power plant operation and over three years experience in hydro-electric development and construction. Expert draughtsman and instrumentman, including experience in steam gauging, and reinforced concrete design and construction. Available at once. Apply to Box No. 1829-W.

CIVIL ENGINEER, B.A.SC. (Toronto '35), JR.E.I.C. Age 26. Experience in highway layout and construction, concrete bridge construction, draughting, office work, and surveying. Further details on request. Good references. Available immediately. Location immaterial. Apply to Box 1832-W.

(Ex-Officio) J. C. MacDONALD, I. C. BARLTROP

THE ENGINEERING JOURNAL

VOLUME XXI, No. 12 DECEMBER, 1938

THE arrangement and contents of this number of the Journal are somewhat unusual inasmuch as a full list of members is published in the place usually occupied by technical papers. Such a list is necessary in the conduct of the business of The Institute, and is useful and informative to the membership at large.

Members are reminded that they should make an effort to keep this number close at hand, as it will probably be necessary or desirable to make frequent reference to it in the future. It is also suggested that each member check his own record in both the alphabetical and geographical list, and notify Headquarters if any error appears. In this way such errors may be removed from any subsequent lists that may be published.

The December number has been selected for the purpose, principally because it marks the end of the year, and is the last number to appear with all the physical characteristics which have identified the Journal for the last several years. Therefore it seems quite appropriate that this cycle should conclude with the tabulation of the full strength of The Institute, and a list of officers, both past and present, who have had responsible charge of its affairs.

This list is issued for the personal use of members only, and each member is requested not to permit his copy to be used as a basis of circulation or for other purposes not in the interest of the membership or The Institute.

THE ENGINEERING INSTITUTE OF CANADA

List of Officers and Members of Council since the establishment of The Institute, showing the years during which office has been held.

GEOGRAPHICAL LIST OF MEMBERS

CORRECTED TO NOVEMBER 15th, 1938

ZONE A

(*The four Western Provinces.*)

Victoria Branch District

(*Vancouver Island and the Gulf Islands Tributary to Vancouver Island.*)

Albert Head (Br. Res.), Member, J. H. Gray.
Bamberton, Tod Inlet (Br. Non-Res.), Associate Member, J. H. McIntosh.
Cadboro Bay (Br. Res.), Member, R. E. Smythies.
Courtenay (Br. Non-Res.), Member, W. Scales.
Duncan (Br. Non-Res.), Associate Member, R. H. Vaughan.
East Sooke (Br. Res.) Associate Member, W. F. Wilson.
Headquarters (Br. Non-Res.), Associate Member, H. E. Stevens.
James Island (Br. Non-Res.), Junior, H. B. Brewer.
Nanaimo (Br. Non-Res.), Associate Member, A. G. Graham.
Port Alice (Br. Non-Res.), Member, C. C. Ryan.
Sidney (Br. Non-Res.), Associate Member, L. S. Daynes.
Victoria (Br. Res.),

Honorary Member

C. A. Magrath.

Members

R. A. Bainbridge, A. L. Carruthers, E. Davis, G. M. Duncan, R. C. Farrow, S. H. Frame, C. W. Gamble, F. C. Green, J. E. Griffith, A. E. Hodgins, H. T. Hughes, G. M. Irvin, E. W. Izard, J. C. MacDonald, K. Moodie, F. J. O'Reilly, G. L. Stephens, G. M. Tripp.

Associate Members

J. N. Anderson, I. C. Barltrop, J. H. Blake, H. F. Bourne, R. F. Davy, K. Dixon, W. S. Drewry, A. W. Ferguson, H. N. Gahan, A. J. Gray, E. I. W. Jardine, D. MacBride, A. S. G. Musgrave, G. Phillips, H. L. Sherwood, N. A. Yarrow.

Juniors

W. M. Davidson, M. C. Nesbitt, K. Reid, J. V. Rogers, W. H. Sparks, R. E. Wilkins.

Students

M. S. Brown, R. J. Carson, G. R. Davidson, L. M. Evans, W. S. B. Latta, V. Wiebe, J. T. Woolsey.

Vancouver Branch District

(*The balance of British Columbia, except that allocated to Lethbridge Branch.*)

Barkerville (Br. Non-Res.), Student, H. N. Curry.
Britannia Beach (Br. Non-Res.), Associate Member, G. W. Waddington.
Clinton (Br. Non-Res.), Student, B. V. Moss.
Deer Park (Br. Non-Res.), Associate Member, C. S. Moss.
Fredrick's Arm (Br. Non-Res.), Associate Member, M. J. Evans.
Kaleden (Br. Non-Res.), Member, A. K. Robertson.
Kamloops (Br. Non-Res.), Member, M. L. Wade; Associate Member, W. Ramsay.
Kelowna (Br. Non-Res.), Hon. Member, Grote Stirling; Members, F. W. Groves, D. K. Penfold
Ladner (Br. Res.), Associate Member, C. E. Cooper.
Likely (Br. Non-Res.), Associate Member, W. P. Young.
Lillooet (Br. Non-Res.), Member, O. W. Smith.
Manson Creek (Br. Non-Res.), Associate Member, W. M. Ogilvie.
Minto (Br. Non-Res.), Member, J. A. Mackenzie.
Nelson (Br. Non-Res.), Member, A. L. McCulloch; Associate Member, H. R. Younger.
New Westminster (Br. Res.), Members, L. B. Elliot, F. L. Macpherson, C. C. Worsfold; Associate Members, H. Balmforth, G. B. Dixon, C. F. P. Faulkner, W. E. Keyt, J. B. Lambert, F. O. Mills, C. Raley, W. A. Richardson, F. J. Simpson, E. Smith, G. N. Stowe.
Ocean Falls (Br. Non-Res.), Associate Members, H. M. Lewis, C. W. E. Locke.
Okanagan Landing (Br. Non-Res.), Student, R. T W. Allen.
Oliver (Br. Non-Res.), Associate Member, D. G McCrae.
Penticton (Br. Non-Res.), Members, F. H. Latimer, A. McCulloch, T. E. Naish; Associate Member, R. A. Barton.
Pioneer Mine (Br. Non-Res.), Student, H. L. Thorne.
Pouce Coupe (Br. Non-Res.), Associate Member, H. L. Hayne.
Powell River (Br. Non-Res.) Members, D. A. Evans, W. Jamieson; Associate Member, N. Beaton; Junior, J. G. D'Aoust.
Prince Rupert (Br. Non-Res.), Associate Members, W. L. Stamford, F. S. Walton.
Radium Hot Springs (Br. Non-Res.), Member, G. F. Horsey.
Revelstoke (Br. Non-Res.), Associate Member, G. B. Alexander.
Rock Creek (Br. Non-Res.), Associate Member, V. J. Melsted.
Rossland (Br. Non-Res.), Member, A. E. Wright; Associate Member, A. C. Ridgers; Student, W. N. Papoff.
Ruskin (Br. Non-Res.), Associate Member, J. C. Johnstone.
Salmon Arm (Br. Non-Res.), Associate Member, G. Macleod.
Smithers (Br. Non-Res.), Associate Member, R. C. Davidson.
South Slocan (Br. Non-Res.), Associate Member, A. S. Mansbridge.
Squamish (Br. Non-Res.), Member, C. L. Eates; Junior, W. A. Madeley.
Trail (Br. Non-Res.), Members, L. A. Campbell, H. A. Moore; Associate Members, G. H. Bancroft, J. P. Coates, J. E. MacDonald, C. E. Marlatt, S. C. Montgomery, H. Vickers; Junior, C. A. Broderick; Students, J. E. Craster, J. H. Nicholson, R. J. Whitehouse.
Vancouver (Br. Res.),

Members

W. Anderson, F. H. Ballou, R. Bell-Irving, W. R. Bonnycastle, C. Brakenridge, P. P. Brown, P. H. Buchan, E. E. Carpenter, E. F. Carter, J. Chalmers, E. A. Cleveland, G. S. Conway, F. P. V. Cowley, A. D. Creer, C. R. Crysdale, C. A. Davidson, V. Dolmage, A. C. Eddy, J. N. Finlayson, J. P. Forde, A. E. Foreman, W. T. Fraser, H. W. Frith, A. S. Gentles, G. M. Gilbert, J. R. Grant, J. Green, J. B. Holdcroft, W. N. Kelly, N. J. Ker, A. T. Kerr, F. Lee, H. F. G. Letson, D. O. Lewis, D. C. Mackenzie, J. P. Mackenzie, H. J. MacLeod, H. N. Macpherson, W. O. Marble, H. St. J. Montizambert, W. T. Moodie, H. B. Muckleston, W. G. Murrin, B. T. O'Grady, F. O. Orr, J. B. Parham, W. H. Powell, W. Rae, H. Rindal, J. Robertson, J. W. Roland, W. O. Scott, W. Smaill, A. J. Smith, F. C. Stewart, L. Stockett, W. G. Swan, A. J. T. Taylor, E. C. Thrupp, G. A. Walkem, J. A. Walker, C. E. Webb, T. H. White, A. S. Wootton, A. C. R. Yuill.

Associate Members

H. P. Archibald, J. B. Barclay, T. V. Berry, R. T. Blair, J. E. Buerk, H. L. Cairns, A. W. G. Clark, S. H. Davis, C. W. Deans, A. Dickson, W. R. Duckworth, S. Farquharson, W. P. Ferguson, H. C. Fitz-James, M. L. Gale, A. Granger, W. B. Greig, C. T. Hamilton, J. B. Hamilton, H. B. Hicks, W. E. Jenkins, G. O. Johnson, A. J. Jones, T. W. Lazenby, R. J. Lecky, E. C. Luke, A. H. Macfarlane, J. McHugh, R. G. MacKenzie, R. M. Martin, H. H. Minshall, A. Peebles, A. H. Perry, A. A. Plummer, T. E. Price, R. C. Pybus, G. W. F. Ridout-Evans, R. Rome, J. M. Rothwell, P. M. Smith, P. B. Stroyan, G. L. Tooker, L. G. Trorey, D. P. Urry.

Juniors

D. C. Crothers, W. L. Kent, K. Y. Lochhead, R. C. Robson, J. A. Tames, R. Walkem.

Students

E. R. Carswell, R. K. Cheng, E. L. Hartley.

Affiliate

G. E. Herrman.

Wells (Br. Non-Res.), Associate Member, E. W. Richardson; Junior, D. W. Miller.
Woodfibre (Br. Non-Res.), Associate Member, W. A. Bain.
Yale (Br. Non-Res.), Member, W. K. Gwyer.

Calgary Branch District

(*The territory in Alberta included between the north boundary of township thirteen from Saskatchewan to the British Columbia boundary, northerly on the interprovincial boundary to the north boundary of township forty-two; east to the east boundary of range twelve (west of the fourth meridian); south to the north boundary of township thirty-seven; east on the north boundary of township thirty-seven to the Saskatchewan boundary; and south on the interprovincial boundary to township thirteen.*)

Banff (Br. Non-Res.), Member, P. J. Jennings; Associate Member, C. K. LeCapelain; Junior, C. R. Cornish.
Black Diamond (Br. Non-Res.), Student, G. A. Connell.
Brooks (Br. Non-Res.), Associate Member, C. C. Elliott; Junior, W. Crook.
Calgary (Br. Res.),

Members

F. K. Beach, P. T. Bone, E. W. Bowness, S. G. Coultis, J. B. deHart, J. Dow, W. S. Fetherstonhaugh, A. Griffin, J. Haddin, R. C. Harris, O. H. Hoover, T. Lees, J. E. McKenzie, J. H. Parks, S. G. Porter, F. M. Steel, J. S. Tempest, B. L. Thorne, J. R. Wood.

Associate Members

J. M. Anderson, W. Anderson, E. Avery, T. Barnecut, F. G. Bird, G. P. F. Boese, R. L. Bonham, W. H. Broughton, J. E. Brown, A. C. Chapman, S. J. Davies, F. S. Dyke, P. A. Fetterley, R. H. Goodchild, L. Green, J. J. Hanna, F. J. Heuperman, J. M. Ireton, M. W. Jennings, H. B. LeBourveau, A. W. P. Lowrie, A. T. McCormick, H. J. McEwen, W. T. McFarlane, R. MacKay, H. J. McLean, S. F. McLeod, J. McMillan, W. St. J. Miller, H. H. Moore, J. S. Neil, V. A. Newhall, G. W. O'Neill. P. F. Peele, J. W. Reid, F. N. Rhodes, J. H. Ross, H. B. Sherman, B. W. Snyder, F. C. Tempest, G. H. Thompson, H. W. Tooker, A. I. Tregillus, W. B. Trotter, R. S. Trowsdale, A. G. Willson, J. W. Young.

Juniors

I. A. Abramson, D. F. Becker, H. W. Becker, C. A. Colpitts, J. C. Dale, W. J. Gold, H. L. Hurdle, G. D. Kellam, L. H. McManus, R. G. Paterson, G. G. D. Robertson, W. G. Sharp, B. H. Sherwood, W. D. Suitor, D. G. Tapley, W. C. Wilde.

Students

J. Blair, R. W. Brews, C. R. Hamilton, C. M. Harding, A. W. Howard, D. C. Jones, E. G. Law, F. R. Park, H. L. Thorne.

Canmore (Br. Non-Res.), Associate Member, C. S. Dewis.
Drumheller (Br. Non-Res.), Junior, E. H. Perlson.
Exshaw (Br. Non-Res.), Associate Member, V. C. Hamilton.
Okotoks (Br. Res.), Junior, J. F. Langston; Student, W. T. T. Reikie.
Olds (Br. Non-Res.), Member, G. N. Houston
Patricia (Br. Non-Res.), Associate Member, H. B. Miller.
Seebe (Br. Non-Res.), Junior, G. V. Eckenfelder; Student, C. W. Elliott.
Strathmore (Br. Non-Res.), Member, E. N. Ridley; Associate Members, G. H. Patrick, T. Schulte, F. B. Young.
Turner Valley (Br. Non-Res.), Associate Members, G. D. Phelps, H. L. Stevens Guille; Junior, A. Stiernotte.

Edmonton Branch District

(*All the Province of Alberta north of the northern boundary of the Calgary Branch.*)

Derwent (Br. Non-Res.), Student, C. A. Algot.
Edmonton (Br. Res.),

Members

J. D. Baker, J. Callaghan, L. C. Charlesworth, W. J. Dick, R. M. Dingwall, C. E. Garnett, J. Garrett, A. J. Gayfer, R. J. Gibb, G. H. N. Monkman, W. R. Mount, A. I. Payne, V. Pearson, C. A. Robb, A. J. Sill, E. Skarin, E. Stansfield, H. R. Webb, R. S. L. Wilson.

Associate Members

A. M. Allen, H. A. Bowden, F. A. Brownie, J. W. S. Chappelle, W. E. Cornish, E. G. Cullwick, P. L Debney, J. M. Forbes, E. D. Greening, F. L. Grindley, A. W. Haddow, D. A. Hansen, R. M. Hardy, H. P. Keith, J. F. McDougall, W. I. McFarland, E. Nelson, M. Polet, R. W. Ross, H. F. Ryan, E. I. Smith, R. H. Stevens, H. H. Tripp, R. G. Watson, T. W. White, E. H. Wright.

Juniors

W. W. Fotheringham, P. Hargrove, H. R. Hayes, G. R. Pinchbeck, B. W. Pitfield, J. W. Porteous, W. W. Preston, L. G. Scott, T. D. Stanley, J. P. Svarich.

Students

W. B. Adamson, E. W. Bogart, E. H. Davis, L. J. Ehly, L. Gads, F. J. Hastie, V. A. Hayward, F. J. Heath, J. H. Hole, W. G. Hole, C. K. Hurst, F. P. Johnson, D. F. Kobylnyk, G. F. McAulay, J. E. Poole, P. J. Prokopy, G. Ross, C. C. Simpson, K. L. Steeves, J. D. Sylvester, L. A. Thorssen.

Grande Prairie (Br. Non-Res.), Student, G. Sinclair.
Jasper (Br. Non-Res.), Associate Member, J. B. Snape.
McLennan (Br. Non-Res.), Member, H. G. Dimsdale.
Peace River (Br. Non-Res.), Associate Member, J. H. Johnston.
Sterco (Br. Non-Res.), Associate Member, W. F. Stevenson.
Vegreville (Br. Non-Res.), Associate Member, J. G. MacGregor.
Vermilion (Br. Non-Res.), Associate Member, B. E. Bury.

Lethbridge Branch District

(*The territory in Alberta and British Columbia included between the United States boundary from Saskatchewan to the 117th degree of longitude in British Columbia; north to the 50th parallel; east to the Alberta boundary; northerly on the interprovincial boundary to the north boundary of township thirteen in Alberta; east to the Saskatchewan boundary, and south on the interprovincial boundary to the United states boundary.*)

Coaldale (Br. Res.), Associate Members, R. S. Lawrence, H W. Rowley.
Diamond City (Br. Res.), Associate Member, C. S. Clendening.
Fernie, B.C. (Br. Non-Res.), Associate Member, G. E. Elkington; Student, B. J. Hawkey.
Lethbridge (Br. Res.),

Members

F. G. Cross, R. Livingstone, P. M. Sauder.

Associate Members

R. F. P. Bowman, N. H. Bradley, G. S. Brown, J. M. Campbell, C. L. Dodge, G. S. Donaldson, J. Haimes, W. L. McKenzie, W. Meldrum, C. J. L. Sanderson, A. L. H. Somerville, A. Thomson, J. T. Watson.

Junior

R. B. McKenzie.

STUDENT

E. A. Lawrence.

Macleod (Br. Non-Res.), ASSOCIATE MEMBER, N. A. Link.

Magrath (Br. Res.), ASSOCIATE MEMBER, M. F. R. Lloyd.

Medicine Hat (Br. Non-Res.), MEMBER, D. W. Hays; ASSOCIATE MEMBERS, A. C. Gardner, C. M. Moore; STUDENT, F. McCallum.

Michel, B.C. (Br. Non-Res.), ASSOCIATE MEMBER, A. Cox.

Monarch (Br. Res.), STUDENT, A. P. Alexander.

New Denver, B.C. (Br. Non-Res.), JUNIOR, W. R. Workman.

Picture Butte (Br. Res.), ASSOCIATE MEMBER, A. J. Branch; JUNIOR, W. R. Craig.

Redcliff (Br. Non-Res.), STUDENT, H. A. McColeman.

Vulcan (Br. Non-Res.), STUDENT, E. L. McPherson.

Saskatchewan Branch District

(*The Province of Saskatchewan.*)

Blenfait (Br. Non-Res.), JUNIOR, H. J. B. Richards.

Carlyle (Br. Non-Res.), ASSOCIATE MEMBER, W. E. Denley.

Claybank (Br. Non-Res.), ASSOCIATE MEMBER, S. Matthews.

Eastend (Br. Non-Res.), ASSOCIATE MEMBER, S. H. Hawkins; JUNIOR, W. N. McCann.

Estevan (Br. Non-Res.), ASSOCIATE MEMBERS, N. W. Dubois, R. J. Lee.

Goldfields (Br. Non-Res.), ASSOCIATE MEMBERS, W. G. Jewitt, E. B. Webster.

Island Falls (Br. Non-Res.), ASSOCIATE MEMBER, E. C. King; AFFILIATE, H. T. Olson.

Kamsack (Br. Non-Res.), ASSOCIATE MEMBER, J. M. Bloomfield.

Lashburn (Br. Non-Res.), STUDENT, R. B. Snyder.

Lloydminster (Br. Non-Res.), ASSOCIATE MEMBER, S. E. Durant.

Moose Jaw (Br. Non-Res.), MEMBERS, H. R. Miles, H. C. Ritchie; ASSOCIATE MEMBERS, C. K. Buchbach, A. W. E. Fawkes, R. M. Henderson, D. S. MacDonald, J. V. McNab, H. I. Nicholl, J. I. Strong; JUNIORS, R. W. Johnson, J. Lundie, J. T. Turner.

North Battleford (Br. Non-Res.), MEMBER, A. E. Sharpe; ASSOCIATE MEMBER, M. H. Stevenson; JUNIOR, J. D. George.

Outlook (Br. Non-Res.), ASSOCIATE MEMBER, B. L. Reid.

Prince Albert (Br. Non-Res.), MEMBERS, W. Christie, J. G. Reid; ASSOCIATE MEMBERS, G. H. L. Dempster, W. J. Dyer, J. B. Hamilton, H. J. Hermanson, J. Jonsson; JUNIOR, D. Lazorka.

Punnichy (Br. Non-Res.), ASSOCIATE MEMBER, S. Harding.

Regina (Br. Res.),

MEMBERS

R. W. Allen, H. S. Carpenter, J. W D Farrell, A C. Garner, D. W. Houston, A. P. Linton, D. A. R. McCannel, C. J. McGavin, T. McGuinness, H. R. MacKenzie, M. H. Marshall, S. R. Muirhead, J. M. Patton, P. C. Perry, M. J. Spratt, L. A. Thornton, S. Young, J. J. White.

ASSOCIATE MEMBERS

J. E. Bennett, W. H. Bentley, C. H. Biddell, E. W. Bull, R. A. Campbell, E. S. C. Carpenter, W. P. Cheney, F. C. Christie, D. C. M. Davies, F. C. Dempsey, H. J. deSavigny, S. G. Dethridge, E. Dickinson, C. W. Doody, E. E. Eisenhauer, G. G. Fitzgerald, H. Forbes-Roberts, W. L. Foss, R. J. Fyfe, P. R. Genders, J. R. Guildford, W. H. Hastings, T. Hogg, R. W. Jickling, W. J. Johnston, H. A. Jones, S. T. Lewis, L. W. Llewellyn, W. O. Longworthy, E. E. Lord, D. D. Low, O. W. Martyn, P. G. McAra, T. S. McKechnie, G. L. MacKenzie, J. C. Meade, J. Mould, J. R. Paget, S. R. Parker, W. W. Perrie, R. E. Phelan, W. R. Pottle, J. H. Puntin, F. B. Reilly, H. L. Roblin, W. H. Ross, J. G. Schaeffer, B. P. Scull, D. C. Stephenson, J. J. A. Street, T. G. Tyrer, W. Waters, J. R. Young.

JUNIORS

N. R. Crump, E. J. Durnin, R. A. Emerson, A. F. S. Fuller, E. C. Hay, J. W. Leach, J. E. Thom, R. W. Warren.

Rosetown (Br. Non-Res.), ASSOCIATE MEMBER, J. C. Todd.

Saskatoon (Br. Non-Res),

MEMBERS

A R. Greig, W. E. Lovell, C. J. Mackenzie, W. G. Worcester.

ASSOCIATE MEMBERS

G. D. Archibald, A. L. Cole, C. A. Cook, I. M. Fraser, N. B. Hutcheon, A. M. Macgillivray, R. A. McLellan, F. J. Martin, A. A. Murphy, E. H. Phillips, E. K. Phillips, R. A. Spencer, W. M. Stewart, J. M. Taylor, J. E. Underwood, H. McI. Weir, G. M. Williams, F. Young.

STUDENTS

M. Fast, C. R. Forsberg, D. S. McArthur.

Swift Current (Br. Non-Res.), MEMBER, B. Russell; ASSOCIATE MEMBER, L. F. Creighton.

Tisdale (Br. Non-Res.), ASSOCIATE MEMBER, J. E. Mollard.

Weyburn (Br. Non-Res.), ASSOCIATE MEMBER, A. W. Shattuck.

Yorkton (Br. Non-Res.), ASSOCIATE MEMBERS, H. M. Bailey, M. Sinclair.

Winnipeg Branch District

(*The Province of Manitoba.*)

Brandon (Br. Non-Res.), MEMBER, W. H. Shillinglaw; ASSOCIATE MEMBERS, E. C. Cowan, S. C. Wilcox.

Churchill (Br. Non-Res.), ASSOCIATE MEMBERS, G. Coutts, G. W. Rowe.

Dauphin (Br. Non-Res.), ASSOCIATE MEMBER, R. C. Robinson.

Duck River (Br. Non-Res.), MEMBER, F. S. Small.

Flin Flon (Br. Non-Res.), ASSOCIATE MEMBER, A. Taylor; JUNIORS, J. T. Nichols, W. C. Weir; STUDENTS, R. H. Moore, M. K. T. Reikie.

Fort Whyte (Br. Res.), ASSOCIATE MEMBER, C. W. Edmonds.

Garson (Br. Non-Res.), ASSOCIATE MEMBER, C. H. Blanchard.

Lydiatt (Br. Non-Res.), MEMBER, W. A. James.

Pine Falls (Br. Non-Res.), ASSOCIATE MEMBER, M. W. Turner.

Pembroke (Br. Non-Res.), Associate Members, J. L. H. Bogart, W. J. Moore.
Perron, Que. (Br. Non-Res.), Associate Member, J. A. Black.
Perth (Br. Non-Res.), Member, G. C. Dunn.
Petawawa (Br. Non-Res.), Student, A. B. Connelly.
Prescott (Br. Non-Res.), Member, W. L. LeRoy; Junior, G. H. Kingston; Students, J. G. Kerfoot, E. L. Kingston.
Renfrew (Br. Non-Res.), Associate Member, J. R. Stewart.
St. Elie de Caxton, Que. (Br. Non-Res.), Associate Member, S. Troop.
Siscoe, Que. (Br. Non-Res.), Associate Member, H. C. Seely; Junior, W. E. Seely.
Smith's Falls (Br. Non-Res.), Associate Member, F. R. V. Billie.
Spencerville (Br. Non-Res.), Member, C. H. Ellacott.
Sullivan, Que. (Br. Non-Res.), Associate Member, I. M. Marshall; Junior, G. M. McLean.
Temiskaming, Que. (Br. Non-Res.), Member, A. K. Grimmer; Associate Members, J. J. Freeland, B. Grav, W. G. Hardy, J. G. MacLaurin.
Thurso, Que. (Br. Non-Res.), Student, A. Clairmont.
Val d'Or, Que. (Br. Non-Res.), Associate Member, H. Mugaas.
Westboro (Br. Res.), Member, A. E. Hopper.
Williamstown (Br. Non-Res.), Associate Members, I. G. Henderson, D. D. MacCrimmon.
Woodroffe (Br. Res.), Junior, G. D. Pooler.
Yellowknife, N.W.T. (Br. Non-Res.), Member, W. G. Stuart.

ZONE C

(*The Province of Quebec.*)

Montreal Branch District

(*The Counties of Compton, Stanstead, Sherbrooke, Richmond, Wolfe, Arthabaska, Megantic, Chambly, Drummond, Yamaska, Richelieu, St. Hyacinthe, Bagot, Shefford, Rouville, Brome, Missisquoi, Iberville, St. Johns, Napierville, La Prairie, Verchères, Chateauguay, Huntingdon, Beauharnois, Jacques Cartier, Laval, Two Mountains, Terrebonne, L'Assomption, Montcalm, Joliette, Berthier, Maskinongé, Argenteuil, Vaudreuil, Soulanges, and also all other territory in Canada not allocated.*)

Asbestos (Br. Non-Res.), Students, W. G. Baker, E. R. Brannen, J. J. Donovan, H. B. Howe.
Beauharnois (Br. Non-Res.), Associate Members, H. F. Abbott, B. K. Boulton, P. H. Morgan, C. H. Pigot.
Beebe (Br. Non-Res.) Student, W. B. Haselton.
Black Lake (Br. Non-Res.), Associate Member, A. D. Porcberon.
Boucherville (Br. Res.), Member, E. S. Mattice.
Brownsburg (Br. Non-Res.), Associate Members, J. W. Houlden, C. H. Jackson; Students, G. F. Clarke, J. H. Peters, H. M. Sberwood, J. W. Suthren.
Bury (Br. Non-Res.), Associate Member, E. F. Hawley.
Cedars (Br. Non-Res.), Associate Member, J. B. Barnum.
Chambly Canton (Br. Non-Res.), Junior, R. W. Phillips.
Como (Br. Non-Res.), Associate Member, H. W. R. Shepherd.
Cowansville (Br. Non-Res.), Associate Member, A. G. Scott.
Danville (Br. Non-Res.), Junior, C. R. Engler.
Drummondville (Br. Non-Res.), Associate Member, F. A. Chisbolm; Juniors, N. W. Kershaw, O. N. Mann; Student, W. B. Guihan.
East Angus (Br. Non-Res.), Associate Member, E. P. Wilson.
Eustis (Br. Non-Res.), Student, H. P. Godard.
Farnham (Br. Non-Res.), Associate Members, R. H. Stenhouse, K. B. Wallace; Student, L. P. L'Homme.
Georgeville (Br. Non-Res.), Associate Member, W. A. Murray.
Granby (Br. Non-Res.), Student, P. R. Martin.
Kilmar (Br. Non-Res.), Associate Member, J. A. Creaser; Student, R. A. Sancton.
Knowlton (Br. Non-Res.), Junior, H. A. Gray.
Lennoxville (Br. Non-Res.), Associate Member, G. M. Sutherland; Student, K. S. Crawford.
McMasterville (Br. Non-Res.), Junior, M. V. MacDonald; Student, A. T. Fell.
Montreal (Br. Res.), (Tbe Island of Montreal),

Honorary Members

F. D. Adams, G. H. Duggan, S. J. Hungerford.

Abstracts of Current Literature

Power-Plant Requirements of a Distillery

By Hiram L. Walton, Mechanical World, September, 2, 1938.

Abstracted by F. G. Green, A.M.E.I.C.

In brief, the operation of a distillery consists:

(*a*) in grinding the grain to meal;
(*b*) mixing this meal with water and steam-cooking it to expand the cells and gelatinize the starch;
(*c*) saccharifying this "mash" by malt;
(*d*) adding yeast to the "wort" so formed;
(*e*) distilling off the alcohol (or whiskey) from the fermented product resulting from the last step (this fermented product is colloquially known as "beer").

By-products include the spent grain sold as "distiller's grains" and, in some cases, dry ice and vegetable oil.

The spent grain is found as suspended matter in the dealcoholized beer or "slop" and is recovered by straining it out. The liquid remaining is known as "thin slop" and, if no stream-pollution regulations exist, is usually run into the district drainage system. If this is not permissible it is concentrated in multiple effect evaporators, mixed with the spent grain and the whole passed through the grain dryers. Dry ice is, naturally, made by compressing the carbon dioxide given off in the fermenting process. Its recovery may require up to 10 per cent of the power used by the distillery.

The Peoria plant of Hiram-Walker-Gooderham and Worts has a mashing capacity of 22,000 bushels per day. A bushel (to the distiller) is 56 lb. regardless of kind of grain used and a yield of five proof gallons of alcohol per bushel is considered fair distilling operation.

The Peoria plant is completely motorized, power being supplied by two non-condensing extraction turbines of 1,500 kw. capacity each. These turbines are supplied with steam at 250 lb. gauge and 100 deg. F. superheat. They exhaust at 20 lb. back pressure and provide for the extraction of steam at 90 lb. pressure. The plant is inter-connected with the power system of the local utility company under agreement so that power may be transferred in either direction as the load conditions for steam and electric power may require. Usually the flow is to the power company's system.

In carrying out the distilling processes, saturated steam is required at 90 lb. pressure for mashing and cooking; at 60-20 lb. for distilling; at 20 lb. for thin-slop evaporation and at 125 lb. for grain drying. Mechanical power is required for conveying, milling, agitation and pumping.

Distribution of steam consumed at Peoria is approximately as under:—

20 lb. steam—	Evaporators	33⅓%	71⅓%
	Distillery	22 %	
	Power house	10 %	
	Heating	6 %	
90 lb. steam—	Stills	3 %	12%
	Cookers	9 %	
125 lb. steam—	Driers	16⅔%	16⅔%

Electric power utilization is as follows:—

Power house	20%	Dry ice	9%
Wells	16%	Bottling	9%
Milling and mashing	15%	Warehouses	6%
Distilling	5%	Miscellaneous	4%
Slop disposal	16%		

The Louisville, Ky., Walkerville, Ont. and Dumbarton, Scotland, plants are also briefly described.

The Cost of Substitute Motor Fuel in Europe

By Dr. Gustave Egloff, Industrial and Engineering Chemistry, October 1938.

Abstracted by A. A. Swinnerton, A.M.E.I.C.

This article discusses the attempts of the various European countries to provide motor fuels from native resources and gives figures showing the costs of these nationalistic efforts.

A number of European nations, directly and indirectly, subsidize indigenous motor fuels by high taxes on imported motor fuels, reduction of taxes on native fuels and on vehicles using such fuels, and in some cases by direct subsidy. The appended table shows the motor fuel consumption, crude oil production, and production of various substitute fuels in 1937 in various European countries.

Motor Fuel Consumption, Production of Crude Oil, and Substitute Motor Fuels—1937
(Thousands of barrels)

	Motor Fuel Consumption	Crude Oil Production	Motor Fuel from Coal Hydrogenation	Benzol
Great Britain	44,200	.....	1,300	1,800
France	25,000	532	110	640
Germany	20,000	3,077	6,400	3,400
Italy	5,200	150	.....	.....
Estonia	.....	.....	.....	.....
All Europe	95,000	263,000*	7,810	6,500

	Compressed Gas (Gasoline equivalent)	Power Alcohol	Producer Gas from Wood, etc. (Gasoline equivalent)	Shale Spirit
Great Britain	.....	130	.....	200
France	.....	1,200	} 500 (France, Germany, Italy)	{ 12
Germany	1,200	1,700		.....
Italy	320	300		.....
Estonia	.....	.....	.....	58
All Europe	2,000	4,000	500	310

*Includes Russia.
The conversion factor, tons to barrels, has been taken as 8 to 1.

Coal

The primary substitute motor fuel in Europe is derived from the hydrogenation of coal, or carbon monoxide (produced from coal or coke). The synthetic liquid motor fuel production in Germany will be at the rate of about 17,000,000 barrels a year, when all plants are in operation. In England, about 1,300,000 barrels of gasoline a year are produced by direct hydrogenation of coal. France is producing about 110,000 barrels a year of motor fuels from water gas. In Europe, it is estimated that the cost of a U.S. gallon of motor fuel, produced by either coal or carbon monoxide hydrogenation, is about $0.18. This compares with a cost of approximately $0.05 a U.S. gallon for gasoline, f.o.b. Gulf terminals. Gasoline costs approximately 59.6 cents per gal. in Germany, of which 36 cents is direct tax on imported gasoline. It is landed in Hamburg at 9 cents per U.S. gal., so that there is a spread of about 50 cents a gallon. Hydrogenated gasoline in England enjoys a preference of 18 cents a gallon. The synthetic gasoline in France enjoys a tariff preference of over £16 per ton, approximately 25 cents a gallon, as well as certain subsidies.

Benzol Motor Fuel

The primary source of benzol is the high temperature carbonization of coal for coke and gas production. The benzol is obtained by stripping the gas, the average yield being about 3 gal. per ton of coal. The production of benzol is dependent on the activity of coke-ovens and gas works, and is, therefore, capable of only slight expansion. Furthermore, in case of war it would be reserved for the manufacture of explosives. Egloff estimates that, in 1937, the extra cost to European consumers, due to using benzol motor fuel in place of gasoline, was more than $49,000,000, equivalent to 20 cents a gallon.

Compressed Gas

Combustible gases obtained from coal carbonization, oil cracking, and natural gas wells, are a growing source of substitute motor fuels in Europe. The greatest development in the use of compressed gases has been in Germany, where it is estimated that there are more than 25,000 motor vehicles using compressed gas as fuel, and that (in 1938) more than 150,000 tons of gasoline will be replaced by using compressed gas. The cost of compressed gas in Germany is equivalent to gasoline at 40 to 60 cents a gallon.

Italy has developed a natural gas field, near Milan, which yields nearly pure methane. The gas is compressed to 3,000 lb. per sq. in., and is distributed, from filling stations, in cylinders, to about 500 trucks and buses in Milan and Florence. At the present time (1938), in Italy, the natural gas fuel used is equivalent to about 40,000 tons of gasoline a year, and for all Europe the amount used is equivalent to 250,000 tons of gasoline a year.

Power Alcohol

The use of power alcohol by European countries is supported by heavy government subsidies, and increased from 59,000 tons in 1930 to 648,000 tons in 1936. However, from now on, the use will probably decrease, due to large economic losses and to its encroachment upon the food supply. The loss of income during 1937 is estimated as equivalent to $105,000,000. Germany and France have been the largest consumers of power alcohol in Europe, and their supply is derived mainly from potatoes and sugar beets. German regulations require a 10 per cent blend of alcohol, and in France the proportion varies from 10-35 per cent. The German subsidy to alcohol producers is about 39 cents a gallon, and the French about 36 cents a gallon. Both in Germany and France the consumption of power alcohol is decreasing due to the diversion of alcohol to munition manufacture and to the drain on the food supply (potatoes, etc.).

Producer Gas from Wood and Coal

Producer gas from wood and coal is not very important as a substitute for motor fuel even in those countries that are urging its wider adoption. France has about 4,500 wood-burning vehicles, Germany about 2,200, and Italy 2,200, and wood filling stations are found in all three countries. The use of wood is desired primarily to replace imported petroleum, the estimated consumption, in Germany, France, and Italy, being 450 million lb., equivalent to 18 million gallons of gasoline. There are, apparently, no figures available as to the number of coal-burning vehicles in Europe, but the number is probably small.

Oil Shales

Oil shales are found in many countries in Europe, but they are developed commercially only in Great Britain, Estonia, and France. Since these countries produce no crude oil, the exploitation of the shale deposits has become increasingly important from the nationalistic standpoint. In all three countries they receive governmental assistance in one form or another, the cost above imported gasoline being nearly $2,000,000. In loss of taxes, the use of shale motor fuel costs the various governments about 18 cents an Imperial gallon.

Other Substitutes

The desperate need of some countries to make themselves self-sufficient in motor fuels is reflected in the attempts to use ammonia, acetylene, and hydrogen in motor vehicles, but so far they are only in the experimental stage. In 1937, the production of substitute motor fuels in Europe was equivalent to about 17 million barrels of gasoline, or about 20 per cent of requirements. In 1938, it is estimated that 25 per cent of the motor fuel requirements will come from substitute fuels. In 1937, the extra cost to the consumer and state, due to the use of substitute fuel was $235,000,000, equivalent to 32 cents a gallon. In 1938, this extra cost will probably reach $300,000,000.

Rubber-Tyred Electric Train

Railway Gazette, October 14, 1938

The French National Railways have just put into experimental service on the Paris suburban lines of the ex-Etat system, a novel experimental electric three-car train, built by the Michelin Company at Clermont-Ferrand. The new vehicle has the characteristic pneumatic tyres of the maker. It is operated on the standard third-rail system, with a nominal voltage of 650. A triple-car articulated arrangement has been adopted, and measures 125 ft. overall. Each of the four bogies has eight pneumatic-tyred wheels, and the construction is similar to that of the bogies on the latest Michelin types of petrol-engined railcars.

In each bogie the two centre axles are driving, and the two end axles carriers. There is one motor driving each bogie, but it is supported on the underframe of the coach and drives the two other axles through a cardan shaft with flexible couplings. The actual drive on all the axles, and the drive in between the two axles is of the worm gear differential type. On the one-hour rating the aggregate h.p. of the four motors is 775 at 1,330 r.p.m., and on the continuous rating the output is 650 h.p. at 1,430 r.p.m. At the one-hour rating the hp. per ton of tare weight is 24.2. The electrical equipment gives an acceleration from rest of about 3.65 ft. per sec. per sec. as a maximum. Multiple-unit control is fitted, so that any number of these triple-car sets can be worked as a train by one man. The maximum permissible speed is 71 m.p.h., but in normal suburban service, working out of St. Lazare, speed will rarely exceed 50 m.p.h. Full application of the brakes enables the train to be stopped from a speed of 50 m.p.h. in 170 yd. Special shoes are provided on each bogie to take the return current to the running rails.

The bodies and framework are of welded all-metal construction, with sheet steel outer panels with interior linings of plywood, faced with imitation leather in a dark green colour. As the car is intended only for use on short-distance services, the seats and interior equipment generally are of a simple character. Just behind the driving cabin at each end is a small baggage compartment, but at rush hours this is used for carrying standing passengers. All the doors on the outside are of the sliding type, and are closed from the driver's cabs by compressed-air motors. There are 136 fixed seats, and 44 folding seats arranged at the entrance vestibules and in the luggage compartments, and, according to the French methods of computation, there is room for 120 standing passengers.

A New Method of Studying the Combustion Process in Boiler Furnaces

By John M. Drabelle, presented before the Iowa State Convention of the National Association of Power Engineers, Marshalltown, Iowa, June 17th, 1938.

Abstracted by Dr. C. A. Robb, M.E.I.C.

Photographing of a boiler furnace fire with colour motion picture film has been made possible through the co-operation of Mr. V. Rayment of the Eastman Kodak Company and the Corning Glass Works. The screens of Aklo glass used transmit most light rays but filter the infra-red or heat rays thus protecting the camera and operator. Other selector filters may be added. Gas stratifications have been observed.

Evidence, that to test the quality of combustion a more comprehensive analysis is required than can be obtained with the conventional apparatus, is provided by publication RI-3379 of the U.S. Bureau of Mines issued in January, 1938. This describes tests conducted in co-operation with the University of Washington on a domestic overfeed stoker burning various coals continuously and intermittently. The flue gas sample was continously withdrawn at a constant rate, as determined by a flow meter, and the results tabulated as follows:—

Constituents of Flue Gas in Per Cent
(From Table V of RI-3379)

Test Number	A	B	C
CO_2	13.8	14	11.8
Oxygen	4.4	5	7.9
CO	0.9	0.3	nil
Hydrogen	0.2	nil	nil
Methane	0.1	nil	nil
Ethylene	0.1	nil	nil

Test B was at a higher rate of combustion than A, and C was at a fairly high rate. Under the conditions of these tests, 0.1 per cent of unsaturated hydrocarbons, considered as ethylene, in the flue gas represents 2.5 per cent of the heating value of the coal. A high smoke density occurred when methane and ethylene were present in the flue gas.

In 1920, Mr. Thomas A. Marsh, then associated with the Combustion Engineering Corporation, and the author, conceived the idea of injecting air over the fire bed in power station boilers, and letters patent were applied for. This was termed "overfired air." A search disclosed a patent granted in 1838 and that the idea was not new. A successful application requires 10 to 15 per cent of the combustion air, at a velocity of 800 to 1,500 ft. per min., which may be provided through a 1 to 1½ in. pipe or nozzle at a pressure of 6 to 8 in. of water, to drive the air blast into the mass of gas coming off the fuel bed, and to create turbulence. When available, preheated air should be used. The effect has been observed in an application of high pressure air to two recently installed boilers at the Boone station of the Iowa Electric Light and Power Company. When the air blast is turned off, the fire becomes smoky yellow and the stack darkens. When the blast is resumed, the fire becomes white and the smoke density is reduced. The same system of air injection, recently applied to three boilers of the Central Fibre Products Co. at Tama, Iowa, has resulted in improved smoke conditions and higher boiler efficiency.

The motion picture film exhibited showed the effect of air injection on an underfeed stoker at the Cedar Rapids Power Station. In this case the air was not properly directed downwards into the flame, but was blowing across the top and the desired results were not produced.

While only a limited number of furnaces have been photographed, further data will probably be available at the next annual meeting of the National Association of Power Engineers.

Marking the Highway Edge

E. J. DuPont de Nemours and Company have issued a bulletin on their new plastic material 'Lucite,' whose optical properties have led to its successful use in reflecting highway markers for outlining the highway edge or curb at night, effectively warning the motorist of road intersections, bends to the left or right and steep grades, without the necessity of installing overhead lights.

In the country the markers are placed 8 ft. from pavement edge or 10 ft. where the shoulder is extra wide; in cities and villages 4 ft. back from the curb face. Uniformity of spacing, location and height is of fundamental importance for effective roadway delineation.

The system has been tried with good results by the Michigan Department of Highways on some seventy miles of U.S. Highway No. 16 (Detroit to Lansing), a highway with extremely heavy traffic. The scheme involved the placing of the reflecting markers on thirty-inch steel standards spaced 100 ft. apart and flanking the road. A break in the line of lights shows as a warning to the motorist; under favourable conditions his car headlights make the markers visible more than a mile ahead. This is made possible by the remarkable reflecting power of the discs, due to the brilliance of the methyl methacrylate resin of which they are made and their effective optical design. The discs are 1⅝ in. dia. and have smooth slightly convex faces, their prismatic backs having accurately moulded facets of a special design developed by J. C. Stimson.

A night-accident analysis of U.S. Highway No. 16, Detroit to Lansing, taken over three months, April to July 1938, shows a reduction of 79 per cent after the installation of this reflector indirect lighting compared with the same period in 1937.

The Michigan Department of Highways states that the average cost for two lines was about $350 per mile installed.

An Investigation into the Causes and Prevention of the Corrosion of Tar Stills

By D. D. Pratt, H. C. K. Ison and R. G. Wood, Great Britain, Chemistry Research Board Special Report 4, January 1938.

Abstracted by A. A. Swinnerton, A.M.E.I.C.

For many years the retorts employed in the carbonization of coal for gas manufacture were of the horizontal type, worked at high temperatures and yielding, as a by-product, a tar somewhat similar to that furnished by coke ovens. In recent years, as is well known, vertical retorts have come into operation, and these yield a tar which is less aromatic than those emanating from horizontal retorts and coke ovens; it contains a higher proportion of resinous and aliphatic constituents and also a higher proportion of tar acids, i.e., of homologues of phenol. These different varieties of tar have an important bearing on the life of the stills employed in their distillation, which are usually made of mild steel. The average life of a 12-ton still, when working entirely on horizontal-retort tar is equivalent to a throughput of 16,000 tons, while throughputs of as much as 30,000 tons have not been uncommon. On the other hand, the corrosive action of a mixture of 75 per cent vertical-retort and 25 per cent horizontal-retort tar is such that the life of the still is reduced by 50 per cent, i.e., the average throughput is only between 7,000 tons and 8,000 tons. It has been calculated that this reduction in the life of the still is equivalent to 5d. per ton of tar distilled, and that the total cost to the tar-distillation industry is of the order of £25,000 annually.

With the object of studying the corrosive properties of coal tars and of finding means to overcome the destructive action on the still of the harmful constituents present, an investigation was put in hand some time ago by Dr. D. D.

Pratt and Messrs. H. C. K. Ison and R. G. Wood, on behalf of the Association of Tar Distillers, at the Chemical Research Laboratory, Teddington. A report of the results of the research has now been published by the Department of Scientific and Industrial Research. This states that an exhaustive examination of a long series of tar fractions has established that, at high temperatures, the resinols, or phenolic resins, are very active in promoting attack, and that in the presence of ammonium chloride this activity is intensified. Whereas coke-oven and horizontal-retort tars are almost devoid of resinols, these components are present in fair quantity in vertical-retort tars. As the resinols are insoluble in petroleum, additions of the latter enable them to be precipitated and removed from the tar, and experimental distillations carried out on the petroleum extract of a corrosive tar have shown that the attack caused by this fraction is much less than that manifested when a so-called non-corrosive tar is distilled. Failing methods such as this, which are based on the preliminary treatment of the tar, the only alternative is to find a constructional material for the still which will withstand the attack of the corrosive constituents of the tar. Efforts made to develop a protective coating for mild steel have proved fruitless, but experiments have shown that a 2.5 per cent nickel-0.6 per cent chromium steel is moderately resistant to the action of the resinols, while the stainless steels tested are quite unattacked. Ternary 80:14:16 nickel-chromium-iron alloys, and 60:40 nickel-copper alloys were also found to be very resistant.

Zinc-Tight Steel Wire

By D. E. Bankart, Electrical News and Engineering, August 1st, 1938.

Abstracted by H. S. Grove, A.M.E.I.C.

The author describes an improved process used for zinc-coating steel wire in a plant recently installed by the Steel Company of Canada at Lachine, Quebec.

The wire, instead of being passed through a tank of molten zinc, as was formerly the practice, is drawn through electrolytic cells, where a coating of zinc from pure zinc anodes is electrically deposited. The thickness of the deposit, which is smooth and uniform, is regulated by the current density and the speed with which the wire moves.

The zinc coating and the wire are so closely united that the wire can be coiled around a rod of its own diameter without flaking taking place—a very much severer test than the wrapping test specified in the Canadian Engineering Standards Specification for Zinc Coated Wire, as revised under No. C3-1937 to cover the maximum of developments in Canadian factories.

This plant is the only one of its kind in Canada and one of four or five similar plants in the whole world.

The Wellington Lake Power Project

By W. P. Dunbar, S.L.S., Canadian Surveyor, July 1938.

Abstracted by J. L. Rannie, M.E.I.C.

This article describes the surveying features of the Wellington Lake hydro-electric power project in Northern Saskatchewan. This development, now under construction by the Consolidated Mining and Smelting Company Limited, has a number of unusual and interesting features. Situated near the company's mining property near Goldfields, Saskatchewan, about fifteen miles north of the easterly end of Lake Athabasca, it is one of the most northerly such projects in the West.

Aeroplanes were used in many of the preliminary investigations; the maps of the whole area were plotted from aerial photographs.

Meteorological observations were commenced in the Goldfields area about two years ago, prior to which the only data were obtained from incomplete records of rain and snowfall and average monthly temperatures at Chipewyan and Fond du Lac, the former 125 miles west of Goldfields. No records were kept of evaporation, nor until lately had any stream flow records been kept for any of the rivers. Thus meteorological and rainfall data were meagre.

In the absence of precise run-off data the areas of the watersheds were first roughly estimated from the air and later calculated from the aerial maps which had just been plotted. Factors of 75 per cent evaporation and 25 per cent run-off were first employed, these being later altered to 68 per cent and 32 per cent from information derived from stream flow measurements and records from similar conditions in Manitoba.

The first surveys made for power purposes were in the fall of 1934 when the power requirements were yet indefinite, and were naturally for the purpose of obtaining general information on the power possibilities, such as a reconnaissance from the air, determining elevations of lakes by use of the plane's altimeter and short traverses in certain sections. The following summer and winter more specific data were secured. By 1936 the situation as regards power needs was clearer and investigation of a power site on Beaverlodge lake only a mile from Goldfields was undertaken. The site had many advantages, but unfortunately the possible power was insufficient for the requirements.

Some 25 miles north the Tazin river watershed and Tazin lake, which discharge west and north to Great Slave lake, seemed attractive as a source of adequate stream flow and considerable water storage, if the water could be diverted towards Lake Athabasca about 433 ft. below Tazin lake. The height of land was close to the south shore of Tazin lake, and the problem was to discover, if possible, an economical diversion of the Tazin lake waters towards Lake Athabasca.

The surveyor's working season in that northern area is short, and speed with reasonable accuracy was essential; the airplane was of the greatest assistance in covering the whole area. The height of land was found to be mostly a plateau except at one point, Taz bay, where a low rock ridge roughly 1,000 ft. across separated the bay from Mud lake whose waters discharged through Charlot river into Lake Athabasca. By excavating at the outlet of Mud lake to lower it 14 ft., raising Tazin lake by a dam at its outlet so its elevation would be higher than Mud lake, and driving a tunnel through the rock ridge between Tazin lake and Mud lake the diversion would be completed.

The final preliminary step was the examination of the river below Mud lake to obtain data on the possibilities of hydro sites, etc. Again the aeroplane was utilized, landing on many small lakes and obtaining their elevations, flying along both sides of the river to observe the fall of the river at different points, the rock formations, soil and water conditions, timber, sand and gravel available for construction and particulars regarding each potential power site.

This diversion was finally selected, and the site for development of power was chosen at Wellington lake.

The present and maximum quantity of water to be diverted is 500 and 1,000 c.f.s. The estimated average head of water available is 70 ft. The estimated initial and maximum horsepower is 3,300 and 6,600. The transmission line from Wellington lake to the Consolidated Mining and Smelting Company's holdings at Goldfields will be about 22 miles long.

It is interesting to note that winter ice conditions which are the bugbear of so many hydro plants in Canada and United States are not serious in these northern areas, as most of the rivers are open and free running even in the coldest of winters.

Seventh International Management Congress, Washington, D.C., September 19th to 23rd, 1938

Papers Presented

An account of this Congress and a list of papers other than the ones printed below were given on pages 474 and 475 of The Engineering Journal, October 1938.

Production:

The Importance of Research and Development in Maintaining Technical Progress—M. W. Smith (U.S.A.).
Basic Factors Governing the Effective Coordination of Manufacture with Other Operating Activities of the Business—A. H. Robinson (U.S.A.).
Purchasing and Profits—Edward T. Gushee (U.S.A.).
Constructive Purchasing Policies—F. Albert Hayes (U.S.A.).
Description of Reorganization of a Works Management —C. P. Turner (Great Britain).
Insurance Management—A Major Phase of Business Administration—Jorh R. Blades (U.S.A.).
The Decentralization of Industry—W. J. Cameron (U.S.A.).
What Savings Have Been Obtained by the Electricity Works of the Municipality of Budapest in the Fields of Technical Operation and Management by the Employment of the Means of Rationalism—Pal Plosz (Hungary).
Rationalization at the Municipal Water Works of Budapest—Ferdinand Liszievicz (Hungary).
Rationalization of the Repair Service of Motor Buses—Alfred Ballo (Hungary).
Maintenance in Air Transportation—S. B. Kauffman (U.S.A.).
Planning the Processes and Equipment for Manufacture and Budgeting for Equipment Replacement—C. E. Bleicher (U.S.A.).
Flow of Work and Non-Continuous Production—Dr. Emanuel Slechta (Czechoslavakia).
Organization for the Control of Manufacture—L. V. Bedell (U.S.A.).
Automatic Luminous Control of Manufacturing Processes and Its Results—Stan. Sliwinski (Poland).
Example of Planning in a Repair Shop—Adam Kucharzewski (Poland).
Les Méthodes de Regulation Appliquées aux Voies Navigables Françaises—L. P. Alvin (France).
The Flow of Work in Non-Continuous Production; Assuring the Flow of Work in Contracting—V. W. van Gogh (Holland).
Modern Quality Control Technique—David Levinger (U.S.A.).
Work Simplification for Promoting Manufacturing Efficiency—Allan H. Mogensen (U.S.A.).
Some Developments in Motion Study Training—A. G. Shaw (Great Britain).
Some Recent Data about the Acquisition of Skill of Apprentices and of Trained Operators—J. F. Cahen (Holland).
Research in Motion and Time Study—Ralph M. Barnes (U.S.A.).
Grading of Labor Occupations—K. O. Schulte (U.S.A.).
The Supervision of Enterprises by Checking Their Estimates of Receipts and Expenditures—Eugene Francis Felsoory (Hungary).
Accounting for the Control of Manufacture—George N. Benoit (U.S.A.).
Objectives of Standard Costs and Their Use in Measuring Performance—Earl A. Green (U.S.A.).
Optimum and the Most Profitable Load—Ignacy Swiecicki (Poland).

Distribution:

Consumer Wants and Product Acceptance—Paul T. Cherington (U.S.A.).
Customer Research for Department Stores—N. Baliol Scott (Great Britain) and R. Robson (Great Britain).
The Merits of Selective Selling—Wroe Alderson (U.S.A.).
Scientific Determination of Regional Sales Potentials—L. D. H. Weld (U.S.A.).
Some Recent Developments of the Problem of Seasonal Variations in Sales and Sales Results—Dr. J. G. Stridiron (Holland).
Fundamentals of Sound Sales Planning—Lawrence B. Whit (U.S.A.).
The Work of the International Chamber of Commerce in the Field of Distribution—The International Chamber of Commerce (France).
Die Arbeiten der Rationalisierung in der Deutschen Absatzwirtschaft 1935-1937—Ein Gemeinschaftlicher Beitrag (Deutschland).
Equalizing the Flow of Goods in Distribution—William H. Ingersoll (U.S.A.).
The Significance of Large Scale Retail Operations in Present Day Distribution of Goods—Prof. Paul H. Nystrom (U.S.A.).
The Agricultural Co-operative Movement in Relation to Consumer Co-operation or Private Trade—A. H. Stensgard (Sweden).
Distribution Cost Statistics and Gross Profit—Dr. F. L. Van Muiswinkel (Holland).
Changes of Operating Expense Ratios at Different Price Levels—Vilem Sada (Czechoslovakia).
Les Limites de la Recherché des Bénéfices—Robert Caussin (Belgique).
Distribution Cost Analysis—Frank M. Surface (U.S.A.).
Pricing Policies and Customer Classification—Williar L. Thorp (U.S.A.).
Educated Consumers—Improved Production—Eleonor Lilliehook (Sweden).
Packaging and Its Effect upon the Standard of Living—Irwin D. Wolf (U.S.A.).
Design as a Constructive Stimulant in Marketing—Walter Derwin Teague (U.S.A.).
Rationalization and Standardization of the Distribution of Goods—Ruben Rausing (Sweden).
Profitable Marketing through Scientifically Planned Advertising—Frank R. Coutant (U.S.A.).
The Role of Control and Measurement in Advertising Management—Prof. Neil H. Borden (U.S.A.).
The Growth and Function of the Advertising Agency—Stanley Resor (U.S.A.) and William G. Palmer (U.S.A.).
Some Features of the Sales-Promoting Activities of the Svenska Sockerfabriks Artiebolaget—Svenska Sockerfabriks Aktiebolaget (Sweden).
The Means and Methods of the Producer to Reach the Consumer—Wilh. Goransson (Sweden).
Modern Methods of Sales Promotion—John Cameron Aspley (U.S.A.).
The Co-ordination of Advertising and Sales Promotion—C. B. Larrabee (U.S.A.).
Scientific Direction of Sales Effort—Clarence Francis (U.S.A.).
Unifying the Efforts of Sales and Engineering Departments in Marketing Industrial Equipment—C. R. Cary (U.S.A.).
Salesmen Training—G. H. Armstrong (U.S.A.).
The Training of Shop Assistants in the Swedish Co-operative Movement—H. Elldin (Sweden).
Salesmen's Compensation and Incentives—Dr. Harry R. Tosdal (U.S.A.).
Expenditure for Distributing Staff in Prosperity and Depression Periods—Dr. Jan Tille (Czechoslovakia).

FIFTY-THIRD

ANNUAL GENERAL MEETING

and

GENERAL PROFESSIONAL MEETING

Under the Distinguished Patronage of

THEIR EXCELLENCIES THE GOVERNOR-GENERAL
AND LADY TWEEDSMUIR

OTTAWA— TUESDAY AND WEDNESDAY FEBRUARY 14 and 15, 1939

PROGRAMME

Tuesday, February 14th—

10.00 a.m.	Opening of Annual Meeting
12.30 p.m.	Luncheon
2.30 p.m.	Continuation of Annual Meeting
4.00 p.m.	Retiring President's Address
7.30 p.m.	Annual Banquet
10.30 p.m.	Dance

Wednesday, February 15th—

10.00 a.m.	Technical Sessions
12.30 p.m.	Luncheon
2.30 p.m.	Technical Sessions
8.00 p.m.	Social Gathering

Ladies will be cordially welcome at all functions. The Meetings will be held in the CHATEAU LAURIER as usual.

Arrangements for the meeting are in the hands of an Ottawa Branch Committee, under the Chairmanship of J. L. RANNIE, M.E.I.C.

ANNUAL BANQUET, Tuesday, February 14th

Guests of honour—Their Excellencies the Governor-General and Lady Tweedsmuir.

Guest speaker—Colonel Willard Chevalier.

Following the banquet there will be dancing.

PAPERS

C. A. McGRATH, Hon.M.E.I.C.
Some Problems Involved in the Expansion of Canada.

D. W. HAYS, M.E.I.C.
Irrigation Developments, Its Possibilities and Limitations.

F. H. PETERS, M.E.I.C.
Mountain Water for the Prairie Grassland.

C. H. ATTWOOD, M.E.I.C.
Soil Water Conservation.

E. S. ARCHIBALD, B.A., D.Sc.
A Livestock Programme in Western Rehabilitation.

G. A. GAHERTY, M.E.I.C.
Rehabilitation Through Water Conservation.

GEORGE SPENCE
Prairie Farm Rehabilitation.

M. W. MAXWELL, M.E.I.C.
American Industry Looks at Canada.

E. V. NEELANDS and J. P. MILLENBACH, MM.C.I.M.M.
Mining Methods at the Canadian Malartic Mine.

THE ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE OF CANADA

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

VOLUME XXI DECEMBER, 1938 No. 12

Once again we approach the joyous season of Christmastide and the New Year—the season when the pulse seems to beat faster, when we remember old friends, when we make plans for the future and give thanks for the past.

The Institute has much for which to be thankful — a record of bridges crossed, of services rendered, of work accomplished, and what is more —the certainty of even more useful work for the future, and the strength with which to accomplish it. Surely this is much for which to be thankful.

The President and the Councillors send to all members, and to all friends of the Institute throughout the world, sincere wishes for a happy Christmas. It is their earnest hope that the coming year will bring peace, happiness and prosperity to them and to all people.

National Voluntary Registration

The Department of National Defence has asked The Institute to assist in a national registration of technically trained men in Canada. Our share of the work is confined to a proper listing of civil, electrical and mechanical engineers, and is to form part of a complete compilation which will include also mining and chemical engineers, chemists, metallurgists, and other technologists. The work is to be carried on by a group known as the personnel sub-committee of the Navy, Army and Air Services Committee, and is made up of one representative from each of the following: The Canadian Institute of Chemistry, the Canadian Institute of Mining and Metallurgy, and The Engineering Institute of Canada, with a chairman and secretary supplied by the Department.

The information is to be gathered on forms prepared by the committee, which are now in the hands of our members. This questionnaire is simple, yet comprehensive. It asks the engineer for no commitments or signature, and places him under no obligation of any kind. There appears to be absolutely no reason why it can not be completed readily, without difficulty or misgivings. The committee asks that it be given preferred consideration, and returned to Headquarters as quickly as possible.

No one will look on an announcement of this kind as good news, and yet no one will think that we can ignore entirely the unhappy trend of events in Europe. The man who stands on his doorstep and sees the water rising to the flood in the river before him, cannot be called foolish if he builds an embankment around his home or if he moves to higher ground for safety. He is simply a provident creature, preparing for a contingency which he foresees as a possibility, and which would bring to him and his family utter disaster if it caught him unprepared. The water may never reach him, but it would be madness for him to ignore the possibility of it.

It is a hopeful sign that the government recognizes now that different men are suited to different tasks, and that an endeavour is being made to find out the qualifications of each person so that he may be fitted to his assignment in case the mad course of events in other countries should reach us here. Probably the task should have been undertaken long ago, but that is no reason why it should not be pushed through now to as rapid and as complete a conclusion as is possible. Council urges all members to answer the questionnaire without delay.

Amendments to the By-laws Proposed by Council

In accordance with Sections 74 and 75 of the By-laws, the Council presents for the consideration of corporate members the following proposals for the amendment of Sections 32 and 35 and for the introduction of a new Section 77.

These proposals will in due course be submitted for discussion at the Annual General Meeting on February 21st, in Ottawa, and will subsequently go out to ballot.

All the proposals now submitted were approved by the Council on November 26th, 1938.

Following each proposal will be found an explanatory note indicating the reasons for Council's action. The proposed changes in wording and figures are underlined.

* * *

Section 32 (As now proposed)

The entrance fees, payable at the time of application for admission to the Institute shall be as follows:

Members	$10.00
Associate Members	$10.00
Juniors	$ 5.00
Affiliates	$10.00

Honorary Members and Students shall be exempt from entrance fees.

Note:—This scale of fees was authorized by resolution at the Annual General Meeting held at London, Ontario, on January 31st, 1938. The proposed change is suggested simply to record the information correctly in the by-laws.

* * *

Section 35 (As now proposed)

The portion of the first annual fee for which a newly elected member shall be liable shall be a proportion of the regular annual fee equivalent to the unexpired portion of the year, calculated from the beginning of the month in which the election takes place.

Note:—This change is desired by Council in order to simplify for all concerned the method of computing the portion of the first annual fee to be paid by new members, and also to put such payments on an absolutely equitable basis. It is expected that the change will be of assistance to the various membership committees.

* * *

Proposed New Section 77

An association which enters into an agreement in accordance with the provisions of By-law 76 shall, when requested by the Association and for the purpose of that by-law, be termed a "Component Association."

Note:—Section 76* of the By-laws, which was approved by a very large majority of corporate members by ballot in February 1938, provides for co-operation between The Institute and any provincial association or corporation of professional engineers.

It has since been found that in one province at least, the conclusion of an agreement for such co-operation would be facilitated if such co-operating associations could be referred to as "component associations" in The Institute by-laws. For this reason the Council recommends the approval of this new section.

*See the Engineering Journal, April 1938, p. 202.

The Fifty-Third Annual General Meeting

Notice is hereby given in accordance with the By-laws, that the Annual General Meeting of The Engineering Institute of Canada for 1939 will begin at Headquarters at eight o'clock p.m. on Thursday, January 26th, 1939, for the transaction of the necessary formal business including the appointment of scrutineers for the Officers' Ballot, and will then be adjourned to reconvene at the Chateau Laurier, Ottawa, Ontario, at ten o'clock a.m. on Tuesday, February 14th, 1939.

L. Austin Wright,
General Secretary

Presidential Activities

Since the 24th of October, the President has visited all the branches of the Institute from Lakehead to Victoria. He was accompanied by the Chairman of the Council Committee on Professional Interests, Mr. Fred Newell, and by the General Secretary. At the branches in Saskatchewan and Alberta, he also had the advantage of the presence of the Chairman of the Institute's Committee on Western Water Problems, Mr. G. A. Gaherty. Details of these branch visits will appear in the news of branches.

At Regina, on the 29th of October, the Headquarters delegation participated in a joint banquet of members of the Institute and of the Association of Professional Engineers of Saskatchewan, at which the formal agreement between the Institute and the Association was duly signed, sealed and delivered. At this banquet also, a brief message from the President of the Association and the President of the Institute was broadcast on an interprovincial hook-up. The significance of this occasion, unique in the history of the engineering profession in Canada, cannot be overemphasized.

On the 30th of October, a very largely attended regional meeting of council was held in Hotel Saskatchewan, Regina, at which the President, the Registrar and the Board of Direction of the Saskatchewan Association were present, by invitation. On the afternoon of the same day, the Presidents of The Institute and the Association with their wives formally received at the Hotel Saskatchewan the Lieutenant-Governor and Mrs. McNab, several ministers of government, the Chief Justice of the Province, leading citizens of the capital city of Saskatchewan and all engineers and their wives attended.

In Winnipeg the President and the members of the party spoke to the third and fourth year engineering students of the University of Manitoba with Student President Sidney E. Smith in the chair. Similar meetings were held at the University of Saskatchewan under the chairmanship of Dean Mackenzie and at the University of British Columbia under the chairmanship of Dean Finlayson. Unfortunately the University of Alberta was closed because of the death of a prominent member of the faculty, and the proposed meeting there had to be cancelled.

At Vancouver, the Headquarters delegation, by invitation, attended the Annual Western General Meeting of the Canadian Institute of Mining and Metallurgy. President Challies was the principal guest speaker at the opening luncheon to the Mining Institute members, when he extolled the contribution made to Canada by the mining and the electrical utility industries. The President also spoke at the Armistice Day luncheon of the Vancouver Rotary Club, when he paid tribute to the International Joint Commission which he termed the best insurance for permanent peace on this continent.

The presentation of the Sir John Kennedy Medal to Past President Col. J. S. Dennis was a very interesting feature of the stay at Victoria. Col. Dennis was in the Hospital but a delegation headed by the President and Mr. C. A. Magrath, Hon.M.E.I.C., visited him there, and under very trying circumstances made the presentation. Col. Dennis was quite feeble but was able to thank Mr. Challies for the honour The Institute was conferring upon him.

By invitation, the Headquarters delegation addressed a round-table conference at Seattle, Washington, on the 12th of November, attended by officers of the Washington section of the Founder Societies.

En route home, the President spoke at Chicago on Tuesday, November 22nd, to the members of the Chicago Engineers Club, and that same evening, in Detroit to the Michigan section of the American Society of Civil Engineers. The following day at noon, he spoke to the Michigan section of the American Institute of Electrical Engineers.

The deep and active interest of the members of the Founder Societies in the status of the engineering profession in Canada greatly surprised and delighted the President.

The Headquarters delegation had the privilege of speaking to over 500 members of the Engineering Society of the University of Toronto at Hart House, on Thursday evening, November 24th. On November 26th, the President presided at the regular November meeting of Council held at Peterborough, which was followed in the evening by the annual banquet of the Peterborough Branch.

1938 Fees—Unpaid

Members who have not already paid their 1938 fees are requested to give this matter urgent consideration. It is of considerable assistance to The Institute to have the fees paid before the end of the year in which they fall due. There is still time to send your cheque.

OBITUARIES

John James Aldred, A.M.E.I.C.

Members of The Institute will learn with regret of the death of John James Aldred, A.M.E.I.C., on October 28th at Twin Pines, West Shefford Mountain, Quebec., He was born at Peckham, Surrey, England, on May 31st, 1872. His engineering experience in Canada began in 1890. He was leveller on the Soulanges Canal, later instrumentman on the Atlantic and Lake Superior Railroad, and then with the Canadian Pacific Railway survey. His railway engineering experience grew as time went on. He took part in the construction of the Rutland Canadian Railroad, the Great Northern Railroad, the Mt. Washington Tunnel, and the Wabash Railroad. Although he engaged in various other engineering enterprises he returned to railway work from 1907-09 when he was field engineer on the National Transcontinental Railway at Dorchester, N.B., and from 1912 to 1913 as inspecting engineer on the same railway at Saint John, N.B.

Some of Mr. Aldred's later activities were outside of the railway field. From 1909 to 1911 he was in charge of transmission line work for Winnipeg Light, Heat and Power Company. From 1911 to 1912 he was superintendent and field engineer of the Mt. Hood Light, Heat and Power Company at Big Sandy Dam, Portland, Oregon. In 1913 he began work on the Welland Ship Canal in which he was engaged for three years. From 1924 to 1927 he was with the Ford Motor Company, Detroit, Michigan. He remained in Michigan until 1931, being located in Saginaw with the Consumers Power Company and the Parks Planning Commission. He returned to Canada and was employed with the Canadian Government in the Department of Northern Development for a year, when he retired from active service.

Mr. Aldred joined the Canadian Society of Civil Engineers in 1907.

Col. John Stoughton Dennis, C.M.G., M.E.I.C.

Many of the senior members of The Institute have been saddened by the announcement of the death of J. S. Dennis, at Victoria on November 26th. Most of his long and active life—he left the east at the age of 16 and died in his 83rd year—was spent in the development of the west. He was in fact an explorer and a leader in the band of pioneers whose efforts prepared that vast area for the stream of settlers who began to flock thither in the eighties and whose activities have made the prairie country what it is today.

The news of his passing will thus have a special and personal meaning to the thousands of people west of the Great Lakes who knew him, appreciated his personal worth and held him in affection and esteem.

John Stoughton Dennis was born at Weston, Ont., on October 22nd, 1856, where he attended Trinity College School, before entering Upper Canada College. He later graduated from the old Military School at Kingston.

In 1872, he first saw the Canadian West, working as assistant to the late H. B. Smith, C.E., in the exploration of Lakes Winnipeg, Manitoba and Winnipegosis and their connecting waters. The following year he was with the late J. Lestock Reed, Dominion Land Surveyor, as head chainman on base line surveys in Northwestern Manitoba, working during the next three years on special surveys under the late Lindsay Russell, Dominion Land Surveyor. After a year of study under the late Bolton McGrath at Aylmer, Quebec, he passed his examinations and received his commissions as Dominion Land Surveyor and Dominion Topographical Surveyor. In 1878 he was appointed to take charge of the surveying party sent out to establish the 4th Meridian in the Northwest Territories.

In 1879, at the age of 23, he joined the service of the Hudson's Bay Company as surveyor and engineer to the Land Department, and during his three years of service with that company, he surveyed and laid out their properties into town lots at Winnipeg, Prince Albert, Edmonton and Laval Portage, now Kenora. In addition to these arduous tasks, he was also in charge of the construction of the company's buildings, also designing and constructing the first sewerage system on their property at Winnipeg, now the southern portion of the city.

Opening his own offices in Winnipeg in 1883, he surveyed and laid out many of the town plots in the West, notably at Brandon, Prince Albert, and part of Regina. During this period he was elected president of the Manitoba Land Surveyors Association. In 1884 he was engaged in surveying and locating mines in the Bow Pass of the Rocky Mountains.

When the Riel Rebellion occurred in 1885, Colonel Dennis was in command of the Dominion Land Surveys Intelligence Corps, which, during the rebellion, was known as Dennis' Scouts. Following Riel's collapse, he joined the staff of the Topographical Surveys of the Department of the Interior, and remained in that service until 1897, when he was appointed Chief Inspector of Surveys. During the latter portion of this period, he was in charge of the administration of the Irrigation Act, with headquarters at Calgary. Here he was responsible for surveying and laying out many of the extensive irrigation systems which were later constructed in southern Alberta.

His history of the Dominion Land Surveys from 1869 to 1889 was published as a portion of the Report of the Department of the Interior in 1891.

In 1896 Colonel Dennis was elected vice-president of the American Association of Irrigation Engineers, and the following year joined the Department of Public Works of the old Northwest Territories Government, with headquarters at Regina, his first position being that of chief engineer. Subsequently he became Chief Commissioner of the Department. During this period he had charge

John Stoughton Dennis, M.E.I.C.

of the design and construction of all public buildings erected by the Government of the territories, the building of all bridges, the operation of ferries, and the supervision of all road improvements.

On January 1st, 1902, he joined the service of the Canadian Pacific Railway Company, first as superintendent and then chief engineer in charge of the construction of the famous C.P.R. irrigation project serving a large tract of land along the main line between Calgary and Medicine Hat. Subsequently he was promoted to manager of the company's Department of Natural Resources. He later became assistant to the second vice-president, then assistant to the President—Lord Shaughnessy—being finally promoted to Chief Commissioner of Colonization and Development, at the head of what is now the Department of Immigration and Colonization of the Canadian Pacific Railway Company. On January 1st, 1930, Colonel Dennis retired from this position, but remained a member of the Advisory Committee which deals with matters affecting the departments of Natural Resources and Immigration and Colonization of the Company. Thus his long experience and his world-wide reputation as a builder of Canada's ever growing structure, were retained to the benefit of both Canada and the Railway Company.

During the war he was appointed representative on the British-Canadian Recruiting Mission in the United States, with the rank of Lieutenant-Colonel, was later promoted to the rank of Colonel, and proceeded to Siberia as Director of Transportation and Intelligence on the General Staff of the Canadian Brigade. During 1918 he acted as Canadian Red Cross Commissioner in Russia, and as Canadian Trade Commissioner in the same territory.

Among the decorations that have been awarded to Colonel Dennis are the Companionship of the Order of St. Michael and St. George, the Northwest Medal, 1885, with clasp, the Great War Medal (with Palm Citation and Mention in Despatches), the Victory Medal, the Cross of Serbia, and the Medal of the Serbian Red Cross.

Colonel Dennis joined The Institute (then the Canadian Society of Civil Engineers) as a Member in 1901, serving on Council in 1906 and in 1911. He was a vice-president in 1907, and was elected President in 1917 just before his service in Serbia. He became a Life Member in 1933.

The last years of his life were spent in well-earned leisure at Victoria, B.C. This year the Council of The Institute, in making the sixth award of the Sir John Kennedy Medal, chose Colonel Dennis as the recipient. His failing health made it evident that the customary personal presentation at an Annual General Meeting would not be possible. President Challies, however, took the medal with him on his recent visit to the West and was fortunately able to place it in the hand of Colonel Dennis at his bedside in hospital at Victoria only a few days before his death.

Those who were present at that simple ceremony were deeply touched by the invalid's evident pleasure and appreciation of the honour that had been conferred upon him. They were happy to think that at the sunset of his life, The Institute's expression of professional esteem and admiration has thus brightened the closing days of this beloved and distinguished Canadian engineer.

Richard L. Latham, M.E.I.C.

We announce with deep regret the death of Richard L. Latham, M.E.I.C., who passed away in the General Hospital, Hamilton, early in the morning of Sunday, November 13th, after a few days' illness.

Mr. Latham was born in Toronto and on Sunday, November 20th, he, with his family, would have observed his 61st birthday.

He graduated from the University of Toronto in Civil Engineering in 1901 and later in the same year joined the Toronto, Hamilton and Buffalo Railway as assistant engineer, under Mr. Fisher. In 1909 he was appointed chief engineer of the same company and held the position until a few days ago.

Under his charge many and varied engineering projects have been carried out successfully; of these the most outstanding are the following: Port Maitland Docks, commenced in 1928; the new engine terminal at Hamilton which was commenced in 1929, and the Hamilton grade separation and new passenger station which were commenced in 1932.

He took an active part in the affairs of the 50th Annual Meeting, which was held in Hamilton in February 1936. He was held in affectionate esteem by his fellow engineers, from coast to coast. His personality was such as to gain the confidence of those over him, in office, and give him and the railway company the untiring loyalty of his engineering staff and all ranks from headquarters away to the end of the farthest siding.

Richard L. Latham, M.E.I.C.

His greatest contribution to engineering was his ability to encourage and give confidence to all those who, in whatever capacity, were connected with the enterprises on which he was engaged.

Mr. Latham joined The Institute in 1906 as an Associate Member, becoming a full Member in 1913.

Othmar Wallace Ross, A.M.E.I.C.

Members of The Institute will regret to learn of the death of Othmar Wallace Ross, A.M.E.I.C., in St. Catharines, Ont., on November 15th, after a prolonged illness. He was born at Burlington Plains, Ont., on January 15th, 1890, and received his B.A.Sc. degree from the University of Toronto in 1912. He obtained his early engineering experience with the city engineer of Brantford. He later joined the Dominion Bridge Company of Montreal where he worked for a time on bridge and structural steel work.

From 1916 to 1918 Mr. Ross served overseas, first as Lieutenant in the C.E.F. and later as Captain in the R.A.F. On returning to Canada he continued work on the Welland Ship Canal. During the time spent on this work he was in charge of the Location and Right of Way Party, assistant to the Ontario Land Surveyor who established the boundaries for the Canal, and later assistant engineer of section one of the Canal work.

Mr. Ross joined the Canadian Society of Civil Engineers as a Student in 1909 and became an Associate Member in 1919 but had been unable for quite some time to take active part in Institute affairs. However, his death will be noted with mourning by his branch and The Institute in general.

PERSONALS

Lieut.-Col. Robert Bickerdike, D.S.O., M.E.I.C., a life member of The Institute and a consulting engineer in Montreal, has been elected president of the Mount Royal Liberal Association.

Floyd K. Beach, M.E.I.C., office engineer for the Petroleum and Natural Gas Division of the Department of Lands and Mines of Alberta, has been moved from Edmonton to Calgary. This move is part of a reorganization following the setting up of a Petroleum and Natural Gas Conservation Board with offices at Calgary. Since the war, he has taken an active interest in militia affairs. Early in 1937 he organized the 9th Army Troops Company, R.C.E. **Capt. R. M. Hardy,** A.M.E.I.C., assistant professor of civil engineering at the University of Alberta, will carry on the unit in his absence.

Charles I. Bacon, S.E.I.C., has been appointed assistant manager of the Stormont Electric Light and Power Company and the Cornwall Street Railway. He is a graduate of the Nova Scotia Technical College, obtaining his B.Sc. degree from there in 1934. Prior to his present appointment he held the position of engineer in charge of the Summerside Municipal Electric Light and Power Plant, Summerside, P.E.I.

Frank L. Grindley, A.M.E.I.C., has recently been appointed hydraulic engineer with the Water Resources Branch of Alberta and will be located in Edmonton.

J. R. Donald, M.E.I.C., Montreal, continues in his position as president of the Donald Inspection Limited, which has changed its name from Donald-Hunt Limited.

Dr. Charles Camsell, C.M.G., LL.D., M.E.I.C., Deputy Minister of the Department of Mines and Resources, was made an honorary fellow of St. John's Anglican College, Winnipeg, at the ceremonies marking the 72nd anniversary of the institution's founding.

J. G. Bradley, Jr.E.I.C., is now with the Demerara Bauxite Company, McKenzie, British Guiana, S.A. He formerly held the position of assistant to the superintendent, Sherwin Williams Company of Canada, Red Mill, Que.

deGaspe Beaubien, M.E.I.C., attended the All-Quebec Safety Conference held in Montreal recently, and was one of the leaders of the open discussion on "The Underlying Causes of Street and Highway Accidents."

M. W. Huggins, Jr.E.I.C., is now lecturer in civil engineering at Queen's University, Kingston, Ont. He was formerly with E. P. Muntz Ltd., Dundas, Ont.

R. H. Pick has been appointed Marconi sales engineer of the Winnipeg office of the Canadian Marconi Company. Mr. Pick has been with this company for thirteen years.

A. Cousineau, A.M.E.I.C., superintendent engineer, Division of Sanitation, Department of Health, Montreal, has been elected vice-chairman of a new organization known as The Conference of Municipal Public Health Engineers which was formed on October 26th during the 1938 sessions of the American Public Health Association, held in Kansas City, Mo.

Y. R. Tassé, S.E.I.C., has recently been transferred to the Quebec office of the Canadian General Electric Company Limited. He has been with the company since 1934 when he entered as a student in the Peterborough plant. The following year he was sent to the Toronto plant where he remained until coming to Montreal in 1937 as sales engineer. Mr. Tasse graduated from the Ecole Polytechnique in 1935 in civil engineering and received the Lieutenant-Governor's medal. He was also awarded the Ernest Marceau Prize by The Institute for his paper on "Le vent pour électrifier nos campagnes."

Meeting of Council

A meeting of the Council of The Institute was held at the Hotel Saskatchewan, Regina, Saskatchewan, on October 30th, 1938, with President J. B. Challies in the chair, and six other members of Council present. By invitation there were also present Messrs. J. W. D. Farrell, I. M. Fraser and J. J. White, President, Vice-President and Registrar respectively of the Association of Professional Engineers of Saskatchewan, W. E. Lovell, R. A. McLellan and S. R. Muirhead, councillors of the Association; five past councillors of The Institute; the chairmen of the Lethbridge, Edmonton and Winnipeg branches; four members of the executive committee of the Saskatchewan Branch, and Mr. G. A. Gaherty, of Montreal, chairman of The Institute Committee on Western Water Problems.

The President having welcomed the President, Registrar and councillors of the Association of Professional Engineers of Saskatchewan, consideration was given to matters arising from the signature on the previous evening of the agreement providing for co-operation between The Institute and the Association.

In regard to the procedure necessary to properly classify in The Institute membership members of the Association who had now become corporate members of The Institute, it was resolved that the executive committee of the branch should be asked to review all such cases and make recommendations to the Council of The Institute as to their classification.

In regard to the provision of the agreement under which the entrance fee of the Association is to be remitted to any corporate member of The Institute resident in the province of Saskatchewan who applies for membership in the Association within twelve months, the President explained that the council of The Institute would endeavour to communicate directly with its members in Saskatchewan who are not now members of the Association, indicating the desirability of their applying immediately for membership in that body.

The Council expressed appreciation of the publicity which had been secured for The Institute and the Association by the Dominion-wide radio broadcast of the proceedings at the recent banquet. The thanks of The Institute were due to Mr. Gordon Pitts, the originator of the idea, and Dr. A. Frigon, the assistant general manager of the Canadian Broadcasting Corporation, whose assistance in the matter had been so valuable.

Professor Spencer reported on the work of his Committee on Membership and Management, and explained that in order to bring the various issues fairly before Council his committee's reports had contained what they believed to be the best methods of bringing about the changes in question, if and when they were decided upon. His committee did not necessarily advocate the changes in question. Professor Spencer was of opinion that all of the issues involved in the changes in the constitution of Council and any changes in classification of Institute members should be thoroughly discussed by all branch executive committees before any action is taken upon his report.

After a long discussion it was the consensus of opinion that there should be no change in the constitution of Council, but that consideration should be given to the establishment of a grade of "Fellow," the change of name of the present class of "Associate Member" to "Member," and revision of the qualifications for the classes of Student and Junior.

After an adjournment for lunch, Mr. Newell, chairman of the Committee on Professional Interests, explained the present status of negotiations for agreements under By-law 76 in the provinces of Nova Scotia, New Brunswick and

Manitoba, in which cases he thought that agreements might be possible in the not too distant future. Mr. Newell further explained the situation in the provinces of Ontario and Quebec, and hoped to report fully at a later date with respect to Alberta and British Columbia.

Mr. Gaherty, the chairman of The Institute Committee on Western Water Problems, reported progress in connection with the symposium of papers on that subject which is being arranged for presentation at the General Professional Meeting in Ottawa on February 22nd. Mr. Gaherty stated that his committee, in arranging for these papers and their discussion, hoped to remove any possible impression that the western water problem was impossible of solution within a reasonable time, a view which he believed was held to a certain extent in the east.

The General Secretary reported progress in regard to the proposed joint meetings with British and American societies in September 1939 in New York during the World's Fair, and also drew attention to the invitation received from the Engineers' Council for Professional Development. They asked The Institute to be represented at the annual meeting of that body which had accordingly been attended by a delegation including the President and the General Secretary. The invitation had been accompanied by a most gratifying offer to make available to The Institute all reports, literature and plans of the E.C.P.D. in order that the welfare of the young engineer might be more effectively sponsored in Canada. The President reported that at the meeting he had willingly accepted this generous offer from the E.C.P.D.

The General Secretary reported that the Department of National Defence at Ottawa had asked The Institute to undertake the registration of all civil, mechanical and electrical engineers in its membership as part of a scheme to catalogue all technically trained men in Canada. The meeting authorized compliance with the request.

Mr. Newell expressed the thanks of the Headquarters delegation to the officers of the Saskatchewan Association and Branch for the warm reception extended to them and to their ladies.

On behalf of the executive committee of the Winnipeg Branch, Mr. Hurst conveyed heartiest congratulations to the Saskatchewan Branch and Association on the signing of the co-operative agreement.

Mr. Farrell, President of the Association, felicitated the President and Council on the manner in which The Institute representatives had participated in the ceremonies incidental to the completion of the agreement. He and Mr. Fraser both expressed their thanks and appreciation of the opportunity to be present at the deliberations of this prairie meeting of Council.

The Council rose at three thirty p.m.

ELECTIONS AND TRANSFERS

At the meeting of Council held on November 26th, 1938, the following elections and transfers were effected:

Members

CARSON, Cecil Edward, B.Sc. (Chem.), (McGill Univ.), gen. supt., Imperial Oil Limited, Sarnia, Ont.

DUBOSE, McNeely, B.E., E.E., (North Carolina State Coll.), gen. supt., Saguenay Power Co. Ltd., Arvida, Que.

WILLIAMS, Charles Gunning, B.A.Sc., (Univ. of Toronto), professor of mining engineering, University of Toronto, Toronto, Ont.

Associate Members

DOBSON, Franklin Alver, B.Sc., (Queen's Univ.), research engr., Canadian Car and Foundry Co. Ltd., Fort William, Ont.

*HEYWOOD, Don W., (Univ. of Alta.), (Milwaukee Sch. of Engrg.), electl. dept. McDougall & Friedman, consltg. engrs., Montreal, Que.

MANN, Arthur Drummond, Lieut., R.C.E., (Grad., R.M.C.), B.A.Sc., (Univ. of Toronto), Works Officer, Military District No. 5, St. Louis Barracks, Quebec, Que.

SPENCE, Howard Clement, B.Sc. (Civil), (Univ. of Man.), secretary, Highway Traffic and Taxicab Office, Municipal and Public Utility Board, Province of Manitoba, Winnipeg, Man.

TAYLOR, Frank Butler, (Liverpool Tech. Sch.), marine supt., Imperial Oil Shipping Company, Montreal, Que.

Juniors

CAWLEY, Hugh Rose, B.Sc. (Mech.), (Univ. of Sask.), asst. locomotive foreman, C.N.R., Melville, Sask.

CONNOR, William Alexander Jr., B.A.Sc., (Univ. of Toronto), asst. to chief engr., Employers' Liability Assurance Corpn. Ltd., Toronto, Ont.

HAMILTON, Harold Percy, B.A.Sc., (Univ. of Toronto), operator, Churchill River Power Company, Island Falls, Sask.

LORIMER, William Clarence, B.Sc. (Mech.), (Univ. of Sask.), operator, Diesel power plant, Canadian Utilities Limited, Kerrobert, Sask.

MANSEAU, Gilbert, B.A.Sc., C.E., (Ecole Polytechnique), engr., B. Trudel & Cie., Montreal, Que.

MONTGOMERY, Mortimer Andrew, B.Sc. (Mech.), (Univ. of Sask.), engr., Canadian Blower & Forge Co. Ltd., Montreal, Que.

Transferred from the class of Associate Member to that of Member

MacKENZIE, Gordon Leslie, B.Sc. (Civil), (Queen's Univ.), office and designing engr., water development, P.F.R.A., Regina, Sask.

WATSON, McClelland Barry, B.A.Sc. (Civil and Mech.), (Univ. of Toronto), consltg. mech. engr., 184 College St., Toronto, Ont.

Transferred from the class of Junior to that of Associate Member

CRUMP, Norris Roy, B.Sc., M.E., (Purdue Univ.), divn. master mechanic, C.P.R., Regina, Sask.

*RICE, Walter Leslie, dftsman., water supply section, Dept. of Works, City Hall, Toronto, Ont.

VINCENT, Paul Emile Albert, B.A.Sc., C.E., (Ecole Polytechnique), district engr., roads and bridges divn., Colonization Dept., Parliament Bldgs., Quebec, Que.

Transferred from the class of Student to that of Associate Member

COUSINEAU, Louis Philippe, B.A.Sc., C.E., (Ecole Polytechnique), welding supt., Marine Industries Ltd., Sorel, Que.

STEVENSON, Charles Lester, B.Sc. (Civil), (Univ. of N.B.), plant engr., Abrasive Co. of Canada Ltd., Arvida, Que.

THOMAS, James Leslie, B.Sc. (Mech.), (Queen's Univ.), 763 Bloomfield Ave., Outremont, Que.

Transferred from the class of Student to that of Junior

BEIQUE, Henri F., B.Eng. (E.E.), (McGill Univ.), engr., Quebec Power Company, Quebec, Que.

TOY, Edwin Letendu, B.Sc. (Elec.), (Univ. of N.B.), supervisor, test. dept., Can. Gen. Elec. Co. Ltd., Toronto, Ont.

WOOLSEY, John Townley, Lieut., R.C.A., Work Point Barracks, Esquimalt, B.C.

Students Admitted

BOURBONNAIS, Georges Valois, (R.M.C.), Royal Military College, Kingston, Ont.

CAMERON, Curtis Burnette, (Univ. of N.B.), 247 Brunswick Street, Fredericton, N.B.

DEMCOE, John William, (Univ. of Man.), University of Manitoba, Fort Garry, Man.

GRAY, James Lorne, M.Sc., (Univ. of Sask.), 426 Park Street, Peterborough, Ont.

McARTHUR, Donald S., (Univ. of Sask.), 613 Clarence Avenue, Saskatoon, Sask.

MacGOWAN, William Hartley, (McGill Univ.), 6515 Cote St. Luc Road, Montreal, Que.

NATHANSON, Sol, (McGill Univ.), 810 Hartland Avenue, Outremont, Que.

PERRY, George Thomas, (Univ. of Toronto), 69 Strathcona Avenue, Toronto, Ont.

READ, Frederick Cyril, (Univ. of Toronto), 1 Bedford Road, Toronto, Ont.

ROBERT, Andre, B.Sc. (Univ. of Man.), 3611 Hutchison Street, Montreal, Que.

SALVADGE, Charles Harold, B.A.Sc., (Univ. of Toronto), 489 King Street, Peterborough Ont.

STAPLETON, David Outram, B.Eng., (McGill Univ.), 1130 Sherbrooke Street, West, Montreal, Que.

TANNER, William John, (McGill Univ.), 138 Longueuil Street, Longueuil, Que.

*Has passed the Institute's examinations.

WOODFIELD, Raymond Percy, (Univ. of Man.), 303 Gwendoline Street, Winnipeg, Man.

Students at Queen's University, Kingston, Ont.

ASKWITH, Francis Lloyd George, 222 Powell Avenue, Ottawa, Ont.
ASQUITH, A. Reginald, Auburn, Ont.
DENOVAN, John J., P.O. Box 255, Asbestos, Que.
HOBA, Joseph George, Thorold South, Ont.
LOCKEBERG, Rolf Siguro, 542 Wellington Street, Ottawa, Ont.
MASON, Harvey Libby King, 78 Wellington Street, Kingston, Ont.
McGEACHY, Donald D. C., 323 University Avenue, Kingston, Ont.
PHEMISTER, William Ian, 445 Morrison Street, Niagara Falls, Ont.
RIGSBY, David L., 318 University Avenue, Kingston, Ont.
SANDERS, Robert Lewis, 15 Union Street, Kingston, Ont.
SMILEY, Donald C., 124 Hamilton Avenue, Ottawa, Ont.
SHISKO, Nicholas, Ansonville, Ont.

Students at the Ecole Polytechnique, Montreal, Que.

BELANGER, Maurice, 53 St. Catherine Road, Outremont, Que.
BOISCLAIR, Robert, 1320 Demontigny East, Apt. 6, Montreal, Que.
BOULVA, Charles, 824 Cherrier Street, Apt. 10, Montreal, Que.
BOUSQUET, Paul, 1430 St. Denis Street, Montreal, Que.
CHARLAND, Roger, 3416 St. Hubert Street, Montreal, Que.
DOUVILLE, Paul-Emile, 7857 Berri Street, Montreal, Que.
FRECHETTE, Gaston, 5216 Chambord Street, Montreal, Que.
HURTUBISE, Marc, 5290 McKenna Avenue, Outremont, Que.
LAVALLEE, Jean, 1232 St. Denis Street, Apt. 9, Montreal, Que.
LeBEL, Raymond, 4387 Christophe Colomb Street, Montreal, Que.
LEMIEUX, Henri Julien, 759b Champagneur Avenue, Outremont, Que.
LESSARD, Roger, 6214 DeNormanville Street, Montreal, Que.
MARTIN, J. Adolphe, 3492 Berri Street, Montreal, Que.
MORIN, Alphonse, 825 Sherbrooke Street, East, Montreal, Que.
MONTI, Attilio, 60 Jean Talon Street, East, Montreal, Que.
ORTIZ, Thomas, 1011 Sherbrooke Street East, Montreal, Que.
PIETTE, Guillaume, 2024 St. Denis Street, Apt. 5, Montreal, Que.
PROULX, Gilbert, 1430 St. Denis Street, Montreal, Que.
PROVOST, Roger, 4027 Harvard Avenue, N.D.G., Montreal, Que.
QUEVILLON, Olivier, 1820 Bennett Street, Montreal, Que.
RACICOT, Jacques, 3834 St. Denis Street, Montreal, Que.
TETREAULT, Armand, 1322 Sherbrooke Street East, Montreal, Que.
TETREAULT, Jacques, 1322 Sherbrooke Street East, Montreal, Que.
VALIQUETTE, Maurice, 2 Church Street, St. Laurent, Que.
VALIQUETTE, Zephirin, 8 rue Chamfoux, Abord-a-Plouffe, Que.

U.S. Bureau of Reclamation Boulder Canyon Project Final Reports, **Slab Analogy Experiments.** Denver, Colorado, 1938. 399, pp., illus., diagrs., tab., 6½ x 9¼ in., cloth, $1.50 (paper $1.00).

U.S. Works Progress Administration **Bibliography of Aeronautics**, Pt. 23 Airships. N.Y., W.P.A., 1938. 8½ x 10¾ in., paper.

BOOK REVIEWS

Design and Shop Practice

Kent's Mechanical Engineer's Handbook, Ed. by Robert Thurston Kent, M.E., Sc.D. 11th ed. New York, John Wiley and Sons Inc., 1938. 1,378 pp., 5½ x 8¾ in., Flexible binding, $5.00.

Reviewed by C. A. Robb, D.Eng., M.E.I.C.,
Prof. of Mechanical Engineering, University of Alberta, Edmonton Alta.

Kent's Mechanical Engineer's Handbook, eleventh edition, bearing the title Design and Shop Practice, is in every sense a thoroughly modern compendium of engineering practice. Compiled by competent authorities in their fields and arranged in a manner which provides a quick reference to the practice, the theory and the authority, this edition takes its place as volume III of the Wiley engineering handbook series, just published, and is a worthy companion for the earlier volume II, Power, published in 1936. The division of the handbook into separate volumes has the advantage of providing the mechanical engineer with more complete information than heretofore has been possible and the new plan is more useful and convenient. The handbook is timely in that much of the new material, which it contains, deals with phases of shop practice of recent origin and developments which have tended to modify earlier methods.

Edited and printed in the United States of America, the book deals in the main with American practice. However, the list of periodicals and publications given in the preamble is international in character and since Canadian engineers have largely adopted American standards in this field, the new edition simply amplifies earlier editions which have long been the standard work in this country. The list of collaborators is impressive and includes many leading authorities whose individual publications are familiar to designers.

In certain cases a slight elaboration of the text would assist alert operating engineers in modernizing old equipment. For example, in the mechanical deaerating of water (3-17), when the feedwater in an open heater is brought up to the temperature of the steam above it and high pressure steam is bubbled through the water, the bubbles of steam entrain the air which is liberally vented from the top of the heater and the heat, which would otherwise be wasted, is reclaimed for the heat balance by means of a gleaner condenser as described in fig. 3 of the text. An appreciation of the phenomenon will often make it possible to provide the desirable deaerating service without the necessity of replacing the old heater. The addition of the high pressure jets and the small gleaner condenser is usually all that is required. The text gives the impression that a reduction to .03 c.c. of oxygen per litre of water provides a satisfactory assurance against corrosion in steam power plant equipment. While this standard was quoted by E. R. Fish* in 1930, and seems a fair limit for mechanical deaerating, it has been usual, in recent years, to reduce the oxygen content to zero as shown by the Winkler test. This is accomplished by the addition of sodium sulphite after the mechanical deaerating is completed. This treatment has been described by A. G. Christie† in 1936.

*Trans. Second World Power Conference, Vol. VII, p. 89, Berlin, 1930.
†Mechanical Engineering, Sept. 1936, p. 550.

The above is in marked contrast to the treatment accorded the viscosity index (*13*-53/7). This section alone is worth the price of the book to the purchaser who wishes to guard against careless and improper blending of lubricants.

In view of the importance of molybdenum in controlling creep, especially in steam turbine construction, the scant consideration given is disappointing.

The "Table of Contents," repeated at the beginning of each section, is helpful to the reader by exposing the setting in which the subject matter is discussed. In this connection it is complementary to the general index at the end of the book.

A lack of uniformity in dealing with the references cited is somewhat disconcerting to the reader. In some cases a bibliography is provided at the end of the section which seems a desirable arrangement and avoids the tendency to confusion which arises when many miscellaneous footnotes are placed at the bottom of the page.

A feature of special merit, placed as a sort of conclusion for certain sections, is a list of references under the heading "Information on the state of the art to date (1938) may be obtained from the following articles."

This is a feature which authors of textbooks might adopt with great advantage in view of the statement, too often true, to the effect that textbooks tend to be about ten years behind the practice at the time of their publication. The criticism is probably justified in many cases when new developments are found to work out well in practice but for which a satisfactory theoretical basis for design has not been devised at the time.

Typographical errors seem bound to find a place in so large a work. In this volume the practising engineer is the victim of the proofreader's first observed lapse (p. viii, par. 1).

The book is nicely bound with a durable cover. The paper is good and the sizes of type are well suited to the text.

Trade Literature*

Leipzig Engineering Fair.—The new booklet outlining the various exhibits at the Great Engineering and Building Fair being held in Leipzig, Germany, March 5 to March 13, indicates the wide scope of this division of the historic Leipzig Trade Fairs. At the 1939 Spring show over 3,500 exhibitors from every major industrial country will place their latest engineering developments on display; an attendance of 300,000 buyers and executives from seventy-two different countries is expected.

The Reyrolle Works.—An interesting 36-page booklet, illustrating and describing the switchgear works of A. Reyrolle and Company Ltd. situated at Hebburn-on-Tyne, has been issued by the company. The text deals with the development of the undertaking since its beginning in 1886.

Natural Laws Applied to Production.—Mathews Conveyer Company Ltd., of Port Hope, Ont. have issued a 32-page booklet entitled "Natural Laws Applied to Production" dealing with the continuous flow principle of handling materials.

Small Size Worm Gear Speed Reducers.—Hamilton Gear and Machine Co., 62-100 Van Horne Street, Toronto, have issued No. 106-B of their series of catalogues which deal with their various products. The present catalogue describes and illustrates small size worm gear speed reducers. Thirteen other catalogues constitute the complete set of sections issued to date.

Machine-Operation Recorders.—A modern installation of Bristol's Machine-Operation Recorders is illustrated in a new bulletin recently published by The Bristol Company of Canada Limited, 64 Princess Street, Toronto.

Some of the helpful information for the manufacturer provided for by these instruments is indicated by the following: cutting or running time of the machine . . . delay time . . . idle time . . . set-up or make-ready time . . . quantity and rate of production.

Wood Pipe and Tanks Catalogue.—Canadian Wood Pipe and Tanks Ltd., of Vancouver, B.C. have issue a revised catalogue of data, designs and reference tables for users of their various products. The catalogue is of convenient size, well bound and contains 100 pages with many illustrations.

Reducing Valves, Regulators, etc.—Crude Oil Engine and Engineering Co. Ltd., have been appointed Canadian representatives of the Leslie Company of Lyndhurst, N.J., manufacturers of Leslie Reducing Valves, Temperature Regulators, Turbine and Reciprocating Pump Governors and Pipe Line Strainers. Bulletins regarding these products are being distributed and may be obtained upon request to the company's office, University Tower, Montreal, Que.

Steel Sheet Piling at Toronto Harbour.—An eight page bulletin dealing with "Toronto Harbour and the use of Larssen Piling in its Development," has been issued by Canadian Sheet Piling Co. Ltd., Castle Bldg., Montreal, from whom copies may be obtained.

Air-Operated Cycle Controller.—A new single-cam Cycle Controller that provides for the control of as many as four separate operations is now being built by The Bristol Co. of Canada Ltd., 64 Princess St., Toronto. These instruments are for Process Manufacturing, being extensively used in vulcanizing rubber products and in plastic moulding.

Centrifugal Pumps.—Darling Brothers Limited of Montreal have announced that copies of their latest Bulletin, No. 46-B, covering all types of Horizontal Side Suction Centrifugal Pumps, Class "D," are now available and can be obtained by writing to Darling Brothers Limited, 140 Prince St., Montreal.

The Bulletin comprises a comprehensive list of specifications, performance data and cross-sectional views which graphically illustrate the efficiency of design and operation for the purpose for which each type of pump is required.

*Copies of these publications may be obtained by writing to the companies mentioned.

New and Revised Specifications

American Society of Testing Materials: 1938 Supplement to Book of A.S.T.M. Standards.

Canadian Engineering Standards Association: C22.2-No. 50-1938 Construction and Test of Knife Switches; C22.2-No. 51-1938 Construction and Test of Armoured Cable and Armoured Cord. C22.2-No. 56 Construction and Test of Flexible Steel Conduit.

BOOK NOTES

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet, the books are not in The Institute Library, but inquiries will be welcomed at Headquarters, or may be sent direct to the publishers.

Handbook of Petroleum Accounting. By R. W. McKee. New York and London, Harper & Brothers, 1938. 496 pp., diagrs., charts, tables, 10 x 6 in., cloth, $5.00.

Marconi, the Man and his Wireless. By O. E. Dunlap, Jr. Rev. ed. New York, Macmillan Co., 1938. 362 pp., illus., 9 x 6 in., cloth, $3.50.

The life of Marconi is portrayed against the background of his invention—wireless telegraphy. The resulting biography constitutes a history of radio as well. Many historic events are related, together with the ordinary occurrences of a man's life and the developments of a new scientific field. This revised edition contains an account of his death.

Master Builders of Sixty Centuries. By J. A. Miller. New York and London, D. Appleton-Century Co., 1938. 315 pp., illus., charts, 8 x 6 in., cloth, $3.00.

An informal account of certain particularly interesting engineering achievements. Covering the whole span of history, it includes the pyramids, the Great Wall of China, the Roman aqueducts and roads, the Mayan temples, and other works down to modern suspension bridges, dams, canals, etc.

Metal Airplane Structures. By F. E. Loudy. New York, Norman W. Henley Pub. Co., 1938. 455 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $5.00.

A practical treatise on the design and construction of the major component parts of metal airplanes. Discusses the various types, materials of construction, structural elements, welded and riveted joints, stressed skin design, metal wings and beams, fuselage, and hull and float design. Contains tables, diagrams, formulae, and numerous illustrations.

Metallurgy. By C. G. Johnson, R. S. Dean and J. L. Gregg. Chicago, American Technical Society, 1938. 149 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $1.50.

A very concise elementary textbook, in which physical metallurgy is emphasized.

Modern Glass Practice. By S. R. Scholes. Chicago, Industrial Publications, Inc., 1937. 344 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $6.00.

Comprehensive information concerning glass and glass manufacture. Covers composition and chemistry of glasses, raw materials, mixing and melting practice, glassworking and annealing, mechanical and physical properties, colouring, and special types of glass and glassware.

Outlines and Lectures—**Program** for the First **Traffic Engineering Training School,** Aug. 16-28, 1937, conducted by Bureau for Street Traffic Research (formerly located at Harvard University) and Institute of Traffic Engineers. Co-operating organizations: American Public Works Association, Automotive Safety Foundation, American Automobile Association, National Safety Council, and National Conservation Bureau. Publ. by Bureau for Street Traffic Research, now located at Yale University, New Haven, Conn. 224 pp., mimeographed, tables, 12 x 9 in., paper, $1.00.

A compilation of the lectures or lecture outlines as given during the two-weeks' period of the training school. Also appended are professional data concerning the traffic authorities who composed the faculty, lists of students attending, with states and colleges represented, and a bibliography.

Photoelectric Cell Applications. By R. C. Walker and T. M. C. Lance. 3 ed. New York and Chicago, Pitman Publishing Corp., 1938. 336 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.00.

Restricted to discussion of the alkali-metal cell (with some reference to the rectifier cell), the circuits and installations used in counting and handling devices, alarms, sound reproduction, phototelegraphy, television and miscellaneous applications are described. Accessory equipment is also considered.

Practical Shell Developing for Steel Shipbuilders. By A. F. Tulin. London, Crosby Lockwood & Son; New York, Simmons-Boardman Publishing Corp., 1938. 153 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $3.00.

A manual for loftsmen, shipfitters, hull draftsmen and others who deal with steel ship construction. The work explains the development and laying-out of the shell of a vessel, considering mainly the points of mold-loft procedure beyond the minor fundamentals which are assumed as familiar.

The **Principles of Motor Fuel Preparation and Application,** Vol. I. By A. W. Nash and D. A. Howes. 2 ed. New York, John Wiley & Sons, 1938. 628 pp., illus., diagrs., charts, tables, 10 x 6 in., cloth, $9.50.

This comprehensive work comprises two volumes, of which Volume I is here considered. It deals fully with the production of motor fuels by distillation, cracking, extraction from natural gas, and hydrogenation. It also contains chapters on the production of benzole and various synthetic fuels, including alcohols, on general storage and distribution, and (in this second edition) pyrolysis and polymerization processes. There is a patent index.

Radio Laboratory Handbook. By M. G. Scroggie. London, Wireless World, Iliffe & Sons, 1938. 384 pp., illus., diagrs., charts, tables, 8 x 5 in., cloth, 8s. 6d.

This handbook has been prepared with special consideration of the needs of amateurs and laboratory workers. Complete information concerning laboratory equipment, necessary instruments and correct operating methods is given. Discussion covers fundamental principles, sources of power and signals, measurements, and certain specialized types of work, such as ultra-high-frequency. A reference chapter contains symbols, abbreviations, formulae, laws, tables and other data.

Railroadman. By C. D. French. New York, Macmillan Co., 1938. 292 pp., illus., 9 x 6 in., cloth, $2.50.

The plain, unvarnished biography of a railroad man who began as a messenger and call-boy at the age of thirteen in 1873, and saw active service until 1930, when he retired at seventy. He served as telegrapher, switchman, brakeman, fireman, engineer, conductor and yardmaster at various periods and on fifteen different railroads west of the Mississippi. His story is an interesting contribution to railroad history.

Rebirth of Monopoly. By W. J. Kemnitzer. New York and London, Harper & Brothers, 1938. 261 pp., charts, diagrs., tables, 9 x 6 in., cloth, $2.50.

The thesis of this book is that monopoly in the petroleum industry of the United States is being reborn and that such rebirth in so large and powerful an industry has great possibilities of danger to the competitive system and the public welfare.

Road Traffic and its Control. (Roadmakers' Library.) By H. A. Tripp. London, Edward Arnold & Co.; New York, Longmans, Green & Co., 1938. 414 pp., diagrs., charts, tables, 9 x 6 in., cloth, $10.00.

This volume presents an unusually comprehensive survey of the traffic problem by the Assistant Commissioner of Police, Scotland Yard, in charge of traffic. Traffic control by law and police, the development of traffic policy, control by construction and mechanical appliances, road transport and road casualties are discussed clearly and in considerable detail, with attention to the problems of legislation, public opinion, psychology and town planning which are involved. Although written for British conditions, the book has much of interest to other countries.

The Rôle of Scientific Societies in the Seventeenth Century. By M. Ornstein. Chicago, University of Chicago Press, 1938. 308 pp., illus., tables, 9 x 6 in., cardboard, $3.00.

An interesting and valuable contribution to the history of science, which calls attention especially to the ways in which scientific development was aided by the scientific societies of the seventeenth century. It also contains valuable accounts of the work of many famous scientists of the period and a description of the scientific work of the universities. There is a bibliography. The new edition retains the text of the original one, but also contains numerous illustrations.

Route Surveys. By H. Rubey. New York, Macmillan Co., 1938. 261 pp., diagrs., charts, tables, 7 x 4 in., lea., $3.75.

A textbook for a course in curves and earthwork intended to treat the problems of route location, curve layout, and the measurement, computation and layout of earthwork, as elements applicable to many forms of engineering work, such as highways, canals, pipe lines, and transmission lines, as well as to railroad construction.

The Science of Production Organization. By E. H. Anderson and G. T. Schwenning. New York, John Wiley & Sons, 1938. 282 pp., 9 x 6 in., cloth, $3.50.

The relation of scientific management to production economics is the subject of this book. The major part is devoted to the physical organization of work through operation study or job analysis and to the various types of organization of workers within small departments, plants, or whole enterprises. The authors also discuss briefly larger aspects of the production problem. There is a large bibliography.

The Silver Magnet. Fifty Years in a Mexican Silver Mine. By G. Shepherd. New York, E. P. Dutton & Co., 1938. 302 pp., illus., 9 x 6 in., cloth, $3.00.

The Soybean Industry. By A. A. Horvath. New York, Chemical Publishing Co., 1938. 221 pp., tables, 9 x 6 in., cloth, $4.00.

This work describes the methods of milling soybeans, the processes of extracting and purifying the oil and the uses of the oil and meal.

Spectrochemical Abstracts, 1933-1937. By F. Twyman. London, Adam Hilger, Ltd., 1938. 52 pp., 10 x 6 in., linen, 3s. 10d.

This bibliography contains abstracts of over two hundred papers on spectrochemical analysis published within the period. The work is in two sections, an alphabetic arrangement by authors and a classed arrangement under substances examined, apparatus and methods.

Steam and Gas Engineering. By T. E. Butterfield, B. H. Jennings and A. W. Luce. 3 ed. New York, D. Van Nostrand Co., 1938. 490 pp., illus., diagrs., charts, tables, 10 x 6 in., cloth, $4.50.

A comprehensive textbook on the subject, covering combustion, fuels and fuel-burning equipment, types of power plants and engines with their mechanical accessories, and refrigeration. Thermodynamical theory is considered as each particular subject is discussed. Practical problems are included.

Structural Aluminum Handbook. Pittsburgh, Pa., Aluminum Company of America, 1938. 211 pp., diagra., tables, 9 x 6 in., lea., $1.25.

This handbook gives the fundamental data concerning the ultimate strength of aluminum-alloy structural members. The characteristics, manufacture and fabrication of structural products are described and the design of structures discussed. The properties of elements of sections for structural shapes are tabulated and specifications, tolerances and commercial sizes given.

Structural Design. By H. Sutherland and H. L. Bowman. New York, John Wiley & Sons, 1938. 402 pp., diagra., charts, tables, plates, 9 x 6 in., cloth, $4.50.

This is a college text covering the fundamentals of the theory and practice of design in steel and timber. The first four chapters and Appendix A contain an amplified résumé of the important considerations met with in the strength of materials course, the remaining chapters apply these fundamentals to common structures, and the remaining appendices provide specifications and design data.

Structure of Steel. By E. N. Simons and E. Gregory, with an introduction by F. C. Lea. New York, Prentice-Hall, 1938. 115 pp., illus., diagrs., charts, tables, 8 x 5 in., cloth, $2.00.

A simple, non-technical explanation of the structure of steel, considering the various combinations of iron with carbon and other alloying constituents, the properties of the various internal structures, with the methods and heat treatments used to produce them, and brief information on corrosion and x-ray examination.

Studies on the Periodicity of Earthquakes. By C. Davison. London, Thomas Murby & Co., 1938. 107 pp., charts, tables, 9 x 6 in., cloth, 13s. 6d.

Dr. Davison has here summarized and thoroughly revised the various articles on the periodicity of earthquakes which he has published during more than forty years. The bearing of these studies upon movements of the earth's crust is discussed.

Technical Progress and Unemployment. Studies and Reports, Series C (Employment and Unemployment) No. 22. By E. Lederer. Geneva, Switz., International Labour Office, 1938. 267 pp., tables, 10 x 7 in., paper, $1.50 [obtainable from U.S. branch, Washington, D.C.].

This study is an analysis of the social and economic effects of technical progress, especially on unemployment and on the formation of capital. The author discusses the various forms of technical progress, the concept of technological unemployment, increasing and diminishing returns, the equilibrium of the labour market, the effects of technical progress on the economic system and the labour and capital market, the elasticity of modern monetary systems, technical improvements and the business cycle, and capital-saving technical improvements.

Television, a Struggle for Power. By F. C. Waldrop and J. Borkin, with an introduction by C. H. Payne. New York, William Morrow & Co., 1938. 299 pp., 9 x 6 in., cloth, $2.75.

Television may be expected to have profound social and political effects, and the question of its control is a matter of great public concern. This book discusses modern developments in communication through movie, radio and television and calls attention to the need for a definite public policy.

Tendances actuelles des techniques de la chaleur. By M. Véron. Paris, Dunod, 1938. 189 pp., illus., diagrs., charts, tables, 8 x 6 in., paper, 48 frs.; bound, 65 frs.

This volume presents a synthesis of present tendencies in heat engineering, based upon a conference held in 1936. The essential notions underlying heating apparatus are reviewed, after which the author describes the practical applications of accelerated convection in boilers and heating furnaces, and discusses the practical consequences of modern work on radiation. A thorough study of present tendencies in boiler design is followed by short accounts of tendencies in furnace and grate construction.

Theory of Mechanical Refrigeration. By N. R. Sparks. New York and London, McGraw-Hill Book Co., 1938. 225 pp., diagrs., charts, tables, 9 x 6 in., cloth, $3.00.

The content of this elementary textbook has been restricted to such material as is necessary for a presentation of the fundamental thermodynamic approach to the subject of refrigeration. The practical data included are only those that will assist in interpreting the text of the book, the aim being to present a general demonstration of the application of fundamentals.

Thermodynamics, Fluid Flow and Heat Transmission. By H. O. Croft. New York and London, McGraw-Hill Book Co., 1938. 312 pp., diagrs., charts, tables, 9 x 6 in., cloth, $3.50.

The purpose of this textbook is to review thermodynamics, introduce dimensional-analysis, fluid-flow and heat-transmission problems, and to combine this material into one continuous study covering fields of engineering knowledge encountered in actual problems. An elementary knowledge of thermodynamics and hydraulics is assumed.

Transformatoren mit Stufenregelung Unter Last. By E. Bölte and R. Küchler. Munich and Berlin, R. Oldenbourg, 1938. 182 pp., illus., diagrs., charts, tables, 10 x 6 in., cloth, 9.60 rm.

This book discusses the theory, construction and use of transformers equipped with tap changers in a comprehensive, practical manner. A brief bibliography is included.

Transformer Engineering. By L. F. Blume, G. Camilli, A. Boyajian and V. M. Montsingar; ed. by L. F. Blume. New York, John Wiley & Sons, 1938. 496 pp., diagrs., charts, tables, 9 x 6 in., cloth, $5.00.

The authors of this volume, who are of the Transformer Department of the General Electric Company, have designed the work to assist engineers in the specification, selection, application and operation of transformers. The treatment emphasizes the essential physics concerned in each problem.

William Tyrrell of Weston. By E. L. Morrison and J. E. Middleton. Toronto and New York, (The) Macmillan Co., 1937. 152 pp., illus., 9 x 6 in., cloth, $3.00.

The story of a young Irishman who went to Canada in the early 19th century and built up a high reputation as an architect and builder, bridge engineer, surveyor, geologist, expert in municipal affairs, magistrate, and gentleman. It provides a picture of the territory around Toronto as it was through the latter half of the last century.

VDI (Verein deutscher Ingenieure) Sonderheft **Flugabwehr.** Berlin, VDI-Verlag, 1938. 51 pp., illus., diagrs., charts, tables, 12 x 8 in., paper, 2.75 rm.

This pamphlet contains nine papers upon various aspects of anti-aircraft defence, reprinted from the Zeitschrift des Vereines Deutscher Ingenieure and the Rundschau Technischer Arbeit. Collectively, they afford a general review of current developments, with emphasis upon the engineering problems involved in the construction and use of defense equipment.

Wireless Servicing Manual. By W. T. Cocking. 4 rev. ed. London, The Wireless World, Iliffe & Sons, Ltd., 1938. 278 pp., illus., diagrs., charts, tables, cloth, 5s. 5d.

This handbook covers the principles and practice of the repair and adjustment of wireless receivers. Methods of fault finding are dealt with in detail, the use of the necessary test apparatus is described, and ganging procedure is fully treated. Specific tables and data are included in appendices. A chapter is devoted to television receivers.

The Modernization of Steam Generating Plants

With the steady increase in electricity consumption—an increase which, so far as the domestic lighting and heating load is concerned, much exceeds that anticipated by many prophets—the problem of expanding the capacity of central supply stations has become one of importance. In most of the older stations, pressures range from 200 lb. to 400 lb. per sq. in., with moderate superheats represented by temperatures varying between 550 deg. and 750 deg. F. More recent plants work at pressures between 650 lb. and 1,850 lb. per sq. in., and steam temperatures in the region of 800 deg. to 900 deg. F. In the case of the newer stations, the problem of increasing capacity is fairly simply solved, and is mainly concerned with the evaporative capacity of new boiler units and the power to be developed by new turbines. With older stations a number of solutions are often possible, from which a choice has to be made.

At a first glance it might, for instance, be thought advisable to build an entirely new plant, designed on modern lines, and to use this for normal load, retaining the old for peak-load service. This plan gives the double advantage of increased capacity coupled with improved thermal efficiency during normal production, and is probably the most common method of attacking the problem. Generally it results, as time goes on, in the gradual replacement of the older plant by modern units. A second solution, and one which is becoming increasingly popular, especially in America, is the super-imposition of high-pressure boiler and turbine equipment on the old plant. In these cases the steam generated by the new high-pressure boiler is taken by the new turbine, exhausted into the original low-pressure main, and is then used with the low-pressure boiler steam in the old turbines. In the latter, the whole is exhausted down to condenser pressure. Obviously this super-imposing, or "topping" as it has come to be termed, not only increases the station capacity, but also adds appreciably to its thermal efficiency, and thus proves very attractive.

The popularity of this method of meeting the situation is largely due to the increased confidence which, it is felt, can now be placed in steam generators working at pressures ranging from 1,000 lb. to 1,850 lb. per sq. in. and delivering steam superheated to temperatures in the neighbourhood of 900 deg. F. It is undoubtedly the fashion at the present time, but though it gives admittedly immediate results of a satisfactory nature, the future presents scope for interesting speculation; for, when the older part of the plant does become obsolescent, as in course of time it must, what will be the correct procedure as regards re-equipment or expansion? Will the newer plant be left, so to speak, high and dry, or will the renewal of the old plant become essential, much on the old lines, in order to preserve the entity of the whole? Sufficient, perhaps, to the day is the evil thereof—so far we have not heard much of the attention paid to this aspect of the matter by those who advocate topping at the present time, though in the effort to "balance dollars and kilowatts" it has doubtless not been altogether overlooked.)—*Engineering.*

Air Raid Precautions and Steel Construction

On September 12, a number of scale models of air-raid shelter construction were exhibited by the British Steelwork Association, Tothill Street, London, S.W.1, at the Hotel Victoria, Northumberland Avenue. The purpose of this exhibition was to demonstrate how the normal every-day products of the steel industry can be applied to the constructional aspects of air raid protection. The models included a block of slum clearance flats showing various alternative constructions for a steel frame building with the roofs and floors reinforced beyond normal requirements, and the strengthening of the basement of an existing multi-storey brick building, using a simple form of construction to take the whole weight of any débris and to give lateral strength. Models of underground shelters were shown in which use was made of experience in colliery arch construction, comprising steel ribs with a covering of corrugated steel sheets, and an "Everyman" shelter consisted of a few standard lengths of galvanized sheet to cover a trench. The models were shown at the Building Exhibition, which opened in London and will afterwards be on loan to A.R.P. organizations and local authorities.—*Engineering.*

General Assembly of the International Union of Geodesy and Geophysics

Following an invitation from the President of the United States, arrangements are being made to hold in the United States the next general assembly of the International Union of Geodesy and Geophysics which will take place in Washington from the 4th to the 15th of September, 1939.

Countries which adhere to the Union, and all other countries or bodies interested in Geodesy and Geophysics, will receive direct from America through diplomatic channels, letters of invitation to attend the Washington Conference.

The various national committees are being asked for recommendations regarding matters which will appear on the agenda.

The objects of the International Union are to promote the study of problems concerned with the figure and physics of the earth; to initiate international co-operation and to provide for their scientific discussion and publication; to facilitate special researches, such as the comparison of instruments used in different countries.

In accordance with the constitution of the Union the Assembly will be attended by delegates from the various national committees and by guests specially invited by the President of the United States on the recommendation of the national committees.

The chairman of the National Committee of Canada is Noel J. Ogilvie, Director, Geodetic Service of Canada, Ottawa, and the secretary Ernest A. Hodgson, Seismologist, Dominion Observatory, Ottawa.

BRANCH NEWS

Border Cities Branch

J. F. Bridge, A.M.E.I.C., Secretary-Treasurer.

The second meeting of the season was held in the Prince Edward hotel, Friday, October 21st, 1938. About thirty were present at the dinner to welcome the speaker, Mr. Jesse McBride, Vice-President of Palmer-Bee Company Detroit. The following is an abstract of his address on:

Conveyor Economics

The conveyor business has grown from practically nothing in the last few decades to a forty million dollar sales volume in 1937.

The materials handled by conveyors are mainly bulk materials, such as coal, grain, cement, sand, gravel, etc., or unit materials, such as cars, radios, washers, stones, etc. Conveyors also find wide application in the processing of materials, as in connection with heat treating and annealing, washing and drying, plating, etc. Conveyors used for the handling of materials are usually either belt conveyors, chain conveyors, screw conveyors or skip hoists.

Belt conveyors either flat or troughed are used for conveying bulk or unit materials long distances. As much as 1,500 tons of coal per hour has been transported four miles by this type of conveyor.

The chain conveyor can be used on greater inclines; it has greater strength but is slower than the belt type. There exists an 8,000 ft. conveyor of this type used in transporting various auto parts.

The screw conveyor, usually employed in handling grain and coal, uses more power but takes less space than the other types.

The advantages of conveyors in factory production methods are: Floor space is saved, as much as 1/10 to ¼ by using the conveyors as transportation systems. Work is often done directly on conveyors.

Conveyors are used as pacemakers. They cause increased production per man, point out weak men not suited for that particular task. As a means of transportation they insure speed, more volume, lack of damage, less handling. They tend to transfer the control of production from workmen to management, create a neat and orderly factory, and reduce losses due to rejections. Better products are turned out, human effort and strength is conserved.

At the completion of his interesting paper, Mr. McBride showed slides of all types of conveyors and answered the many questions that were asked.

It was moved by T. H. Jenkins, A.M.E.I.C., that Mr. McBride be given a hearty vote of thanks. All present agreed.

Calgary Branch

B. W. Snyder, A.M.E.I.C., Secretary-Treasurer.
J. S. Neil, A.M.E.I.C., Branch News Editor.

Our annual golf tournament was held at Strathmore, under ideal weather conditions and with approximately 50 members, wives and friends present, on September 10th, 1938. The Strathmore course was in excellent condition and more than half of those present played the royal and ancient game.

Non-golfers were conducted over the C.P.R. supply farm and irrigation headquarters gardens and orchards, by T. Schulte, A.M.E.I.C. This tour proved most interesting and was greatly enjoyed.

Tea was served on the spacious lawn at the residence of Mr. and Mrs. G. H. Patrick, with Mrs. E. W. Bowness and Mrs. G. P. F. Boese officiating at the table.

A most pleasant afternoon was concluded by a short address by the Branch chairman, E. W. Bowness, M.E.I.C., who thanked Mr. and Mrs. Patrick and Mr. and Mrs. G. P. F. Boese and all those responsible for the tournament, the tea party and the trip over the C.P.R. headquarters.

A general meeting of the branch was held on Friday, October 7th, 1938. This meeting took the form of a dinner entertainment provided through the kindness of the Canadian Western Natural Gas, Light, Heat and Power Company Limited. Dinner was served at 6.30 p.m., with 54 members and 4 guests in attendance.

During the course of the dinner, E. W. Bowness, M.E.I.C., having to leave early, turned the chair over to S. G. Coultis, M.E.I.C., but before doing so he urged the members to make themselves acquainted with the new and younger members of the Branch, as this was one of the primary reasons behind this informal gathering. Mr. Bowness also announced the impending visit of Dean C. J. MacKenzie, M.E.I.C., of the University of Saskatchewan on November 18th.

Mr. Coultis thanked Mr. Bowness on behalf of those present.

At the conclusion of the dinner, the guests were welcomed by Mr. Coultis and new members were introduced by the secretary.

After a short address by G. A. Gaherty, M.E.I.C., of the Calgary Power Company, and a short intermission, all present were entertained by the Gas Company's orchestra comprised of Messrs. Ted Forsey (at the piano), Banks, McDougall and Brailey; Mr. Stan James with his piano accordion; Mr. Brailey with his marimbaphone; Miss Fay Thoms and Miss Maisie Foster with songs and tap dances. G. H. Patrick, A.M.E.I.C., also contributed to the entertainment by singing a couple of his rousing songs, which were much appreciated.

A vote of thanks to the Gas Company, Mr. Bowness and his staff was unanimously carried.

The meeting adjourned with one and all of the opinion that this was the best yet.

A branch general meeting was held on October 20th in the Palliser Hotel with about 50 present. This meeting was turned over to our secretary, Mr. Snyder, who delivered an interesting paper entitled "The Operation of Calgary's Natural Gas System."

Calgary Branch Dinner for the President and Party.

Calgary Branch Executive Committee Luncheon with President and Party.

On November 3rd, 1938, we had the pleasure of a visit from Dr. J. B. Challies, L. Austin Wright, A.M.E.I.C. and Fred Newell, M.E.I.C., president, secretary and council member of The Institute respectively.

A dinner was arranged to which were invited all members of the E.I.C., the Canadian Institute of Mining and Metallurgy and the Association of Professional Engineers of Alberta, and their ladies. The city of Calgary was represented by Deputy Mayor, Frank R. Freeze.

A most enjoyable dinner was served at the Renfrew Club, at the conclusion of which an address was given by Dr. Challies, followed by short addresses by G. A. Gaherty, M.E.I.C., of the Calgary Power Company, Mr. Newell and Mr. Wright. Greetings on behalf of the city of Calgary were extended by Mr. Freeze in the absence of Mayor "Andy" Davidson.

E. W. Bowness, M.E.I.C., local chairman of the E.I.C., presided in his own inimitable way. Col. Steele of the C.I.M.M. made a few short remarks and welcomed the party to the C.I.M.M. Western Annual General Meeting to be held at Victoria, B.C., in the near future.

Those present were greatly pleased with the speeches and a most enjoyable and instructive evening came to a close with the singing of the National Anthem.

At noon of the same day, a splendid luncheon meeting was held with the Branch executive at the Ranchman Club, at which the affairs of the engineer, The Institute and the Branch were thoroughly discussed.

Edmonton Branch

F. A. Brownie, A.M.E.I.C., Secretary-Treasurer.
J. W. Porteous, Jr.E.I.C., Branch News Editor.

Special meetings of the Edmonton Branch were held on Tuesday, November 1st, 1938, to meet and hear members of President J. B. Challies' party from Montreal.

Dr. Challies, Councillor Newell, G. A. Gaherty, M.E.I.C., and L. A. Wright, A.M.E.I.C., spoke at a noon luncheon and executive meeting dealing particularly with business matters.

During the day the ladies of the party were entertained at a noon luncheon and an afternoon tea at the home of Mrs. R. S. L. Wilson.

In the evening a formal mixed dinner was held, to which members of the Association of Professional Engineers of Alberta and of the Canadian Institute of Mining and Metallurgy were invited. Major General A. G. L. McNaughton, M.E.I.C., President of the National Research Council, Mrs. McNaughton, President and Mrs. W. A. R. Kerr of the University of Alberta, and L. A. Thorssen, S.E.I.C., President of the Engineering Students Society of the University, were special guests. The meeting was in charge of Branch Chairman W. E. Cornish, A.M.E.I.C.

At the instigation of Mr. Wright, Mr. Challies presented the Plummer Medal to Mrs. E. Stansfield in recognition of her husband's paper, "The Burning of Low Rank Alberta Coals." The Engineering Institute Prize was presented to Mr. L. Thorssen.

The toast to the profession was ably proposed and answered by A. W. Haddow, A.M.E.I.C., and Mr. Challies respectively.

The toast to the ladies which was wittily proposed by Mr. Wright, was responded to with equal wit by Mrs. E. Stansfield. During the evening several short speeches were given by some of the visitors and entertainment in the form of songs was provided by Mr. E. F. McGarvey accompanied by Mr. R. R. Couper.

Altogether it was very pleasant to meet Dr. Challies, Mr. Newell, and Mr. Wright and to renew acquaintance with Mr. Gaherty.

Edmonton Branch Dinner During President's Visit.

Halifax Branch

R. R. Murray, A.M.E.I.C., Secretary-Treasurer.
A. D. Nickerson, A.M.E.I.C., Branch News Editor.

The first meeting of the winter season was held at the Halifax hotel on October 20th, 1938. Mr. R. D. McKay, Sanitary Engineer, Department of Public Health, spoke on the proposed new world calendar which is being sponsored by the World Calendar Association of New York City.

Mr. McKay spoke briefly on the history of the calendar pointing out the early difficulties in devising one that would keep exactly in step with the seasons over a long period of time. Our present calendar—which is the Roman calendar with one modification—is out of step by one day in 20,000 years.

The proposed new calendar will contain 12 months, each with 26 working days. The calendar will repeat itself each year, thus eliminating one important disadvantage of the present calendar. January will have 31 days beginning on Sunday. February will have 30 days beginning on Wednesday. March will have 30 days beginning on Friday. April will have 31 days beginning on Sunday. Each quarter of the year is thus a repetition of the previous quarter. It is proposed that the 365th day in the year be an extra Saturday to be known as Year End Day. On leap years an extra Saturday would be inserted at the end of June. All holidays would be adjusted to come on Mondays in the new calendar.

Church bodies universally have approved of the new calendar; they are particularly interested since it will lead to the establishment of a fixed date for the celebration of Easter. The League of Nations have approved the new calendar and have submitted it to all governments for proposed adoption, in 1940.

It is felt in some circles that the advantages of the new calendar are slight, and that the effort of changing to it is not justified.

Hamilton Branch

A. R. Hannaford, A.M.E.I.C., Secretary-Treasurer.
W. E. Brown, Jr.E.I.C., Branch News Editor.

The regular monthly meeting of the Hamilton Branch was held on November 15th, 1938, in the lecture theatre at McMaster University, the subject being "The Story of Dynamite" and "Power in Industry" by Mr. G. C. Grubb.

In opening the meeting the Chairman, W. J. W. Reid, M.E.I.C., said that as during the afternoon many of the members had attended the funeral of R. L. Latham, he would ask R. K. Palmer, M.E.I.C., to say a few words about our departed member and friend. We quote Mr. Palmer:

"I am surprised to find myself addressing you tonight but, because we have today performed the last service we can render to one of our most esteemed members, I have been asked to say just a few words to you in appreciation, more because Dick Latham and I have known one another, and been friends, since the early years of the century and have been next door neighbours for the past twenty years, rather than because I can do it in as fitting terms as can many of his other friends.

"Richard L. Latham, born in Toronto, a graduate of Toronto University, 1901 in Civil Engineering, came to Hamilton very shortly after his graduation and joined the engineering staff of the then young Toronto, Hamilton and Buffalo Railway, under Mr. Fisher who was then chief engineer. A few years thereafter he became chief engineer and has held that position with distinction down the years to the present time.

"Now, there is no question that Dick Latham was technically competent in all those things that pertain to day in and day out railway engineering which is evidenced by the fact that the Toronto, Hamilton and Buffalo Railway has been kept in a state of efficiency since its beginning. But there is more than that.

"Dick Latham has held the respect of every member of his staff and I personally know that he has always had their esteem and co-operation in all the railway's undertakings. He has likewise had that same esteem and co-operation from the heads of all the other departments. And more than that. He has had the esteem of those engineers who are in charge of the engineering departments of the other Canadian and American railways, as is evidenced by the presence here today of J. M. R. Fairbairn, M.E.I.C., Chief Engineer of the Canadian Pacific Railway; W. A. Duff, M.E.I.C., Engineer of Roads and Bridges, Canadian National Railways; S. B. Clement, M.E.I.C., Chief Engineer, Temiskaming and Northern Ontario Railway; D. G. Kilburn, M.E.I.C., Division Engineer, Board of Railway Commissioners, Ottawa; J. R. W. Ambrose, M.E.I.C., Superintendent, Toronto Terminals, and Mr. Neubert, Chief Engineer, New York Central System.

"He held the confidence and trust of those men who are ultimately and finally responsible to their stockholders for the successful operation of their railway.

"In his dealings with the City and the Province and with the many contractors, he always worked for his company as every engineer should do but, so far as I am aware, there never has been any feeling but one of confidence and fairness in all the broad aspects of such dealings.

"Gentlemen, we have lost a good friend, a good neighbour, and finally, a good engineer, and one who has been a credit to our profession."

At the close of his remarks Mr. Palmer asked the assembly to rise for a few moments silence and reflection.

The speaker of the evening Mr. Grubb, Manager of the Explosives Division of the Canadian Industries Limited was introduced by J. R. Dunbar.

Mr. Grubb's lecture was divided into the following sections,

1. Brief history of the development of explosives.
2. General description of a modern explosives plant.
3. Raw materials used in manufacture.
4. Brief description of manufacture.
5. Importance of explosives to our present civilization.

The speaker prefaced his talk with this important definition. An explosive reaction is the rapid transformation of a material into other more stable substances, largely or entirely gaseous; such reaction always produces intense heat. It is the rapid expansion of the gases so formed into a volume very much larger than that occupied by the original substance which accomplishes the useful work which is intended.

Black blasting powder is the oldest of all explosives and while the Chinese are often given credit for the invention, the most authentic records indicate that the monk, Roger Bacon, invented it about 1252. For 300 years it was put to no useful purpose but in 1613 it was used for mining in Saxony and towards the end of the century for road building in Switzerland.

The most important modern explosive is one with a nitroglycerine base.

Nitroglycerine, the most powerful explosive known, was discovered by Sobrero at Turin in Italy in 1846. He made little use of it but Alfred Nobel, the father of high explosives, was a Swedish engineer who in 1860 started to carry on most of his work in Scotland. In 1870 he made the epoch making discovery of dynamite; this was followed by his discovery, by reason of necessity through the danger entailed by carrying the liquid, of gelatin as a solidifier or base.

Nobel is perhaps better known as the donor of prizes for the advancement of literature, science and peace.

Approximately 90 per cent of all high explosives in the world are of the dynamite or gelatin class. In Canada about 70 per cent of the high explosives used are of the gelatin class. This explosive is suitable for use in gaseous places and dusty mines.

The most common explosive for military purposes is trinitrotoluene (TNT) and cordite. These explosives are normally unsuitable for industrial use.

The arrangement of an explosive plant requires from 500 acres to 1,000 acres of ground so that danger zones may be given much space. Such a plant will contain an extensive power house also many conveniences for workers with a complete village of from 50 to 100 houses, also a school and church and all modern city conveniences.

Of the raw material nitrate of soda is now largely made synthetically from atmospheric nitrogen. This artificial production is one of the greatest triumphs of chemical engineering.

The speaker dealt with the use of glycerine, nitric acid and sulphuric acid in the work of the manufacture of explosives.

It will interest all to know that the degree of civilization and prosperity of a country can be closely measured by its relative per capita consumption of explosives for useful purposes, a few of which follow; fishing industry, breaking ice so that sealing and whaling ships may reach their hunting grounds; lumber industry, blowing out stumps, breaking up log jams, breaking up ice jams; excavating, mining, etc. Probably the largest blast on record was made recently at Flin Flon, Manitoba, where 280,000 lb. of explosives were set off in one huge blast to shatter 500,000 tons of ore for the Hudson Bay Mining and Smelting Company, Limited.

The lecture was followed by two moving picture reels: "The Manufacture of Explosive" and "Power in Industry."

Owing to inclement driving weather the meeting for this instructive meeting was attended by only 48 members, and E. G. MacKay, A.M.E.I.C. in moving a vote of thanks to Mr. Grubb regretted this detail.

At the close of the meeting members adjourned for the usual social half hour and coffee and sandwiches.

Lakehead Branch

H. Os, A.M.E.I.C., Secretary-Treasurer.

The President and party arrived at Port Arthur on October 25th, 1938, at 10.20 p.m. Members of the local branch and their ladies met the train to welcome the visitors to the Lakehead Branch and escorted them to the Prince Arthur hotel.

After registering at the hotel, Dr. and Mrs. J. B. Challies, Mr. and Mrs. Newell, and L. Austin Wright, together with members of the local branch and their wives, motored to Fort William where they were entertained at the home of Mr. and Mrs. G. R. Duncan.

An informal luncheon, with Dr. J. B. Challies and Mr. F. Newell and L. Austin Wright as guests, was held at the Royal Edward hotel, Fort William, at 1.00 p.m., October 26th. Present were the members of the Executive committee and prominent members of the local branch. The object of this meeting was to enable local members to meet the visiting officers of The Institute to discuss Institute affairs.

Dr. Challies spoke on consolidation. The speaker contended that the contemplated consolidation of The Engineering Institute with the Professional Associations came before the membership at large was ready for this change and that this issue was voted down in practically every province. He stated, however, that the Consolidation Committee's work had not been in vain. He spoke of the great step forward in the general approval by the membership of by-law 76 giving wide power to enter into close co-operation with the Provincial Associations.

The speaker also discussed the proposed reduction of council and voiced his conviction that this change would not be beneficial.

Mr. F. Newell, Councillor of The Institute, discussed means and methods whereby a closer co-operation between The Engineering Institute and other engineering organizations could be realized.

The different grades of membership were clarified by L. Austin Wright, A.M.E.I.C., General Secretary.

Mr. Wright also gave a very interesting talk on a meeting held last summer at New York as a joint meeting of the Engineering Council of Professional Development.

Other speakers were Messrs. J. Antonisen, M.E.I.C., P. E. Doncaster, M.E.I.C., and G. R. Duncan, S.E.I.C.

E. L. Goodall, A.M.E.I.C., chairman of the local branch, presided at the meeting.

A Dinner Meeting of the Lakehead Branch, at which the President and Party were present

Engineers and their wives attended a dinner meeting of the Lakehead Branch in the Prince Arthur hotel on October 26th. Eighty-eight persons sat around the tables.

A feature of the evening was the introduction of Miss E. M. G. MacGill, A.M.E.I.C., a member of the engineering staff of the Canadian Car and Foundry Co. aeroplane plant in Fort William. Miss MacGill, who is a member of the Lakehead Branch, is the only woman member of The Institute in Canada.

President J. B. Challies, in the principal address of the evening, paid tribute to an old friend, Hon. C. D. Howe, Hon.M.E.I.C., Minister of Transport, as "one of our great engineers, rendering outstanding service to the country." He also commended Dr. Thomas Hogg, M.E.I.C., chairman of the Hydro-Electric Power Commission of Ontario, as an engineer doing great public service.

"Fifty years ago the few outstanding engineers in Canada were self-made men, with no colleges in Canada to give them training. Last year 3,500 students graduated in various branches of engineering from 11 Canadian colleges," Dr. Challies said.

Councillor Fred Newell, M.E.I.C., spoke on the movement for co-operation between the engineering associations, which would reach one of its climaxes in Regina on Saturday with the signing of an agreement between The Institute and the Saskatchewan body.

L. A. Wright, A.M.E.I.C., General Secretary, outlined advantages of membership in the organization.

Mr. Newell was introduced by H. G. O'Leary, and Dr. Challies was introduced by R. J. Askin, district councillor for The Institute. A vote of thanks was tendered by G. R. Duncan and J. M. Fleming. E. L. Goodall, chairman of the branch, presided.

Joint Luncheon of the Lethbridge Branch of The Engineering Institute of Canada and the Association of Professional Engineers of Alberta. Left to right: C. S. Clendening, A.M.E.I.C., G. H. Thompson, A.M.E.I.C., C. S. Donaldson, A.M.E.I.C., F. G. Cross, M.E.I.C., J. Haimes, A.M.E.I.C., C. M. Moore, A.M.E.I.C., J. B. Burke, D. W. Hays, M.E.I.C., N. H. Bradley, A.M.E.I.C., G. A. Gaherty, M.E.I.C., R. Livingstone, M.E.I.C., J. T. Watson, A.M.E.I.C., C. E. MacKinnon, A.M.E.I.C., W. L. McKenzie, A.M.E.I.C., Dr. J. B. Challies, M.E.I.C., R. F. P. Bowman, A.M.E.I.C., Fred Newell, M.E.I.C., A. J. Branch, A.M.E.I.C., G. F. Hilliard, E. A. Lawrence, S.E.I.C., P. M. Sauder, M.E.I.C., L. A. Wright, A.M.E.I.C., G. S. Brown, A.M.E.I.C., H. W. Rowley, A.M.E.I.C., R. S. Lawrence, A.M.E.I.C., J. M. Campbell, A.M.E.I.C.

Lethbridge Branch

E. S. Lawrence, S.E.I.C., Secretary-Treasurer.

The members of the Lethbridge Branch of The Engineering Institute of Canada and the Association of Professional Engineers of Alberta met at a luncheon on Thursday, November 3rd, 1938, under the chairmanship of R. F. P. Bowman, A.M.E.I.C., with Dr. J. B. Challies, M.E.I.C., the President of The Engineering Institute of Canada; L. Austin Wright, A.M.E.I.C., the General Secretary, and Fred Newell, M.E.I.C., Councillor for the Montreal Branch, present as guests. About thirty members representing electrical, mining, municipal, irrigation, highway and railway engineers attended the meeting.

P. M. Sauder, M.E.I.C., introduced President Challies.

Dr. Challies outlined the efforts which The Engineering Institute of Canada, the Dominion-wide organization, is now making to more closely co-ordinate the work of the various associations of provincial engineers with a view to establishing more uniform standards for admission to the engineering profession and to facilitate the exchange of technical information amongst its members.

An agreement to facilitate this objective, between the Association of Professional Engineers of Saskatchewan and The Engineering Institute, was consummated during the visit of Dr. Challies and party at Regina last week, and the details for a similar arrangement suitable for conditions existing in Alberta were discussed at meetings held at Edmonton, Calgary and Lethbridge.

Dr. Challies introduced Mr. Wright and Mr. Newell. Mr. Wright spoke briefly about The Engineering Journal and secretarial work at Headquarters. Mr. Newell then gave a clear picture of the feelings in the various Provinces across Canada with regard to co-ordinating The Engineering Institute of Canada and the Provincial Professional Associations.

J. T. Watson, A.M.E.I.C., introduced G. A. Gaherty, M.E.I.C., of Montreal, president of the Calgary Power Company, who spoke briefly regarding the annual meeting of The Institute to be held in Ottawa next year.

A hearty vote of thanks was tendered Dr. Challies and the members of his party for their excellent addresses by J. M. Campbell, A.M.E.I.C., who assured them of the full support of the Lethbridge Branch in their efforts to bring about a better understanding between the E.I.C. and the Provincial Professional Association.

Immediately following this meeting the Executive committee of the Lethbridge Branch met with Dr. Challies and his party regarding matters of increased rebates to smaller branches, The Engineering Journal and more intimate matters dealing with co-ordinating the two engineering bodies, particularly the formation of a Provincial Division in Alberta for the purpose of uniting the three Alberta branches as a unit for negotiating with the Association of Professional Engineers of Alberta.

Those present at this executive meeting were: President J. B. Challies, M.E.I.C., L. Austin Wright, A.M.E.I.C., Fred Newell, M.E.I.C., G. A. Gaherty, M.E.I.C., R. F. P. Bowman, A.M.E.I.C., Chairman, J. T. Watson, A.M.E.I.C., Vice-chairman, and Councillor, E. A. Lawrence, S.E.I.C., Secretary-Treasurer, J. M. Campbell, A.M.E.I.C., Past-Chairman, G. S. Brown, A.M.E.I.C., Past-Councillor, C. S. Donaldson, A.M.E.I.C., P. M. Sauder, M.E.I.C., W. L. McKenzie, A.M.E.I.C.

London Branch

D. S. Scrymgeour A.M.E.I.C., Secretary-Treasurer.
Jno. R. Rostron, A.M.E.I.C., Branch News Editor.

The regular monthly meeting was held on October 26th, 1938, and formed a joint meeting with the Military Engineers Association in the Richmond Street Armouries by kind permission of Lt.-Col. W. M. Veitch, A.M.E.I.C.

By courtesy of the Bethlehem Steel Corporation, sound pictures were exhibited under the direction of Mr. C. G. Lamb, representative of the Corporation.

Our Branch chairman, A. O. Wolff, has been promoted to the position of Assistant District Engineer of the C.P.R. and is now located at Toronto. In his unavoidable absence the chair was taken by H. F. Bennett, M.E.I.C., who opened the meeting by introducing Mr. Lamb.

The first film shown was entitled the "Production of Structural Steel." Views were given of the Corporation's extensive plant in Pennsylvania and every stage of the manufacture of steel was shown from the arrival and unloading of the iron ore, coal, etc. to the rolling of the structural steel shapes. The cranes used in the unloading of the materials from the ships' hold are of a unique pattern. The operators are located in steel cages immediately over the grab buckets and travel with their load. The lowering and raising is done by the steel jibs of the cranes and the operators steel cages are kept vertical—no wire hoisting ropes appear to be used, the cranes travel bodily on steel rails and deposit their load exactly where required.

The blast furnaces were shown in operation and the method of handling the skips, containing tons of molten metal, by massive machinery; the pouring into the ingot moulds and finally the conversion of the ingots at the rolling mills to the form of I-beams, angles, etc. and steel rods. The ease and precision with which the machinery handles, conveys and deposits the heavy and dangerous loads is simply marvellous.

The second film was entitled the "Golden Gate Bridge, San Francisco." This showed the erection of the steelwork from the tops of the foundations to the completion of the bridge. The first operation shown was the grinding by machinery of the tops of the foundations to a perfectly level and even surface.

The construction and erection of the towers was then shown. These towers are 746 ft. high (roughly only about 150 ft. less than the Eiffel Tower at Paris) and of steel honeycomb "built-up" sections. The sections were hoisted into position by steel cranes fixed on each successive top section, the steelworkers being raised and lowered in steel cages. After the fixing of the saddles at the top, the spinning and erection of the steel wire cables was shown. These (by Roeblings) were built up of 3/16 in. wire and were compacted to 36½ in. dia. and bound around their circumference by steel wire. Some idea of the gigantic strength of the two cables may be formed when it is realized that they have to carry, in addition to their own weight, the dead and live load of the road structure over a span of 4,200 ft.—practically four-fifths of a mile.

The erection of the wire suspenders (cradled) and the floor system was begun at each end and carried forward to the centre. The cross floor beams, carrying stiffening trusses and stringers, were hung from the suspenders and the concrete deck was laid over this system. The film showed up the marvellous agility and nerve of the steelworkers who seemed just as much at home up in the air traversing, swinging loads, etc., as on the ground.

The photographer who took these "close up" views must have been something of a steeple-jack to accomplish it.

The films, considering the difficult positions from which they were taken, were beautifully clear.

A hearty vote of thanks was moved by H. A. McKay, A.M.E.I.C., and seconded by W. G. Ure, A.M.E.I.C., to the Bethlehem Steel Corporation for the exhibition, and unanimously carried.

Sixty members, military engineers and guests were present.

Niagara Peninsula Branch

G. E. Griffiths, A.M.E.I.C., Secretary-Treasurer.
J. G. Welsh, S.E.I.C., Branch News Editor.

On November 18th, 1938, the members of the Niagara Peninsula Branch of the E.I.C. spent an exceedingly interesting afternoon and evening in the study of aircraft construction and development.

In the afternoon the members visited the plant of the Fleet Aircraft Co. at Fort Erie, Ontario. There the construction of aeroplanes, from light training ships to four ton gross weight freighters, was observed. Every stage in their transition from the stock room to the finished product was in evidence. Keen interest was taken in the structural framework. The planes were practically entirely of metal, all main members being tubular. The lighter structural members were of an aluminum alloy which, when heated to 920 deg. F., became quite soft and pliable. In that form the flat bars or sheets could be moulded to whatever shape or section that was required. On quenching in air, the metal regained its original structural strength and rigidity. It was worthy of note that welding was used on all main connections and whenever possible on the remaining structure. As yet, no satisfactory method of welding the light aluminum alloy was available.

With the sections moulded and cut to length, all assemblies were made in jigs which held each member rigidly until assembly section was completed. The steel workers present, noted that the members to be riveted were held together, drilled, and riveted, rather than completely prefabricated.

The radial motors, with the single throw counterbalanced crankshaft, and master connecting rod to the hub of which the remaining rods were pin-connected, proved very puzzling, especially in view of the excellent balance attained when the principle necessitates a slightly different stroke on the radial cylinders.

In the evening an excellent dinner was enjoyed at the Mather Arms hotel, Fort Erie. Wing Commander D. G. Joy, District Inspector of Civil Aviation, Department of Transport, spoke briefly of the Trans-Canada Airways, and of his trip to Vancouver and back, just completed that morning on a regular test schedule of the T.C.A. Mr. Joy spoke of the dangers encountered in this service, but also of the many precautions taken. In view of the numerous newspaper accounts of accidents to aircraft it was very interesting to hear that from actual statistics the chance of an accident is one in 8,000,000 miles of travel.

The speaker of the evening was Mr. Richard Young, Chief Designing Engineer of the Fleet Aircraft Company. In light of the fact that his company is just starting production on a new freighter designed especially for Canadian conditions, he was admirably fitted to talk on the subject "Steps in the Design of a Bush Transport Aeroplane." Many questions were brought up for discussion following this address.

A. J. Grant, M.E.I.C., dean of the Niagara District engineers, expressed the appreciation of the members of the branch to the Fleet Aircraft Company for their courtesy of the afternoon, to Mr. Joy for his attendance and talk, and to Mr. Young for his excellent paper and resultant discussion.

Ottawa Branch

R. K. Odell, A.M.E.I.C., Secretary-Treasurer.

STEEL—MAN'S SERVANT

A technicolour sound film, "Steel—Man's Servant," prepared by the United States Steel Products Company, was shown at an evening meeting on November 17th at the Canadian Government Motion Picture Bureau before a capacity audience. This film showed the process of iron and steel making from the mining of the ore to the production of the many kinds of steel required for modern commercial purposes.

W. F. M. Bryce, A.M.E.I.C., Chairman of the Ottawa Branch, presided at the meeting.

Peterborough Branch

A. L. Malby, Jr.E.I.C., Secretary-Treasurer.
J. L. McKeever, Jr.E.I.C., Branch News Editor.

At the regular meeting of the Branch held on October 27th, 1938, the speaker was Mr. J. W. McFarlane, of the Eastman Kodak Company, Rochester, N.Y., and his subject "Colour Photography." As this is a subject of wide interest, and as Mr. McFarlane wished to reach as large an audience as possible, the meeting was held jointly with the Foreman's Association of the Canadian General Electric Company, and was held in the Collegiate Auditorium, the public being invited to attend.

Mr. McFarlane started his talk by telling something of the nature of light, and then went on to illustrate by means of coloured gelatine filters in three separate projectors, how the three colour process of colour printing is effected. He then showed how the same effect could be achieved in photography by a subtractive process by coating the film with three separate emulsions sensitive to blue, green and red light respectively. These emulsion layers are selectively sensitized. Instead of lumping all colours together as an ordinary single emulsion film does, each of the Kodachrome film emulsions picks out a particular colour band and records only that. If some hue of the subject is a combination of colours, the emulsion will divide up that hue into its elements, each emulsion layer recording its proper part of the colour combination. After processing, the finished positive is placed in a projector and light is passed through these separate images, they re-combine into the original colours.

A large and appreciative audience listened to Mr. McFarlane's explanation of the Kodachrome colour process, and viewed the many slides and reels of colour film which were shown in illustration.

At the regular meeting of the Branch held on November 10th, the speaker was Mr. A. C. T. Sheppard, D.L.S., of the Bureau of Geology and Topography, Department of Mines and Resources, Ottawa, and his subject,

Canada's Contribution to Aerial Photographic Mapping

Mr. Sheppard has been engaged on topographical mapping for the Department of Mines, later the Department of Mines and Resources, since 1910, and has had a great deal to do with the development of photographic mapping, hence he was in a position to give an authoritative talk on the subject.

Aerial mapping in Canada began shortly after the war, when use was made of open cockpit military flying boats. The oblique method of photography was used, and the camera was not automatic, but directed and controlled by the operator. The results were encouraging, but difficulty was experienced in registering the prints with the ground maps and large overlaps had to be used to make up for the deficiencies of the camera.

Since that time, much progress has been made. The mapping is now part of the duty of the R.C.A.F. under the Department of National Defence, and the planes used are cabin types equipped with either floats or skis, depending upon the season. Both oblique and vertical mapping are used, depending upon the nature of the country to be mapped, but control of the camera is now automatic. Many different types of cameras were tried, but at the present time the Fairchild F.3 with 4 in. aperture and focal length of about 8 in. is used as standard. Each plane is equipped with three of these cameras set so that the three pictures overlap by about forty per cent. Lately, infra-red film has been used with greatly increased clearness of picture.

A library of aerial photographic prints is maintained in Ottawa, of which use can be made by the public. 50,000 prints (9 in. by 9 in.) have been added this year, and over 100,000 have been used or loaned in the same period. To date approximately 770,000 square miles of Canada has been covered by aerial photographic mapping, and more territory is being added each year.

At the conclusion of his talk on mapping, Mr. Sheppard showed a film of a trip by air and water from Edmonton to Cameron Bay, which film proved of great interest to and was much appreciated by his audience.

The attendance was 35.

Saskatchewan Branch

J. J. White, M.E.I.C., Secretary-Treasurer.

The regular October meeting of the Saskatchewan Branch of The Engineering Institute of Canada was cancelled in order to co-operate with the Association of Professional Engineers of Saskatchewan, which organization held its semi-annual meeting for all engineers in Saskatchewan.

This meeting, held at the Hotel Saskatchewan, Regina, on October 29th, was of a rather significant nature since it was set aside for the signing of the co-operative agreement entered into by the Saskatchewan Branch of The Engineering Institute of Canada and the Association of Professional Engineers of Saskatchewan. The purposes of this agreement are to build up a common membership within the Province, endeavour to reduce fees, simplify the collection of these fees and have a common executive for the management of engineering affairs.

It was further rather significant because it afforded an opportunity of a visit from Headquarters in the persons of Dr. J. B. Challies, President of The Institute, F. Newell, Councillor of The Institute, L. Austin Wright, General Secretary of The Institute and G. A. Gaherty, Chairman of The Institute's Committee on Western Water Problems.

The meeting took the form of a dinner at which 106 engineers were present. The chairman was J. W. D. Farrell, M.E.I.C., President of The Association of Professional Engineers of Saskatchewan. Seated at the head table with Mr. Farrell were L. A. Wright, A.M.E.I.C., L. A. Thornton, M.E.I.C., Geo. Spence, H. S. Carpenter, M.E.I.C., Dr. J. B. Challies, M.E.I.C., F. Newell, M.E.I.C., I. M. Fraser, A.M.E.I.C., G. A. Gaherty, M.E.I.C., D. A. R. McCannell, M.E.I.C., R. A. Spencer, A.M.E.I.C., and H. R. Mackenzie, M.E.I.C.

After dinner the guests of the evening were introduced by executive members of the organizations present, and Mr. Spencer, Councillor for Saskatchewan, spoke on the problems which had confronted the engineering organizations and the steps which had been taken leading up to the agreement which was to be signed later in the evening.

The presiding officer then called on the speaker of the evening, Dr. Challies, who outlined conditions within The Institute generally. He was particularly glad to have the opportunity of visiting all the Western Branches of The Institute and discussing with them their own peculiar problems. He conveyed greetings from Headquarters to all members of The Institute and extended a very warm welcome to all who would become members automatically with the signing of the agreement. Dealing with matters of policy he emphasized his objections to an increase in the quorum of Council, suggesting that such an increase would delay the business of Council at a time when Council should have more freedom in being able to act with dispatch in the almost national desire for closer co-operative relations with the Provincial Professional Associations. He felt that The Institute was on the threshold of a new era, in which the policy of closer co-operation with all engineering bodies would become effective and more particularly so with the Professional Associations.

Following the President's address, the co-operative agreement between the two organizations was signed by Dr. J. B. Challies and

Banquet to Celebrate Signing of Co-operative Agreement between The Engineering Institute of Canada and the Professional Engineers of Saskatchewan, Regina, October 29th, 1938.

Seated at Head Table: J. J. White, M.E.I.C., L. A. Wright, A.M.E.I.C., L. A. Thornton, M.E.I.C., George Spence, H. S. Carpenter, M.E.I.C., Dr. J. B. Challies, M.E.I.C., J. W. D. Farrell, M.E.I.C., F. Newell, M.E.I.C., I. M. Fraser, A.M.E.I.C., G. A. Gaherty, M.E.I.C., D. A. R. McCannel, M.E.I.C., R. A. Spencer, A.M.E.I.C., H. R. MacKenzie, A.M.E.I.C.

L. Austin Wright for The Institute, witnessed by H. S. Carpenter and F. Newell and signed by J. W. D. Farrell and J. J. White for the Professional Association, witnessed by I. M. Fraser and W. E. Lovell. Immediately following, Dr. Challies presented Mr. Farrell with a solid gold fountain pen, the one used by the parties who executed the co-operative document, as a memento of the occasion.

An Institute Committee in Montreal, of which Gordon McL. Pitts was the chairman, feeling that this historic event in the annals of the engineering profession in Canada should be put on the air, had succeeded in arranging to have part of this programme broadcast from coast to coast over the Canadian Broadcasting Corporation national network.

After a brief introduction by Mr. Farrell, the following message was delivered by the President of The Institute and was heard by a nation-wide audience.:—

"Tonight in Regina two great engineering bodies gather to celebrate a special occasion—an occasion that permits them to render a better and broader service to their fellow men. In the Province of Saskatchewan from today there will be a common membership between the provincial association and The Engineering Institute. This will guarantee that the resident members of the national body will gain the privileges and will assume the responsibilities that go with the right to practise as a professional engineer in the Province. Reciprocally, the members of the Association will obtain the advantage of participating in all the social and technical activities of a national body which enjoys great prestige not only on both sides of the international boundary, but abroad as well.

When the average citizen thinks of an engineer and his work, he thinks of those things which he can see—great bridges like the Lion's Gate Bridge which is nearing completion at Vancouver—the Borden Bridge over the Saskatchewan River just west of Saskatoon—the International Blue Water Highway Bridge that joins Canada to the United States, at Sarnia and Port Huron. He thinks of great buildings like this hotel and the massive grain elevators that are so essential to this great West. He thinks of the oil fields with all their machinery and the great wealth which they are pouring forth.

And yet the greatest accomplishments of engineers are not readily available to the eye of the average citizen. When you flip on the switch that floods your room with useful light, you do not think of all the engineering that lies back of that small piece of hardware on your wall. You are not aware of a power site, that is perhaps a hundred or more miles away; of the structure that impounds that water, of the flumes that direct it, of the powerful turbines and the magical generators that transform water power into electricity, and of the great buildings that house them; of the transmission lines or even of the wiring within your own building, and yet they constitute an engineering triumph.

When you turn on the tap that gives you continuously a flow of water that is inexhaustible, you do not think of intakes, pumping stations, filtration plants, water treatment and water control. To you it is just a modern convenience, and yet it is an engineering triumph.

Similarly with your telephone. When you put the receiver to your ear, you are not aware of all the years of patient intelligent effort that lie back of it, the great cable systems, the machinery that with superhuman intelligence carries your spoken word to your friends or the corner grocer. To you it is just a telephone—practically a gadget—and yet it too is an engineering triumph.

And so it is with this agreement which we have signed tonight. The average citizen will never be aware of its existence, will not know of the years of patient effort on the part of many people, of the trials and disappointments that accompanied its development or of its significance to the engineers in other parts of Canada. And yet there it is, a completed document which in its own quiet way makes it possible for the engineers of this province to give to his fellow man a greater and a better service. *It too is an engineering triumph.*

It seems only natural that this forward step should be made first of all in the West. So many great things have been done for the first time, out here, that we have been accustomed to seeing pioneering in many things come from this section of our great Dominion. In spite of much privation and years of disappointment, their spirit still survives. We people of the East salute you and we give great thanks that we are permitted to participate with you in this brilliant future that lies before us all.

As a feature of this celebration, it is my privilege to announce the decision of the Council of The Engineering Institute to honour two eminent elder engineer statesmen whose careers had much to do with the development of the Prairie Provinces. Since its inception fifty-one years ago The Engineering Institute has awarded only forty-three honorary memberships. Sixteen of these recipients are now living, of whom the most distinguished is His Excellency the present much beloved and greatly respected Governor-General of Canada. It is, therefore, appropriate that at its Annual General Meeting in Ottawa next February, Lord Tweedsmuir will, on behalf of the Council, hand a Certificate of Honorary Membership in The Engineering Institute of Canada to Chas. A. Magrath, M.E.I.C. This honour is in recognition of Mr. Magrath's services to this country—

As a pioneer Dominion Land Surveyor all over the Prairie Provinces;

As an early mayor of Lethbridge, Alberta;

As a member, first of the Territorial Legislature, and then of the Territorial Government, being Minister in the administration of Sir Frederick Haultain;

As a representative of the Province of Alberta in the Parliament of Canada;

As a member, and, for many years, the Chairman of the Canadian Section of the International Joint Commission;

As a chairman for six years of the Hydro-Electric Power Commission for Ontario;

As a member of a British Royal Commission which aided in solving the economic problems of the ancient and Royal Colony of Newfoundland; and

Finally, for being one of the outstanding senior engineer statesmen of the Dominion.

I am also privileged to announce that in the City of Victoria, one week from tonight, it is expected that His Honour The Lieutenant-Governor of British Columbia, will, on behalf of the Council of the Institute, present to Col. John Stoughton Dennis, M.E.I.C., the Sir John Kennedy Gold Medal. This is an award greatly prized among engineers, and one rarely conferred. It was established to commemorate the life of a distinguished pioneer member of the Engineering Profession of Canada, John Kennedy, whose engineering career in the development of the Harbour of Montreal was suitably recognized when our late lamented Beloved Sovereign George the Fifth conferred upon him a Knighthood in Nineteen Hundred and Sixteen. Only six Sir John Kennedy Gold Medals have been awarded. They are as follows:

To the late Past President, Col. R. W. Leonard, St. Catharines, for his contributions to mining and as a generous founder of the Royal Institute of International Affairs.

To Past President Dr. George Herrick Duggan, Montreal, as one of the leading bridge builders of this continent.

To the late Past President, John G. Sullivan, Winnipeg, for his connection with the Panama Canal and as a pioneer railway builder.

To Past President Alex. J. Grant, Ottawa, as the builder of the Welland Canal.

To the late Past President, Dr. Robt. Alexander Ross, for his leadership in the electrical utility industry of Canada.

To Dr. Andrew Harkness, Toronto, for his prominence in the field of structural and architectural engineering.

The seventh Sir John Kennedy Gold Medal now goes to Col. J. S. Dennis, a Companion of the Distinguished Order of St. Michael and St. George, for distinguished service to his country,

as an explorer of the western plains;

as a pioneer surveyor of the prairies;

as a Commissioner of Public Works, in Regina;

as a promoter of irrigation in Alberta;

as a colonizer for a great railway system;

as a life-long soldier with distinguished service in the Riel Rebellion and during the Great War;

and

as a distinguished and senior Past President of The Engineering Institute of Canada.

It is an interesting fact that when Col. Dennis came West in eighteen hundred and seventy-seven, sixty-one years ago, to start his first exploratory survey of the prairies, he brought with him as assistant, Mr. Chas. Magrath. Their relations, professional and personal, have been very close ever since.

Both recipients of these premier honours of The Engineering Institute of Canada are now living in retirement in Victoria, that haven of rest for so many professional men who have lived a long life of useful service. It will be a happy circumstance that will permit Mr. Chas. A. Magrath to see the professional career of his first chief so fittingly recognized by the award, through His Majesty's representative, of the Sir John Kennedy Gold Medal. In honouring these two great public benefactors, these two courtly gentlemen, these two outstanding leaders for so many years of a great profession, The Engineering Institute of Canada is honouring itself.

Finally, to those members of the engineering profession within sound of my voice who cannot be present at the engineers' banquet at Regina tonight to see the completion of this progressive agreement between the Institute and the Association of Professional

Engineers of Saskatchewan, I have this brief message—*The engineering profession in every province of the Dominion was never more alert to the opportunity for rendering public service, and was never better prepared to serve the public, than it is today.*"

Following the broadcast the meeting was addressed by Mr. Newell and Mr. Wright, both of whom contributed to the success of the evening by very timely remarks.

During the banquet a party of ladies, 60 in number, enjoyed a dinner bridge and listened to the broadcast in the Spanish Room of the Hotel Saskatchewan. Souvenirs in the form of silver teaspoons were presented to Mrs. Challies and Mrs. Newell during the evening. In addition to these visiting ladies, out of town guests were Mrs. R. A. Spencer, Mr. I. M. Fraser, Saskatoon, Mrs. Jonsson, Prince Albert, and Mrs. E. C. S. Carpenter, Melville.

This function was a very delightful affair and much appreciated by all the ladies present.

The following day a Reception was held in the Blue Room of the Hotel Saskatchewan under the auspices of The Engineering Institute of Canada and The Association of Professional Engineers of Saskatchewan. Receiving the guests, of which 180 signed the register, were Dr. J. B. Challies and Mrs. Challies, Mr. J. W. D. Farrell and Mrs. Farrell and Mr. H. S. Carpenter and Mrs. Carpenter. Officiating at the tea urns, serving and generally attending to the pleasure of the guests were the wives of the officers of the local organizations. An interesting feature of the tea was a display of the illuminated addresses presented to the Institute on the occasion of its semicentennial anniversary in 1937.

Our thanks are hereby extended to the President and his party on coming to Regina, helping us generally in our deliberations and assisting in creating a new feeling of esprit de corps within our ranks.

VISIT OF HEADQUARTERS DELEGATION TO SASKATOON

Saskatoon engineers were glad to welcome the delegation on Monday, October 31st. A visit to the Engineering College in the morning, a luncheon at noon, and a public address by the President in the afternoon provided a busy day.

At the Engineering College, the delegation addressed an audience of over one hundred students of the two senior years. Most of the faculty were also present. Dean Mackenzie, M.E.I.C., as chairman, introduced the speakers. President Challies emphasized the value of contacts, and in humorous vein illustrated his remarks by examples from his own experience. The student group appreciated to the full the opportunity given them of hearing from the President. Mr. Gaherty, Mr. Wright and Dean Mackenzie, infected by the note of levity introduced by the President, recalled some highly amusing personal experiences in such far-flung localities as the citadel at Halifax, the shell holes of Passchendaele, the South American Republics, and the Falls of Montmorency. Their remarks drew enthusiastic applause. Mr. Newell was more serious. He prefaced his address by stating that, as he felt that he could not compete in humour with the preceding speakers, he would confine himself to such advice to the young engineers as he could draw from his own experiences. In this he was a tremendous success. One member of the faculty afterward expressed general

Some of the Saskatoon Engineers who attended the Luncheon held during the President's Visit there. Left to right, 1st row: A. R. Greig, M.E.I.C., J. B. Mawdsley, A. M. Macgillivray, A.M.E.I.C., C. J. Mackenzie, M.E.I.C., R. D. Overholt, W. G. Worcester, M.E.I.C., A. B. Olsen, B. Chappel. Second row: J. E. Underwood, F. H. Edmunds, V. Howie, E. Chan, I. M. Fraser, A.M.E.I.C., Third row: R. A. Spencer, M.E.I.C., E. H. Phillips, A.M.E.I.C., F. Young, A.M.E.I.C., C. Hay, C. R. Forsberg, S.E.I.C., H. C. Bear, T. J. Boyle, L. M. Howe. Fourth row: W. M. Courtenay, G. D. Archibald, H. McI. Weir, R. J. Baker, N. B. Hutcheon, J. Jonsson, W. G. Dyer, A.M.E.I.C.

opinion when he said that this was one of the finest addresses of its type that he had ever heard. The suggestion was seriously made that the Institute should ask Mr. Newell to make a "talkie" of his address so that it might be sent to all the engineering schools in Canada.

At noon the delegation members were the luncheon guests of about fifty of the practising engineers of the city and vicinity. Mayor Pinder, M.P.P., extended a welcome to the party on behalf of the city and each of the delegates spoke briefly. It was intended that these addresses should inform those who had been unable to make the Regina trip and others, who up to the present had not been particularly interested, of the present situation as regards engineering organizations in Canada.

At the afternoon session, President Challies addressed an audience composed of over 250 University students, engineers and guests from the city. His subject was "The Great Lakes to Ocean Waterway." Such addresses as this one of the President make clear to the public that engineers are becoming actively interested in political and economic, as well as technical, phases of our national problems, and this reacts in many ways to the benefit of the profession. Local publicity given this address (as also to the whole visit of the delegation) was excellent. The meeting was held in the Chemistry Theatre of the University with Professor I. M. Fraser as chairman. A pleasing preliminary was the presentation by Mr. Challies of the certificate accompanying the third year E.I.C. prize to Mr. J. L. deStein.

In the meantime the ladies of the party were being entertained at tea at the home of Mrs. C. J. Mackenzie. Among the guests were the wives of all the engineers of the city.

At 5.30 we were sorry to see the group depart for Edmonton. Thinking back, we probably worked them too hard, especially after their extremely arduous activities in Regina. In fact, we were vastly relieved to find that there were no hospital cases as a result.

Finally, we have to note that it is very seldom indeed that we in Saskatoon have visits from a President of The Institute. In view of the great value attending these presidential visits, and also the visits of the others of the delegation who have just been with us, we suggest that an effort be made to find some means by which similar groups may visit us more often in the future.

Sault Ste. Marie Branch

N. C. Cowie, Jr.E.I.C., Secretary-Treasurer.

The Sault Ste. Marie Branch of The Engineering Institute of Canada held a general meeting at the Windsor hotel, Sault Ste. Marie, Ont. on Friday, November 18th, 1938.

Following an enjoyable dinner served to twenty-nine members and guests, the Chairman of the Branch, J. S. Macleod, A.M.E.I.C., called the meeting to order.

In announcing that John L. Lang, M.E.I.C., would introduce the General Secretary of the Institute, Mr. Macleod said that he was very glad Mr. Wright had found it possible to visit us on his way home from his trip to the western branches.

Mr. Lang, introducing Mr. Wright to the meeting mentioned that the Branch had been looking forward to Mr. Wright's visit and would be much interested in his talk which would deal with his trip to the Western Branches, and general Institute affairs.

Mr. Wright expressed his pleasure on visiting the Sault Branch and that his remarks would be a kind of "shop talk" on the subjects Mr. Lang had mentioned. The high light of his western trip had been the dinner meeting in Regina on October 29th, at which the agreement between the Association of Professional Engineers of Saskatchewan and the Engineering Institute of Canada had been completed. He expressed the hope that with this as a beginning The Institute would serve as a common bond for all Canadian engineers, and that further agreements would be arranged in the other Provinces. The possibilities, of an early agreement in two of the other provinces were very good, he said. In this regard he pointed out the superiority of the state of affairs in the profession in Canada as compared to that in the United States, where the large number of divisions into specialized branches of the profession made co-operative agreements much harder to work out.

The advantages of membership in The Engineering Institute were described by Mr. Wright. Respect of the engineer for himself and his profession, the employment service, the library service and the privilege of obtaining subscriptions to our own journal and to those of the societies in United States, the opportunities of engineers to express themselves at Branch meetings and the fraternalism among engineers being among the subjects mentioned by the speaker.

Several questions were answered by Mr. Wright for individual members in the discussion that followed his address. Following this discussion A. E. Pickering, M.E.I.C., tendered Mr. Wright the thanks of the meeting. This motion, which was seconded by C. W. Holman, A.M.E.I.C., was warmly approved.

Toronto Branch

J. J. Spence, A.M.E.I.C., Secretary-Treasurer.
D. D. Whitson, A.M.E.I.C., Branch News Editor.

The Branch held its opening meeting of the season at Hart House on October 13th, 1938, assembling to hear an address by Col. E. J. C. Schmidlin, M.C., R.C.E., Director of Engineering Services, Department of National Defence, Ottawa. His subject was:

TECHNICAL ASPECTS OF ATTACK AND DEFENCE IN MODERN WARFARE

Col. Schmidlin was of the opinion that if war broke out tomorrow it would be fought along lines similar to the Great War except for minor differences due to minor improvements in guns, shells, rifles, and explosives and transportation. "Attack" involved the delivery in enemy territory of destructive material in the form of explosives or gas at points designated, in the shortest possible time, with the best possible aim, and in the desired quantity; whereas "defence" consisted of efforts to defeat all the aims of the attackers by using counter attacks, or by passively awaiting the attackers in forts or trenches. The best example of passive defence preparations was France's Maginot line, or Germany's Siegfried line. In the speaker's view the infantry were still the backbone of military operations, and the dire results of gas and bombs in Ethiopia, Spain, and China were very largely due to lack of defence; he stressed the fact that last minute preparations for defence were very likely to prove ineffective against modern forms of attack.

In the field of transportation many specialized vehicles had been developed, particularly for cross-country work, but commercial types of motor vehicles were favoured wherever possible. Cross-country transportation was possible only in certain type of terrain, under fairly good conditions when there had not been too much rainfall. Tanks had been developed that weighed 15 tons and could go 35 m.p.h. on broken ground, but in the speaker's opinion these vehicles were still extremely vulnerable and could be easily stopped with the right kind of defensive preparations; due to the jolting, uneven progress of a tank, it was extremely difficult to make hits with its guns, and if the tank stopped, it usually became easy prey for anti-tank guns which fired two-pound shells or steel clad bullets. Tanks, crawler type trucks, and tractors now used articulated rubber endless belts as a means of propulsion instead of the old type steel belts. Despite the advances in cross-country vehicles, travel by this procedure is so difficult and uncertain that the modern tendency is to build more and more military roads such as have been constructed across Germany in recent years.

Turning to aircraft, the speaker noted the greatly increased speed, range, and bomb-carrying capacity of the recent models, but felt that the bogey of mass aerial bombardment of cities was not so fearsome as it seemed. The attacking planes would be met by anti-aircraft defences which would cause them to fly at great heights for safety. In this connection, Col. Schmidlin pointed out that a bomber flying 250 m.p.h. at an altitude of 20,000 ft. must release its bombs approximately 1¾ miles before reaching the desired target in order to register a direct hit. The difficulty would be further increased if the bomber had to alter its speed and direction due to anti-aircraft fire from the defence artillery or defending planes.

Col. Schmidlin described the French Maginot Line as a tremendous engineering work, extending for 200 miles, built at a cost of $400,000,000 without its armaments, and capable of accommodating 200,000 men in its underground labyrinth which is about 40 feet below the surface of the ground. Its series of fortified areas are studded with large numbers of massive concrete toadstools, containing weapons ranging from machine guns up to 6 in. howitzers, all interconnected with deep dugouts below, completely equipped with supplies, living quarters, communication systems, etc.

In Canada, the speaker said we had the beginnings of a coast-defence system centered around points such as Vancouver, Esquimault, and Halifax.

Anti-aircraft defence was described as being particularly expensive, with three rings of guns around the large cities at fairly close spacing in each ring, and with the rings a few miles apart. About two searchlights are required for each gun installation with candlepower running into the millions. Fast defending planes must also be used to harass the attacking planes; the general idea of anti-aircraft defence is to keep the enemy high and disturbed, thus lessening the chances of direct hits on his part.

Col. C. S. L. Hertzberg, M.E.I.C., moved a vote of thanks to Col. Schmidlin, and those present retired to the Great Hall for refreshments, an innovation for Toronto Branch meetings.

C. E. Sisson, M.E.I.C., Branch chairman, conducted the meeting and announced that the Toronto Branch had joined the Affiliated Engineering Societies of Toronto and that this organization would hold joint meetings at stated times.

Dr. A. E. Berry, M.E.I.C., in charge of papers, outlined a very attractive programme for the coming season.

The meeting of the Toronto Branch held on November 3rd was very well attended. C. E. Sisson, M.E.I.C., occupied the chair, and A. U. Sanderson, A.M.E.I.C., last year's chairman, moved that the Branch congratulate Dr. J. B. Challies on receiving the degree of Doctor of Engineering. This motion met with unanimous approval.

B. K. Read of Canadian Industries Limited presented a very interesting address on the "Production of Synthetic Rubber," a synopsis of which follows.

The Production of Synthetic Rubber

Outstanding, and in some cases spectacular, achievements in science and industry are casually accepted as commonplace today. Synthetic rubber certainly falls in this category—it is a highly specialized development.

Synthetic rubber, like other important discoveries of recent times, goes back a good many years. Bouchardat in 1875 isolated isoprene as the mother substance of rubber. Tilden in 1884 synthesized isoprene from turpentine. Fritz Hoffman laid the foundation for the partially successful manufacture of synthetic rubber in Germany during the 1914 war. 2,300 tons were produced. After the war there was a lull in activity, but in 1925 the price of crude rubber rose. The chemists in the major industrial countries got busy and at least eight commercial types of synthetic rubber-like materials were the result.

There is usually a wasteful lag between the announcement and the reduction to practice of technological achievements. Ten years ago this lag was in all countries. Today this is not so.

We are being reminded—unpleasantly perhaps—that certain nations of the world (the totalitarian group) are demonstrating a rising energy level. It is predicted that sooner or later we shall feel the economic impact of these more energetic countries. We may perhaps frighten ourselves into a rekindled spirit of enterprise by contemplating this threat to our security.

The lag period in utilizing the benefits of modern technological achievements seems a carry-over of habit of thought from the handicraft days. It is going by the board in the energetic countries and needs to be dispensed with elsewhere as well.

A suggested solution to the problem is for technical men to accept their share of the responsibility for public education and enlightenment.

New developments raise living standards and increase employment, and the public must be made to see this side of the picture. Since 1928 DuPont has brought out twelve new groups of products that employ today 18,000 men and represent a plant investment of about $175,000,000.

DuPont announced neoprene in 1931—built a plant with about 10 tons monthly capacity, and began supplying to the rubber industry. The product was very much like the present material—not quite as good but almost. In eight years the production has grown to ten or fifteen times this quantity.

In Germany a different type was chosen, but progress, despite a late start, has been much more rapid—German production has been estimated at about 25 million pounds annually.

Their first synthetic rubber factory in Russia was built in 1931, and was reported to be supplying 75 per cent of current rubber needs. The annual output is said to be 140 million pounds. Japan and Italy have projected plants for synthetic rubber manufacturing—so did Czechoslovakia. To date England and France have shown no announced intention of entering the field.

The raw materials for neoprene manufacture are (1) coal, from which is obtained carbide and acetylene, (2) salt, yielding hydrogen chloride and water, all plentiful and cheap. The modern carbide furnace is the last word in electrical perfection—in size the only limits are the electrodes and the electrical equipment to operate the furnace.

Acetylene generated from carbide has been known since 1836. Father Niewlands, late of Notre Dame, was the first to discover how to polymerize acetylene. From his research DuPont chemists created neoprene.

Commercial neoprene is a substance resembling rubber—it can be easily processed on modern rubber machinery and needs no new installation of equipment or new technique.

The superior properties of neoprene constitute its claim to distinction. It is more resistant to sunlight, heat, most oils, fats, etc., high voltage discharge, decidedly less inflammable, and with a much longer vital life compared to rubber. The x-ray examination of neoprene shows a physical structure very similar to the natural product.

These superior properties may be converted to economic advantage in an increasing number of ways. The petroleum industry alone stands to benefit by many millions of dollars annually by the growing use of neoprene finished products of proven value.

In conclusion, attention may be called to the fact that when the charges against any one successful product are added up, the sum is a huge loss, which may take years to cancel out. Millions of dollars have been expended since 1875 on synthetic rubber, but the public at large will benefit by the progress in the long run.

There was an attendance of 125 at the meeting of the Branch on November 17th at Hart House. Tracy D. LeMay, Commissioner of City Planning of the City of Toronto, addressed the meeting on the subject of "Regulation of Traffic in a City." C. E. Sisson, M.E.I.C., was in the chair.

Vancouver Branch

T. V. Berry, A.M.E.I.C., Secretary-Treasurer.
J. B. Barclay, A.M.E.I.C., Branch News Editor.

Visit of Dr. J. B. Challies and Official Party

The Vancouver Branch were honoured by a four day visit from Dr. J. B. Challies, President of The Institute; Mr. Fred Newell, Chairman of The Institute Committee on Professional Interest, and Mr. L. Austin Wright, recently appointed General Secretary of The Institute.

This four day visit coincided with the annual meeting of the B.C. division of the Canadian Institute of Mining and Metallurgy and several functions of a joint nature were enjoyed by members of both Institutes.

Meeting of the Vancouver Branch Addressed by the President.

Among those present were: Front row: James Robertson, M.E.I.C., J. D. Galloway, G. S. Eldridge, J. Alexander Walker, M.E.I.C., L. Austin Wright, A.M.E.I.C., Lt.-Col. J. P. MacKenzie, M.E.I.C., Fred Newell, M.E.I.C., Dr. J. B. Challies, M.E.I.C., R. R. Hedley, A. E. Foreman, M.E.I.C., F. W. Anderson, Frank Lee. Second row: W. G. Swan, M.E.I.C., Group Captain Johnson, A.M.E.I.C., Col. Keen. Back row, standing: T. V. Berry, A.M.E.I.C., P. H. Buchan, M.E.I.C. Back row, sitting: Prof. A. Peebles, A.M.E.I.C., Charles Brakenridge, M.E.I.C., Dr. E. A. Cleveland, M.E.I.C., Dr. Victor Dolmage, M.E.I.C.

Joint Public Meeting, Tuesday, November 8th

Perhaps the highlight of the visit was the public meeting held in the Aztec Ballroom of the Hotel Georgia on Tuesday evening, November 8th. To this meeting had been invited the Council and members of the B.C. Association of Professional Engineers, the B.C. division of the Canadian Institute of Mining and Metallurgy, the Architectural Institute of B.C., the Vancouver Section of the American Institute of Electrical Engineers and the Building and Construction Industries Exchange, to hear Dr. Challies speak on "The Status of the Engineer." About one hundred and thirty-five attended.

Dr. Challies outlined the great progress made by the engineering profession in Canada since Confederation and told of the high esteem in which Canadian engineers are held both abroad and at home. He felt that the growing desire of engineers to enter public life was good for the country and good for the engineering profession.

Mr. Fred Newell next spoke, confining his remarks to the recent co-operative agreement signed by The Engineering Institute of Canada and the Association of Professional Engineers of Saskatchewan and outlining plans for further agreements of a similar nature with other Canadian provinces in the near future.

Following a short address by Mr. Wright, the meeting was given over to a spirited discussion on Institute-Association relations as they affected British Columbia.

Refreshments were then served and an opportunity given for members and friends to meet Dr. Challies and the official party.

Joint Luncheon

Vancouver Board of Trade (Engineering Bureau) and Canadian Institute of Mining and Metallurgy, held a joint luncheon on Wednesday, November 9th, 1938.

The address was given by Dr. Challies. The Engineering Bureau of the Vancouver Board of Trade were hosts to the visiting delegates of the Mining Convention and to members of The Engineering Institute and the B.C. professional association at a luncheon in the Vancouver hotel on Wednesday, November 9th. At the head table with Dr. Challies were prominent men in the mining industry in Western Canada, and the Ministers of Mines from three Western Provinces.

Dr. Challies in an interesting address dealt with the great progress, present and future of the power industry in Canada. It was the expressed opinion of a well known Canadian economist that in spite of the late depression, increased corporation taxes and increased labour costs, the two great Canadian industries, that of mining and hydro power production, had been the greatest steadying influences on the Canadian economy during a very difficult period.

In Canada we are very fortunate as regards power for industrial and domestic purposes. Great Britain depends entirely on coal for its source of power and in the United States only about 25 per cent of its power comes from hydro developments. In striking contrast with these two great industrial countries, hydro-electric developments in Canada supply about 98 per cent of the total power concerned. It is interesting to note that our per capita hydro power development is larger in Canada than any other country, and in no other country is the technique of hydro development more advanced.

* * *

Perhaps one of the most interesting functions held during the visit of Dr. Challies was the meeting with the engineering students in the Faculty of Applied Science at the University on Thursday midday, November 10th.

About fifteen members of the Vancouver Branch with the President visited the University where approximately one hundred and fifty engineering students listened to interesting and instructive addresses by Dr. Challies, Mr. Newell and Mr. Wright. An interesting incident on this occasion was the presentation by the President to A. L. Sutton of The Engineering Institute of Canada award for the year 1938. The Institute members later enjoyed luncheon as the guests of J. N. Finlayson, M.E.I.C., Dean of the Faculty of Applied Science and head of the Department of Civil Engineering.

The official party were kept very busy during their stay. Besides functions reported above, they were the guests of the Vancouver Branch executive on Tuesday, November 8th, at an informal dinner, on which occasion Institute affairs were discussed.

At noon on Tuesday, Dr. Challies was the guest speaker at the Rotary Club, choosing as his address "Insurance for Peace."

The University of Toronto School of Science graduates entertained on Thursday at a cocktail party at the Jericho Golf Club, and on Armistice Day a luncheon under the auspices of the Association of Professional Engineers of B.C. was addressed by Mr. Wright.

Later in the day, the official party were guests at the annual convention dinner of the Canadian Institute of Mining and Metallurgy.

Neither were the visiting ladies neglected. On Tuesday, Mrs. Challies and Mrs. Newell were guests at a luncheon at the Jericho Golf Club and on Thursday about forty wives of members entertained them at a reception in the Georgia Club.

The Vancouver Branch members enjoyed every minute of the time that the visitors were in Vancouver, and feel that the inspiration gathered from the social contacts and discussions of Institute matters with these gentlemen will do much to cement relations between the East and the West and further the interests of Canadian engineers wherever they may be.

Victoria Branch

Kenneth Reid, Jr.E.I.C., Secretary-Treasurer.

It was with a great deal of pleasure that the Victoria Branch of The Institute had the privilege of entertaining President Challies and his party on the occasion of their tour of the Western Branches on November 5th and 6th, last. The President was accompanied on his visit to Victoria by Mrs. Challies; Councillor Fred Newell and Mrs. Newell; Mrs. W. G. Swan of Vancouver; J. Robertson, M.E.I.C., of the Dominion Bridge Company, Vancouver, and L. Austin Wright, A.M.E.I.C., General Secretary of The Institute.

Great honour was conferred on two members of the Victoria Branch now living in retirement here for their contributions to the engineering profession in Canada, namely Col. J. S. Dennis, M.E.I.C.,* and C. A. Magrath, M.E.I.C., the former being awarded the Sir John Kennedy Gold Medal, and the latter by the announcement of his election to Honorary Membership in The Institute. Due to the very grave condition of his health it was considered inadvisable to have Col. Dennis go to Ottawa next February to receive this award and arrangements were made to have the medal brought West by the President on this occasion for presentation here. Unfortunately Col. Dennis was too ill to attend any of the functions held in Victoria and presentation of the medal was made by President Challies to Col. Dennis at his bedside in hospital. The very touching nature of the simple ceremony to such a great and distinguished engineer did not fail to impress all who were privileged to be present.

The Victoria Branch held a luncheon at the Empress hotel on Saturday noon for the President and other Institute members of the party which was attended by the executive committee and other members of the Branch, and was followed by an informal discussion of Institute affairs.

*Col. Dennis, since deceased.

While the luncheon was in progress the visiting ladies were the guests of Mrs. Magrath at luncheon in her home on St. Charles Street and enjoyed a delightful afternoon in her charming company.

On Saturday evening the Branch was host to the distinguished visitors at a formal reception and dinner at the Empress hotel to which the ladies, and members of the Professional Association and other kindred engineering bodies and their families were invited, about fifty persons being present. It was deeply regretted that due to a previous engagement His Honour the Lieutenant-Governor of the Province was unable to be present. The honours of the evening went to Mr. Magrath when his election to Honorary Membership in The Institute was announced by the President. In a simple but dignified and touching address Mr. Magrath expressed his sincere appreciation of the honour conferred upon him. The toast to the profession by J. N. Anderson, A.M.E.I.C., addresses by Dr. Challies, Mr. Newell, Mr. Wright, K. Moodie, M.E.I.C. chairman of the Branch, and Mr. Freeland of the Professional Association gave the finishing touches to what proved to be a most enjoyable evening.

On Sunday afternoon the visiting party was entertained by drives to points of interest in and around Victoria, including the famous Butchart gardens at Brentwood. Following the drives the visitors, together with the members of the Victoria executive and their families, gathered for afternoon tea around the huge fireplace in the rotunda of the Empress hotel and spent a most pleasant social hour together before bidding adieu to one of the most pleasing and distinguished delegations from Headquarters to be entertained in Victoria for many years.

Victoria Branch Holds Dinner for Visitors.

Winnipeg Branch

J. Hoogstraten, A.M.E.I.C., Secretary-Treasurer.

At the regular joint meeting held on October 13th, 1938, H. L. Briggs, A.M.E.I.C., operating engineer of the Winnipeg Hydro-Electric System, gave an interesting address on

Keeping the Lines Alive

Total prime mover capacity connected to the circuits of the City of Winnipeg Hydro-Electric System is 170,000 hp. The load is supplied over two widely separated transmission lines interconnected at both ends, there being a total of 496 circuit miles of 66 kv. lines. Tables summarizing six years of experience, 1932 to 1937, in operating these lines showed lightning to be the largest single cause of trouble. In the same period there have been three total interruptions of power. The procedure whereby operating staffs restore service after a shutdown was described, as were several innovations which are expected to expedite and assure restoration of power in the event of serious trouble in the future. Fault detector relays recently added are expected to further improve continuity of service.

With reference to regulating the system load, 50,000 hp. in off peak electric boiler load is controlled in a manner which results in raising the daily system load factor from 60 per cent to 90 per cent. The flexible procedure whereby the generating stations are maintained at their safe full load, and the hydraulic turbines in their most efficient operating range, was dealt with in considerable detail.

Visit of Delegation from Headquarters

On October 27th and 28th, the Winnipeg Branch was host to President and Mrs. J. B. Challies, Mr. and Mrs. F. Newell and Mr. L. A. Wright. On October 27th, members of the visiting delegation were introduced at a mixed luncheon at the Fort Garry hotel. In the afternoon, the delegation met with the Committee on Consolidation, including members of the Provincial Professional Association, and later with members of the executive committee and other senior members of the Branch.

Winnipeg Luncheon Meeting.

L. A. Wright, A.M.E.I.C., J. J. White, M.E.I.C., A. J. Taunton, M.E.I.C., Mrs. Newell, A. E. Macdonald, M.E.I.C., Mrs. Challies, W. D. Hurst, A.M.E.I.C., Mrs. Taunton, President Challies, Mrs. Hurst, Mr. Burke Gaffney, Mrs. Macdonald, F. Newell, M.E.I.C., J. Hoogstraten, A.M.E.I.C.

At 6.30, the visitors were entertained at dinner, which was attended by members of the executive committee, past chairmen and councillors of the Branch, and the ladies.

At the regular joint meeting in the evening, Mr. Wright spoke on "Reasons for Belonging to The Institute," and Mr. Newell spoke briefly on the progress made in co-operation with the Provincial Associations.

Mr. Aaron Gusen, student in engineering at the University of Manitoba, and winner of The Engineering Institute of Canada Prize, was presented by President Challies with the Certificate of Award.

President Challies, in a short address, traced the history of The Institute and the Provincial Associations of the last fifty years, and pointed with pride to the progress made by the profession.

On October 28th, President Challies addressed a luncheon meeting of the Empire Club on "The Great Lakes to Ocean Waterways," and in the afternoon, members of the visiting delegation addressed the students in engineering at the University of Manitoba.

MEETINGS

American Society of Civil Engineers—Annual Meeting, January 18th-21st, 1939, New York, N.Y.

American Society of Heating and Ventilating Engineers—Annual Meeting, January 23rd to 26th, 1939, William Penn Hotel, Pittsburgh, Pa.

American Water Works Association, Canadian Section—Annual Meeting, April 12th-14th, 1939, at the Royal York Hotel, Toronto. Secretary, Dr. A. E. Berry, Parliament Buildings, Toronto, Ont.

Canadian Construction Association—January 10th-12th, at Winnipeg, Man.

Canadian Pulp and Paper Association—Annual General Meeting, January 25th-26th, 1939, at the Mount Royal Hotel, Montreal.

Ontario Good Roads Association—Annual Meeting, February 22nd and 23rd, 1939, in Toronto. Secretary T. J. Mahony, Court House, Hamilton, Ont.

The Engineering Institute of Canada—Annual General and Professional Meeting, February 14th-15th, 1939, at Ottawa.

Montreal Branch—Smoker at the Windsor Hotel on Thursday, February 2nd, 1939.

Twelfth National Asphalt Conference—February 20th to 24th, 1939, Biltmore Hotel, Los Angeles, Calif.

Additional information about any of these functions may be secured from the General Secretary.

EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted after a lapse of one month, upon request.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Situations Vacant

COMMISSIONED OFFICERS, ROYAL CANADIAN SIGNALS

At the present time there are two vacancies in the Royal Canadian Corps of Signals for commissioned officers and they anticipate having three or four more between now and the spring. These vacancies are available to graduates of Royal Military College and also to graduates in Electrical Engineering of a recognized university where military training forms part of the curriculum. Copies of the application forms and pamphlets which outline the qualifications necessary for appointment to a commission, may be obtained from the District Signal Officer at any of the headquarters of Military Districts, or from The Institute.

GRADUATE ENGINEER, with ten to fifteen years experience. With particular knowledge of cost estimating of hydro-electric power plants, transmission systems and substations. A knowledge of French and English is an essential requirement. Location Montreal. Apply to Box No. 1816-V.

ELECTRICAL ENGINEER, capable of making inventory in the field. Must be familiar with Overhead and Underground distribution systems. Must be able to make neat records of equipment. Apply to Box No. 1817-V.

ELECTRICAL ENGINEER, capable of making inventory in the field of Power Houses and Substations. Must be familiar with Power House and Substation operation. Must be able to make neat records of equipment. Apply to Box No. 1818-V.

SENIOR ENGINEER, required for radio development work on transmitters and receivers. Must be engineering graduate. and preferably have some experience in radio. Applicants should state salary expected and when their services would be available. Apply to Box No. 1819-V.

JUNIOR ENGINEER required for radio development work. Must be engineering graduate. Applicant should state salary expected and when services would be available. Apply to Box No. 1820-V.

Situations Wanted

ENGINEER, A.M.E.I.C., Combustion specialist heat balance. Steam, Mechanical. Refrigeration. Office routine. Correspondence. Plant layout. Apply to Box No. 5-W.

ELECTRICAL ENGINEER, Jr.E.I.C., B.Sc.; age 31; at present employed, desires change in location. Experience includes; three summers experience in power conduit construction; two years in telephone engineering; four years experience in radio, both development engineering and production; two and one half years in a paper mill on electrical maintenance, with a short time in the cost accounting and draughting departments. Would be interested primarily in electrical maintenance. Apply to Box 12-W.

PAPER MILL ENGINEER A.M.E.I.C., Married, Ten years experience in the design, construction, maintenance and costs of pulp and paper mills is seeking a permanent position. Available on short notice. Apply to Box No. 150-W.

SALES ENGINEER REPRESENTATIVE. Mechanical graduate with fifteen years experience in Eastern Canada in sales and service of mechanical equipment; full details upon request to Box No. 161-W.

ENGINEER-DRAUGHTSMAN, experienced in design of machines for widely varied purposes and arrangement of motor drives. Accustomed to layout of small mill buildings, steel and timber. Good references. Present location Montreal. Apply to Box No. 329-W.

Situations Wanted

CIVIL ENGINEER, M.A.Sc., A.M.E.I.C. eight years survey and municipal engineering experience, and three years draughting, detailing steel, concrete, and timber structures. Apply to Box No. 467-W.

CIVIL ENGINEER, B.Sc. (McGill '20), A.M.E.I.C. Married. Twelve years experience in pulp and paper mill design, and six years general construction. Available immediately. Location immaterial. Apply to Box No. 547-W.

ELECTRICAL ENGINEER, B.Sc. '28. Two years student apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660-W.

CIVIL ENGINEER, B.A.Sc. (Toronto '27), age 34, married. Five years railway and construction work as building inspector and instrumentman. Level engineer and on construction of a long timber flume for a pulp and paper mill. Field engineer for a sulphite company, in charge of the following mill buildings, acid, digester, blow pit, barker room, chip storage and acid towers. Available immediately. Apply to Box No. 714-W

ELECTRICAL ENGINEER, B.Sc. '31 (U.N.B.), Jr.E.I.C. Age 30 years. Single. Experience in electrical wiring, construction of concrete wharves, inspection of piling, rip rap, concrete reinforcing, forms, and dredging. Also junior engineer. Available at once. Apply to Box No. 722-W.

CIVIL ENGINEER, B.Sc., M.Sc., P.P.E.; Lieut. C.E., R.O. Sixteen years municipal, highway and construction. Five years overseas. Married. Read, write and talk French. Will go anywhere. Apply to Box No. 737-W.

ELECTRICAL ENGINEER, B.Sc. '31. Jr.E.I.C. Age 31. Experience includes: eight months on installation of power and lighting equipment; three years as supervisor of an electrical and service dept.; seven months testing power and radio equipment; one year as inspector on electrical equipment and control. At present employed. Available on one month's notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, A.M.E.I.C. Experienced in general construction, buildings, gravel and asphalt roads. Acting in charge P.W.D. West Africa. Chief field engineer refinery construction. Survey Angola Rly. West Africa. General Office work. Apply to Box No. 765-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 41. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experience in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

TECHNICALLY TRAINED EXECUTIVE. General experience administrative, organization and management in business and industrial fields, including; business, plant, property and estate management; plant maintenance, modernization, production and personnel; economic studies, company reorganizations and amalgamations, valuations; railroad, highway, hydro, pulp, newsprint, housing, industrial surveys, investigations and construction; B.Sc. degree in engineering, age 49, married, Canadian. Apply to Box No. 1175-W.

CHEMICAL ENGINEER, grad. McGill '34, experienced in meter repairs, control work; and also chemical laboratory experience. Apply to Box No. 1222-W.

Situations Wanted

ELECTRICAL ENGINEER, B.Sc. '31. Age 35. Experience in oil field work and railways construction survey. Two years on installation and maintenance of mine equipment, and two years industrial plant engineering on design and layout of equipment. Available immediately. Will go anywhere. Apply to Box No. 1249-W.

MECHANICAL ENGINEER, B.Eng (McGill). Age 25. Experience includes—one year marine engineering, Diesel and steam; over two years general engineering work in paper mills including draughting, building and equipment layouts, power plant work, mill maintenance planning and costing. Seeking permanent position to acquire thorough knowledge of operation and maintenance. Available immediately. Apply to Box No. 1272-W.

FIELD ENGINEER AND DRAUGHTSMAN, A.M.E.I.C. Age 36. Married. Fifteen years experience in civil engineering, general draughting and instrument work. Experience covers office and layout work on construction of sewers, water mains, gas mains, (6" to 30" dia.) and transmission line structures; topographic and stadia surveys. Draughting covers general civil, reinforced concrete and steel design, mechanical detailing and arrangements, and mapping. Present location Montreal, but willing to locate anywhere. Available at once Apply to Box No. 1326-W.

CIVIL AND ELECTRICAL ENGINEER, Jr.E.I.C. (Univ. of Man.). Married. Age 25. Good draughtsman. Four months draughting, one year instrumentman on highway location and construction, inspection and miscellaneous surveying and estimating. Six months as field engineer on pulp and paper mill construction. Prefer electrical or structural design. Available at once. Apply to Box No. 1633-W.

CIVIL ENGINEER, B.Sc. in C.E. '34. S.E.I.C. Age 27. Five years experience, including harbour construction, highway paving, one and a half years paper mill construction, instrument work, draughting, estimating, interested in design. Available on short notice. Apply to Box No. 1737-W.

CHEMICAL ENGINEER, graduate, Toronto '31. Seven years experience in paper mill, meter maintenance, control work and chemical laboratory. Speaking French and English. Location immaterial. Available at once. Apply to Box No. 1768-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C. (Toronto '35). Age 24. Experience in structural design, construction and surveying, including one year in South America. Details on request. Apply to Box No. 1784-W.

ELECTRICAL ENGINEER, Jr.E.I.C. B.Sc. Age 25. At present employed, but desiring change of location. Three years maintenance and test work, toll and automatic telephone equipment; two years sales engineering, telephone and electrical equipment. Prefer to remain in telephone field, but would be interested in any opportunities in electical engineering. Apply to Box No. 1817-W.

CIVIL ENGINEER, B.E., Jr.E.I.C., 28 years of age. Married. Desires position with reliable construction firm. Intends to make construction life work. Over five years experience on permanent highway construction, inspection, estimates and instrument work. Available on short notice. Apply to Box No. 1820-W.

ELECTRICAL ENGINEER, B.A.Sc. '33. Age 27. Married. Jr.E.I.C. One year's experience in power plant operation and over three years experience in hydroelectric development and construction. Expert draughtsman and instrumentman, including experience in steam gauging, and reinforced concrete design and construction. Available at once. Apply to Box No. 1829-W.

CIVIL ENGINEER, B.A.Sc. (Toronto '35), Jr.E.I.C. Age 26. Experience in highway layout and construction, concrete bridge construction, draughting, office work, and surveying. Further details on request. Good references. Available immediately. Location immaterial. Apply to Box 1832-W.

ELECTRICAL ENGINEER, B.Sc. (Manitoba '36), S.E.I.C. Practical and theoretical experience in radio. Have done experimental work. At present doing radio service work. Available at once. Apply to Box No. 1833-W.

CIVIL ENGINEER, B.Sc. '37, S.E.I.C. Age 22. At present employed, desires position with construction firm. Experience includes field instructing of transit and chain survey crews, draughting for geologist, instrument work and general supervision on highway construction work, purchasing in papermill. Available on few weeks' notice. References and details on request. Willing to locate anywhere that offers required class of work. Apply to Box No. 1840-V.

Preliminary Notice

of Applications for Admission and for Transfer

November 25th, 1938.

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in January 1939.

L. Austin Wright, General Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BALL—ELMER LANGDON, of 113 South Park St., Halifax, N.S., Born at Botwood, Nfld., March 24th, 1916; Educ., B.Eng. (Civil), N.S. Tech. Coll., 1938; 1935-36-37 (summers), Geodetic Survey of Nfld.; July 1938 to date, junior engr., Engineering Service Company, Halifax, N.S.
References: I. P. MacNab, W. P. Copp, S. Ball, W. M. Dennis, J. R. Kaye, P. A. Lovett.

BIRD—WILLIAM HENRY STEPHENSON, of 338 So. Marks St., Fort William, Ont., Born at Fort William, April 18th, 1910; Educ., Bach. Aero. Engrg., Univ. of Minn., 1935; Dec. 1935 to June 1936, aeronautical design, layout, dfting., etc., and June '36 to July 1937, chief dftsman., J. D. Akerman and H. W. Barlow Co., Minneapolis, Minn.; July '37 to Dec. '37, project engr., Porterfield Aircraft and Engineering Corpn., Kansas City; Dec. '37 to Sept. '38, group leader i/c landing gear, hydraulic system, wings, tail surfaces, etc., and at present, chief dftsman., Canadian Car and Foundry Company, aviation divn., Fort William, Ont.

Consumers of Canada

Through the kindness of Consumers' Research, Inc., sample copies of that body's publication "Consumers' Digest" are being furnished to The Institute library and will be placed on the reading room table at Headquarters. This body, which has for years been active in the United States, is planning to extend its operations to Canada, for which purpose a similar organization, Consumers of Canada, Inc., has been formed. A Federal Charter has been secured and the objectives of the new body, like those of Consumers' Research are:—

1. To provide its subscribers with accurate, scientific, complete and unbiased information about the everyday commodities which they buy, giving comparisons by brand-name and price so that intelligent selections may be easily made.
2. To expose deceits, frauds and hazards wherever they may occur.
3. To develop a widespread consumer-consciousness which will be strong enough eventually to effect much-needed reforms in business and government.

The Canadian organization, like that in the United States, will be supported entirely by subscriptions to its publication, a monthly magazine informing its subscribers as to the results of tests of household appliances, examinations of fuels, foods, materials, and equipment etc., offered for sale to and used by the public.

Among examples of the information recently furnished by the American organization may be cited the results of tests on nine brands of mayonnaise as to odour, consistency, taste, fat content and character of the oil used as a base. In another article information is given which is of great value to a householder contemplating the installation of an oil burner for domestic heating, emphasis being laid on the technical characteristics of the various makes. A third article gives data as to the relative appreciation by the public which has been accorded to a long list of motion pictures which are now being shown, this rating being based upon an analysis of the reviews published in current papers and periodicals.

It will thus be seen that the information service available will be of wide scope, and if intelligently used, will furnish much-needed guidance and protection.
